Forms and Procedure) Regulations 2009

VOLUME 2, CHAPTER 19, APPENDIX A : GROUNDWATER AND
SURFACE WATER: NUMERICAL MODELLING REPORT

CONTENTS

1	INTRODUCTION	16
1.1	Project context.....	16
1.2	Report objectives and structure	18
1.3	Limitations	19
2	SITE DESCRIPTION	19
2.1	Location	19
2.2	Topography and land use	20
2.3	Climate	21
2.4	Geology	23
2.5	Local geology	25
2.6	Hydrogeology	30
2.7	Hydrology	35
2.8	Proposed developments.....	35
3	HISTORICAL BASELINE MODEL DEVELOPMENT AND CALIBRATION.....	37
3.1	Previous model development	37
3.2	Revised model description.....	39
3.3	Results.....	61
3.4	Model validation.....	68
3.5	Sensitivity analysis.....	75
4	SCENARIO MODEL DEVELOPMENT	92
4.1	Introduction.....	92
4.2	Future climate scenarios.....	93
4.3	Development aspects	102
5	SCENARIO MODEL RESULTS.....	111
5.1	Main simulations	111
5.2	Sensitivity analysis.....	125
6	SUMMARY AND CONCLUSIONS.....	139
6.1	Background and overview	139

6.2	Summary of historical modelling	140
6.3	Summary of future projections.....	142
6.4	Summary of future sensitivity analyses.....	144

Table E.1 Total baseline recharge, construction water management zone recharge and water management zone surface water discharge across temporary construction area impermeable catchments (2022-2032)..... 161

PLATES

Plate 2.1: Observed daily and annual rainfall for the 5 km grid square centred on TM450650 (Met Office, Hollis, D. and McCarthy, M., 2017) 22

Plate 2.2: Observed seasonal variations in rainfall for the 5 km grid square centred on TM450650 (Met Office, Hollis, D. and McCarthy, M., 2017)..... 22

Plate 2.3: Observed daily maximum and minimum temperatures per month for the 5 km grid square centred on TM450650 (Met Office, Hollis, D. and McCarthy, M., 2017) 23

Plate 2.4: Inferred geological cross sections based on borehole log data 29

Plate 3.1: Recharge zones assigned to the FEFLOW model..... 43

Plate 3.2: Rainfall data (2013-2015) from the Sizewell C weather station, MORECS (40 x 40 km square centred on TM400600) and UKCP09 (5 x 5 km square centred on TM450650) 47

Plate 3.3: Model horizontal hydraulic conductivity in a) Slice 1 b) Slice 3 and c) cross-section through the Main Development Site	57
Plate 3.4: Model vertical hydraulic conductivity in a) Slice 1 b) Slice 3 and c) cross-section through the Main Development Site	58
Plate 3.5: Model specific yield in a) Slice 1 b) Slice 3 and c) cross-section through the platform area	59
Plate 3.6: Model specific storage in a) Slice 1 b) Slice 3 and c) cross-section through the Main Development Site.....	60
Plate 3.7: Modelled recharge zones within the G5 topographic catchment for baseline and construction scenarios.....	70
Plate 3.8: Observed rainfall and stage-discharge derived flows at G5 from December 2015 to December 2017	71
Plate 3.9: Stage-discharge derived and modelled flow at G5 from December 2015 to December 2017	73
Plate 3.10: Relationship between estimated recharge and observed stage at G1	74
Plate 3.11: Modelled ‘floodplain channels’ and sub-catchment boundaries in MIKE11	77
Plate 3.12: Modelled ‘floodplain channels’ and sub-catchment boundaries in MIKE11	78
Plate 4.1: Comparison of potential evapotranspiration estimates derived from UKCP09 data and MORECS (2010-2015).....	98
Plate 4.2: Relationship between mean temperature and rainfall anomalies for all RCP scenarios (2010-2099)	99
Plate 4.3: Projected recharge time series for Pasture/Sand2/Crag	100
Plate 4.4: Main Development Site fixed head boundary conditions	108
Plate 5.1: Modelled transient groundwater balance in Sizewell Marshes for all baseline scenarios (2015-2040)	112
Plate 5.2: Groundwater level change duration curves in selected Peat piezometers during the 2022-2032 construction period (construction minus baseline levels: dry scenario)	116
Plate 5.3: Modelled transient groundwater balance in Sizewell Marshes under baseline and construction conditions in the dry scenario (2015-2040)	117
Plate 5.4: Groundwater level change duration curves in selected Peat piezometers (wet scenario).....	119
Plate 5.5: Modelled transient groundwater balance in Sizewell Marshes under baseline and construction conditions in the wet scenario (2015-2040).....	120

Plate 5.6: Groundwater level change duration curves in selected Peat piezometers (intermediate scenario)..... 122

Plate 5.7: Modelled transient groundwater balance in Sizewell Marshes under baseline and construction conditions in the intermediate scenario (2015-2040) 123

Plate 5.8: Groundwater level change duration curves in selected Peat piezometers (higher permeability cut-off wall) 126

Plate 5.9: Modelled transient groundwater balance in Sizewell Marshes under dry baseline and construction conditions, assuming standard and higher permeability cut-off walls (2020-2040)..... 127

Plate 5.10: Groundwater level change duration curves in selected Peat piezometers (natural recharge in TCAs) 129

Plate 5.11: Modelled transient groundwater balance in Sizewell Marshes under intermediate baseline and construction conditions, assuming natural and modified recharge in the TCAs (2022-2032)..... 131

Plate 5.12: Groundwater level change duration curves in selected Peat piezometers (extreme drought)..... 134

Plate 5.13: Modelled transient groundwater balance in Sizewell Marshes under baseline and construction conditions during extreme drought (2022-2025).... 135

Plate 5.14: Groundwater level change duration curves in selected Peat piezometers (low stream bed conductance) 137

Plate 5.15: Modelled transient groundwater balance in Sizewell Marshes under intermediate baseline and construction conditions, assuming low stream bed conductance (2022-2032)..... 138

Please note that the red line boundary used in the figures within this document was amended after this document was finalised, and therefore does not reflect the boundaries in respect of which development consent has been sought in this application. However, the amendment to the red line boundary does not have any impact on the findings set out in this document and all other information remains correct.

1 INTRODUCTION

1.1 Project context

- 1.1.1. EDF Energy is required to assess potential impacts from the proposed Sizewell C power station development on groundwater in the vicinity of the site, as part of the Development Consent Order (DCO) process. The proposed development includes several aspects with the potential to modify the groundwater flow regime, including a cut-off wall, water management zones and a temporary construction area (TCA). In addition to direct impacts on the groundwater flow regime, there is potential for changes to the surface water network (and vice versa) and for these changes to affect ecological receptors dependent on the wetland habitats they sustain. To inform predictive assessments of the potential effects of the development, EDF Energy has constructed and calibrated a transient 3D numerical groundwater flow model. Outputs from the groundwater modelling will be used to inform other studies relating to the potential environmental changes resulting from the proposed development.
- 1.1.2. A robust conceptual understanding of the groundwater flow regime has been developed, based on site investigation and monitoring data collected over a period of several years as well as review of publicly available information and literature sources. A conceptual model of the site is presented in this report, based on a previous, detailed Conceptual Site Model (CSM) developed by Atkins (2015a).
- 1.1.3. The preliminary approach to numerical model selection and development was set out in a Model Approach Report (Atkins, 2015b). The translation of the conceptual understanding into the numerical groundwater model has previously been described in reports on both steady state (Atkins, 2015c) and transient modelling (Atkins, 2016a) of the site under baseline conditions. The transient modelling report included a comparison of modelled groundwater levels, surface water stage and surface water flow with observed values, to demonstrate the suitability of the model for assessing potential impacts on groundwater and supported environments (i.e. surface water and ecology).
- 1.1.4. Following consultation with stakeholders and feedback received, EDF Energy has made further refinements to the baseline model, leading to an improved calibration to observed data. This report describes the refinements made to the model and presents the results of the revised calibration.
- 1.1.5. This report describes how the calibrated model has been used to assess the potential changes in groundwater regime and supported environments resulting from the proposed development. EDF Energy has compared the

simulated behaviour of the groundwater system under development and baseline conditions, covering the various phases of the proposed development from the present day until 2130. This comparison has been carried out for a range of future climatic scenarios (wet, dry and intermediate), based on the outputs from the recent UKCP18 projections (Bernie, Gohar, Good, & Lowe, 2018).

1.1.6. The outputs of the scenario modelling are used to inform the following:

- Environmental Impact Assessment (EIA);
- Habitats Regulations Assessment (HRA);
- Water Framework Directive (WFD) compliance;
- Flood Risk Assessment (FRA); and
- Hydrogeological assessment (Engineering Hydrogeology).

1.1.7. The numerical modelling is primarily based on the understanding developed during the development of the CSM, however model development has also been cognisant of the following work, previously undertaken in the area:

- Groundwater modelling performed by Vatnaskil Land and Water Resource Consultants Ltd (VLWRC) in 2010 (VLWRC, 2010);
- Studies conducted by AMEC and Royal Haskoning DHV (RHDHV) in 2014 (AMEC, 2014a; AMEC, 2014b; Amec and RHDHV, 2014);
- Environment Agency North East Anglian Chalk (NEAC) groundwater flow modelling (AMEC, 2015a); and
- Scenario modelling carried out by AMEC to assess suitability of the FEFLOW model domain (AMEC, 2015b).

1.1.8. While previous modelling works have been referred to, the intention is not to duplicate existing groundwater models. Knowledge gained from review of documentation describing the development of previous models by others has been taken into consideration when developing the current numerical model. In particular, the NEAC groundwater flow model, which covers the wider Northern East Anglia region, has been used to define boundary conditions. The NEAC model was developed for use in understanding regional groundwater flow and as such has a spatial resolution that is too low to accurately predict potential changes associated with the development. The area of the FEFLOW model, described in this report, is situated within the boundaries of the NEAC model, and the FEFLOW model

domain has been defined to allow an appropriate interface with the NEAC model at the model boundaries. The FEFLOW model that has been developed covers approximately 0.4% of the area of the NEAC model domain.

1.2 Report objectives and structure

1.2.1. The primary objective of this report is to present modelled projections of potential impacts from the proposed development on groundwater and supported environments under the likely range of future climatic conditions.

1.2.2. These projected impacts do not take proposed mitigation measures into account. As such, the scenarios presented will be used to understand the likely locations and magnitudes of unmitigated impacts, to inform and refine the overall approach to monitoring, mitigation and betterment. This approach will be presented in the associated Monitoring and Mitigation Plan, which will form part of the DCO submission and be used to proactively assess the real-world changes to ensure no unacceptable impacts occur.

1.2.3. As the future health of wetland ecosystems near the proposed development will be highly sensitive to future variations in climate, a range of future climate scenarios have been considered in the model. This will assist in understanding:

- the potential for impacts associated with construction and operation of the proposed development to be more or less severe under specific climatic conditions; and
- differences between current and future conditions in the absence of development, so that future water management at the site can be optimised to offset the impacts of climate change.

1.2.4. The report is structured as follows:

- Section 2 provides a summary of the site, its hydrogeological setting and other factors with the potential to influence current and future behaviour of the groundwater system, including a description of the proposed Sizewell C development;
- Section 3 describes development, calibration, verification and sensitivity analysis of the historical baseline model;
- Section 4 describes development of the future scenario models;
- Section 5 presents the results of the future scenario models; and

- Section 6 comprises a summary of the modelling conducted and overall conclusions.

1.3 Limitations

- 1.3.1. The current assessment has been based on the collation and evaluation of readily available documentation and data that in part have been provided by others (e.g. AMEC, the Environment Agency, and the Meteorological Office) as detailed in various sections of this report.
- 1.3.2. Data and information from third parties has not been fully verified by EDF Energy, however a high-level validity check has been carried out to ensure there are no immediately apparent errors or omissions. Based on this EDF Energy believes that the data can be relied on as input parameters for development of the groundwater model and its use in undertaking an impact assessment.
- 1.3.3. Modelling of the proposed development is based on the most recent available design information in February 2019. To allow for subsequent refinements to the proposed design and uncertainties in the properties of materials used in construction, conservative assumptions have been made to ensure that the maximum likely potential change is represented by the model in each scenario.

2 SITE DESCRIPTION

2.1 Location

- 2.1.1. The proposed Sizewell C power station would be located on the coast close to the existing Sizewell nuclear site. The Sizewell nuclear site has supported nuclear power facilities since 1966 and currently has one operational plant (Sizewell B) and one plant being decommissioned (Sizewell A).
- 2.1.2. The proposed Sizewell C main development site, herein referred to as 'the site', is located at National Grid Reference (NGR) TM472640 and is adjacent to the North Sea, as shown in Figure 19A.1. It lies less than 3 kilometres (km) to the east of the town of Leiston, and north of the small coastal village of Sizewell, which lies to the south of the existing Sizewell A power station.
- 2.1.3. The site is on the Suffolk Heritage Coast, within the Suffolk Coast and Heaths Area of Outstanding Natural Beauty (AONB). A small area of the Sizewell Marshes Site of Special Scientific Interest (SSSI), the majority of which lies to the west of the site, is within the site boundary. The Minsmere

– Walberswick Heaths and Marshes (MWHM) Special Area of Conservation (SAC), Special Protection Area (SPA), Ramsar and SSSI is located to the north of the site, while the Leiston – Aldeburgh SSSI is located to the south of the site. The limits of the three SSSIs are shown on Figure 19A.2.

2.1.4. The study area referred to in this report is equivalent to the extent of the groundwater model, as shown in Figure 19A.3. A detailed description of the model is provided in Section 3.

2.2 Topography and land use

2.2.1. The current topography of the site and surrounding area was defined using LiDAR data at 2 m lateral resolution, obtained from the Environment Agency. These data were consistent with the topographically surveyed top of casing elevations of groundwater monitoring boreholes across the site (see Section 2.6). A contour map of the local topography, produced using these LiDAR data, is presented in Figure 19A.4. The implications of topography on model accuracy is discussed further in Section 3.2b).

2.2.2. The landscape in the vicinity of Sizewell is a low plain falling away gently to the east towards the coast, with arable cropping and scattered woodland on sandy soils. Moving eastwards from the higher land towards Sizewell Marshes and the coast, the topography becomes more dissected, with deeply incised short dendritic valleys located around the margin of the marsh. The marshes themselves comprise a low, apparently flat, area of rectilinear fields permanently under pasture and separated by linear drainage ditches.

2.2.3. The Sizewell Marshes SSSI is formed in an embayment set back from the coast. Typical ground surface elevations are between 0.5 and 1 m above Ordnance Datum (AOD) (equivalent to between 2 and 2.5 m above chart datum at Lowestoft, 30 km to the north of the Main Development Site), although localised areas below 0.5 m AOD occur in the eastern and northern fringes of Sizewell Marshes, towards the MWHM SSSI.

2.2.4. The platform area of the Main Development Site lies predominantly at an elevation of 1 to 2 m AOD, although a ridge along its eastern edge, running parallel to the coast reaches elevations of 5-12 m AOD.

2.2.5. The Main Development Site surrounds an area of Riparian Peat (Sizewell Marshes), which is abutted to the north by an area of coniferous woodland and to the south by pasture and small areas of deciduous woodland, as shown in Figure 19A.5. The northern, western and southernmost parts of the site are dominated by arable land, while the North Sea lies to the east of the site.

2.2.6. A relatively narrow strip of riparian loam pasture extends northwards from the platform area of the site, while Sizewell B lies to the south of the platform, separated from the sea by a thin strip of pasture.

2.3 Climate

2.3.1. Long-term climate data were obtained from the Met Office (Met Office, Hollis, D. and McCarthy, M., 2017) for the 5 km grid square centred on NGR TM450650, which lies at the north-western corner of the proposed Main Development Site.

2.3.2. These data were obtained from 1981 onwards, as the period from 1981-2010 has been used as the baseline period for applying climate change anomalies during the future scenario modelling, as described in Section 4.2.

2.3.3. Average annual rainfall in this area since 1981 is 628 mm. The driest year in this period was 1991, with an annual total of 434 mm, while the wettest year was 2000, with a total of 865 mm (Plate 2.1).

2.3.4. Rainfall is fairly evenly distributed throughout the year, although autumn is typically the wettest season, with average daily rainfall of 2.0 mm and spring and summer are the driest, with average daily rainfall of 1.6 mm (Plate 2.2).

Plate 2.1: Observed daily and annual rainfall for the 5 km grid square centred on TM450650 (Met Office, Hollis, D. and McCarthy, M., 2017)

Plate 2.2: Observed seasonal variations in rainfall for the 5 km grid square centred on TM450650 (Met Office, Hollis, D. and McCarthy, M., 2017)

- 2.3.5. Plate 2.3 shows observations of daily maximum and minimum temperature over the period of interest, averaged over each month. Daily maximum temperatures commonly reach 20°C to 25°C in summer, falling to 1°C to 10°C in winter. Mean daily maximum values are close to 8°C during winter and approximately 21°C in summer.
- 2.3.6. Daily minimum temperatures commonly range from -3°C to 4°C during the winter months and 9°C to 15°C during summer. Mean daily minimum temperatures over the period of interest are approximately 2°C in winter, rising to approximately 12°C in the summer months.

Plate 2.3: Observed daily maximum and minimum temperatures per month for the 5 km grid square centred on TM450650 (Met Office, Hollis, D. and McCarthy, M., 2017)

2.4 Geology

a) Data sources

- 2.4.1. The geology of the Sizewell C site and surrounding area has been interpreted using geological maps and memoirs produced by the British Geological Survey and more than 400 borehole logs. Individual data sources are listed in the conceptual site model report (Atkins, 2015a).

b) Regional geology

2.4.2. The mapped superficial and bedrock geology of the site are shown in Figures 19A.6 and 19A.7 respectively, while a summary of the stratigraphy across the study area is provided in Table 2.1.

Table 2.1 Summary of stratigraphy in the study area

	Unit	Sub-Unit	Age		Occurrence
Superficial Deposits	Marine Deposits	Tidal Flats	Quaternary	Holocene	Close to coast
		Sand and Gravel			
	Peat	-			Low lying marshy areas
	Alluvium	-			River valleys
	Head	-		River valleys	
	Lowestoft Formation	Lowestoft Till		Anglian	Locally absent
Lowestoft Sand and Gravel		Locally absent			
Bedrock	Crag Group	Red Crag Formation	Tertiary (Palaeogene)	Pliocene-Pleistocene	Throughout study area
	Thames Group	London Clay Formation		Palaeocene -Eocene	Throughout study area – absent 3 km beyond western boundary
		Harwich Formation			
	Lambeth Group	Woolwich and Reading Formation			
	Thanet Group	Thanet Sand Formation			
	Lista Formation	Ormesby Clay Member			
	Chalk Group	White Chalk			

- 2.4.3. As indicated by Figure 19A.6 and Table 2.1, the majority of the study area is underlain by Anglian Superficial Deposits, comprising Till (mapped as diamicton or clay and silt) and Sand and Gravel of the Lowestoft Formation of Anglian age. The Lowestoft Till reaches a maximum thickness of approximately 20 m in the west of the study area and thins out completely towards the coast. The Lowestoft Sand and Gravel is approximately 8 to 10 m thick across the central part of the study area, increasing to around 20 m thick near the Minsmere Old River/Minsmere New Cut in the north and also near the Hundred River in the south. Below the Sizewell C site and Sizewell Marshes the sand and gravel is typically less than 6 m thick, and in some places locally absent.
- 2.4.4. The Lowestoft Formation unconformably overlies the Pliocene-Pleistocene Crag, which in turn unconformably overlies the Cretaceous Chalk. The Crag is between 19 and 49 m thick across the study area; thicknesses of less than 30 m have been recorded only to the south of Hundred River, while the only values exceeding 40 m have been recorded immediately to the south of Sizewell Marshes. Site investigations undertaken in 2010 (Soil Mechanics, 2011) suggest that spatial changes in the depth to the base of the Crag are gradual in this area, and hence the increase in thickness is unlikely to be related to any particular structural feature.
- 2.4.5. Tertiary age deposits, comprising the Thames Group (London Clay Formation and Harwich Formation), Lambeth Group, Thanet Sand and Ormesby Clay Member are present throughout the study area, forming a wedge that thickens eastward and southward between the Crag and Chalk. This wedge is often referred to as the Paleogene deposits, with the Lambeth Group, Thanet Sand and Ormesby Clay Member also referred to collectively as the Lower London Tertiaries. The London Clay thins out completely to the west of Sizewell with the Crag overstepping the Woolwich and Reading Formation, and finally the Chalk, around 3 km beyond the western boundary of the study area. Within the study area itself, the thickness of the Tertiary age deposits ranges from approximately 20 m in the north-west to around 65 m in the south-east, near Aldeburgh.
- 2.4.6. Within the river valleys, the Lowestoft Formation has generally been removed, while younger deposits of Head and Alluvium (sand, silt and clay) and Peat are present in the valley bottoms. In some local areas the superficial deposits have been completely eroded and the Crag Formation crops out.

2.5 Local geology

- 2.5.1. Table 2.2 presents a summary of the stratigraphy of the Sizewell C site and the immediate surrounding area, including Sizewell Marshes.

Table 2.2 Summary of stratigraphy near Sizewell C

	Unit	Sub-Unit	Age		Remarks
	Made Ground	-	Recent	-	Placed during construction of Sizewell B
Superficial Deposits	Marine Deposits	Tidal Flats	Quaternary	Holocene	Present near coast
		Sand and Gravel			
	Peat	-			Present beneath Sizewell C, Sizewell Marshes and to the north, possibly as far as Minsmere – Walberswick Heaths and Marshes SSSI
	Alluvium	-			
	Head	-			
	Lowestoft Formation	Lowestoft Till		Anglian	Locally absent
		Lowestoft Sand and Gravel			Locally absent
Crag Group	Red Crag Formation	Pliocene-Pleistocene	-		
Bedrock	Thames Group	London Clay Formation	Tertiary	Palaeocene-Eocene	-
		Harwich Formation			Collectively referred to as Lower London Tertiary deposits
	Lambeth Group	Woolwich and Reading Formation			
	Thanet Group	Thanet Sand Formation			
	Lista Formation	Ormesby Clay Member			
	Chalk Group	White Chalk			Cretaceous

- 2.5.2. The Sizewell C site itself predominantly comprises Made Ground directly overlying the Crag (EDF NNB GenCo, 2014a). Other superficial deposits are locally absent, except for a relatively thin cover of Peat in the north and north-west of the site.
- 2.5.3. The Made Ground beneath the site is up to 12 m thick, comprising material excavated during the construction of Sizewell A and Sizewell B. The base of the Made Ground rises towards the east, reflecting the original topography. The Made Ground comprises reworked Superficial Deposits and Crag, which makes it difficult to distinguish from natural strata.
- 2.5.4. Marine Deposits, comprising sand and gravel, are present in a strip approximately 100 m wide along the coastline to the east of the site and extend along the coast to the north and south. To the north of the site, tidal flats extend approximately 500 m inland of the beach deposits. Tidal flats are locally present at the site, beneath the Made Ground.
- 2.5.5. Alluvium is locally present at the site and in the surrounding area but is not laterally persistent. To the west of Dunwich Forest, up to 2 m of Alluvium has been identified in individual borehole logs, and clay layers between 1 m and 4 m thick have been recorded in boreholes at the site.
- 2.5.6. Peat deposits with an average thickness of 3 to 4 m are present in the northern and north-eastern part of the site, coincident with the Sizewell Marshes. The Peat contains a variable degree of clay, silt and sand in a matrix of highly organic soil. Following the emplacement of the Made Ground, the Peat deposits at the Sizewell C site have become compacted. Peat deposits extend to the west of the site and increase in thickness in the Sizewell Marshes SSSI. The thickest deposits of approximately 8 to 10 m are located in Sizewell Marshes SSSI, directly adjacent to the Sizewell C site. Peat deposits are also present within the MWHM SAC, SPA and SSSI, to the north of the site. No boreholes have been installed within the MWHM SAC, SPA and SSSI that have fully penetrated the peat. However, it is considered that the thickness of the Peat deposits will be similar to those observed in Sizewell Marshes SSSI, with Peat decreasing in thickness with distance from the Sizewell C site.
- 2.5.7. Where present inland, Alluvium and Peat passes beneath the sand and gravel of the Marine Deposits, and has been shown to extend beneath Sizewell Bank (Soil Mechanics and Wimpey Laboratories, 1982).
- 2.5.8. Deposits of the Lowestoft Formation are typically limited to areas of higher ground in an arc from the north-west of the site to the coast south of Sizewell A. Lowestoft Till is present at higher levels to the west, with the underlying Lowestoft Sand and Gravel exposed as the ground levels decrease towards the coast. The Lowestoft Formation is generally absent

in the low-lying area immediately to the west of the site. However, sand and gravel, potentially from the Lowestoft Formation, is locally present beneath the Peat. It is difficult to differentiate these sand and gravel deposits from the Crag, and it is likely that they are in hydraulic continuity acting as one hydrogeological unit.

- 2.5.9. The Crag Group is overlain by Superficial Deposits at the site and across the surrounding area, with the exception of eastern and northern sections of the site where the Crag crops out. The Crag is not homogeneous and is reported (VLWRC, 2010; Moorlock, B. S. P. et al, 2000) to contain two discrete low hydraulic conductivity layers: the Chillesford Clay Member in the upper part of the Crag and an unnamed silty layer at approximately -13 to -17 m AOD in the vicinity of the Sizewell Marshes SSSI. Site investigations undertaken in 2010 (Soil Mechanics, 2011) suggest some structure to the upper surface of the Crag, taking the form of an asymmetric shallow trough with the axis roughly aligned east-west. The majority of the borehole logs for the area do not show the Chillesford Clay and the unnamed silty layer and therefore these layers are not considered to be laterally continuous beneath Sizewell C or the SSSI Marshes.
- 2.5.10. The Paleogene Deposits, comprising approximately 15 m of London Clay overlying 25 m of Lower London Tertiaries, are present beneath the site and surrounding area. These deposits thin to the west, where they ultimately pinch out approximately 8 to 10 km inland, allowing the Crag to directly overlie the Chalk, which is present at the site and in the surrounding area beneath the Paleogene Deposits.
- 2.5.11. Plate 2.4 shows the inferred geological cross-sections in a north-south and southwest-northeast orientation in the vicinity of the Main Development Site.

Plate 2.4: Inferred geological cross sections based on borehole log data

2.6 Hydrogeology

a) Groundwater levels

i. Peat

2.6.1. Groundwater levels within the Peat were not recorded historically at the Sizewell C site nor neighbouring areas of Sizewell Marshes SSSI and Minsmere - Walberswick Heaths and Marshes SSSI. Piezometers were installed into the Peat within the marshes to the north and west of the Sizewell C site in 2013 to address this data gap.

2.6.2. Piezometers P1 to P15 were installed by hand auger to approximately 1.5 m bgl and partially penetrate the Peat (AMEC, 2012). Construction details for these piezometers are presented in Table A.1 of Appendix A. Groundwater levels in these locations have been monitored from October 2013 to present and are presented in Figure 19A.8.

2.6.3. Winter maximum water levels in the Peat piezometers are typically between 0.6 and 0.7 m AOD. These maximum values are influenced by the local topography, although it is noteworthy that in some cases, they represent ponding of water at the surface; in several piezometers, the recorded values exceed the ground surface elevation by up to 20 cm.

2.6.4. Summer minimum water levels vary notably between monitoring locations; values range from approximately 0.5 m AOD, to close to 0 m AOD, with P4 displaying values of less than -0.1 m AOD on occasion. Typically, piezometers with the lowest summer minima are those closest to permanent drainage channels, at the downstream end of Sizewell Marshes.

ii. Crag

2.6.5. To minimise disturbance to the sensitive ecosystems of Sizewell Marshes and the Minsmere – Walberswick Heaths and Marshes SSSI, no boreholes have been drilled into the Crag in these areas, although numerous piezometers have been installed on the periphery of the wetlands and to the north and west, in the proposed temporary construction area of the Main Development Site. Regular groundwater level monitoring has been conducted in these piezometers and used for the purposes of model calibration. Construction details for these piezometers are presented in Table A.1 of Appendix A.

2.6.6. Groundwater level monitoring in these piezometers was conducted in 2010 and, following an interruption to the monitoring programme, regular monitoring was resumed in October 2013. The available data from these piezometers, spanning a wide range of depths within the Crag, are shown in Figures 19A.9 to 19A.11. Data from the shallowest piezometers are

presented in Figure 19A.9, while Figure 19A.11 presents data from the deepest monitoring locations.

- 2.6.7. In the vicinity of the platform, groundwater levels in the Crag typically range from 0.4 to 1 m AOD. Seasonal variations are notable in this area, with a typical range of 0.3 m between winter maxima and summer minima. Semidiurnal fluctuations are also apparent, which can be attributed to tidal influences from the coast.
- 2.6.8. Average groundwater levels in the Crag typically increase with distance from the coast and the low-lying wetland areas of Sizewell Marshes and the Minsmere – Walberswick Heaths and Marshes SSSI.
- 2.6.9. The highest recorded groundwater levels in the monitoring network occur in the far north of the Main Development Site, with a maximum value of more than 2.5 m AOD in borehole C7. Maximum water levels typically exceed 1.5 m AOD in the northern and western parts of the Main Development Site, while to the south, in piezometers GW20 and GW21, groundwater levels generally vary between 0.8 and 1.3 m AOD.
- 2.6.10. Piezometers in these more distal areas may display seasonal water level variations of up to 0.3 m, although the magnitude of these variations is reduced in the deepest boreholes, where longer-term, interannual changes in groundwater level are apparent. Semidiurnal fluctuations are absent or greatly reduced in these areas, suggesting a limited hydraulic connection to the coast.
- 2.6.11. Comparison of observed groundwater levels in dual install piezometers C2S and C2D indicates a slight increase in hydraulic head with depth, although this phenomenon is not apparent in other dual-install piezometers (C1S/D, C3S/D and C4S/D).

iii. Overview

- 2.6.12. Overall, groundwater levels reflect the local topography, with a general decrease in hydraulic head towards the coast, low-lying wetland areas and drainage channels. Groundwater levels are typically highest in the Crag, largely as a result of the local topography.
- 2.6.13. Seasonal variations in groundwater levels are most apparent in the shallow parts of the system, while semidiurnal variations decrease in magnitude with distance from the coast.

b) Aquifer properties

2.6.14. The available aquifer properties data for strata encountered in the study area are summarised in Table 2.3.

Table 2.3: Summary of aquifer properties data

Unit	K (m/d)	T (m ² /d)	S (-)	S _y (-)	Source
Peat	0.01 to 0.32 mean = 0.12	Not available			Falling head tests (AMEC, 2013)
	Horizontal: 0.009 to 17, mean = 0.35; Vertical: 0.009 to 17, mean = 0.09	Not available			Groundwater model (VLWRC, 2010)
Crag	Not available	1.75 to 4231, mean = 394	7 x 10 ⁻⁵ to 0.62, mean = 0.02	Not available	East Anglia pumping tests (Jones et al, 2000)
	Not available	300 to 1000	3 x 10 ⁻⁴ to 0.001	0.04 to 0.1	Long duration pumping test (VLWRC, 2010)
	22 to 37	687 to 1168	4.4 x 10 ⁻⁵ to 0.001	Not available	Long duration pumping test (Soil Mechanics, 2011)
	0.02 to 33	Not available			Rising and falling head tests (AMEC, 2014a; Soil Mechanics, 2011; Structural Soils, 2014)
London Clay	0.001 to 0.01	Not available		Core tests – not site-specific (Jones et al, 2000)	
Thanet Group	1.4 to 3.9	Not available			
Tertiary (overall)	Vertical: 9 x 10 ⁻⁶ to 0.009, mean = 9 x 10 ⁻⁴	Not available		Calibrated groundwater flow model of study area (VLWRC, 2010)	
Chalk	Not available	Mean = 255	Mean = 0.003	Not available	East Suffolk pumping tests (Allen, et al., 1997)
	Horizontal: 8 to 35; Vertical: 13 to 26	Not available			Groundwater model (VLWRC, 2010)

Note: All mean values shown are geometric means.

- 2.6.15. The available data indicate that, on average, the Peat is substantially less permeable than the underlying Crag aquifer, while the Tertiary deposits form a low permeability layer between the Crag and the underlying Chalk.
- 2.6.16. Previous studies, cited by Wong et al (2009), indicate that the hydraulic conductivity and porosity of peat are inversely related to both the degree of compaction and decomposition. In turn, this suggests that the deeper parts of the Peat within the study area are likely to have relatively low values of hydraulic conductivity and specific yield compared to Peat encountered near the surface.

c) Groundwater flow

i. Recharge

- 2.6.17. Previous modelling of the study area by AMEC (2015a) suggests that direct infiltration from rainfall is the dominant mechanism of recharge. The results from the NEAC model suggest a contribution of nearly 90% to long-term average recharge from direct infiltration, with substantially smaller components from runoff recharge and leakage from streams.
- 2.6.18. The distribution of recharge in the study area, as in most areas, is likely to be strongly influenced by local variations in soil type, geology and land use. The NEAC model assigned the highest values of recharge within the study area to outcrops of Crag and sandy or gravelly superficial deposits.
- 2.6.19. The low-permeability Lowestoft Till limits recharge to the underlying Crag and the majority of recharge that occurs in these areas is likely to be via bypass flow through fractures (Ander, Shand, & Wood, 2006).
- 2.6.20. Although the permeability of the Peat is low in comparison to other strata in the study area, the nature of the low-lying wetland areas where it occurs suggests that soil moisture deficits are likely to be minimal throughout the year, thereby allowing recharge to occur more readily than in other low-permeability units.
- 2.6.21. Previous studies indicate that groundwater flow within the Crag is predominantly intergranular and variations in recharge can be attributed to local variations in lithology, rather than the presence of fractures (Ander, Shand, & Wood, 2006). While piston flow is likely to be an important mechanism for recharge across much of the Crag, rapid bypass flow may also occur due to the presence of these local changes in lithology.

ii. Abstractions

- 2.6.22. Data provided to Atkins by AMEC as part of a data transfer from the Environment Agency's NEAC model (AMEC, 2015a) indicate 98 licensed abstraction points in the vicinity of model area. These abstractions are either for potable water supply, or for agricultural purposes, commonly for irrigation.
- 2.6.23. A number of these abstractions have been revoked, were no longer active as of 2008, are duplicates, can be found at the same coordinates as another licensed abstraction, or are outside the model domain. As such, 24 unique groundwater abstraction points were identified within the model domain (see Section 3.2h) for further details.
- 2.6.24. Average monthly abstraction rates over the period from 2008 to the end of the available data in 2012 are provided in Table B.1 of Appendix B.
- 2.6.25. In addition to licensed abstractions, a 10-day pumping test was conducted in the platform area of the Main Development Site in early 2011, to assess aquifer properties in the Crag and neighbouring Peat; this test produced an average discharge of approximately 30 l/s (2592 m³/day) (WJ Groundwater, 2011).

iii. Groundwater flow directions

- 2.6.26. The available groundwater level data indicate regional flow towards the coast and more locally, flow from the Crag to the adjacent, low-lying wetlands.
- 2.6.27. Within Sizewell Marshes itself, groundwater flow directions may locally vary seasonally, although the available data suggest that the drainage channels receive baseflow from the underlying Peat for much of the year.
- 2.6.28. In the deeper parts of the groundwater system, the low hydraulic conductivity and high thickness of the London Clay within the Palaeogene deposits provides hydraulic separation between Crag and Chalk aquifers. The geological memoir for the region, produced by the British Geological Survey (2000) confirms that Palaeogene deposits provide a continuous separation between the Crag and the Chalk across the study area, with no evidence of higher hydraulic conductivity areas.
- 2.6.29. In the Environment Agency's NEAC model (AMEC, 2015a), differences in hydraulic head exist between Chalk and Crag groundwater across the study area, with Chalk levels higher than Crag levels. This suggests a limited hydraulic connection between these units and the presence of limited upward flow of groundwater across the London Clay and other Tertiary deposits.

- 2.6.30. Previous work suggests that even relatively large changes in hydraulic head within the Crag would have relatively localised and minimal impacts on head within the Chalk (Atkins, 2016a).

2.7 Hydrology

a) Surface water features

- 2.7.1. The study area is bounded to the north by the Minsmere Old River and Minsmere New Cut, and by the River Alde and River Fromus in the south. Hundred River also lies within the study area discharging to the coast around 4 km to the south of the proposed site of the Sizewell C Power Station (the platform area).
- 2.7.2. Extensive wetlands are present to the west and north of the platform and a dense network of permanent and ephemeral drainage channels is present, particularly within the Sizewell Marshes SSSI. Further details on these drainage channels and their implementation in the model are presented in Section 3.2g).
- 2.7.3. The outlines of the Water Framework Directive surface water operational catchments within the model domain are shown in Figure 19A.12. The catchment of the Leiston Beck covers the Main Development Site, while the Minsmere Old River catchment extends across the north-western and far northern parts of the model domain. The Hundred River catchment covers much of the southern part of the model domain, while narrow areas along the coast and along the margins of the River Alde and River Fromus lie outside of any operational catchment, due to tidal influences in these areas.

b) Abstractions

- 2.7.4. Based on data supplied to Atkins by AMEC, two surface water abstractions (licence numbers 7/35/03/*S/0051 and 7/35/03/*S/0075) lie within the Sizewell Marshes area.
- 2.7.5. Average monthly abstraction rates over the period from 2008 to the end of the available data in 2012 are provided in Table B.2 of Appendix B.

2.8 Proposed developments

- 2.8.1. The Sizewell C development proposals are highly complex and extend beyond the main development site (MDS). In this study, only features which may affect groundwater in the vicinity of the MDS and Sizewell Marshes have been incorporated into the groundwater flow model in order to assess their potential impacts. This section provides a brief description of these

development features; further details on design parameters and their implementation in the model are provided in Section 4.3.

a) **Aldhurst Farm Habitat Creation Scheme**

2.8.2. Aldhurst Farm Habitat Creation Scheme (HCS) is a permanent feature completed in 2015. Operational agricultural land was converted to managed wetland and grassland. The site is located to the west of Sizewell Marshes and Lover's Lane, centred on approximate NGR TM450634.

b) **SSSI Crossing**

2.8.3. A permanent causeway over the Sizewell Marshes SSSI will link the MDS to Goose Hill and provide vehicle access to Sizewell C during construction, operation and decommissioning. The crossing, which is proposed for construction in 2020, would be located directly to the north of the MDS, centred on NGR TM473645. The works would involve the installation of sheet piling, piles and a culvert structure, excavation and replacement of natural materials and laying of impermeable road surfaces.

c) **Sizewell Drain realignment**

2.8.4. As part of the development of the MDS, a small parcel of the SSSI known as Goodram's Fen (centred on NGR: TM471643), to the north-west of the current platform area would be incorporated. The land-take requires Sizewell Drain to be permanently realigned to flow along the western edge of the development, tying in with Leiston Drain to the north-west of the MDS.

d) **Main Development Site embankment toe sheet pile walls**

2.8.5. During construction, the MDS would be raised above natural ground level, with embankments along its boundaries. At the toe of the western and northern MDS embankments, immediately adjacent to the MDS, it is proposed that sheet piles would extend from ground level into the underlying geology, providing structural stability to the embankments.

e) **Main Development Site**

2.8.6. Along the perimeter of the MDS (centred on NGR: TM473642), a low-permeability cut-off wall would be constructed to isolate the MDS from the surrounding groundwater regime. Within the cut-off wall, dewatering would lower groundwater levels across the MDS, enabling natural materials to be excavated and backfilled with site-won granular fill, and building foundations to be laid. The completed MDS would have a predominantly hardstanding cover, with site drainage discharging surface water directly to the sea.

f) Borrow pits

2.8.7. Borrow pits would be located to the north-west of Kenton Hills, centred on NGR TM455653, where the natural elevation of the ground surface ranges from approximately 12 to 15 m AOD. The borrow pits would provide granular Crag material for construction purposes, and receive material excavated from the MDS.

g) Temporary Construction Area and Water Management Zones

2.8.8. The Temporary Construction Area (TCA) would be located to the north of the Sizewell Marshes SSSI, between the B1122 to the west and the sea to the east. It would house a number of facilities required for the construction of the power station, including an accommodation campus, a rail terminal and construction contractors' compounds. As part of the TCA, a series of Water Management Zone (WMZ) ponds would be constructed, acting as storage ponds and discharging to groundwater and surface water when excess surface runoff is generated.

h) Car park

2.8.9. Following construction, a car park is proposed to the north of the platform area throughout site operation.

3 HISTORICAL BASELINE MODEL DEVELOPMENT AND CALIBRATION

3.1 Previous model development

3.1.1. Following the development of a detailed Conceptual Site Model (CSM), the preliminary approach to numerical model selection and development was described in a Model Approach Report (Atkins, 2015b), which proposed the use of the finite element package FEFLOW.

3.1.2. FEFLOW was chosen for subsequent steady state and transient groundwater modelling of the site, due to:

- the flexibility of its finite element mesh in simulating complex geometries;
- the capacity to represent groundwater and surface water interactions via coupling to the surface water modelling package, MIKE11; and
- its overall stability in simulating a range of standard benchmark problems, as described by Trefry & Muffels (2007).

3.1.3. The transient model, completed in 2016, was used to simulate groundwater and surface water during the period from September 2010 to August 2015. It was calibrated with the aims of matching:

- observed groundwater levels in the Peat of the Sizewell Marshes to within 10 cm;
- observed groundwater levels in the Crag to within 25 cm near the Sizewell Marshes and to within 50 cm elsewhere within the model domain;
- surface water flows to within 10% of observed values;
- low flows to within 25% of observed values; and
- peak flows to within 30% of observed values.

3.1.4. These targets were largely achieved in most cases, although the model commonly overestimated the magnitude of seasonal groundwater level fluctuations. In the Peat, this led to the model producing excessively high groundwater levels in winter and excessively low groundwater levels in summer, while in the underlying Crag aquifer, simulated groundwater levels were too low on average, leading to relatively large calibration errors in summer as a result of the exaggerated seasonal fluctuations.

3.1.5. Following stakeholder feedback, EDF Energy has revisited the 2016 transient model and implemented the following to improve calibration and maintain or improve consistency with the CSM:

- reduced evapotranspiration with depth below the water table in wetland areas;
- drainage of groundwater that exceeds the elevation of the ground surface;
- aquifer properties and recharge consistent with the presence of extensive sandy made ground material within the platform area;
- reduced hydraulic conductivity with depth in the superficial deposits of Sizewell Marshes, reflecting additional compaction of the peat and the potential presence of more clay-rich material;
- increased specific yield applied to the Sizewell Marshes;
- assignment of stream boundary nodes to all mapped drainage channels within Sizewell Marshes at shallow depth;

- removal of all stream boundary nodes in Sizewell Marshes below -2 m AOD; and
- assignment of tidal flats aquifer properties and recharge within the Minsmere – Walberswick Heaths and Marshes SSSI.

3.1.6. A comprehensive description of the revised groundwater model is provided in the following section.

3.2 Revised model description

a) Model extent

3.2.1. The model covers an area of approximately 62 km², extending from Minsmere Old River/Minsmere New Cut in the north to the River Alde and River Fromus in the south. The western boundary of the model follows the 6 m AOD average groundwater level contour from the Environment Agency's NEAC model, while the eastern boundary of the model extends approximately 1 km beyond the coast, as shown in Figure 19A.3.

b) Finite element mesh

3.2.2. A plan view of the finite element mesh is shown in Figure 19A.13. Mesh refinement is greatest around the Main Development Site and Sizewell Marshes, where element diameters of less than 1 m are common, while the mesh is coarsest near the model boundaries, where element diameters may exceed 500 m. The overall aims of mesh refinement were to:

- facilitate the simulation of development structures; and
- optimise the accuracy and resolution of projected changes in the groundwater system near the Main Development Site and Sizewell Marshes.

3.2.3. Additional minor refinements to the mesh were implemented in modelling the development scenarios (described in Section 4.3), to reflect the most recent revisions to the proposed design.

3.2.4. LiDAR data at 2 m lateral resolution were used to define the modelled ground surface. Inaccuracies in the LiDAR dataset due to the presence of above-ground features, such as individual trees or shrubs, are unlikely to affect model accuracy significantly for the following reasons:

- The model simulates water levels relative to ordnance datum, rather than relative to the ground surface.

- Modelled recharge is applied directly to the water table and is insensitive to the thickness of the unsaturated zone above it.
- Water levels in the wetland areas are controlled by the stage of nearby surface water features (see Section 3.2g) and rates of evapotranspiration (See Section 3.2e), as well as the local ground surface elevation (see Section 3.2f).
- The stage of nearby surface water features is primarily controlled by assigned stage and flow boundary conditions, which are based on observations from gauging stations (see Section 3.2g) and surveyed stream bed elevations, rather than LiDAR topographic data.
- In the wetland areas, above-ground features with the capacity to reflect the LiDAR signal are likely to be limited to a few centimetres in height, or in the case of larger tussocks, of limited lateral extent, such that the majority of data points are expected to provide an accurate approximation of the ground surface.
- Above-ground features would need to be extensive to allow groundwater mounding to occur, without groundwater seepages or high evapotranspiration rates manifesting in the model within neighbouring mesh elements.

3.2.5. The mesh has been divided into 12 layers to:

- represent variations in geology and aquifer properties with depth;
- improve numerical representation of groundwater head where substantial contrasts in aquifer properties exist, through the implementation of thin, ‘dummy’ layers, with a thickness of 0.1 m; and
- facilitate representation of subsurface development structures.

3.2.6. Layer elevations were assigned using kriging of the base and top elevations of individual strata, as indicated by more than 400 borehole logs across the study area. The number of boreholes used to define each unit is presented in Table 3.1; some of the 400 borehole logs have been used to define multiple strata.

3.2.7. The resulting layer elevations are consistent with those assigned to the previous FEFLOW model, with the exception of layer 1, which was subdivided into 2 separate layers to facilitate the representation of shallow development features in the future scenario modelling. In wetland areas, the thickness of layer 1 was set to 1 m below the ground surface, to facilitate the assignment of evapotranspiration, as described in Section 3.2e).

Table 3.1: Number of boreholes used to define each geological unit

Unit	Number of boreholes
Made Ground and Marine Deposits	111
Alluvium	98
Peat	83
Lowestoft Till	37
Lowestoft Sand and Gravel	148
Crag	246

3.2.8. Superficial deposits have been represented within the top 7 layers of the model, alongside areas of Crag, which crops out across much of the model domain.

3.2.9. Layers 8-12 of the model comprise the Crag exclusively. The boundary between the base of the Crag and the underlying, low-permeability Tertiary deposits forms the base of the model.

c) **Model boundaries**

3.2.10. Constant hydraulic head (Dirichlet) boundary nodes were applied to the lateral boundaries of the model domain, as shown in Table 3.2.

3.2.11. The locations of these specified head boundary nodes are shown in Figure 19A.14, alongside the locations of stream boundary (Cauchy) nodes, which have been implemented across the low-lying wetland areas near the site and are discussed further in Section 3.2g).

Table 3.2: Lateral boundary conditions applied to the model

Boundary	Values	Rationale
West	Head of 6 m AOD applied throughout.	Location of western boundary coincides with 6 m AOD average contour line from Run 598 of the Environment Agency NEAC groundwater model.
East	Equivalent freshwater head of 0.14 m AOD applied to all nodes beneath the sea floor.	Value equivalent to that applied to Run 598 of the 2015 NEAC model. Equivalent freshwater heads account for vertical pressure gradients at the coast, due to saturation of the pore space with high density sea water.
North	Applied heads vary linearly from 6 m AOD in the west to 0.14 m AOD at the coast.	Represents approximate water levels in the Minsmere River.
South	Applied heads vary linearly from 6 m AOD in the west to 0.14 m AOD in the estuary of the River Alde, c. 4 km from the coast.	Water levels in the River Alde estuary are considered to be representative of sea level.

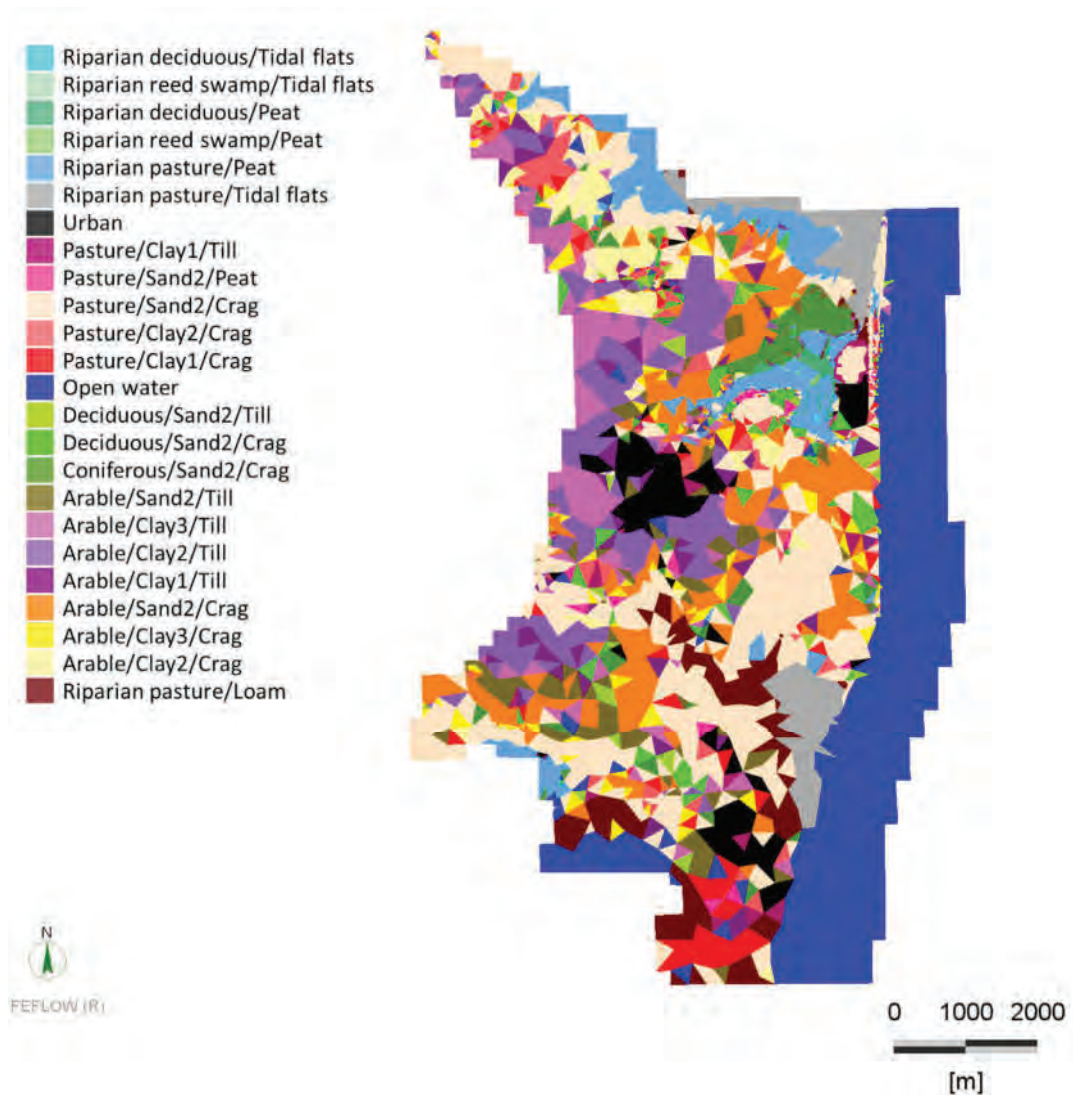

d) Recharge and run-off

i. Recharge zones

3.2.12. Rates of recharge were largely determined using a soil moisture balance model (SMBM), applying a modified version of the 4R approach applied in the Environment Agency’s NEAC model (AMEC, 2015a). The SMBM incorporates temporal variability in rainfall, evapotranspiration, soil moisture and vegetation development; and spatial variability in land use (including vegetation type), soil type and geology, to estimate recharge to the underlying aquifer.

3.2.13. A total of 24 recharge zones were defined within the model domain, based on combinations of soil type, land use and geology, as shown in Plate 3.1.

Plate 3.1: Recharge zones assigned to the FEFLOW model

3.2.14. Net average recharge rates applied to each of these zones throughout the model calibration period are shown in Figure 19A.15, which presents the combined influence of applied recharge and evapotranspiration from the water table for a fully saturated ground surface, a phenomenon applied to wetland areas of the model. The approach to simulating changes in evapotranspiration rates with depth of the water table below the ground surface is described further in Section 3.2e).

3.2.15. Comparison of the data in Figure 19A.15 with Figures 19A.6 to 19A.7 and the named zones in Plate 3.1 shows how applied recharge varies as a function of geology, with average values of less than 50 mm/yr across the Lowestoft Till and more than 150 mm/yr in areas of outcropping Crag; the effective average recharge rate across the entire domain is 69 mm/yr. The

negative values applied across the Sizewell Marshes and MWHM SSSIs reflect the magnitude of evapotranspiration that occurs in these wetland areas when fully saturated.

ii. Overview of the soil moisture balance

3.2.16. Diffuse recharge for the various combinations of soil type, land use and geology within the model was estimated using a soil moisture balance (SMB), based on the standard Food and Agriculture Organisation (FAO) method described by Allen et al. (1998). Using this approach, recharge can only occur when the soil exceeds its field capacity; during drier periods, a soil moisture deficit (SMD) occurs. The value of SMD_i for a given day, i , is calculated based on the following factors (given as equivalent water depths in millimetres):

- daily precipitation (P);
- the soil moisture deficit from the previous day (SMD_{i-1});
- total available water (TAW), which represents the total amount of water that can be removed from the soil by transpiration;
- readily available water (RAW), which represents the amount of water that can transpire from the soil before transpiration is reduced;
- total evaporable water (TEW), which represents the total amount of water that can be removed from the soil by evaporation;
- readily evaporable water (REW), which represents the amount of water that can transpire from the soil before evaporation is reduced;
- potential evapotranspiration (ET_0), which describes the rate of evapotranspiration that would occur from well-watered grass; and
- actual evapotranspiration (AE), which differs from ET_0 when SMD exceeds either RAW or REW.

3.2.17. SMD_i is given by:

$$SMD_i = SMD_{i-1} - P_i + AE_i. \quad (1)$$

3.2.18. In the SMB model, values of SMD_i cannot exceed zero. Any additional precipitation is assigned to recharge, up to the infiltration capacity of the underlying geology; these values were consistent with those applied to the NEAC model. Once the infiltration capacity of the soil is exceeded, additional precipitation is designated as surface runoff and does not affect subsequent calculations within the SMB model.

- 3.2.19. Diffuse recharge estimates derived by the SMB model do not fully characterise recharge during summer, when hydrographs show recharge during periods when a soil moisture deficit has been calculated. This behaviour is consistent with previous publications that indicate recharge via preferential pathways, also known as bypass flow, in both the Till and the Crag, during periods when a soil moisture deficit exists (e.g. Ander, Shand & Wood (2006), AMEC (2015a)).
- 3.2.20. There is no consistent means of quantifying bypass flow in the literature. While values of 10% and 15% of effective rainfall (rainfall minus potential evapotranspiration) are quoted in respective studies by Quinn et al. (2012) and (Holmes, 1984), most studies agree that any estimate of bypass flow should be based on site-specific considerations. On days when there is a soil moisture deficit and rainfall exceeds evapotranspiration, a contribution of 20% of effective rainfall was assigned to bypass recharge in the Crag, in line with the parametrisation used in the NEAC model (AMEC, 2015a). The same coefficient for bypass recharge was applied to the Till, to reflect its likely presence in this unit (Ander, Shand, & Wood, 2006).
- 3.2.21. As noted by Heathcote et al. (2004), bypass flow is not subject to the normal evaporative losses that occur in the SMB model and assigned volumes of bypass recharge were offset in the overall water balance by an equivalent reduction in losses from evapotranspiration. While empirical relationships between effective rainfall and bypass flow have proven to be effective in matching observed groundwater level fluctuations, their dependence on effective rainfall and hence, potential evapotranspiration, is perhaps misleading.

iii. Derivation of input parameters

- 3.2.22. Daily precipitation and potential evapotranspiration data were obtained from the Meteorological Office Rainfall and Evaporation Calculation System (MORECS) for the time period between 1 January 2000 and 31 August 2015. The data represent a 40 km by 40 km grid cell covering the Sizewell site and centred on NGR TM400600. The dataset effectively captures seasonal rainfall trends observed in site data and provides an estimate of rainfall on a daily time step across the 5-year simulation period.
- 3.2.23. MORECS data were used in preference to data from the site weather observation station installed at Sizewell C in October 2013, which experienced outages during the monitoring period due to a malfunction (which has since been resolved). MORECS rainfall data are compared to site-specific data in Plate 3.2. UKCP09 rainfall data (Met Office, Hollis, D. and McCarthy, M., 2017) representing the 5 x 5 km grid square centred on TM450650 are also shown for comparison.

3.2.24. There is close agreement between the UKCP09 and MORECS data sets, which each represent spatially averaged values across a comparable area to the model domain (which spans approximately 11 km north-south x 7 km east-west). These Met Office datasets have been used in preference to data collected from the Sizewell C weather station, due to gaps in the site data record, discrepancies with respect to the two Met Office datasets and the limited applicability of data collected from a single point to conditions across the model domain as a whole.

3.2.25. ET_0 was converted to AE using:

$$AE = K_C \cdot K_S \cdot ET_0, \quad (2)$$

where K_C is a crop coefficient, that reflects seasonally-varying differences in evapotranspiration between the well-watered grass reference and any given vegetation and K_S is a water stress coefficient, that reflects the reduction in evapotranspiration that occurs when plants are under drought stress (i.e. SMD exceeds the RAW).

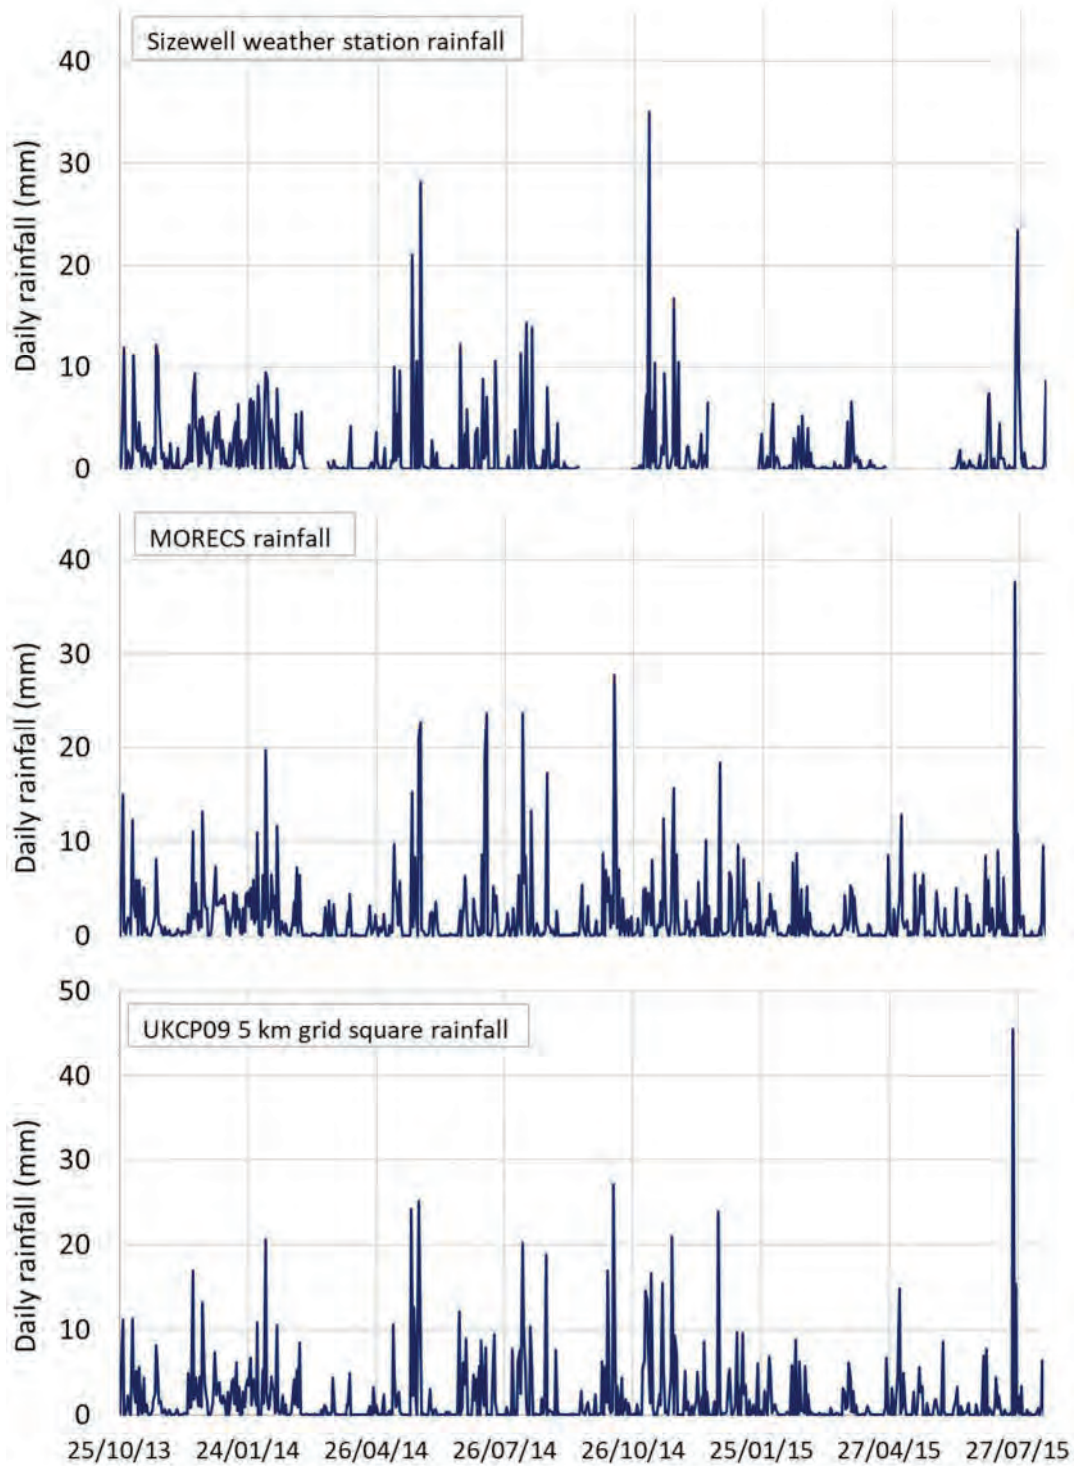

3.2.26. With the exception of reed swamp (see below), monthly K_C values were provided by AMEC (2015a) for each land use in the NEAC model. These values represent K_C on the first of every month. In the current soil moisture balance model, values were derived on a daily time step through linear interpolation of monthly K_C values. Monthly K_C values for each land use are consistent with those previously reported by Atkins (2016a) and are presented in Appendix C.

3.2.27. The available data from the NEAC model do not include suitable K_C values for reed swamp, which are present in some areas of the Sizewell Marshes. A K_C time series for reed swamp was derived using the FAO approach described by Allen et al. (1998).

3.2.28. The water stress coefficient is applied when $RAW < SMD_{i-1} < TAW$ and is given by:

$$K_S = \frac{TAW - SMD_{i-1}}{TAW - RAW}. \quad (3)$$

Plate 3.2: Rainfall data (2013-2015) from the Sizewell C weather station, MORECS (40 x 40 km square centred on TM400600) and UKCP09 (5 x 5 km square centred on TM450650)

3.2.29. Total available water is calculated as follows:

$$TAW = 1000(\theta_{FC} - \theta_{WP})Z_r, \quad (4)$$

where θ_{FC} is the moisture content of the soil at field capacity (m^3/m^3), θ_{WP} is the wilting point (m^3/m^3) and Z_r is the rooting depth (m).

3.2.30. During periods when evaporation is the dominant mechanism of water losses from the soil, TAW and RAW in Equation (3) are replaced by TEW and REW respectively.

3.2.31. TEW is given by:

$$TEW = 1000(\theta_{FC} - 0.5\theta_{WP})Z_e, \quad (5)$$

where Z_e is the depth of the surface soil layer subject to evaporation (which ranges from 0.1-0.15 m (Allen et al. 1998)) and REW varies with soil type, as listed by Allen et al. (1998).

3.2.32. Seasonally varying TAW/TEW and RAW/REW values for each soil type and land use combination in the NEAC model were provided by AMEC and applied to the corresponding areas within the FEFLOW model domain.

3.2.33. Monitoring data across the Sizewell Marsh area show that a shallow winter water table exists, with average Peat/Tidal Flat groundwater levels approximately 0.10 m below ground level. This led to the assumption that a ready supply of water was available to vegetation, directly from Peat/Tidal Flat groundwater and indirectly from the capillary fringe, enabling evapotranspiration to occur at close to its maximum rate for much of the year. As a result, a simple recharge calculation was applied across the Sizewell Marshes, subtracting potential evapotranspiration from precipitation to give a potential recharge value on each day. Any component of potential recharge exceeding the daily infiltration capacity of the vegetation-specific land use (see Appendix C) was assigned as surface run-off, with the remainder assigned as actual recharge.

e) Evapotranspiration

3.2.34. Evapotranspiration within the unsaturated zone is accounted for in the SMB model across the majority of the FEFLOW model domain. In the Peat of the Sizewell Marshes and MWHM SSSIs, evapotranspiration from the saturated zone was applied directly to the FEFLOW model, on days where potential evapotranspiration exceeded precipitation due to the presence of consistently shallow water tables in these areas.

3.2.35. Evapotranspiration in these areas was applied as a flux boundary condition, that varies inversely with saturation in the top layer of the model. At full

saturation (i.e. when the water table is at the ground surface), the applied value is equal to the excess of potential evapotranspiration over rainfall. A constant thickness of 1 m was applied to the top layer in mapped areas of peat and hence, when water levels are 0.2 m below the surface, evapotranspiration is reduced by 20% as a result.

- 3.2.36. When scaling fluid sources or sinks in this way, FEFLOW applies the same proportional reduction to hydraulic conductivity in the affected elements. To maintain model stability while ensuring an appropriate decrease in evapotranspiration with depth, a maximum reduction of 90% is applied as water levels approach the base of the top layer.

f) Groundwater seepages

- 3.2.37. Drainage boundaries are applied at the ground surface; these become active when hydraulic head exceeds the top of the model's uppermost layer.
- 3.2.38. Water removed from the model by these drainage boundaries is captured in the flow budget, which is output on a weekly basis.
- 3.2.39. FEFLOW applies these drainage boundaries across the full extent of the model's top layer. To ensure baseflow to streams is represented appropriately, a minimum elevation of 0.6 m AOD is assigned to the ground surface in the vicinity of surface drainage channels. This is equivalent to the 90th percentile of observed stage values at Minsmere sluice during the model calibration period, thus ensuring that groundwater levels can oscillate freely below this elevation near drainage lines and contribute to modelled surface water-groundwater interactions, as described in section 3.2g).
- 3.2.40. The top elevation of the model offshore is set to a constant value of 0.14 m AOD and allows an equivalent hydraulic head to be applied in this area without activating drainage boundaries at the model surface. The applied head of 0.14 m AOD is consistent with the average sea level applied to the NEAC model (AMEC, 2015a). The top elevation of the model was adapted during the future scenario simulations (see section 4.2h)) to account for projected rises in sea level.

g) Groundwater-surface water interactions

i. Approach

- 3.2.41. Surface water channels in Sizewell Marshes in the transient FEFLOW model are represented by 3rd kind (Cauchy) boundary conditions. These fluid-transfer boundary conditions represent surface water-groundwater

interactions by allowing the transfer of water in and out of the model as a function of the relative head differences and the conductance of the exchange surface (the river bed). However, the ability to define specific features of the surface channels, and model the effect of changing groundwater levels on surface water levels using only these boundary conditions, is limited.

3.2.42. To more accurately represent the channel morphology and impact of changing Peat groundwater levels on surface water in the ditches and drains of Sizewell Marshes, the channels were modelled using MIKE11. MIKE11 is a one-dimensional channel flow model that is coupled to the Cauchy boundary nodes in FEFLOW via the interface manager lfmMIKE11. In MIKE11 the morphology of the channel network is defined in detail using measured channel cross-sections so that the lateral and longitudinal channel profiles are accurately represented.

ii. [Coupling of FEFLOW and MIKE11](#)

3.2.43. The transfer of water between FEFLOW and MIKE11 occurs between Cauchy boundary nodes and “H-points” within the MIKE11 model, via the interface manager lfmMIKE11. H-points are located at all the nodes in the MIKE11 model where a cross-section has been defined, and additionally, in areas where there are limited cross-section data, at intervals of 100 m along the channel branches. At H-points where no cross-section is defined, the MIKE11 model interpolates between the nearest cross-sections to estimate the channel cross-section at that H-point.

3.2.44. Water is transferred from FEFLOW into MIKE11 at the end of each FEFLOW timestep as a point source volumetric input from each boundary node to the closest H-point. The discharge is calculated in FEFLOW by using the water levels from MIKE11 at the end of the previous timestep to define the actual boundary values at the coupled boundary nodes. The MIKE11 model then runs the required number of timesteps to reach the actual time of FEFLOW, and the final water levels are transferred from MIKE11 back to the FEFLOW boundary nodes to be stored for calculating the flux from FEFLOW in the next timestep. This coupling means that surface water processes can be modelled with a short timestep (of the order of minutes to hours), better suited to modelling surface water processes which are naturally higher frequency than groundwater fluctuations. Coupling in this manner means that changes in the surface water will affect groundwater levels and flows and vice versa.

3.2.45. Flow Q_{FM} [m^3d^{-1}] between the Cauchy nodes in FEFLOW and the H-points in MIKE11 is calculated based on the relative head difference between them Δh [m] and a stream bed conductance term Φ [d^{-1}]:

$$Q_{FM} = A\Phi\Delta h, \quad (6)$$

where A is the area of the stream bed [m^2].

- 3.2.46. An initial stream bed conductance of 1 d^{-1} was applied throughout the model and adjusted to 0.1 d^{-1} during model calibration. This is equivalent to a 1 m thick clogging layer, with a vertical hydraulic conductivity of 0.1 m/d, which lies close to the mean values listed for Peat in Table 2.3. Given the uncertainty in this parameter, stream bed conductance was varied as part of the sensitivity analysis, as described in Section 3.5.

iii. Channel morphology

- 3.2.47. The MIKE11 channel network extends across the Sizewell Marshes from stream gauge G5 (645400 263463), which lies on the Leiston Drain at the upstream end of the network, to the Minsmere Sluice at the downstream end (647742 266134). In the Sizewell Marshes, there are two main channels: the Leiston Drain and the Sizewell Drain. Cauchy nodes in FEFLOW and H-points in MIKE11 have been assigned along both channels, as well as their most significant tributary drains and ditches, as shown in Figure 19A.16.
- 3.2.48. The MIKE11 model domain is based on the surface water gauging network. This network was agreed with stakeholders and is focussed on the area where changes due to the Sizewell C development would be anticipated, based on the conceptual understanding.
- 3.2.49. Channel cross-section data from watercourse surveying carried out in November 2013 and May 2015 (Storm Geomatics, 2013; 2015) were used to define the cross-sectional geometry of the channels. MIKE11 interpolates between the assigned cross-sections to define the channel shape and longitudinal profile elevation throughout the network of branches. For channels or reaches where there were no measured cross-sections, the cross-sectional area was estimated based on channel cross-sections measured up-or downstream, or based on observations of the approximate channel width and depth recorded during site visits.
- 3.2.50. The roughness of the channels is defined based on literature values taken from (Chow, 1959), and adjusted during model calibration. In the Leiston Drain and Sizewell Drain, a Manning's n value of 0.075 was applied, and in the smaller side channels Manning's n was taken as 0.12. This agrees with reported data for vegetated wetland streams, although for clean straight banks at full stage and without rifts or deep pools, the Manning's n value could be as low as 0.035 – 0.04 (Natural Resources Conservation Service, 1997). The ditches and drains in Sizewell Marshes tend to be overgrown, with regular stands of reeds and water weed, tree branches etc, and

support the use of relatively high values for Manning's n . Initially, a global roughness of 0.05 was used, but this was increased during the MIKE11 model calibration.

- 3.2.51. The roughness is assumed to be greater in the smaller side channels because these channels tend to be more highly vegetated than the Leiston Drain and Sizewell Drain.
- 3.2.52. Changing the roughness coefficient during the calibration process showed that long term average flows and stage are not affected by changes in this parameter, although peak flows are sensitive to changes in Manning's n , particularly in the downstream gauges. For example, halving the roughness coefficients applied across the network leads to increases in the magnitude of peak positive and negative flows by up to 100%.

iv. Boundary conditions

- 3.2.53. Boundary conditions must be defined within the MIKE11 model at any open ends of the channel network, as shown in Figure 19A.16. The drainage network within Sizewell Marshes has a single upstream input at Leiston Drain and a single output at the sluice at Minsmere. Boundary conditions have been defined at these points based on available data from the on-site flow gauging network.
- 3.2.54. For December 2013 onwards, measured data from the site have been used directly as the time series for the boundary conditions. Upstream flow data were taken from the G5 gauging point (645400 263463), which monitors the Leiston Drain, west of Lover's Lane, downstream of the inputs from Leiston Sewage Treatment Works and Brick Kiln Farm. The discharge time series here has been calculated from stage and velocity data collected at G5 using the rating relationship provided to Atkins by Hydro-Logic Services LLP. A stage boundary condition was applied to the Minsmere sluice, based on data collected at stream gauge G1. G1 lies approximately 1500 m south of the outflow at Minsmere sluice, so by applying these data as the boundary condition, water levels at G1 are taken as representative of those at the sluice. It was not possible to use the data from G8, which lies only 500 m south of the sluice, as flow gauging and levelling (relative to Ordnance Datum) had not been completed for this location at the time of model calibration.
- 3.2.55. For the period prior to December 2013, when no measured surface water data are available, time-series have been derived based on a rainfall-flow relationship at G5, and a water level at G1 following the same cyclic trends observed between December 2013 and September 2015. These derivations were previously presented by Atkins (2016a) and are included as Appendix D of this report (provided electronically due to file size).

- 3.2.56. The flow in the channel at G5 is dominated by input from the Leiston Sewage Treatment Works, which is augmented during rainfall events by surface runoff from Leiston (Atkins, 2015a). An examination of flows at G5 during dry periods (defined as two consecutive days with total rainfall <0.5 mm) showed that an average flow of 0.04 m³/s was maintained in the channel. This was taken as a baseline flow condition on dry days.
- 3.2.57. Flows at G5 are calculated from measured velocity and stage using a calibrated rating equation. Stage and flows were compared with rainfall to ascertain any relationship. This comparison showed that on days where there was rainfall, there was a positive linear relationship between rainfall and stage. There was no clear relationship between rainfall and velocity (in general, velocity was much less variable than stage). For the majority of the calibration dataset, observed velocities were close to their average value of 0.09 m/s, although values close to 0.1 m/s were observed when daily rainfall exceeded 10 mm.
- 3.2.58. Based on these findings, the rainfall-runoff relationship derived for G5 can be summarised as follows:
- a baseline flow of 0.04 m³/s is applied on days when less than 0.5 mm of rainfall has been recorded over the preceding 48 hours; and
 - on all other days, the G5 rating relationship is used to calculate flow, with stage calculated from the derived linear rainfall-stage relationship and an assumed velocity of 0.09 m/s, unless the average rainfall for the previous two days is greater than 10 mm, in which case a velocity of 0.1 m/s is applied.
- 3.2.59. To check the validity of this rainfall-runoff relationship, recorded flows at G5 were compared with the calculated flows for the 20-month monitored period (as described previously by Atkins (2016a)). Average flows are well represented, but there is underestimation of some short-duration, peak flows, which cannot be simulated accurately using daily MORECS data that do not represent short duration, high-intensity rainfall. Furthermore, the MORECS data are provided for an area of 40 km × 40 km, so localised rainfall events may not be captured. Although there is a weather observation station installed at Sizewell C, it experienced outages during the monitoring period due to a malfunction (which has since been resolved), and hence MORECS data were used for generating the time series. A more detailed discussion of calibration quality is provided in Section 3.3b).
- 3.2.60. The upstream ends of the smaller drains and ditches in the marshes have been defined as closed boundaries i.e. with incoming discharge equal to zero. This means that these ditches effectively act as stores of water, which are connected to the main channels. The only other input that these

channels receive is from Peat groundwater, via coupling with FEFLOW. The upstream end of the Sizewell Drain was also defined as a closed boundary. Although water quality evidence suggests that storm runoff from Sizewell Gap contributes to Sizewell Drain during storm events (Royal Haskoning DHV, 2015), there is no evidence to suggest that there are any continuous inputs to the upstream reach of Sizewell Drain. As there are no hydrometric data to constrain the volumes the storm runoff contributes, and the outfall has been observed to be dry during site walkovers, a closed boundary was considered to be the most appropriate at this location.

3.2.61. Rainfall-runoff is not included in the historical baseline MIKE11 model, although this parameter is calculated within the soil moisture balance model, described in Section 3.2d). The inclusion of run-off explicitly within the MIKE11 model forms part of the sensitivity analysis in Section 3.5.

3.2.62. The implementation of hydraulic head boundaries at the surface when the water table rises above ground level ensures that groundwater levels are not overestimated across the model domain. In low-lying areas close to drainage lines, this mimics the effects of baseflow on the elevation of the water table.

3.2.63. As described in this section, groundwater-surface water interactions are represented explicitly within Sizewell Marshes and the MWHM SSSI, downstream of stream gauging station G5. G5 is located to the west of Sizewell Marshes along the Leiston Drain, with all surface water inflows passing this stream gauge, thus ensuring that the MIKE11 model incorporates the combined contributions of baseflow and run-off upstream of this point.

v. Control structures

3.2.64. Three control structures were included in the channel network: the double-pipe culvert under Lover's Lane at 645466, 263477; the thin plate weir at G3 (646124, 263840); and the thin plate weir at G4 (645831, 263780), as shown on Figure 19A.16.

3.2.65. The sluice at Minsmere was not included in the MIKE11 model as it lies beyond the downstream boundary condition of the MIKE11 model; the sluice lies at the outflow of the Leiston Drain into the sea and any upstream effects from the operation of the sluice are accounted for during the baseline period by the tidally-fluctuating boundary condition in the baseline model. Tidal effects are not included in the derived boundary condition during the development scenarios (section 3.4.9).

3.2.66. For the culvert at Lover's Lane, the geometry and elevation of the culvert pipes were defined in the MIKE11 model, and the model was used to derive the Q/h relationship for water passing through the culvert. For the thin-plate

weirs at G3 and G4, the Q/h relationships are known, and were supplied by Hydro-Logic Services LLP based on the international standard for thin plate weirs and were inputted directly into the MIKE11 model. The validity of using these standard relationships has been confirmed by 12 months of flow gauging measurements. It should be noted that the weir plate at G4 was moved in April 2014 and its current elevation has been used in the MIKE11 model throughout the modelled period. Observed data prior to April 2014 for G3 and G4 have not been used in the calibration as a result.

vi. MIKE11 calibration

3.2.67. Initial model development and calibration was conducted using MIKE11 as a standalone model, not coupled to FEFLOW. Subsequent fine-tuning of the calibration was completed when the MIKE11 model was coupled with the FEFLOW model. Apart from the flow and stage boundary conditions applied at G5 and G1 respectively, measured flows and stages at the seven gauging stations were used as calibration targets. During the calibration, flow-duration curves for the modelled and observed data were compared.

3.2.68. The results of the calibrated coupled model runs are discussed in Section 3.3b). The observed flow data from gauges G1, G5, G6 and G7 are calculated from measured velocity and stage using a calibrated rating equation, supplied by Hydro-Logic Services LLP. Monthly gauging results have shown that the calculated flows based on the ratings at these gauges can be subject to significant errors. This is most noticeable at G6 and G1, where errors of up to 75% and 100% respectively have been recorded; errors at G5 and G7 are generally less than 40%. Flows calculated at G3 and G4, which are weir gauges, are subject to smaller errors (on average 15%). It should be noted that these errors are at the time of the flow gauging and their sign or magnitude is not systematic; it is therefore expected that the average long-term error in the observed dataset would be substantially less than the maximum errors reported herein.

h) Abstractions

3.2.69. Groundwater and surface water abstractions were applied to the model at the locations shown in Figure 19A.17. Abstraction rates applied to the model are based on the monthly average values listed in Table B.1 and Table B.2 of Appendix B.

- i) Aquifer properties
- i. Hydraulic conductivity

3.2.70. Hydraulic conductivity has been applied to the model, based on:

- the inferred lateral and vertical extent of geological strata, as indicated by borehole records and geological maps of the area (see Section 2.4a));
- hydraulic testing data for these strata (see Table 2.3); and
- calibration to observed groundwater and surface water levels, constrained by the aquifer properties data shown in Table 2.3.

3.2.71. The largest hydraulic conductivity values (shown in red in Plates 3.3 and 3.4) represent the Crag, the smallest hydraulic conductivity values in the west of the model domain represent the Lowestoft Till, while intermediate values have been assigned to the Peat and Tidal Flats deposits of Sizewell Marshes and the MWHM SSSI.

3.2.72. The data presented in Plates 3.3 and 3.4 represent hydraulic conductivity in the model at full saturation. As discussed in Section 3.2e), scaling of evapotranspiration rates with saturation of the top layer in the model leads to the same proportional reduction in hydraulic conductivity. This mimics the inverse relationship between saturation and hydraulic conductivity that typically occurs in the vadose zone.

Plate 3.3: Model horizontal hydraulic conductivity in a) Slice 1 b) Slice 3 and c) cross-section through the Main Development Site

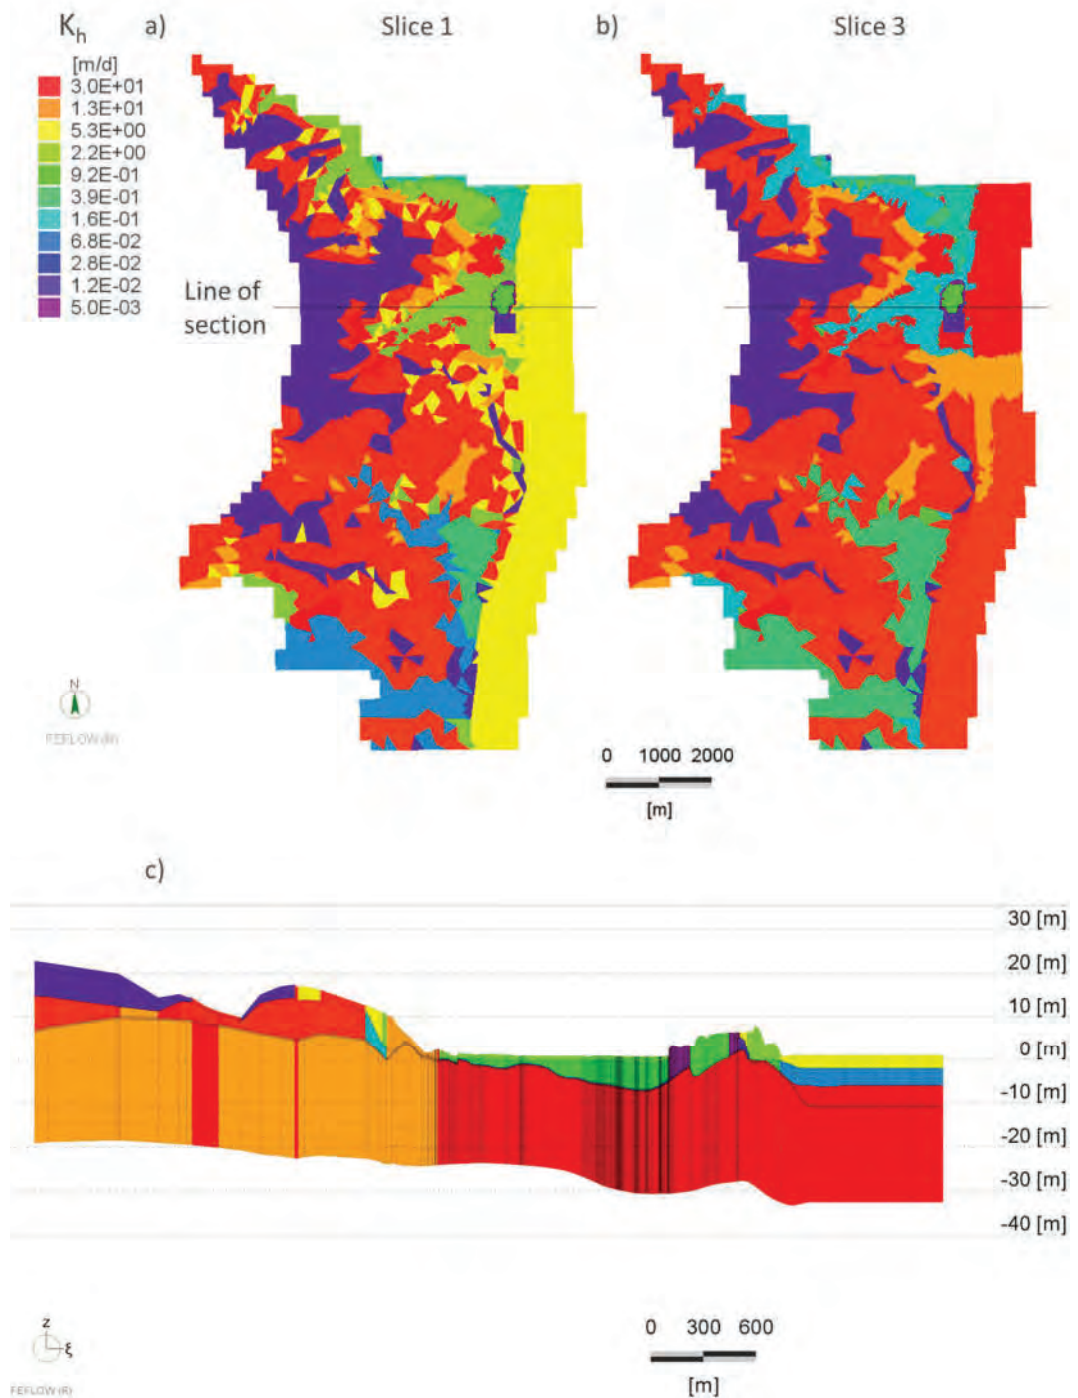

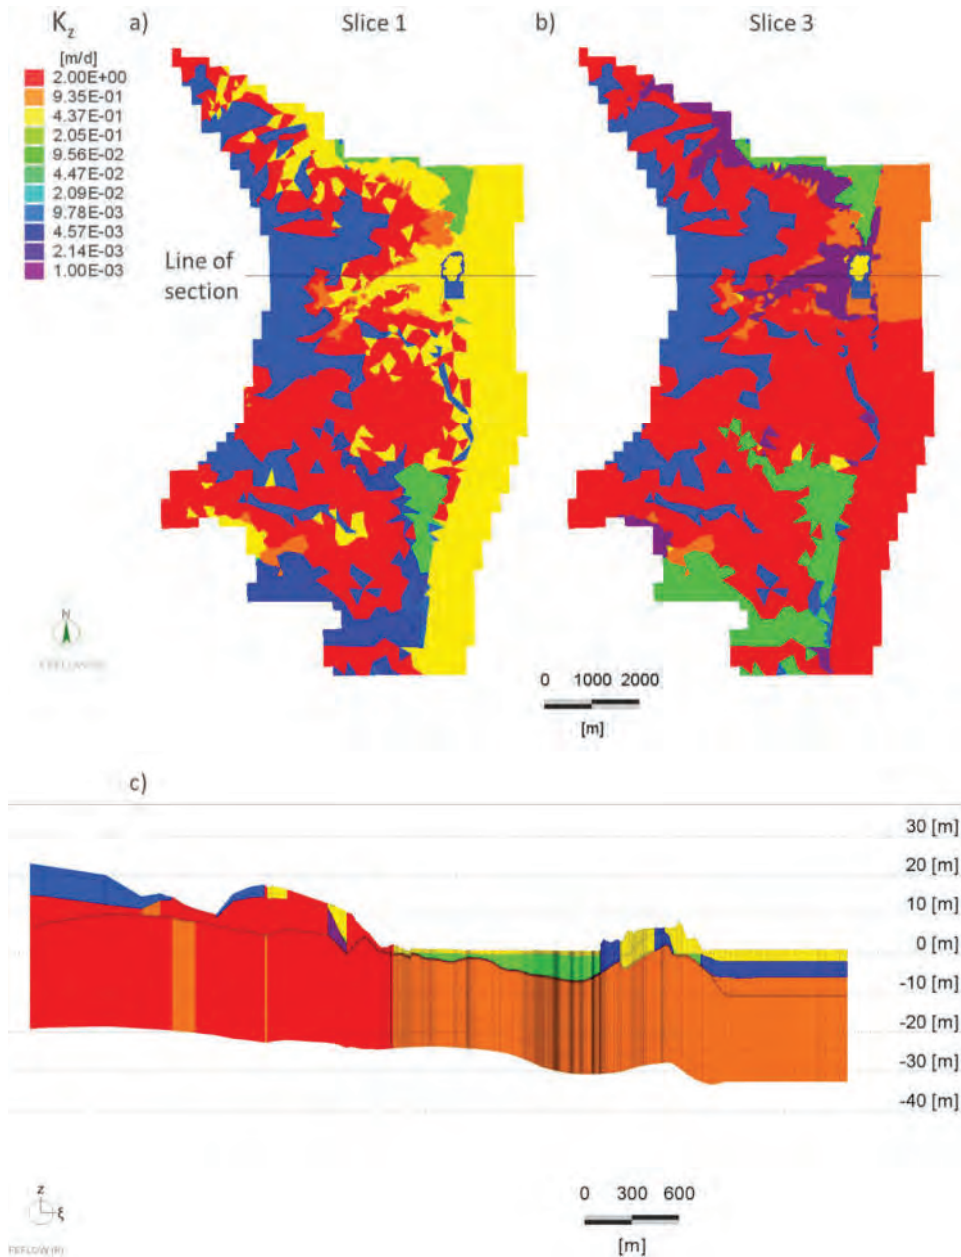

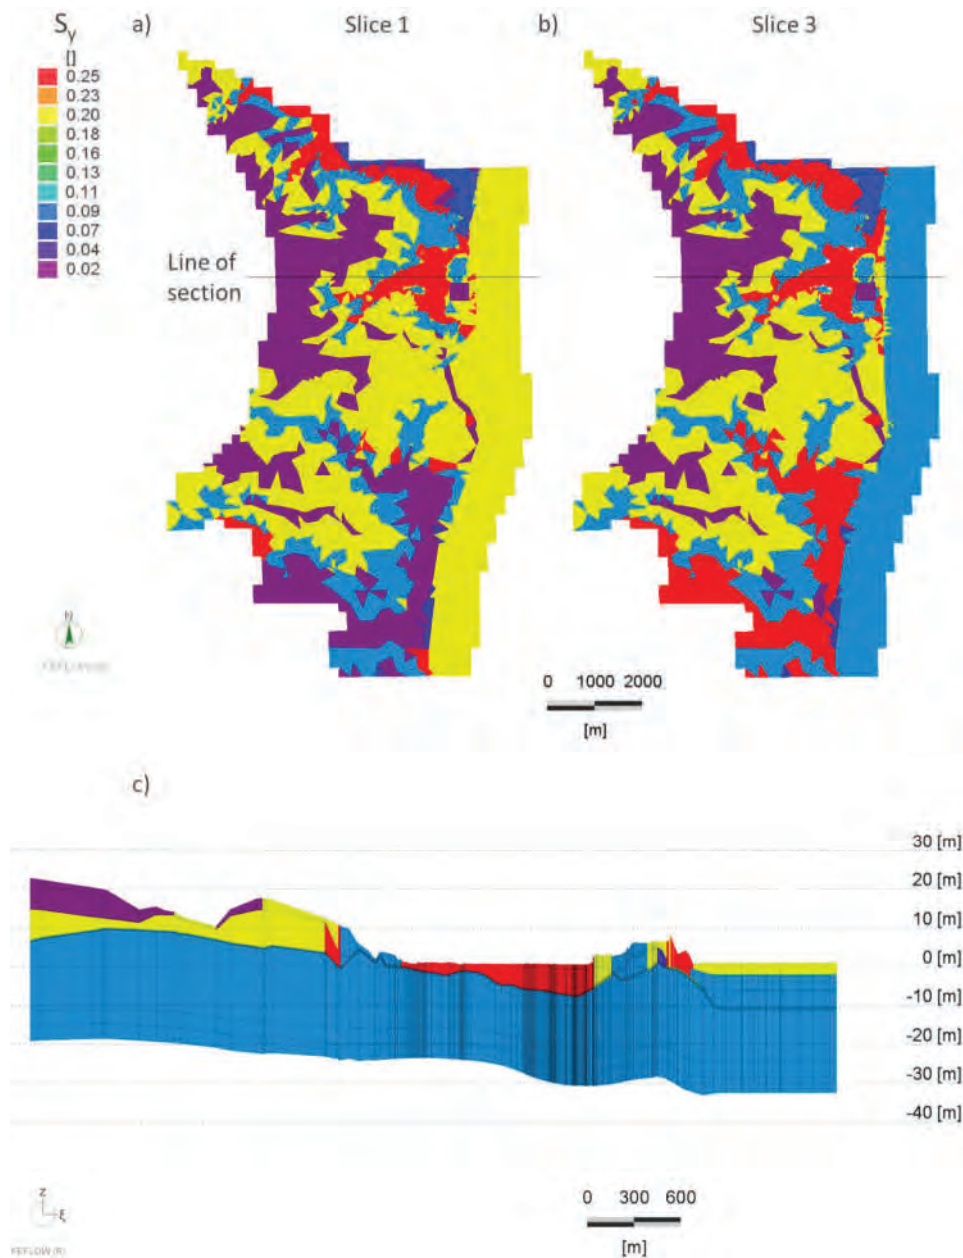

Plate 3.4: Model vertical hydraulic conductivity in a) Slice 1 b) Slice 3 and c) cross-section through the Main Development Site

ii. Specific yield

3.2.73. The distribution of specific yield, shown in Plate 3.5, is similar to that for hydraulic conductivity, with the lowest values assigned to the Lowestoft Till in the west of the model domain and higher values assigned to the Crag. The highest values of all have been assigned to Peat, a lithology known to have a high storage capacity.

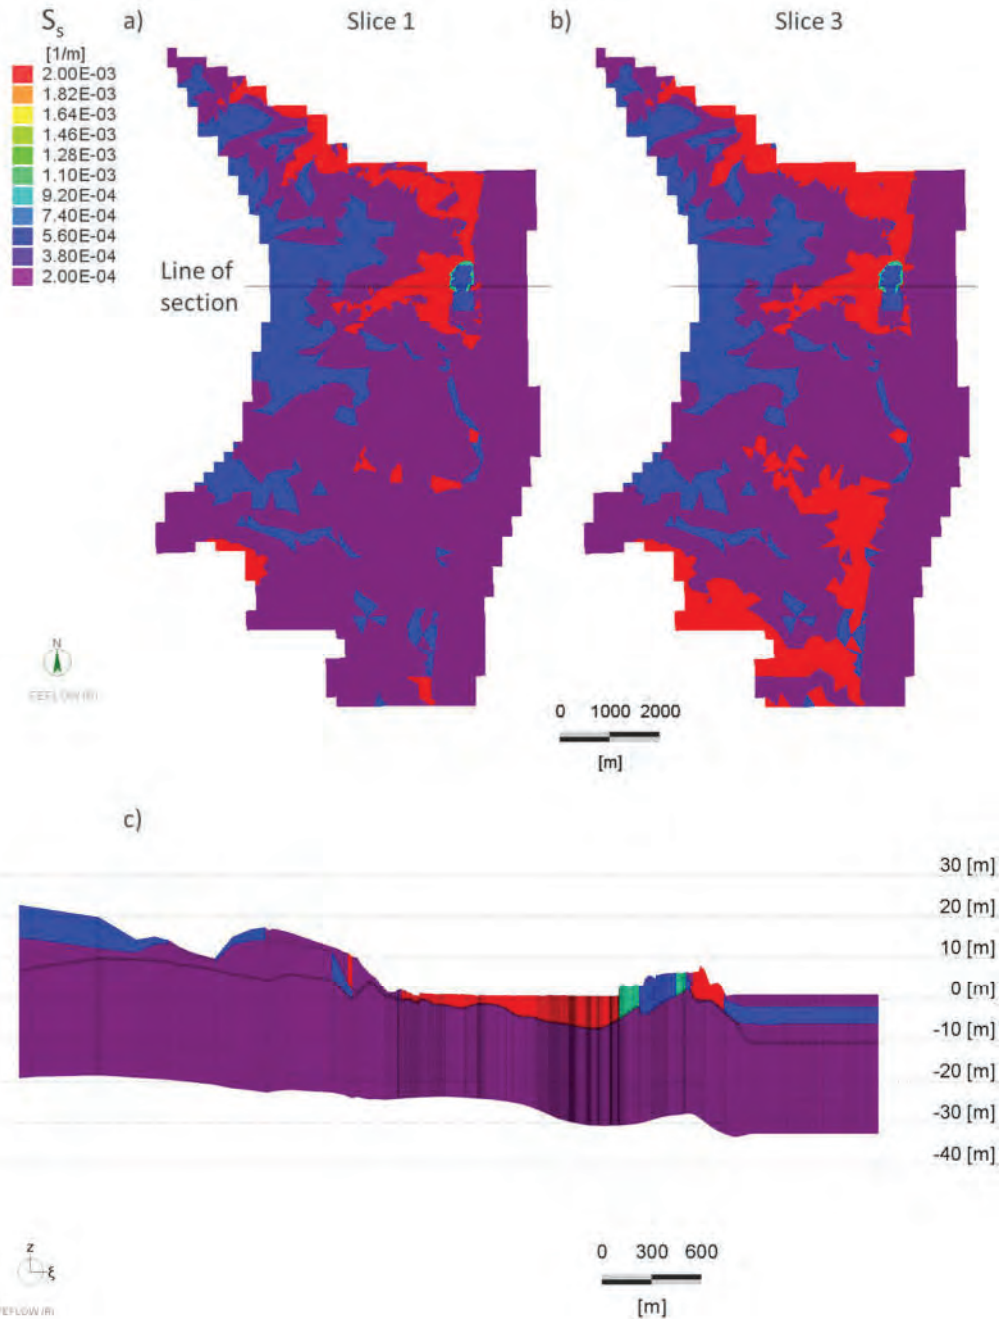

Plate 3.5: Model specific yield in a) Slice 1 b) Slice 3 and c) cross-section through the platform area

iii. Specific storage

3.2.74. Specific storage values assigned to the model are shown in Plate 3.6 below. Specific storage is automatically applied without any contribution from specific yield when FEFLOW detects that groundwater has become confined.

Plate 3.6: Model specific storage in a) Slice 1 b) Slice 3 and c) cross-section through the Main Development Site

j) Sea floor geometry

3.2.75. A constant elevation of -1 m AOD was assigned to the sea floor. This allowed the application of a single value of hydraulic head across each model slice (representing the upper or lower bound of a FEFLOW layer)

during the historical model calibration and a single time-series, representing rising sea levels, to each layer in the future scenario modelling.

3.3 Results

a) Calibration data and acceptance criteria

- 3.3.1. The transient model was set up to simulate heads for the time period between 1 September 2010 and 31 August 2015, with the main calibration period between December 2013 and September 2015.
- 3.3.2. For this 20-month period there is an extensive observed data record of groundwater and surface water levels across the Sizewell Marshes area, and consequently, this period is suitable for the calibration of heads and flows in this area. Subsequent groundwater and surface water data were used for the purposes of model verification, as described in section 3.4.
- 3.3.3. The observation record includes 46 borehole locations (across Peat and Crag) where groundwater levels are recorded by data loggers at 15-minute intervals, and a further 31 locations where monthly dip data have been collected. There are also 7 surface water gauging stations, which record stage and flows at 15-minute intervals. The network of monitoring locations was previously agreed with stakeholders.
- 3.3.4. For the first three years of the calibration period (between September 2010 and November 2013), the observed data are limited, with no groundwater or surface water levels in the area of the Sizewell Marshes. For this period, surface water boundary conditions were estimated as discussed in Section 3.2g)iv.
- 3.3.5. The FEFLOW model was calibrated with the aim of matching simulated heads to observed heads, with the following accuracies:
- +/- 10 cm in Peat observation points in the Sizewell Marshes;
 - +/- 25 cm in Crag observation points immediately adjacent to the area of the Sizewell Marshes; and
 - +/- 50 cm in all other Crag monitoring points.
- 3.3.6. Given the low flow nature of the surface water system, the primary calibration target for the surface water system was to achieve an agreement of approximately 30% between the modelled and observed flow-duration curves and a match to observed stage within 10 cm. A model which achieves a match to this degree of accuracy is considered by Atkins to be well calibrated, given the uncertainties in the observed flow data

(section 3.2g)vi). The following secondary objectives were also used to guide the calibration process:

- mean flows to within 10% of the observed data;
- low flows to within 25% of the observed data; and
- peak flows to within 30% of the observed data.

b) Comparison with observed data

- 3.3.7. Figure 19A.18 shows a comparison of simulated and observed groundwater heads in the Peat of the Sizewell Marshes. There is a close match between the revised model and observation data, both in terms of long-term average values and seasonal variations in all Peat groundwater monitoring boreholes. Figure 19A.18 also shows that the quality of fit represents a substantial improvement with respect to the original transient model, following the revisions described in section 3.1.
- 3.3.8. The flattening of the model hydrographs during winter reflects the drainage of groundwater when the water table intercepts the ground surface, as described in Section 3.2f). These groundwater seepages are immediately removed from the FEFLOW model. Sensitivity analysis, described in Section 3.5b), has been conducted to simulate the presence of standing water at these locations and subsequent drainage via the MIKE11 drainage network.
- 3.3.9. Figures 19A.19 to 19A.21 show that the calibration objectives were also achieved across various depths within the Crag aquifer and again, the quality of fit is substantially improved with respect to the original transient model. The only exception to this amongst the 41 Crag observation boreholes is in C7, where the observation data differ substantially from those collected in nearby monitoring locations. While the model has been unable to replicate these localised head differences, the distal location of C7 and the presence of its target zone within the deepest part of the Crag aquifer mean that there are no significant implications regarding the model's ability to simulate changes in groundwater levels within the Sizewell Marshes and Minsmere South Levels.
- 3.3.10. Another clear discrepancy is in the absence of semidiurnal fluctuations in groundwater levels near the coast, particularly in Crag piezometers. This can be attributed to the use of a daily time step within the model. Given the objective of the modelling is to assess seasonal and interannual changes in groundwater levels within the Main Development Site and adjacent SSSIs, this discrepancy is not considered significant.

- 3.3.11. The model's ability to represent vertical differences in head between the Peat and Crag aquifers provides confidence in its suitability for simulating the effects of construction activities within the Crag on the nearby wetlands.
- 3.3.12. Modelled stage, flow and flow duration for the stream gauging locations are presented in Figures 19A.22 to 19A.24.
- 3.3.13. The model closely replicates observations of both average stage and temporal variations in the downstream locations G1, G6 and G7. As stated in Section 3.2g)v, the model was not calibrated to conditions at G3 and G4 prior to moving of the weir plate in April 2014. Following this change to the control structure, the model provides a reasonable match to observed average stage values and a good match to temporal variations in stage.
- 3.3.14. Although average stage values at G5 are not well matched by the model, observed temporal variations in stage are reproduced consistently. The mismatch at G5 is attributed to features of this upstream reach that are not being fully represented in the MIKE11 model. For example, several natural "dams" have been observed in this reach during site walkover visits, associated with accumulations of vegetation and storm debris. These features affect stage but cannot be included in the MIKE11 model because they are irregular and potentially mobile. Additionally, silt build-up has been recorded in the area of G5; any silt build-up in the culvert would affect its geometry and therefore the stage upstream of it. As G5 is away from the key area of interest at the Sizewell C platform, underestimation of stage in this area is not considered to be detrimental to the overall calibration of the coupled model.
- 3.3.15. Time series flow data shows that, across the 20-month calibration period, average flows are matched to within approximately 10% of observed values at all gauges apart from G7, where flows are underestimated. The underestimation of the 20-month average flows at G7 is partly because the modelled flows show significantly more negative flows than in the observed data, as seen in the G7 flow duration curve. The tendency towards negative flows is also slightly exaggerated in the MIKE11 model at G6 and G1. The time series show that although the average flows are approximately correct, the modelled flows fluctuate much more significantly than the observed. These fluctuations are initiated by the tidal fluctuation in the downstream water level boundary condition, and have the greatest impact at G7, because it has the lowest positive flows to counteract this effect. In the real channel network, there are natural dams and blockages which will act to damp the negative flows. These features effectively act as control structures, but as they are transient and mobile, they cannot be represented effectively in the MIKE11 model. A high Manning's roughness coefficient was used to represent the natural roughness of the channels, but the damping effect of any natural "dams" could not be represented

using roughness alone, without using excessive and unrealistic values that would reduce peak positive flows as well as negatives. The oscillating “noise” in the modelled flows is not considered to have a significantly detrimental effect on the groundwater model calibration, as the oscillations in the surface water flows are generally over a period of a few hours, while average flows and trends, which will have a greater impact on Peat and Crag groundwater are still well-matched.

- 3.3.16. The modelled time series at G1, and to some extent at G7, show a poor match in terms of peak flows. Underestimation of peak flows is likely to be a result of not including rainfall-runoff in the MIKE11 model. The effect from this would be greatest at downstream locations (i.e. at G6, G7 and G1), which have a greater catchment for inputs from potential runoff.
- 3.3.17. Mismatches in peak flows and trends in the downstream gauges are also attributed to high errors in the observed data at these stations; peak flows and trends are well matched at G3 and G4, which have smaller measurement errors. The velocity sensors at G7 and G1 are particularly susceptible to weed growth in the summer, which can lead to frequent misreads which are difficult to distinguish from “true” data. It should also be noted that channel clearance activities are carried out periodically by Suffolk Wildlife Trust particularly in the downstream reaches, and these may have effects on flow and stage that cannot be accounted for. Indeed, anecdotal observations from site visits have shown that channel management activities can have very significant effects on flows and water levels within Sizewell Marshes.
- 3.3.18. Peak flows are most noticeably underestimated in the period from July-September in both 2014 and 2015, particularly at G7. Several reasons for this have been considered. For example, there could be additional inputs to the Sizewell Drain in the summer that are not accounted for in the MIKE11 model, such as additional discharges from any fields/tile drains as a result of summer irrigation. However, although there are licensed abstractions for irrigation at the upstream reaches of the Sizewell Marshes, no evidence has been found of irrigation in the vicinity of the Sizewell Drain, so this mechanism seems unlikely. The possibility that additional inputs were coming from drainage runoff from the future Sizewell C construction platform was considered. However estimated volumes suggest this contribution would be relatively small (0.006 m³/s assuming 100% runoff from the platform area), which only approximates to 15% of average flows recorded at G7. It also seems unlikely that any contribution from such runoff would be limited to the summer. Overall it is concluded that underestimation here is most likely attributed to misreads and errors as a result of weed growth in the channel, and inputs from storm runoff at Sizewell Gap.

c) Water balance

i. Atmospheric water balance

3.3.19. The atmospheric water balance applied to the FEFLOW model over the duration of the calibration period (2010-2015) is shown in Table 3.3. For comparison, the atmospheric water balance applied to Run 598 of the NEAC model within the FEFLOW model domain is also shown, covering the period from 2007-2012.

Table 3.3 Atmospheric water balance for FEFLOW and NEAC models (all values in m³/d averaged over simulation period)

Component	FEFLOW (2010-2015)		NEAC (2007-2012)*	
	In	Out	In	Out
Rainfall	103,605		112,586	
ET from soil		-55,675		-66,684
Runoff		-35,350		-25,879
Recharge to water table		-13,321		-18,185
Change in moisture storage	741			-1,637
Total in	104,346		112,586	
Total out		104,346		112,585
Imbalance	0		1	

* Incorporates only land-based component of model domain

3.3.20. Despite the different periods represented by the models, the components of each water balance are similar, although the SMB for the FEFLOW model produces lower average recharge and evapotranspiration than its NEAC counterpart, and a higher rate of runoff.

ii. Groundwater model domain water balance

3.3.21. A comparison of the water balance for the FEFLOW and NEAC models themselves are shown for the study area in Table 3.4.

Table 3.4 Groundwater balance for FEFLOW domain in FEFLOW and NEAC models (all values in m³/d averaged over simulation period)

Component	FEFLOW (2010-2015)			NEAC (2007-2012)		
	In	Out	Net	In	Out	Net
Recharge minus ET from water table	13,321	-2,298	11,023	18,144	-2,055	16,089
Leakage from streams	112	-1,124	-1,112	340	-13,806	-13,466
Seepages at surface ^{1,2}	0	-9,689	-9,689	-	-	-
Upflow to Crag (from London Clay/Chalk)	398	-63	335	232	-78	154
<i>Lateral GW flow – west³</i>	5,499	-	5,499	4,764	-24	4,740
<i>Lateral GW flow – north^{2,3}</i>	2,383	-	2,383	724	-804	-80
<i>Lateral GW flow – south³</i>	-	-3,623	-3,623	118	-500	-382
<i>Lateral GW flow – east³</i>	-	-1,439	-1,439	29	-1,964	-1,935
Abstraction from Crag	-	-3,770	-3,770	0	-3,849	-3,849
Storage change	973	-981	-8	165	-174	-9
General head boundaries ⁴				0	-77	-77
Imbalance		113			-8	

¹ Not reported for NEAC

² Groundwater seepages occurring near the northern boundary effectively reduce net inflows to the rest of the model domain

³ FEFLOW's standard water budget outputs provide net inflows only from lateral boundaries

⁴ Not implemented in FEFLOW

3.3.22. The two water balances are similar in most respects, although the FEFLOW model displays a slightly larger mass balance error. This may be attributed to the finer mesh within the FEFLOW model, where element diameters of

less than 1 m are common, in comparison to the NEAC model, which incorporates 200 x 200 m grid squares.

3.3.23. Baseflow to streams in the FEFLOW model is represented explicitly for the drainage channels within the wetland areas and by groundwater seepages at the surface elsewhere. The total of these components is comparable to that generated by the NEAC model.

3.3.24. The comparison of flow across the model boundaries is misleading, particularly at the northern and southern edges of the model, where low-lying ground near the Minsmere Old River/New Cut, the River Alde and the River Fromus leads to substantial groundwater seepages at the surface within the FEFLOW model.

iii. Sizewell Marshes water balance

3.3.25. The FEFLOW and NEAC water balances for Sizewell Marshes are shown in Table 3.5.

Table 3.5 Groundwater balance for Sizewell Marshes in FEFLOW and NEAC models (all values in m³/d averaged over simulation period)

Component	FEFLOW (2010-2015)			NEAC (2007-2012)		
	In	Out	Net	In	Out	Net
Recharge minus ET from water table	1,123	-911	211	269	-62	207
Leakage from streams	103	-827	-724	0	-1,023	-1,023
Seepages at surface	0	-527	-527	-	-	-
Upflow from Crag	1,481	-433	1,048	991	-167	824
Storage change	973	-981	-8	165	-174	-9
Total in	3,680	-	-	1,425	-	-
Total out	-	-3,680	-	-	-1,426	-
Imbalance	1			-1		

3.3.26. Net flows for each component are similar for the two models, although the finer mesh in FEFLOW leads to a greater magnitude of both inflows and outflows, due to the representation of smaller-scale features.

3.3.27. In both models, flow to streams, either directly as baseflow or via surface seepages, represents the largest loss of water from the Sizewell Marshes, while the Crag represents the largest source of inflows.

3.4 Model validation

a) Validation approach

i. Overview

3.4.1. To validate the model, the simulation was extended beyond the original calibration period and compared to observation data collected since August 2015. Observed climate data for a 12 km grid-square surrounding the Main Development Site were obtained from the Met Office up to the end of 2017 (Met Office, Hollis, D. and McCarthy, M., 2017); this represents the end of the validation period.

3.4.2. Reliable groundwater level data are available for the majority of piezometers listed in Table A1 of Appendix A during the validation period. However, data from some of these piezometers are considered to be invalid, due to the following factors:

- movement of piezometers installed in the Peat, presumably by livestock, leading to sudden or progressive changes in the elevation of the measurement datum (top of casing); and
- intermittent failures of automated data loggers.

3.4.3. The model has been validated against the full set of reliable groundwater level data.

3.4.4. Amendments to the model were made to account for the following factors:

- development of the Aldhurst Farm Habitat Creation Scheme between July and October 2015;
- dredging of the Leiston Drain near the upstream boundary condition at G5; and
- sea level rise.

3.4.5. Groundwater and surface water abstractions were applied at the same rates as those implemented in the 2010-2015 model (also shown in Tables B.1 and B.2 of Appendix B).

3.4.6. To provide further validation of the model, the groundwater level response to the 2011 pumping test (WJ Groundwater, 2011), conducted in the

platform area of the Main Development Site was compared to observed data from that period.

ii. Revised recharge zones

3.4.7. The development of the Aldhurst Farm HCS has led to the establishment of new areas of reed swamp and associated landscaping (EDF NNB GenCo, 2014b), leading to inferred changes to recharge in this area, which lies immediately upstream of the G5 boundary condition. Across the newly-formed wetland areas, reed swamp recharge is applied. Recharge is calculated as described in Section 3.2d), with vegetation-specific evapotranspiration subtracted from rainfall to determine recharge. Across the grassland areas, recharge as calculated by the SMBM was applied using a pasture land use, Clay 2 soil type and Crag geology.

3.4.8. Changes in the assignment of recharge zones within the G5 catchment as a result of the Aldhurst Farm HCS are summarised in Table 3.6; the extent of the G5 catchment was defined based on LiDAR topographic data.

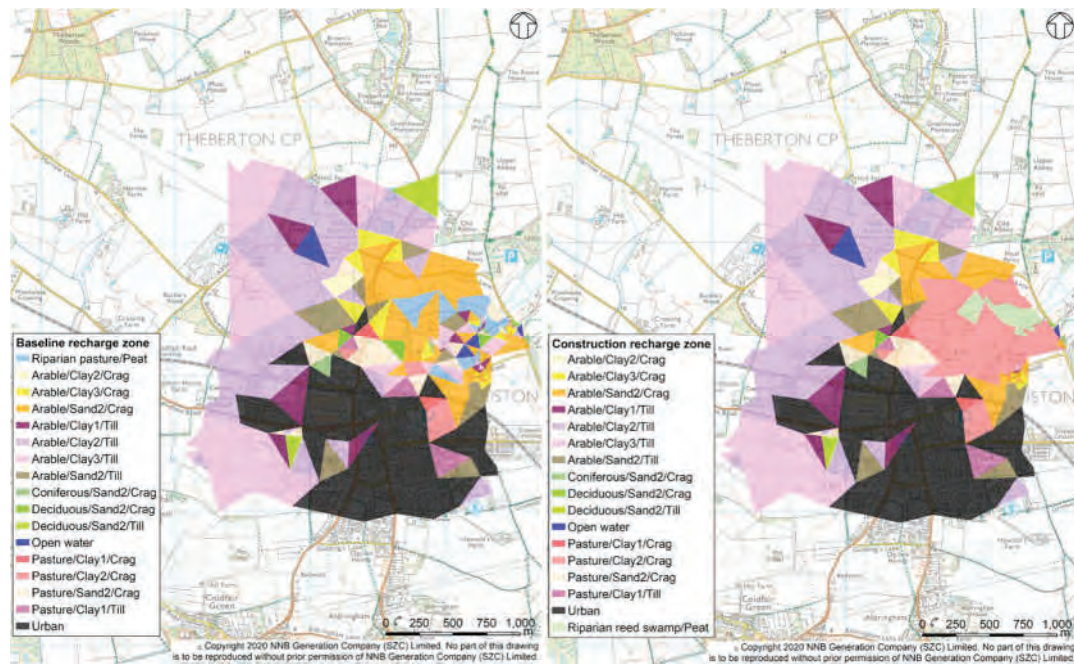

Table 3.6 Recharge zones assigned to the G5 catchment

Recharge zone	% of G5 catchment in model (no AFHCS)	% of G5 catchment in model (with AFHCS)
Riparian pasture/Peat	1.0	0.0
Arable/Clay2/Crag	1.4	1.4
Arable/Sand2/Crag	16.7	8.5
Arable/Clay2/Till	25.1	25.1
Arable/Clay3/Till	19.7	19.7
Arable/Sand2/Till	5.3	3.7
Deciduous/Sand2/Crag	0.4	0.3
Deciduous/Sand2/Till	0.9	0.8
Pasture/Clay2/Crag	1.9	12.2
Pasture/Sand2/Crag	3.1	2.7
Pasture/Sand2/Peat	0.3	0.1
Urban	24.3	24.3
Reed Swamp/Peat	0.0	1.2

3.4.9. The spatial distribution of these zones is shown in Plate 3.7. The image on the left hand side represents zones assigned to the model in the absence of the Aldhurst Farm HCS; this approach was taken for the future baseline

simulations described in Section 4. The image on the right hand side incorporates recharge zones associated with the Aldhurst Farm HCS; these zones were applied to the future construction simulations.

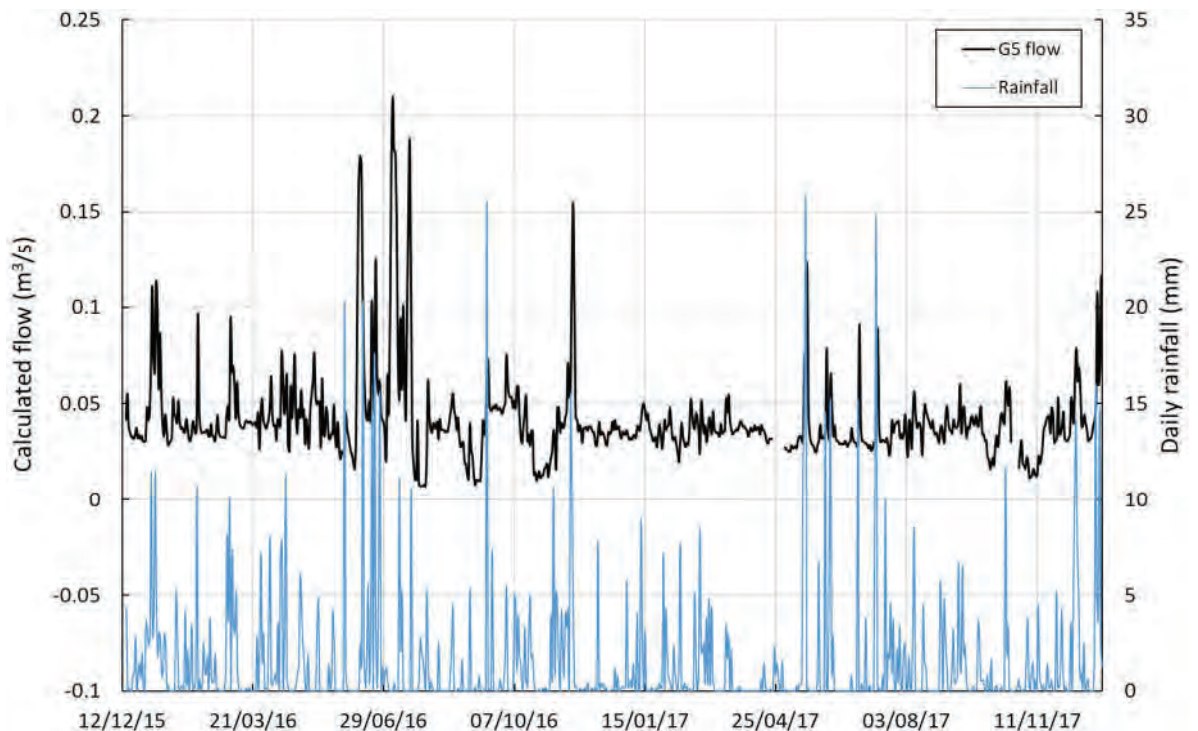

Plate 3.7: Modelled recharge zones within the G5 topographic catchment for baseline and construction scenarios

iii. Revised surface water boundaries

- 3.4.10. The calibrated rating equation used to derive flows at G5 from September 2010 to September 2015 is not valid after December 2015, when dredging of the channel took place (Hydro-Logic Services, 2016a; 2016b).
- 3.4.11. Furthermore, changes to recharge zones within the G5 catchment are likely to affect the relationship between rainfall and flow at the G5 gauging station, following creation of the Aldhurst Farm HCS.
- 3.4.12. A revised algorithm for modelling flow at G5 has been developed as a result, based on the available climatic and flow data collected since December 2015. The use of this algorithm means that future flow boundaries assigned to G5 are linked to projected changes in climate, as described in section 4.2.
- 3.4.13. The algorithm was developed firstly by analysing the flow response at G5 to rainfall events. Observed rainfall (Met Office, 2018) and stage-discharge derived stream flows at G5 (Hydro-Logic Services, 2018) are shown in Plate 3.8.

Plate 3.8: Observed rainfall and stage-discharge derived flows at G5 from December 2015 to December 2017

- 3.4.14. The available data indicate a reasonable correlation between individual rainfall events and peak flows throughout most of the monitoring period. However, it is notable that the largest recorded flow occurred in July 2016, in the absence of preceding rainfall events. Discrepancies can also be seen in early 2017, when flows of 0.03-0.04 m³s⁻¹ were maintained, despite limited rainfall.
- 3.4.15. Consented discharges from the Leiston Sewage Treatment Works (STW) contribute to flow in the Leiston Drain at G5 and these can occur in the absence of rainfall. The reported mean daily discharge from 2005-2011 is 1,112 m³ (0.013 m³s⁻¹), with a maximum daily value of 3,497 m³ (0.040 m³s⁻¹) recorded during this period and a minimum daily discharge of 0 m³ recorded on ten occasions (Royal Haskoning DHV, 2015). In addition, combined storm overflows are discharged from the STW following periods of heavy rainfall.
- 3.4.16. Natural baseflow, fed by recharge within the Leiston Drain catchment, is also expected to contribute to flow at G5, based on the distribution of recharge zones shown in Table 3.6.
- 3.4.17. The following relationship was used to link observed flow Q at G5 to rainfall and baseflow from natural recharge and anthropogenic inputs:

$$Q = ar_{2d} + Q_n + Q_a, \quad (7)$$

where a is a dimensionless coefficient relating rainfall (r_{2d}) to short-term variations in stream flow, Q_n is the estimated contribution to natural baseflow from recharge in non-urban areas [m^3s^{-1}] and Q_a represents a constant contribution to stream flow that is independent from rainfall and is assumed to be from anthropogenic sources [m^3s^{-1}], including the STW and leakage from urban services.

- 3.4.18. Recharge to the G5 catchment over the preceding 30 days was estimated using the soil moisture balance model and the land uses in Table 3.6; the resulting values were assigned to Q_n over the period of interest. The total area of the G5 catchment within the model is 4.8 km^2 , compared to a total catchment area of 7.7 km^2 (Royal Haskoning DHV, 2015); it is assumed that the land uses in Table 3.6 are representative of the catchment as a whole.
- 3.4.19. After accounting for natural baseflow, the remaining component of observed flow Q was compared to rainfall and an assumed constant contribution from anthropogenic sources.
- 3.4.20. For the purposes of calibration, the high flows observed from 9th-13th June and 5th-22nd July 2016 were removed from the analysis, as they are considered likely to be caused by short-term peaks in discharge from the STW, given the absence of significant rainfall events at this time. This gives best-fit values ($R^2=0.29$) of $a = 0.0034$ and $Q_a = 0.0248 \text{ m}^3\text{s}^{-1}$. The latter value exceeds the long-term average discharge from the STW since 2005-2011 and may indicate the influence of additional discharges from the urban environment, or an increased contribution from the STW.
- 3.4.21. A comparison of modelled and stage-discharge derived flows since channel dredging was completed in December 2015 is shown in Plate 3.9, which also shows modelled flows for baseline conditions, which do not include the Aldhurst Farm HCS and rely on the corresponding recharge zones shown in Table 3.6.

Plate 3.9: Stage-discharge derived and modelled flow at G5 from December 2015 to December 2017

- 3.4.22. The model results are similar for both scenarios, with a slight reduction in baseflow as a result of the Aldhurst Farm HCS. Neither model replicates calculated flows in the weeks following dredging, or the peak flows in June and July of 2016, which are assumed to be caused by discharges from the STW. However, the subsequent modelled flows match the observed data closely and the proposed approach is considered suitable for representing recent historical flows at G5, while the dependence of modelled flows on climatic conditions, indicate that the algorithm could be applied under a range of projected climatic conditions, as discussed in section 4.2.
- 3.4.23. A revised algorithm was also developed for the downstream boundary condition at Minsmere sluice, to ensure that applied values of stage are linked to projected changes in recharge and sea level, which is assumed to increase in line with the median of UKCP18 projections following the end of the calibration period in August 2015.
- 3.4.24. In the absence of stage data for Minsmere sluice, observed stage at G1, at the southern edge of the Minsmere South Levels, was plotted against mean recharge over the preceding 30-days, based on the soil moisture balance estimate of recharge for riparian pasture, which covers the majority of the Minsmere South Levels area. The results are shown in Plate 3.10.

Plate 3.10: Relationship between estimated recharge and observed stage at G1

3.4.25. There is considerable scatter in the data between November 2013 and March 2014, where some of the lowest water levels were recorded, despite high rainfall during this period and the observations occurring in winter, when river levels are typically highest. As such, these data are deemed to be unreliable and were excluded from further analysis.

3.4.26. Subsequent data show a strong correlation between antecedent recharge and river stage, via the following relationship:

$$h = 1.5153R + 0.1283, \tag{8}$$

where h is stage [m AOD] and R is 30-day average recharge [mm/day].

3.4.27. The relationship in Equation (8) was applied to the downstream boundary condition in MIKE11, with an additional factor to account for projected sea level rise, as described in section 3.4a)iv. The boundary condition does not include a tidal oscillation.

iv. Sea level rise

3.4.28. To account for projected rises in sea level following the end of the calibration period, an additional factor of approximately 0.55 cm per year was applied to the stage boundary condition described by Equation (8) after August 2015. This is equivalent to the 50th percentile of sea-level rise in the UKCP18 climate change projections (Met Office, 2018).

3.4.29. The equivalent freshwater head (see section 3.2c)) assigned to sea-floor boundary nodes in the model was also increased by approximately 0.55 cm per year during the model validation period.

b) Validation results

3.4.30. Simulated groundwater levels during the validation period are compared to observed data from the Peat and Crag in Figures 19A.25 to 19A.27. The model continues to produce a close match to observed groundwater levels throughout the Peat and in most Crag boreholes, both in terms of average levels and in the magnitude and timing of seasonal fluctuations.

3.4.31. As discussed in Section 3.3b), flattening of hydrographs within the Peat during winter reflects the drainage of groundwater when the water table intercepts the ground surface. Sensitivity analysis, described in Section 3.5b), has been conducted to simulate the presence of standing water at these locations and subsequent drainage via the MIKE11 drainage network.

3.4.32. The largest discrepancies between the modelled and observed data are in the deepest parts of the Crag, particularly in the far north of the Main Development Site (e.g. C7). However, the response zones of these piezometers are separated by a considerable distance, both laterally and vertically from sensitive wetlands and the main construction areas, where dewatering is proposed. As such, these discrepancies do not compromise the model's ability to simulate potential impacts from construction activities on Sizewell Marshes and the MWHM SSSIs.

3.4.33. Simulated groundwater levels during the 2011 pumping test are shown next to observed data in Figure 19A.29. The modelled response closely matches observations and, where discrepancies exist between the datasets, these can be attributed largely to differences in groundwater level at the start of the test, rather than differences in the system's response to pumping.

3.4.34. Matching of the response to pumping in this area is particularly significant, as it provides additional confidence in the model's ability to simulate the effects of proposed construction dewatering.

3.5 Sensitivity analysis

a) Summary of simulations completed

3.5.1. Sensitivity analyses were completed on the calibrated model, covering the following:

- Explicit representation of groundwater flooding within Sizewell Marshes by defining flood plain topography in MIKE11, assigning

Cauchy nodes throughout the Sizewell Marshes area and no longer limiting the water table elevation to the ground surface.

- Explicit assignment of run-off to the MIKE11 drainage channels.
- Varying vertical hydraulic conductivity in the Peat at depth beneath the Sizewell Marshes to assess changes in the vertical hydraulic gradient between the Peat and the underlying Crag. Assigned values were both raised and lowered by an order of magnitude.
- Varying stream bed conductance. Assigned values were both raised and lowered by an order of magnitude to assess the impact on the water balance for Sizewell Marshes and the quality of calibration to observed groundwater levels in the Peat.
- Varying changes in evapotranspiration rates with depth within Sizewell Marshes. An initial run comprised a linear reduction in evapotranspiration to a depth of 0.5 m below the surface, as opposed to the linear reduction over the top 1 m assigned within the main simulation. A subsequent run assigned the maximum rate of evapotranspiration regardless of water table depth.

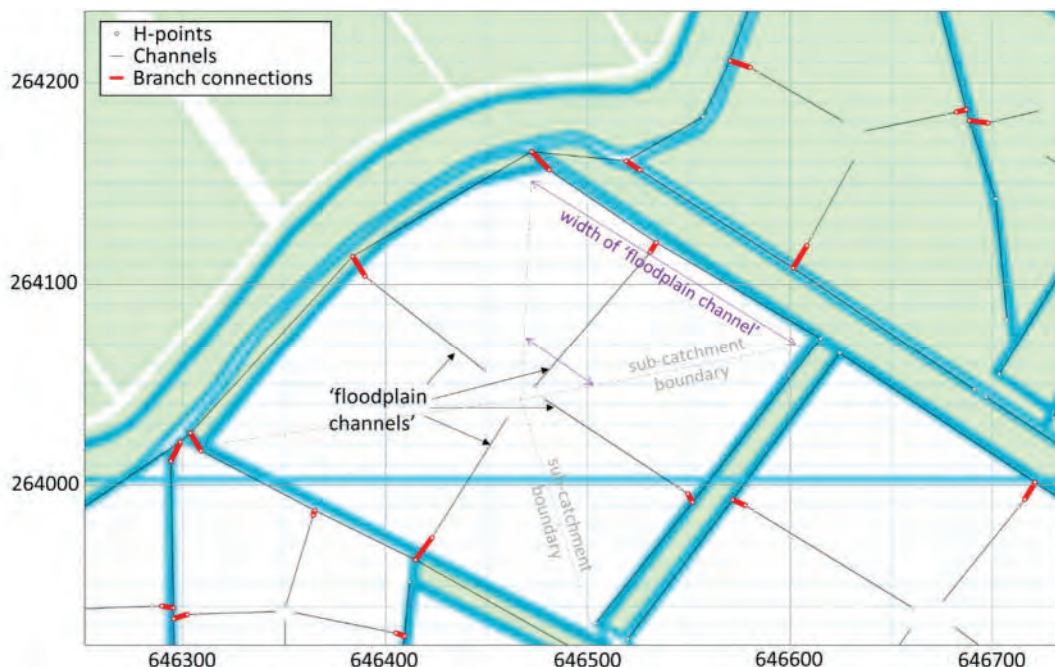

b) Representation of flood plain inundation

i. Overview

- 3.5.2. The calibrated model described in Section 3.2 does not permit water levels in the Marshes to exceed the modelled ground surface. Water is removed from the model using specified head boundaries when it reaches this level and is captured in the water balance.
- 3.5.3. The ground surface represented by the calibrated model was raised to a maximum level of 0.6 m AOD in localised areas around drainage channels to accommodate regular inundation. This allows simulated water levels to mimic observed values in these areas during winter.
- 3.5.4. Limiting maximum water levels to the modelled ground surface prevents excessive groundwater mounding from occurring within the low permeability wetland areas, but neglects the effect of ponding at the surface, which would restrict the upward flow of groundwater from the underlying wetlands.
- 3.5.5. Conversely, whilst the raising of the ground surface allows the model to replicate winter maximum water levels, this is likely to restrict flows to the surface water system on occasion, as water lying between the modelled and true ground surfaces is subject to flow through an assumed porous medium, rather than more rapid flow above the ground surface.

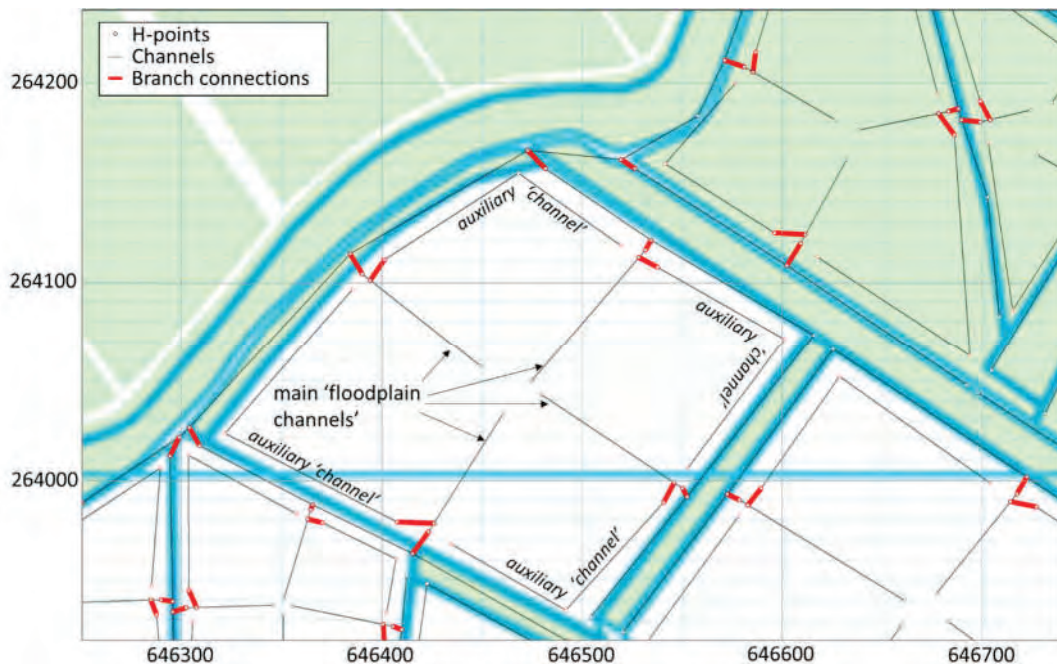

- 3.5.6. The implications of this approach were investigated by expanding the MIKE11 drainage network to include floodplains, such that groundwater intercepting the modelled ground surface can be routed to nearby drainage channels, rather than removed from the model entirely. When the local stage within the surface water network exceeds the ground surface, then water levels can exist above the level of the floodplain.
- 3.5.7. Each area of the floodplain was divided into local sub-catchments, which relate to the nearest defined drainage channel, as shown in Plate 3.11. Channels were defined through the centre of each floodplain catchment, linking the centre of the floodplain to the downstream drainage channel via a new branch connection. H-points were assigned at each end of these channels, to allow flow between FEFLOW and MIKE11 to be calculated at these locations.
- 3.5.8. The base elevation of each 'floodplain channel' is equal to that of the local ground surface, ensuring that flow can occur only when stage exceeds this elevation; when water levels are below the ground surface, flow occurs through the underlying porous medium (i.e. the Peat). The channel width varies linearly with that of the sub-catchment, ensuring an appropriate stage-volume relationship.

Plate 3.11: Modelled 'floodplain channels' and sub-catchment boundaries in MIKE11

- 3.5.9. A Manning’s n value of 0.12 was assigned to these flood plain channels, which agrees with reported data for vegetated wetland streams (Natural Resources Conservation Service, 1997).
- 3.5.10. The MIKE11 interface manager (see Section 3.2g) links each Cauchy node in FEFLOW to the nearest H-point. This poses difficulties in the corners of each floodplain, where the Cauchy nodes would be linked to the nearest true drainage channel. During dry periods, when water levels sit below the level of the floodplain, this would allow ongoing surface water flow to occur from these areas to nearby active drainage channels, where lower channel bases permit flow to occur throughout the year.
- 3.5.11. To address the above issue, auxiliary channels were defined at the edge of each floodplain, running parallel to the true drainage channels and linking to the main floodplain channels, as shown in Plate 3.12. A low Manning’s n value of 0.02 was applied to the auxiliary channels, ensuring a rapid connection to the main floodplain channel and preventing unrealistic delays in the transfer of water to the main MIKE11 drainage network.

Plate 3.12: Modelled ‘floodplain channels’ and sub-catchment boundaries in MIKE11

- 3.5.12. The base elevation of each auxiliary channel is equal that of the local ground surface. Each auxiliary channel was assigned a nominal width of 1 m, to prevent any significant increase in the overall stage-volume relationship of the floodplain.

ii. Results

- 3.5.13. As shown in Figure 19A.30, calibration to both seasonal and short-term groundwater level variations in the Peat is slightly improved in most piezometers by the inclusion of groundwater flooding. In a small number of piezometers (P3, P4, P13 and P14), there is a slightly poorer calibration, although both simulations match the observed data to within 10 cm for the majority of the time at each location.
- 3.5.14. In the majority of piezometers, the magnitude of seasonal variations is reduced, with higher summer minima. This provides a less conservative representation of the system's response to dry conditions.
- 3.5.15. As shown in Figure 19A.31, there is little overall change in calibration quality within the shallow part of the Crag, although a small number of piezometers show either a slight, but discernible improvement (PZ20) or deterioration (GW3 and PZ19) in the fit to observed data.
- 3.5.16. The groundwater balance for Sizewell Marshes in this scenario is compared to that of the calibrated model in Table 3.7.

Table 3.7 Groundwater balance for Sizewell Marshes in original calibration and with inclusion of floodplain inundation (all values in m³/d averaged over simulation period)

Component	Original calibration			Floodplain inundation		
	In	Out	Net	In	Out	Net
Recharge minus ET from water table	1,123	-911	211	1,122	-934	188
Leakage from streams	103	-827	-724	224	-1,711	-1,487
Seepages at surface	0	-527	-527	-	-	-
Upflow from Crag	1,481	-433	1,048	1,758	-431	1,327
Storage change	973	-981	-8	1,087	-1,115	-28
Total in	3,680	-	-	4,192	-	-
Total out	-	-3,680	-	-	-4,192	-
Imbalance	1			0		

- 3.5.17. The term describing groundwater seepages at the surface in the calibrated model is no longer present, as groundwater intercepting the surface of the floodplain instead drives increased outflows to the stream network.

- 3.5.18. There is an overall increase in the total amount of groundwater flowing to the surface water system, either as baseflow to defined channels or as groundwater discharging to the floodplain. This can be attributed to the slight lowering of the ground surface in low-lying areas (see Section 3.5b)i), which allows water above this elevation to discharge more rapidly to neighbouring drainage channels as surface water, rather than porous medium flow.
- 3.5.19. The increase in flows to groundwater from the surface water system can be attributed to the model allowing ponding of flood water above the ground surface, which would drive infiltration to the underlying groundwater system.
- 3.5.20. The increased upflows from the Crag in the sensitivity analysis can be attributed to the lowering of the modelled ground surface in low-lying areas, allowing water in the Peat to drain more freely to nearby drainage channels and driving increased upward flow from the underlying Crag aquifer.
- 3.5.21. The increased drainage of groundwater to the surface water system manifests as a substantial increase in both projected stage and flow at the stream gauging stations (Figures 19A.32 to 19A.34). The surface water results from the sensitivity analysis do not match the observed data and suggest incorrect parameterisation of the flood plain areas.
- 3.5.22. Despite assigning a roughness coefficient to the floodplains, the model still allows significant flow to occur in these areas, as evidenced by the substantial increase in downstream stage and flow at G1 and G6 in particular. In reality, significant ponding of stagnant water may occur in wetland areas, which in winter time would be subject to open water, rather than typical peat wetland evaporation rates.
- 3.5.23. As shown in Appendix C, the assigned crop coefficients used to convert from grassland reference evapotranspiration rates to values in the Peat range from 1.0 to 1.2 across the different vegetation types that occur in wetland areas. However, empirical factors given by the Environment Agency for converting reference evapotranspiration values to open water rates substantially exceed 1.0 for most of the year, with values exceeding 1.4 from September to January inclusive (Environment Agency, 2001).
- 3.5.24. As the approach taken to modelling floodplain inundation does not incorporate localised ponding of water, evaporative losses are likely to be substantially underestimated, leading to excessive contributions to the surface water system.
- 3.5.25. Detailed modelling of small-scale variations in topography and vegetation would be required to understand the potential for ponding to occur in any wetland area, alongside a mechanism to change the assignment of

evapotranspiration rates accordingly and these are outside the scope of this report.

c) Inclusion of run-off

i. Overview

- 3.5.26. The calibrated model described in Section 3.2 does not simulate surface run-off explicitly. However, upstream flow and downstream stage boundary conditions are used to constrain the MIKE11 drainage network, such that observed hydrographs (which are influenced by run-off) and modelled hydrographs show similar behaviour (Figures 19A.22 to 19A.24).
- 3.5.27. The sensitivity analysis described herein is used to assess the impact of explicitly assigning surface run-off on groundwater levels within the Sizewell Marshes and MWHM SSSIs.
- 3.5.28. The catchment of the MIKE11 drainage network was defined based on the local topography, as shown in Figure 19A.4. Run-off rates given by the soil moisture balance model for each recharge zone (Plate 3.7) were used to develop a daily time series of average run-off per m² of the catchment. The resultant time-varying run-off rates were distributed throughout the MIKE11 drainage network.
- 3.5.29. The run-off rates applied to each recharge zone within the MIKE11 drainage network during the model calibration period are summarised in Table 3.8. The largest run-off rates as a percentage of effective rainfall (typically around 70%) were assigned in areas of Till and Tidal Flats deposits, based on the approach described in Section 3.2d). As a result of its relatively high infiltration capacity, no run-off was assigned in areas underlain by the Crag, while intermediate proportions of run-off (typically around 30%) were assigned to the Peat.

Table 3.8 Run-off assigned per recharge zone in the MIKE11 catchment

Recharge zone	Areal extent (km ²)	% of MIKE11 catchment	Average run-off 2010-2015 (m ³ /d)	Average run-off (% of effective rainfall)
Riparian pasture/Loam	0.06	0.8%	8.4	44.4%
Arable/Clay2/Crag	0.20	2.6%	0.0	0.0%
Arable/Clay3/Crag	0.20	2.5%	0.0	0.0%
Arable/Sand2/Crag	1.56	20.1%	0.0	0.0%
Arable/Clay1/Till	0.16	2.1%	36.5	67.7%
Arable/Clay2/Till	0.61	7.9%	160.3	70.7%
Arable/Clay3/Till	0.14	1.8%	37.9	71.6%
Arable/Sand2/Till	0.20	2.6%	55.0	71.6%
Coniferous/Sand2/ Crag	0.68	8.7%	0.0	0.0%
Deciduous/Sand2/ Crag	0.35	4.5%	0.0	0.0%
Deciduous/Sand2/Till	0.09	1.1%	0.0	0.0%
Open water	0.03	0.3%	N/A	N/A
Pasture/Clay1/Crag	0.10	1.2%	0.0	0.0%
Pasture/Clay2/Crag	0.26	3.3%	0.0	0.0%
Pasture/Sand2/Crag	1.21	15.6%	0.0	0.0%
Pasture/Sand2/Peat	0.06	0.8%	3.2	13.2%
Pasture/Clay1/Till	0.13	1.6%	18.0	57.0%
Urban	0.15	1.9%	264.4	100.0%
Riparian pasture/Peat	0.91	11.7%	325.5	30.0%
Riparian pasture/Tidal flats	0.41	5.3%	346.9	76.9%
Riparian reed swamp/Peat	0.02	0.2%	6.1	30.3%
Riparian deciduous/Peat	0.23	2.9%	73.7	30.4%
Riparian reed swamp/Tidal flats	0.00	0.03%	1.9	77.0%
Riparian deciduous/Tidal flats	0.01	0.1%	7.9	77.1%
Total	7.75	100%	1345.6	22.2%

ii. Results

- 3.5.30. Figure 19A.35 shows how model calibration in the Peat of the Sizewell Marshes and MWHM SSSIs is not affected by the explicit inclusion of surface run-off. As shown in Figure 19A.36, model calibration in the shallow part of the Crag is also unaffected.
- 3.5.31. There is also little discernible change in the modelled flow and stage hydrographs at each gauging station (Figures 19A.37 to 19A.39), while the groundwater balance for Sizewell Marshes is almost identical to that of the initial model calibration, as shown in Table 3.9.

Table 3.9 Groundwater balance for Sizewell Marshes in original calibration and with inclusion of run-off in the MIKE11 model (all values in m³/d averaged over simulation period)

Component	Original calibration			Run-off included		
	In	Out	Net	In	Out	Net
Recharge minus ET from water table	1,123	-911	211	1,122	-911	212
Leakage from streams	103	-827	-724	103	-827	-724
Seepages at surface	0	-527	-527	0	-527	-527
Upflow from Crag	1,481	-433	1,048	1,481	-433	1,048
Storage change	973	-981	-8	973	-980	-8
Total in	3,680	-	-	3,679	-	-
Total out	-	-3,680	-	-	-3,678	-
Imbalance	1			1		

- 3.5.32. The results suggest that by constraining upstream flow and downstream stage in the surface water system, the model is largely insensitive to additional inputs to the surface water system.

d) Variations in vertical hydraulic conductivity of Sizewell Marshes

i. Overview

- 3.5.33. Construction dewatering is proposed in the platform area of the Main Development Site, which will draw down water levels substantially below the top of the Crag (see Section 4.3a)vii). Despite the proposed presence of a low permeability cut-off wall, this dewatering has the potential to affect water levels in the Crag beneath the Sizewell Marshes and MWHM SSSIs.

- 3.5.34. Drawdown of the water table in the Sizewell Marshes and MWHM SSSIs during construction is likely to be highly sensitive to the vertical permeability of the Peat and underlying superficial deposits (see Table 2.2). However, it is unclear whether modelled behaviour is sensitive to this parameter, under the range of natural conditions.
- 3.5.35. A sensitivity analysis has been conducted to investigate whether different vertical hydraulic conductivity values would lead to a similar quality of model calibration and hence, whether the true vertical hydraulic conductivity of the wetlands may differ substantially from that implemented in the initial model.
- ii. **Increased hydraulic conductivity**
- 3.5.36. Figures 19A.40 and 19A.41 show how modelled groundwater levels in the Sizewell Marshes and MWHM SSSIs are affected by increasing the vertical hydraulic conductivity of the superficial deposits in these areas by an order of magnitude.
- 3.5.37. Calibration within the Peat (Figure 19A.40) is essentially unchanged in this scenario, but the quality of calibration in the underlying Crag (Figure 19A.41) deteriorates significantly, as evidenced by the lowering of modelled water levels below observed values.
- 3.5.38. As shown by the comparison of water balances in Table 3.10, the increased vertical hydraulic conductivity leads to a substantial increase in upflow from the Crag, driving increased discharges to drainage channels within the wetlands, either directly or via groundwater seepages at the ground surface.
- 3.5.39. As shown in Figures 19A.42 to 19A.44, modelled stage, flow and flow duration hydrographs for this sensitivity analysis are indistinguishable from those produced by the calibrated model.

Table 3.10 Groundwater balance for Sizewell Marshes in original calibration and with Peat vertical hydraulic conductivity raised by one order of magnitude (all values in m³/d averaged over simulation period)

Component	Original calibration			High vertical K in Peat		
	In	Out	Net	In	Out	Net
Recharge minus ET from water table	1,123	-911	211	1,123	-911	212
Leakage from streams	103	-827	-724	81	-1,389	-1,309
Seepages at surface	0	-527	-527	0	-879	-879
Upflow from Crag	1,481	-433	1,048	2,763	-783	1,980
Storage change	973	-981	-8	972	-976	-4
Total in	3,680	-	-	4,939	-	-
Total out	-	-3,680	-	-	-4,938	-
Imbalance	1			1		

iii. Reduced hydraulic conductivity

- 3.5.40. Figures 19A.45 and 19A.46 show how modelled groundwater levels in the Sizewell Marshes and MWHM SSSIs are affected by decreasing the vertical hydraulic conductivity of the superficial deposits in these areas by an order of magnitude.
- 3.5.41. Modelled water levels within the Peat (Figure 19A.45) are notably lower in this scenario and no longer match observed values, while modelled water levels in the Crag (Figure 19A.46) exceed observed values, leading to an overall deterioration in calibration quality.
- 3.5.42. As shown by the comparison of water balances in Table 3.11, the decreased vertical hydraulic conductivity leads to a substantial reduction in upwards flow from the Crag, driving reduced discharges to drainage channels within the wetlands, either directly or via groundwater seepages at the ground surface.

Table 3.11 Groundwater balance for Sizewell Marshes in original calibration and with Peat vertical hydraulic conductivity reduced by one order of magnitude (all values in m³/d averaged over simulation period)

Component	Original calibration			Low vertical K in Peat		
	In	Out	Net	In	Out	Net
Recharge minus ET from water table	1,123	-911	211	1,123	-843	280

3.5.43. As shown in Figures 19A.47 to 19A.49, modelled stage, flow and flow duration hydrographs for this sensitivity analysis are indistinguishable from those produced by the calibrated model.

e) Variations in stream bed conductance

i. Overview

3.5.44. Proposed construction dewatering in the platform area has the potential to affect surface water stage and flow within Sizewell Marshes and MWHM SSSIs, which in turn may affect groundwater levels in the surrounding wetlands.

3.5.45. The potential magnitude of these impacts is likely to be sensitive to the conductance of stream beds, which were set to 0.1 d⁻¹ in the calibrated model (see Section 3.2g)ii). This parameter has not been measured directly at the site, although it may affect the quality of model calibration.

3.5.46. A sensitivity analysis has been conducted to investigate whether different stream bed conductance values would lead to a similar quality of model calibration and hence, whether the true values for this parameter may differ substantially from those implemented in the initial model.

ii. Increased stream bed conductance

- 3.5.47. Figures 19A.50 and 19A.51 show how groundwater levels in the Sizewell Marshes and MWHM SSSIs are affected by increasing the stream bed conductance in these areas by an order of magnitude.
- 3.5.48. Modelled summer minimum water levels within both the Peat (Figure 19A.50) and shallow Crag (Figure 19A.51) are notably lower in this scenario and no longer match observed values, leading to an overall deterioration in calibration quality.
- 3.5.49. As shown by the comparison of water balances in Table 3.12, the increased stream bed conductance leads to a substantial increase in overall leakage from streams to the underlying wetlands when stage exceeds the elevation of the water table. There is also a substantial increase in baseflow from the wetlands to these streams when the water table is relatively high and an associated reduction in groundwater seepages at the surface.
- 3.5.50. The overall reduction in evapotranspiration from the water table indicates lower average water levels within the wetlands and is consistent with the reduced summer minima shown in Figure 19A.50. The reduced upwards flow from the Crag highlights the overall reduction in head within this underlying aquifer, a phenomenon evident in the majority of piezometers shown in Figure 19A.51.

Table 3.12 Groundwater balance for Sizewell Marshes in original calibration and with stream bed conductance increased by one order of magnitude (all values in m³/d averaged over simulation period)

Component	Original calibration			High bed conductance		
	In	Out	Net	In	Out	Net
Recharge minus ET from water table	1,123	-911	211	1,112	-808	305
Leakage from streams	103	-827	-724	640	-1,372	-732
Seepages at surface	0	-527	-527	0	-376	-376

Total out	-	-3,680	-	-	-4,418	-
Imbalance	1			0		

- 3.5.51. As shown in Figures 19A.52 to 19A.54, modelled stage, flow and flow duration hydrographs for this sensitivity analysis are indistinguishable from those produced by the calibrated model.
- iii. **Reduced stream bed conductance**
- 3.5.52. Figures 19A.55 and 19A.56 show how groundwater levels in the Sizewell Marshes and MWHM SSSIs are affected by decreasing the stream bed conductance in these areas by an order of magnitude.
- 3.5.53. The quality of calibration in both the Peat (Figure 19A.55) and the shallow part of the Crag (Figure 19A.56) is similar in this scenario, with P10 the only notable exception.
- 3.5.54. As shown by the comparison of water balances in Table 3.13, reduced stream bed conductance leads to a substantial reduction in overall leakage from streams to the underlying wetlands when stage exceeds the elevation of the water table. There is also a substantial decrease in baseflow from the wetlands to these streams when the water table is relatively high and an associated increase in groundwater seepages at the surface.
- 3.5.55. The overall increase in evapotranspiration from the water table indicates slightly higher average water levels within the wetlands and is consistent with the increased summer minima shown in Figure 19A.55.

Table 3.13 Groundwater balance for Sizewell Marshes in original calibration and with stream bed conductance reduced by one order of magnitude (all values in m³/d averaged over simulation period)

Component	Original calibration			Low bed conductance		
	In	Out	Net	In	Out	Net
Recharge minus ET from water table	1,123	-911	211	1,123	-999	124

Seepages at surface	0	-527	-527	0	-804	-804
Upflow from Crag	1,481	-433	1,048	1,449	-462	987
Storage change	973	-981	-8	880	-901	-21
Total in	3,680	-	-	3,469	-	-
Total out	-	-3,680	-	-	-3,468	
Imbalance		1			1	

3.5.56. As shown in Figures 19A.57 to 19A.59, modelled stage, flow and flow duration hydrographs for this sensitivity analysis are indistinguishable from those produced by the calibrated model.

f) Representation of evapotranspiration with depth

3.5.57. As indicated in Section 3.2e), evapotranspiration from the water table is reduced linearly over the top 1 m of the calibrated model. This provides an important control on the system's response to prolonged dry periods and has particular relevance for assessments of future dewatering, when climatic conditions may differ substantially from recent observations.

3.5.58. The relationship between evapotranspiration from the water table and water table depth has not been measured, although this relationship may affect the quality of model calibration.

3.5.59. A sensitivity analysis has been conducted to investigate whether changes to the above relationship would lead to a similar quality of model calibration and hence, whether the true values for this parameter may differ substantially from those implemented in the initial model.

i. No reduction in evapotranspiration with depth

3.5.60. Figures 19A.60 and 19A.61 show how groundwater levels in the Sizewell Marshes and MWHM SSSIs are affected by implementing no reduction in evapotranspiration rate as the depth to the water table increases.

3.5.61. Modelled summer minimum water levels within both the Peat (Figure 19A.60) and shallow Crag (Figure 19A.61) are notably lower in this scenario and no longer match observed values, leading to an overall deterioration in calibration quality.

3.5.62. The comparison of water balances in Table 3.14 shows an expected, substantial increase in evapotranspiration from the water table. The lower water levels in the Peat drive increased upwards flow from the underlying Crag and reduced outflows to drainage channels within the Sizewell Marshes.

Table 3.14 Groundwater balance for Sizewell Marshes in original calibration and with no reduction in evapotranspiration with depth (all values in m³/d averaged over simulation period)

Component	Original calibration			No reduction in ET		
	In	Out	Net	In	Out	Net
Recharge minus ET from water table	1,123	-911	211	1,116	-1,760	-644
Leakage from streams	103	-827	-724	207	-663	-456
Seepages at surface	0	-527	-527	0	-414	-414
Upflow from Crag	1,481	-433	1,048	1,812	-333	1,479
Storage change	973	-981	-8	1,240	-1,205	35
Total in	3,680	-	-	4,376	-	-
Total out	-	-3,680	-	-	-4,375	-
Imbalance	1			0		

3.5.63. As shown in Figures 19A.62 to 19A.64, modelled stage, flow and flow duration hydrographs for this sensitivity analysis are indistinguishable from those produced by the calibrated model.

ii. **Reduced evapotranspiration depth**

3.5.64. Figures 19A.65 and 19A.66 show how groundwater levels in the Sizewell Marshes and MWHM SSSIs are affected by implementing a more rapid reduction in evapotranspiration rate, over a depth of 50 cm from the surface, as opposed to 1 m in the calibrated model.

3.5.65. Modelled summer minimum water levels within both the Peat (Figure 19A.65) and shallow Crag (Figure 19A.66) are notably higher in this scenario and no longer match observed values, leading to an overall deterioration in calibration quality.

3.5.66. The comparison of water balances in Table 3.15 shows an expected, substantial reduction in evapotranspiration from the water table. The higher summer water levels in the Peat restrict net upwards flow from the underlying Crag by approximately 20% and increase net outflows to drainage channels within the Sizewell Marshes by approximately 14%.

Table 3.15 Groundwater balance for Sizewell Marshes in original calibration and with reduction in evapotranspiration over 0.5 m interval (all values in m³/d averaged over simulation period)

Component	Original calibration			ET reduced over top 0.5 m		
	In	Out	Net	In	Out	Net
Recharge minus ET from water table	1,123	-911	211	1,123	-367	756

Imbalance	1			0		

3.5.67. As shown in Figures 19A.67 to 19A.69, modelled stage, flow and flow duration hydrographs for this sensitivity analysis are indistinguishable from those produced by the calibrated model.

g) Discussion of sensitivity analysis results

3.5.68. Several parameters were varied during the sensitivity analysis, to assess, based on the quality of calibration, whether representative values for these variables may differ substantially from those applied to the calibrated model.

3.5.69. Variations in evapotranspiration with depth and changes in the vertical hydraulic conductivity of Sizewell Marshes produced significantly poorer fits to observed data, as did increasing the vertical conductance of stream beds. The results suggest that these sensitivity parameters are not representative of the system.

3.5.70. Applying surface run-off to the model does not change the modelled stream hydrographs significantly. As such, it appears that flow and stage within existing surface water channels are sufficiently constrained by the applied upstream and downstream boundary conditions, that the modelled surface water results are insensitive to the explicit inclusion of run-off. It is worth noting that these stage and flow boundary conditions are linked to observations at the upstream and downstream gauging stations, which

already incorporate the combined effects of baseflow and run-off. Regardless, if the surface water system is not affected discernibly by this change to the model, it follows that the groundwater system is also insensitive to the explicit inclusion of surface run-off.

- 3.5.71. A reasonable calibration to the observed data is achieved when the stream bed conductance is lowered by an order of magnitude, suggesting that the true value for this parameter may be lower than that implemented in the calibrated model. This may be significant when assessing the system's response to construction dewatering, as enhanced leakage from drainage channels could mitigate drawdown within the adjacent groundwater system. Less conductive stream beds would reduce this mitigating affect and could potentially lead to more significant impacts from dewatering.
- 3.5.72. As such, the application of lower stream bed conductance has been included as a sensitivity analysis within the future modelling scenarios, which are described further in Sections 4 and 5.
- 3.5.73. The explicit representation of floodplain inundation reduces seasonal fluctuations in water levels within the Peat and therefore provides a less conservative representation of the system's response to dry conditions. While simulating floodplain inundation may reduce projected dewatering impacts as a result, the model is unable to replicate ponding of stagnant water within these areas accurately, leading to underestimation of evaporative losses and excessive contributions to surface water stage and flow.
- 3.5.74. The implementation of groundwater seepages in the main calibrated model, which remove ponded water from the system, leads to an improved calibration to observed surface water stage and flow. As such, this mechanism appears to be a more accurate representation of the evaporative losses that are likely to occur in flooded areas. For these reasons, the future scenario modelling described in Sections 4 and 5 does not incorporate floodplain inundation, although it is likely that the ability of the system to flood may reduce dewatering impacts associated with proposed dewatering activities.

4 SCENARIO MODEL DEVELOPMENT

4.1 Introduction

- 4.1.1. As the site is expected to operate until the year 2130, future changes in climate must be considered as part of the modelling investigation. To capture the range of uncertainty in future climate, this includes simulation of the wet and dry extremes of future climate projections, as well as intermediate projections of climate change, representing a 'best-estimate' of

future conditions. The data used to model each scenario are obtained from the UKCP18 suite of climate change projections (Met Office, 2018).

- 4.1.2. In addition to simulating the phases of development at Sizewell in a 'construction model', the three climatic scenarios will be applied to a 'baseline model', to allow comparison against natural conditions in the absence of development.

4.2 Future climate scenarios

a) Introduction

- 4.2.1. As described in section 3.2d), recharge values applied to the model have been calculated using a transient soil moisture balance, which requires daily rainfall and evapotranspiration data as input parameters.
- 4.2.2. MORECS data were used to supply rainfall and evapotranspiration values to the historical baseline model, covering the period from 2010-2015.
- 4.2.3. To model future recharge, projections of rainfall and evapotranspiration are required.
- 4.2.4. The Met Office Hadley Centre issued a suite of climatic projections, known as UKCP18, in November 2018 (Met Office, 2018), covering rainfall, temperature, wind speed and several other parameters until 2100. A summary of the available projections is provided in section 4.2d).
- 4.2.5. The rainfall projections are applied directly to the soil moisture balance model for Sizewell C, while the other parameters are used to derive estimates of evapotranspiration, using the Food and Agriculture Organisation (FAO) method described by Allen et al. (1998).

b) Rainfall

- 4.2.6. UKCP18 projected rainfall data are provided both as absolute values and as percentage anomalies, relative to a historical baseline dataset. The projected absolute rainfall values are given for each month of the year within a series of 30-year future time slices (e.g. 2020-2049). However, this format implies constant daily rainfall values throughout each month, thereby reducing the variability of the dataset in comparison to historical time series.
- 4.2.7. By contrast, the use of rainfall anomaly projections allows for daily variations in rainfall. Rainfall anomalies in the UKCP18 projections are provided relative to the following historical time series:

- 1961-1990;

- 1981-2000; and
- 1981-2010.

4.2.8. The 1981-2010 dataset, which covers the most recently available historical period, is used as the baseline for the Sizewell C scenario modelling. As well as representing the closest match to the original model calibration period (2010-2015), it incorporates a full 30 years of climatic variability. Daily time series were generated by applying the appropriate monthly anomaly in each decade to a corresponding daily value in the historical record.

c) Evapotranspiration

i. Derivation of parameters

4.2.9. The reference potential evapotranspiration value ET_0 is estimated using the Penman-Monteith equation (e.g. Allen et al. (1998)):

$$ET_0 = \frac{0.408\Delta(R_n - G) + \gamma \frac{900}{T + 273} u_2 (e_s - e_a)}{\Delta + \gamma(1 + 0.34u_2)} \quad (9)$$

where Δ is the rate of change of saturated vapour pressure with temperature [$\text{kPa } ^\circ\text{C}^{-1}$], R_n is net radiation [$\text{MJ m}^{-2} \text{day}^{-1}$], G is soil heat flux [$\text{MJ m}^{-2} \text{day}^{-1}$], γ is the psychrometric constant [$0.067 \text{ kPa } ^\circ\text{C}^{-1}$ for altitudes less than 100 m AOD], T is mean daily air temperature at 2 m above ground level [$^\circ\text{C}$], u_2 is the wind speed at 2 m above ground level [m s^{-1}], e_s is the saturation vapour pressure of the air [kPa] and e_a is the actual vapour pressure of the air (kPa).

4.2.10. The parameters required to solve equation (9) were derived using UKCP18 radiation, air temperature, air humidity and wind projections. The slope of the saturation vapour pressure curve Δ is dependent on temperature and is given by (Allen et al. (1998)):

$$\Delta = \frac{4098[0.6108\exp(\frac{17.27T}{T + 237.3})]}{(T + 237.3)^2} \quad (10)$$

4.2.11. Net radiation R_n is given by (Allen et al., 1998):

$$R_n = R_{ns} - R_{nl} \quad (11)$$

where R_{ns} is net incoming short-wave radiation [$\text{MJ m}^{-2} \text{day}^{-1}$] and R_{nl} is outgoing long-wave radiation [$\text{MJ m}^{-2} \text{day}^{-1}$]. UKCP18 offers projections of

both R_{ns} and R_{nl} as anomalies relative to baseline conditions. The projections are given in $W\ m^{-2}$, which were converted to $MJ\ m^{-2}\ day^{-1}$.

4.2.12. Historical observations for R_{ns} and R_{nl} are not available for the Sizewell C model domain. However, Allen et al. (1998) describe a method for deriving these parameters, using observations of daily hours of sunshine n [$hr\ day^{-1}$] and actual vapour pressure e_a [kPa], which were taken from publicly available Met Office datasets (Met Office, Hollis, D. and McCarthy, M., 2017).

4.2.13. Net shortwave radiation was derived using (Allen et al. (1998)):

$$R_{ns} = (1 - \alpha)R_s, \quad (12)$$

where α is the dimensionless albedo coefficient, which is 0.23 for the hypothetical grass reference crop and R_s is incoming solar radiation [$MJ\ m^{-2}\ day^{-1}$], given by (Allen et al. (1998)):

$$R_s = (0.25 + 0.5 \frac{n}{N})R_a, \quad (13)$$

where N is the maximum possible duration of sunshine [$hr\ day^{-1}$] and R_a is extra-terrestrial radiation [$MJ\ m^{-2}\ day^{-1}$].

4.2.14. The FAO provides monthly data for both N and R_a at a latitude of $52^\circ N$ (Allen et al. (1998)), which were applied across the Sizewell C model domain (centred at approximately $52.2^\circ N$).

4.2.15. Net longwave radiation is given by (Allen et al. (1998)):

$$R_{nl} = \sigma \left[\frac{T_{max,K}^4 + T_{min,K}^4}{2} \right] (0.34 - 0.14\sqrt{e_a}) \left(1.35 \frac{R_s}{R_{so}} - 0.35 \right), \quad (14)$$

where σ is the Stefan-Boltzmann constant [$4.903 \times 10^{-9}\ MJ\ K^{-4}\ m^{-2}\ day^{-1}$], $T_{max,K}$ is the maximum daily temperature in Kelvins [K], $T_{min,K}$ is the minimum daily temperature in Kelvins [K] and R_{so} is the clear-sky radiation [$MJ\ m^{-2}\ day^{-1}$], calculated from (Allen et al. (1998)):

$$R_{so} = (0.75 + 2 \times 10^{-5}z)R_a, \quad (15)$$

where z is elevation above sea level [m].

4.2.16. Daily maximum and minimum temperatures were obtained by applying monthly UKCP18 anomalies in these parameters to daily historical observations for the 1981-2010 baseline period, provided by the Met Office (Met Office, Hollis, D. and McCarthy, M., 2017).

4.2.17. In estimating ET_0 over periods of one day duration, the soil heat flux G can be considered negligible relative to R_n (Allen et al. (1998)) and a value of zero was assigned to this parameter.

4.2.18. Data are available only for wind speed at 10 m above ground level u_{10} from the UKCP18 projections. These were converted to wind speed at 2 m above ground level using the following relation (Allen et al. (1998)):

$$u_2 = 0.747951u_{10} . \quad (16)$$

4.2.19. The saturation vapour pressure of the air was estimated from (Allen et al. (1998)):

$$e_s = \frac{e^\circ(T_{max}) + e^\circ(T_{min})}{2} , \quad (17)$$

where $e^\circ(T_{max})$ is the saturation vapour pressure at the maximum daily air temperature [kPa] and $e^\circ(T_{min})$ is the saturation vapour pressure at the minimum daily air temperature [kPa].

4.2.20. Saturation vapour pressures for each temperature were derived from (Allen et al. (1998)):

$$e^\circ(T) = 0.6108 \exp \left[\frac{17.27T}{T + 237.3} \right] . \quad (18)$$

where the mean daily air temperature T was obtained by applying monthly UKCP18 anomalies in this parameter to daily historical observations for the 1981-2010 baseline period, provided by the Met Office (Met Office, Hollis, D. and McCarthy, M., 2017).

4.2.21. The actual vapour pressure of the air was estimated using (Allen et al., 1998):

$$e_a = \frac{RH}{100} \frac{e^\circ(T_{max}) + e^\circ(T_{min})}{2} , \quad (19)$$

where RH is the mean relative humidity [%]; projections of this parameter were obtained from UKCP18.

ii. [Data availability](#)

4.2.22. Stochastic data from the UKCP18 projections are available for the following parameters:

- mean air temperature at 1.5 m, T [°C];

- net surface short-wave radiation flux R_{ns} [W m⁻²];
- net surface long-wave radiation flux R_{nl} [W m⁻²];
- maximum air temperature at 1.5 m, T_{max} [°C]; and
- minimum air temperature at 1.5 m, T_{min} [°C].

4.2.23. These data are available as monthly anomalies for a series of 30-year time slices until 2100, relative to 1981-2010 values (e.g. the mean daily temperature for January in the 2020-2049 period is given as a change in °C relative to the baseline). Daily time series were generated by applying the appropriate monthly anomaly in each decade to a corresponding daily value in the historical record.

4.2.24. The baseline period for UKCP18 projections runs from 1981-2010 inclusive, while the first projections cover the period from 2010-2039 inclusive. As such, absolute values for 01/01/2010 were generated by applying the 2010-2039 January anomaly to historical data for 01/01/1981.

4.2.25. Observation datasets for T_{min} , T and T_{max} covering the 1981-2010 baseline period were obtained from the Met Office (Met Office, Hollis, D. and McCarthy, M., 2017).

4.2.26. Observation datasets for actual vapour pressure e_a (in hPa) and hours of sunshine n (in hours per month) for the 1981-2010 baseline period are also available from the Met Office and were used to calculate net long-wave and short-wave radiation, based on equations (12)-(15).

4.2.27. No stochastic data are available for mean relative humidity, RH and u_{10} . However, UKCP18 data from 12 regional projections are available for these parameters up to and including 2080.

4.2.28. Analysis of the RH and u_{10} projections showed no overall decreasing or increasing trend from 2010-2080, although seasonal and interannual variability was observed. Values for these parameters for 2080 onwards were obtained by cycling through the original projection dataset.

iii. Method validation

4.2.29. The method described in Section 4.2c)i has been validated by comparing the values generated from 2010-2015, using UKCP09 data obtained from the Met Office (Met Office, Hollis, D. and McCarthy, M., 2017) with those obtained from MORECS over the same period. This comparison, which shows similar behaviour throughout the calibration period is shown in Plate 4.1.

Plate 4.1: Comparison of potential evapotranspiration estimates derived from UKCP09 data and MORECS (2010-2015)

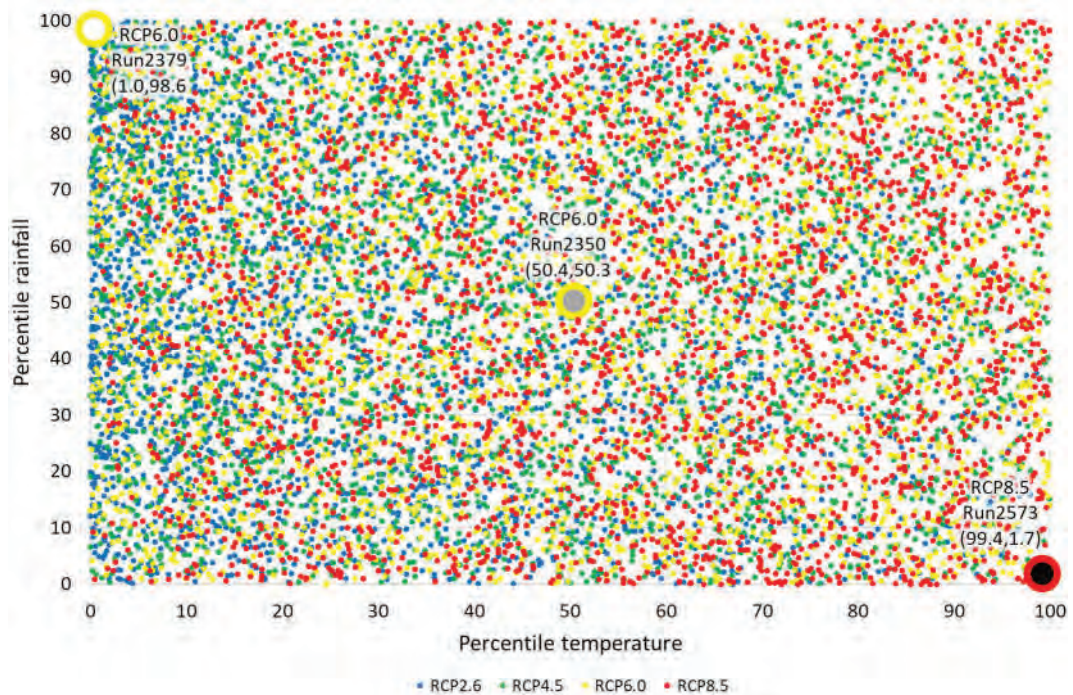

d) Choice of projection data

- 4.2.30. As described in section 4.1, UKCP18 climate projections were used to derive recharge time series representing ‘wet’, ‘intermediate’ and ‘dry’ conditions during construction and operation of Sizewell C.
- 4.2.31. Climatic projections are available for a variety of climate change scenarios from the UKCP18 website (Met Office, 2018), which reflect different emissions pathways. These are termed ‘Representative Concentration Pathways’ (RCPs), with each RCP representing a target amount of radiative forcing at the top of the atmosphere by 2100, relative to preindustrial levels. Four forcing levels have been set: 2.6, 4.5, 6.0 and 8.5 W/m², with the increasing values representing increasing levels of emissions.
- 4.2.32. To produce 3,000 separate projections of future climate for each of the RCP scenarios, the Met Office applied statistical methods to an initial suite of UKCP18 models, thus capturing the range of uncertainty in the model results. These probabilistic projections are available from the UKCP18 website (Met Office, 2018).
- 4.2.33. UKCP18 provides output data for each projection for the whole of the UK across 25 km grid cells, allowing local conditions to be analysed.

- 4.2.34. Percentile changes in temperature and rainfall across all four RCP scenarios are shown in Plate 4.2. Whilst the higher emissions scenarios show the highest temperature anomalies, there is no systematic relationship between temperature and rainfall overall.
- 4.2.35. It is important to ensure that the modelling captures potential impacts under a broad range of plausible climatic conditions. If projected impacts during extreme wet, dry and normal conditions are either not significant or can be mitigated, this will provide confidence that the mitigated or unmitigated impacts are not significant under all plausible climatic conditions.
- 4.2.36. Based on these considerations and the data presented in Plate 4.2, the following projections have been used in future scenario modelling of the site:
- Wet scenario: RCP6.0 simulation 2379 (giving the 1st percentile of temperature and 99th percentile of rainfall across all scenarios)
 - Intermediate scenario: RCP6.0 simulation 2350 (50th percentile of both temperature and rainfall)
 - Dry scenario: RCP8.5 simulation 2573 (giving the 99th percentile of temperature and 1st percentile of rainfall)

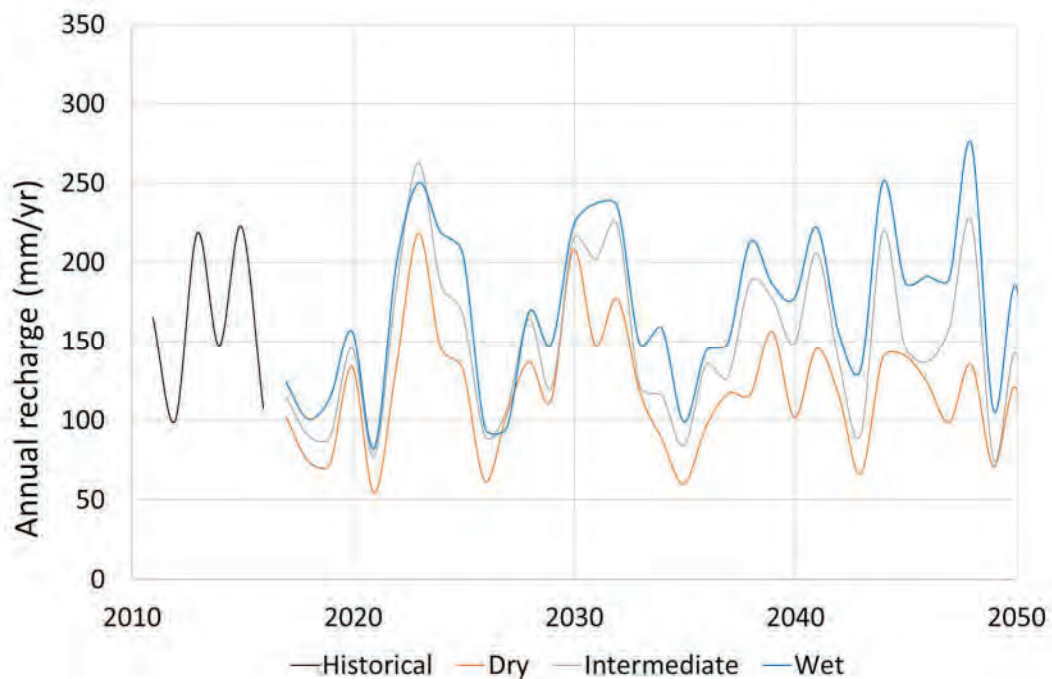

Plate 4.2: Relationship between mean temperature and rainfall anomalies for all RCP scenarios (2010-2099)

e) Applied recharge

- 4.2.37. The climate projection data described in Section 4.2d) were applied to the transient soil moisture balance model and used to generate long-term recharge time series for each of the zones shown in Plate 3.1 in each climate scenario.
- 4.2.38. Example time series for a single recharge zone (Pasture/Sand2/Crag, shown in Plate 3.1) are presented in Plate 4.3.

Plate 4.3: Projected recharge time series for Pasture/Sand2/Crag

- 4.2.39. Projected recharge for the wet scenario is typically more than double that for the dry scenario. The wide range of conditions represented by these datasets provides confidence that the model scenarios can cover the full range of uncertainty in future climate.
- 4.2.40. Average net annual recharge (recharge minus evapotranspiration from the water table when the ground is fully saturated) applied to the calibrated model is shown in Figure 19A.15 for the period 2010-2015. Figures 19A.70 to 19A.72 show how net recharge in the model from 2015-2040 differs from these historical values for the dry, intermediate and wet scenarios respectively.

f) Surface water

4.2.41. Future stage at Minsmere sluice and flow at G5 are represented using the algorithms described in Section 3.4.9. In addition, a time-varying increase in stage was applied to the Minsmere sluice boundary condition, to account for different rates of sea level rise in each scenario (see Section 4.2h))

4.2.42. Due to the implementation of the Aldhurst Farm HCS in 2015, recharge applied to the construction model differs slightly to that implemented in the baseline model; this has implications for flow at the G5 boundary, which are discussed further in Section 4.3a)i.

g) Abstractions

4.2.43. Groundwater and surface water abstractions were applied at the same rates as those implemented in the 2010-2015 model (also shown in Tables B.1 and B.2 of Appendix B).

h) Sea level

4.2.44. Long-term increases in sea level were applied to each of the climate scenarios, based on data from the UKCP18 projections. At the time of writing, only the 5th, 50th and 95th percentiles of projected sea level rise were available at yearly intervals (thus preventing the application of the 1st and 99th percentiles to the wet and dry climatic scenarios). These were applied as follows:

- Dry scenario. The 95th percentile of sea level rise (equivalent to approximately 1.2 cm/yr on average between 2015 and 2099) was applied to reflect a high degree of ice melt and thermal expansion of the oceans, in keeping with the high projected temperatures in this scenario.
- Wet scenario. The 5th percentile of sea level rise (equivalent to approximately 0.6 cm/yr on average between 2015 and 2099) was applied, reflecting a lower rate of temperature increase, reduced thermal expansion of the oceans and less ice melt.
- Intermediate scenario. The 50th percentile of sea level rise was applied (equivalent to approximately 0.9 cm/yr on average between 2015 and 2099).

4.2.45. The application of these data provides appropriate boundary conditions for the groundwater and surface water systems near the coast. However, it should be noted that the FEFLOW model is not able to simulate potential coastal flooding and does not incorporate current or future coastal flood

defences. As such, this report does not indicate whether low-lying areas of Sizewell Marshes and MWHM will be inundated as a result of projected rises in sea level.

4.3 Development aspects

a) Implementation in model

4.3.1. The following section sets out how development aspects have been applied to the model. The timing of application of each of the features in the model is based on:

- available information at the time of writing;
- the model year running from 1 September to 31 August; and
- simplification of complexities to aid model setup and interpretation.

4.3.2. Development features have been applied to the model, based on the start and end dates shown in Table 4.1.

Table 4.1: Timing of implementation of development features

Feature	Start date	End date
Aldhurst Farm HCS	01/09/2015	31/08/2130
SSSI Crossing	01/09/2020	31/08/2130
Sizewell drain realignment	01/09/2020	31/08/2130
MDS cut-off wall	01/09/2022	31/08/2130
MDS sheet pile wall	01/09/2022	31/08/2130
Borrow pits	01/09/2022	31/08/2130
Construction dewatering	01/09/2022	31/08/2032
MDS foundations	01/09/2024	31/08/2130
Temporary construction area	01/09/2022	31/08/2032
Car park	01/09/2032	31/08/2130
Operational conditions at MDS	01/09/2032	31/08/2130

4.3.3. The design extent of these development features is shown in Figure 19A.73. Their extent in the model, which employs a triangular mesh, is shown in Figure 19A.74.

4.3.4. Mesh refinement, and hence the accuracy of feature extents, is greatest in the vicinity of the platform area and adjacent wetlands, where the impacts of construction are expected to be most significant. Coarser elements have been implemented towards the edges of the Main Development Site, where slight discrepancies between the design and model extents of features are not expected to affect the key outputs of the model in a significant manner.

i. Aldhurst Farm HCS (2015-2130)

4.3.5. The development of the Aldhurst Farm HCS has led to changes in vegetation and land use compared to the 2010-2015 baseline period. A series of basins were excavated in the centre of the scheme to a depth below the existing water table, creating a wetland habitat. Surrounding these wetlands, a grassland habitat has been cultivated, incorporating excavated material from the basins. The extent of the Aldhurst Farm HCS is shown in Figure 19A.73., based on detailed descriptions and plans presented in EDF NNB GenCo's Construction Management Strategy (EDF NNB GenCo, 2014b).

4.3.6. Aldhurst Farm HCS was completed in 2015. Changes to recharge and flow at G5 associated with Aldhurst Farm HCS are implemented in the construction model from 1 September 2015 to 31 August 2130 and are omitted from the baseline simulations. The application of recharge in this area, and the associated modifications to the flow boundary condition at G5 nearby, is discussed in Sections 3.4a)ii and 3.4.9.

ii. SSSI Crossing (2020-2130)

The proposed SSSI crossing would comprise a causeway running in a north-north-west orientation, from the MDS across the SSSI to the permanent access road at Goose Hill. Where the causeway crosses the existing Leiston Drain, the channel would be culverted. During construction, a bridge would provide temporary access to the MDS before being removed following completion of a permanent access route across the causeway. The location of the SSSI crossing is shown in Figure 19A.73, based on drawing SZC-SZ0100-XX-000-DRW-100015 (EDF NNB Genco, 2018b). Parameterisation of this area in the model was based on Mott MacDonald's SSSI Crossing Embankment Option Preliminary Design Report (Mott MacDonald, 2016).

4.3.7. Embankments would run parallel to the causeway on either side, with sheet piling at the toe of each, extending through superficial deposits including

the Peat aquifer, into the underlying Crag aquifer. The dimensions of the sheet piles have not been confirmed; however, in Mott MacDonald (2016), it has been suggested that they would extend to a minimum depth of 3.5 m below the top of the Crag.

- 4.3.8. In the model, hydraulic conductivity is reduced in the location of the sheet piles to represent the decreased lateral flow associated with their presence. Parallel to the structure, a hydraulic conductivity of 6×10^{-8} m/d is applied to elements based on the Sellmeijer et al. (1995) study assessing the hydraulic resistance of steel sheet pile joints. Perpendicular to the structure a scaled hydraulic conductivity of 1×10^{-5} m/d is applied to take into account the thickness of model elements (approximately 1.5 m) versus sheet pile thicknesses (approximately 0.01 m). This change is applied across elements extending from the ground surface (layer 1) to 3.5 m below the top of the Crag (layer 9).
- 4.3.9. To maintain flow along Leiston Drain, the channel would be culverted under the causeway, with a bridging structure supporting the overlying causeway. Sheet piles would run parallel to the culvert, extending through superficial deposits including the Peat aquifer into the underlying Crag aquifer. The dimensions of the sheet piles have not been confirmed; however, in Mott MacDonald (2016) it has been suggested that they would extend to a minimum depth of 3.5 m below the top of the Crag.
- 4.3.10. In the model, hydraulic conductivity is reduced at the location of the culvert to represent the decreased lateral flow associated with the presence of the structure and the sheet piles. A hydraulic conductivity of 3×10^{-5} m/d is applied across the approximately 10 m-thick elements in the footprint of the culvert (based on (Sellmeijer, 1995)), extending from the ground surface (layer 1) to 3.5 m into the Crag (layer 9). The reduction in conductance is only assigned in the y-axis, as the sheet-piles would primarily limit flow in a north-south direction with limited impact in an east-west direction.
- 4.3.11. Below the culvert, it is proposed that any superficial materials are excavated and replaced by site-won granular fill, supporting concrete slab foundations for the culvert (Mott MacDonald, 2016). To represent the granular fill in the model, Crag material properties (specific storage, drainable porosity, and x-axis hydraulic conductivity) are assigned to elements with superficial material properties (layers 1-5) across the footprint of the culvert.
- 4.3.12. To the north of Leiston Drain, it is proposed that any superficial soils would be excavated to the depth of the Crag and replaced by granular fill (Mott Macdonald, 2016). To represent the granular fill in the model, Crag material properties (specific storage, drainable porosity, and hydraulic conductivity)

are assigned to elements with superficial material properties (layers 1-4) across the footprint of this area.

- 4.3.13. To the south of Leiston Drain a number of ground improvement proposals have been discussed in Mott MacDonald (2016). The two options taken forward involve placement of a grid of continuous flight auger piles (CFAs) or controlled modulus columns (CMCs). The CFAs/CMCs would be spaced 1.25-1.5 m apart centre to centre and have a diameter of 450-600 mm. To the south of Sizewell Drain they would extend to a depth of 12-13 m below ground level (bgl), and between Sizewell Drain and Leiston Drain they would extend to a depth of 9-10 m bgl, penetrating the underlying Crag in both instances. The piles would cover approximately 10% of the footprint. In the model, the piles are represented as a reduction in hydraulic conductivity, porosity and specific yield by 10%, extending 12 m bgl (layers 1-9) and 10 m bgl (layers 1-9) in line with the design.
- 4.3.14. On completion of the SSSI Crossing, the causeway would have hardstanding cover. Drainage from the causeway would discharge to the drainage network on the MDS, before discharging to the sea (Mott MacDonald, 2016). This is represented in the model as a zone of zero recharge across the SSSI Crossing.
- 4.3.15. The SSSI Crossing would be a permanent feature that would provide vehicle access to Sizewell C during construction, operation and decommissioning. Construction would begin prior to other works on the MDS (EDF NNB GenCo, 2018c). Within the model changes associated with the SSSI Crossing are applied between 1 September 2020 and 31 August 2130.

iii. Sizewell Drain realignment (2020-2130)

- 4.3.16. Atkins' outline design report for Sizewell Drain realignment (Atkins, 2016b) details design considerations and shows the proposed course of the realigned drain. It notes that Sizewell Drain realignment would take place prior to work on the MDS. As such, the drainage realignment is included in the model between 1 September 2020 and 31 August 2130. The MIKE11 surface water drainage model has been amended, with realignment of Sizewell drain to run alongside the proposed SZC western embankment and link with Leiston Drain to the north. Stream boundary conditions in FEFLOW have also been amended to correspond with the updated Sizewell Drain layout.
- 4.3.17. The stream bed conductance of the realigned drain was set to 0.1 d^{-1} , in line with the values applied to the rest of the modelled stream network, as stated in Section 3.2g)ii.

iv. Main Development Site cut-off wall (2022-2130)

- 4.3.18. The cut-off wall would fully penetrate superficial deposits and the Crag aquifer and partially penetrate the underlying London Clay (Preene Groundwater Consulting, 2016). It is anticipated to be 0.8 m thick, with a hydraulic conductivity of 1×10^{-8} m/s (Preene, 2016). The proposed location of the cut-off wall is shown in Figure 19A.73, based on design drawing SZC-SZ0100-XX-000-DRW-100027 (EDF NNB GenCo, 2018a).
- 4.3.19. Construction would commence at the start of the construction phase and be completed in 55 weeks (Jacobs, 2014). Changes to the model associated with the cut-off wall are applied from 1 September 2022 and 31 August 2130.
- 4.3.20. In the model, nodes are adjusted to reflect the shape of the cut-off wall in SZC-SZ0100-XX-000-DRW-100027 (EDF NNB GenCo, 2018a). The wall is represented by 2 m-thick elements, extending to the base of the Crag/top of London Clay. A hydraulic conductivity of 2.5×10^{-8} m/s is applied across the cut-off wall model elements, to maintain a conductance consistent with Preene (2016). Zero recharge is applied across the cut-off wall elements to reduce computational stress within the model; in reality recharge will be close to zero at the cut-off wall due to its low permeability.

v. Main Development Site sheet pile wall (2022-2130)

- 4.3.21. The inferred location of the sheet pile wall is shown in Figure 19A.73, based on design drawing SZC-SZ0100-XX-000-DRW-100027 (EDF NNB GenCo, 2018a), which shows the location of the western and northern embankments, along which the sheet piles would run.
- 4.3.22. The depth of the sheet piles has not been confirmed; however, it is assumed that they would extend through the superficial deposits into the underlying Crag to provide the required stability.
- 4.3.23. In the model, the hydraulic conductivity is reduced for elements in the location of the sheet pile wall, extending from the ground surface (layer 1) to 3.5 m below the top of the Crag (layer 9). Parallel to the structure, a hydraulic conductivity of 6×10^{-8} m/d is applied to elements based on Sellmeijer (1995). Perpendicular to the structure a scaled hydraulic conductivity of 6×10^{-6} m/d is applied to take into account the thickness of model elements (approx. 1 m) versus sheet pile thicknesses (approx. 0.01 m). Zero recharge is applied across the sheet-pile wall elements to reduce computational stress within the model. The recharge loss associated with this is limited due to small surface area covered by the sheet pile elements.

4.3.24. There are no details of when the sheet pile wall would be constructed; however, it is assumed that it would be installed early in the construction period. The sheet pile wall is included in the model from 1 September 2022 to 31 August 2130.

vi. Borrow pits (2022-2130)

4.3.25. The locations of the proposed borrow pits are shown in Figure 19A.73, based on design drawing SZC-SZ0100-XX-000-DRW-100027 (EDF NNB GenCo, 2018a). It is anticipated that Crag material would be excavated from the borrow pits to a depth of approximately 8 m bgl (Costain, 2015) and replaced by excavated MDS material. Due to the natural elevation of the ground surface in this area (see Section 2.8f), the base of the borrow pits in the model lies at an elevation of 4 to 7 m AOD. Excavation of the borrow pits would begin at the start of the construction period and the site would start to receive material from the MDS after 10 months (Costain, 2015).

4.3.26. In the model, changes associated with the borrow pits have been implemented from 1 September 2022 to 31 August 2130. This includes changing soil properties (horizontal hydraulic conductivity = 1 m/d; vertical hydraulic conductivity = 0.5 m/d; drainable porosity = 0.1; specific storage = 0.0006 m^{-1}) to match properties allocated to the majority of the platform in the baseline model (for comparison, the original Crag material in this area was assigned horizontal hydraulic conductivity = 21.6 m/d; vertical hydraulic conductivity = 2 m/d; drainable porosity = 0.2; specific storage = 0.0002 m^{-1}). Properties have been applied from ground surface to 8 m bgl (layers 1-4). A "Pasture Sand" recharge zone has also been allocated to the borrow pits, consistent with that applied to the majority of the platform in the baseline model.

vii. Construction dewatering within the cut-off wall (2022-2032)

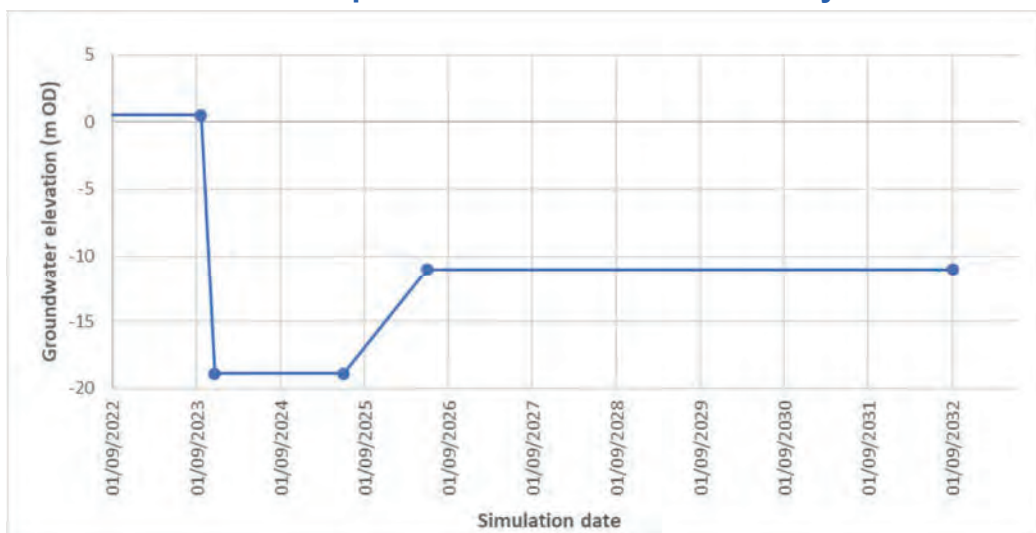

4.3.27. Proposed dewatering within the cut-off wall on the MDS would facilitate construction of Sizewell C. Dewatering would commence on completion of the cut-off wall, 55 weeks after the start of the construction period (Jacobs, 2014), with an initial target drawdown of -18.9 m AOD (Preene Groundwater Consulting, 2016).

4.3.28. A bulk excavation level of -10 m AOD would exist across the majority of the site, with locally deeper excavations, as shown in 60PO5502/001 (EDF NNB GenCo, 2014c). Backfilling to the level of foundations would be complete 33 months after the start of the construction phase (Jacobs, 2014). It is assumed that ongoing dewatering to a depth of 1m below these levels (-11 m AOD) would be required from this point onwards to facilitate the remainder of construction.

4.3.29. Additional dewatering to -27 m AOD would be required in the tunnel boring machine (TBM) launch chambers, each comprising a 50 m by 15 m cofferdam against the inner face of the eastern cut-off wall (Preene Groundwater Consulting, 2016). Steel sheet pile walls would be used to support the sides of the launch chambers (Jacobs, 2014). Two launch chambers would be required, at the locations shown in SZC-SZ0100-XX-000-DRW-100011 (EDF NNB GenCo, 2018d). Works on the tunnels and associated infrastructure would commence 2 years after the start of the construction phase and continue until nearly 6 years after the start of the construction phase (SZC-SZ0400-XX-000-SCH-100001, (EDF NNB GenCo, 2017)). As a conservative assumption, dewatering to the base of the launch chambers would be required throughout this period. At the end of the construction period dewatering would cease across the MDS.

4.3.30. In the model, specified hydraulic head boundary nodes have been applied across the platform area from slices 1-11 to simulate dewatering. In line with proposals, specified head nodes are activated 385 days into the construction phase (2022), decreasing linearly from natural groundwater elevation to a constant head of -18.9 m AOD over a period of 60 days. Between days 1,006 and 1,371 groundwater elevation is set to linearly increase to a level of -11 m AOD. From day 1371 to the end of the construction period in 2032, a groundwater elevation of -11 m AOD is maintained across the MDS. Following completion of the construction period, the fixed head boundary nodes are deactivated, and unconstrained groundwater levels are allowed to develop. Plate 4.4 shows the changes in fixed head boundary conditions at the MDS across the construction phase.

Plate 4.4: Main Development Site fixed head boundary conditions

4.3.31. A maximum flow rate constraint of 0 m³/d is applied to the specified head nodes in the platform area, to prevent injection of water occurring and allow groundwater levels to recover naturally from -18.9 m AOD to -11 m AOD.

4.3.32. At the proposed locations of TBM cofferdams within the MDS, low permeability elements (with a conductance equivalent to that of a 6×10^{-8} m/d for a 0.01 m thick sheet pile wall (Sellmeijer, 1995) have been assigned 2 years after the commencement of the construction phase. Within these areas, specified heads of -27 m AOD have been applied from 2-6 years into the construction phase to simulate dewatering associated with these structures.

viii. Construction on Main Development Site

4.3.33. The foundations of the nuclear island buildings, the turbine hall, the service water pump building and the outfall pond building would extend to the levels shown in 60PO5502/001 (EDF NNB GenCo, 2014c). In the model, a low hydraulic conductivity (1×10^{-8} m/s) is assigned to elements within the MDS to represent foundation structures between 1 September 2024 and 31 August 2130. Across the footprint of the nuclear island buildings and turbine hall elements, the foundations extend to a depth of -10 m AOD; across the footprint of the service water pump building they extend to a depth of -17 m AOD and across the footprint of the outfall pond building they extend to a depth of -19.5 m AOD beneath the outfall pond building.

4.3.34. During construction, recharge across the MDS would reduce, due to the interception of rainfall by drainage and dewatering systems. There will also be an increase in the proportion of impermeable ground cover during the construction phase, with only very limited recharge once all impermeable surfaces are in place. The use of specified head boundaries to represent dewatering in the model means that water levels in the platform area would be insensitive to any assigned recharge during the construction phase. As such, within the model it is assumed that recharge would be zero throughout the construction and post-construction phases to reduce numerical errors and run-time.

ix. Temporary Construction Area and Water Management Zones (2022-2032)

4.3.35. Drawing SZC-SZ0100-XX-000-DRW-100027 (EDF NNB GenCo, 2018a) shows the proposed location of the TCA. Development of the TCA would increase surface runoff across the area, due to reductions in permeable surfaces. As such, a strategy has been developed to manage surface runoff.

4.3.36. Figure 1 of WSP's Water Management Study (WSP, 2017) shows that the TCA would be split into seven catchments, which are presented in Figure 19A.73 of this report. Surface runoff generated at each catchment would be managed by either discharging to surface water and groundwater (catchments 1, 2, 3 and 6) or discharging to groundwater only (catchments

4, 5 and 10). Catchments 1-6 would have associated Water Management Zone (WMZ) ponds, where surface runoff would infiltrate to groundwater and/or discharge to surface watercourses and catchment 10 would discharge to groundwater via sub-surface tanks (WSP, 2017). The volume of surface runoff generated at each catchment would be determined by the proportion of impermeable surface, as detailed by WSP (2017). The proposed size of each WMZ is also provided by WSP (2017).

- 4.3.37. To simulate the impermeable area set aside as part of the TCA, zones of zero recharge have been applied in the model corresponding to the catchment 1, 2, 3, 4 and 6 impermeable areas detailed in WSP (2017). Catchment 5 covers the area set aside for the borrow pits. It is assumed that works at the borrow pits will have no significant impact on recharge, therefore the impermeable area and WMZ have not been applied. Catchment 10 covers the proposed campus area. Since surface runoff would discharge directly to sub-surface tanks, no amendments to recharge have been applied within the model.
- 4.3.38. To calculate the daily runoff volume generated across each catchment, effective rainfall (rainfall - potential evapotranspiration) has been multiplied by each catchment's impermeable area. This volume is then divided by the area of the corresponding WMZ pond, to generate the WMZ recharge timeseries for inclusion within the model. The maximum daily infiltration rate from the WMZs is limited to the maximum infiltration rate (50 mm/day, based on (AMEC, 2015a)) of the underlying Crag aquifer. On days when WMZ recharge exceeds 50 mm/day, it is assumed that the excess volume would discharge to surface watercourses in catchments 2, 3 and 6 (as shown in Figure 19A.73); or infiltrate to groundwater on the following day in catchment 4.
- 4.3.39. Surface water discharges are included as point source discharges to Leiston Drain at the point nearest to the respective WMZs within the MIKE11 model, as shown in Figure 19A.74. The discharge point for excess runoff from WMZ1 is located downstream of the model's downstream boundary condition at Minsmere sluice and hence the discharge has not been assigned to the model.
- 4.3.40. The TCA would be operational for the construction period, before being reinstated to pre-construction following completion of Sizewell C (EDF NNB GenCo, 2017). As such, changes associated with the impermeable areas and WMZs have been applied between 1 September 2022 and 31 August 2032.
- 4.3.41. Table E.1 in Appendix E shows the recharge volumes across the impermeable areas of each catchment for the baseline scenarios. It also

shows the recharge volumes across the WMZs and the surface water discharge from the WMZs for the construction scenarios.

x. **Car park (2032-2130)**

- 4.3.42. A car park is proposed to the north of the platform area, which will remain as an effectively impermeable area, following reinstatement of the TCA. The proposed location of the car park is shown in Figure 19A.73, based on design drawing SZC-SZ0100-XX-000-DRW100004 (EDF NNB GenCo, 2018f).

xi. **Operational conditions at the Main Development Site (2032-2130)**

- 4.3.43. Following excavation of existing material at the MDS, it would be backfilled and raised to a level of 7.3 m AOD by the end of the construction phase (EDF NNB GenCo, 2018e). Site-won granular material from the Crag aquifer would be used to raise levels, with excavated materials being placed in borrow pits away from the MDS (EDF NNB GenCo, 2018e). The site would be covered by hardstanding with minimal infiltration capacity by the end of the construction phase and surface runoff would discharge to the sea via a drainage network (WSP, 2017).

- 4.3.44. In the model, Crag material properties and zero recharge have been applied across the MDS. The changes have been included between 1 September 2032 and 31 August 2130.

b) **Sensitivity analysis**

- 4.3.45. EDF Energy has identified the as-built permeability of the cut-off wall and the management of surface run-off and recharge in the temporary construction areas as key factors that may affect the response of the local groundwater system to construction activities. Sensitivity analyses, based on these factors, have been run on the model projections as a result; these and other sensitivity analyses are described in Section 5.2.

5 SCENARIO MODEL RESULTS

5.1 Main simulations

a) **Baseline results**

- 5.1.1. A comparison of simulated groundwater levels in the Peat for all three climatic scenarios under baseline conditions is shown in Figure 19A.75, over the period from 2015-2040. This covers the phases leading up to, during and immediately following construction, which is scheduled to occur from 2022-2032.

- 5.1.2. Annual variations appear similar in each scenario, although summer minima during the dry simulations are typically at least 5 cm less than those produced by the intermediate scenario and at least 10 cm less than those produced in the wet scenario.
- 5.1.3. Components of the transient groundwater balance in the Sizewell Marshes for each climatic scenario are shown in Plate 5.1. Total annual inflows to the groundwater system are shown as positive values, outflows are negative and positive storage values indicate an overall increase in groundwater levels.

Plate 5.1: Modelled transient groundwater balance in Sizewell Marshes for all baseline scenarios (2015-2040)

- 5.1.4. The respective components of the dry, wet and intermediate scenarios are comparable in the first few years of the simulation before the projected impacts of climate change lead to divergence.
- 5.1.5. As expected, the highest recharge typically occurs in the wet scenario, along with the lowest (least negative) evapotranspiration rates. This corresponds to greater volumes of discharge to streams, either directly as baseflow or via groundwater seepages.
- 5.1.6. These increased outflows to streams are likely to moderate water levels in the Peat, driving larger inflows from the underlying Crag, which is also subject to relatively high rates of recharge and is less well-connected to the surface water network.

- 5.1.7. These contrasting flow components lead to projected differences in groundwater storage between the wet and dry scenarios of up to 60 ML across Sizewell Marshes by 2040. Based on an areal extent of approximately 1.75 km² and an assumed specific yield (drainable porosity) of 0.25, this is equivalent to an average difference in groundwater levels of approximately 14 cm across the SSSI.
- 5.1.8. It is notable that groundwater storage in Sizewell Marshes is projected to increase relative to present conditions in all three scenarios, driven by relatively high recharge in the wet model (see Plate 4.3 and Figure 19A.72), with moderate increases in sea level (see Section 4.2h) and by rapid increases in sea level in the dry model, despite limited recharge (see Plate 4.3 and Figure 19A.70).
- 5.1.9. The differences in groundwater storage can be related to differences in groundwater level within the Peat, as shown in Figure 19A.76, which presents the difference in water levels during the dry scenario with respect to the outputs of the wet scenario model. In the majority of the Peat piezometers, a deficit of close to 10 cm is apparent in the dry scenario with respect to wet conditions at the start of the simulation period, trending towards a 20 cm deficit by 2040 as differences in climatic projections become more pronounced.
- 5.1.10. To provide context to projected changes from proposed construction activities, the maximum discrepancy in groundwater levels between the wet and dry scenarios during the construction period (from 2022-2032) has been contoured in Figure 19A.77. The maximum discrepancy was defined by calculating the median discrepancy across all 15 Peat piezometers on each day of the simulation and identifying the day when this median discrepancy is greatest; this maximum discrepancy was found to occur within the model on 17 July 2031. Contours were produced at the same spatial resolution as the FEFLOW simulation, using projected heads in each run at all nodes in the top slice of the model.
- 5.1.11. Water levels are more than 10 cm lower in the dry scenario across the majority of Sizewell Marshes and MWHM SSSIs. On higher ground, where maximum water levels during groundwater high stands are less constrained by ground elevation and evaporation from the water table has not been implemented, discrepancies range from 0.2 m to 1 m across the model domain.
- 5.1.12. Differences between the wet and dry baseline scenarios are shown for the Crag in Figures 19A.78 to 19A.81. These discrepancies are minimal in the vicinity of the platform area and the low-lying ground of Sizewell Marshes and MWHM SSSIs, where topography and evapotranspiration depths moderate the impacts of climatic variations, although short-term differences

of up to 20 cm can be seen, due to individual recharge events. The high permeability of the Crag allows substantial recharge to occur following heavy rainfall.

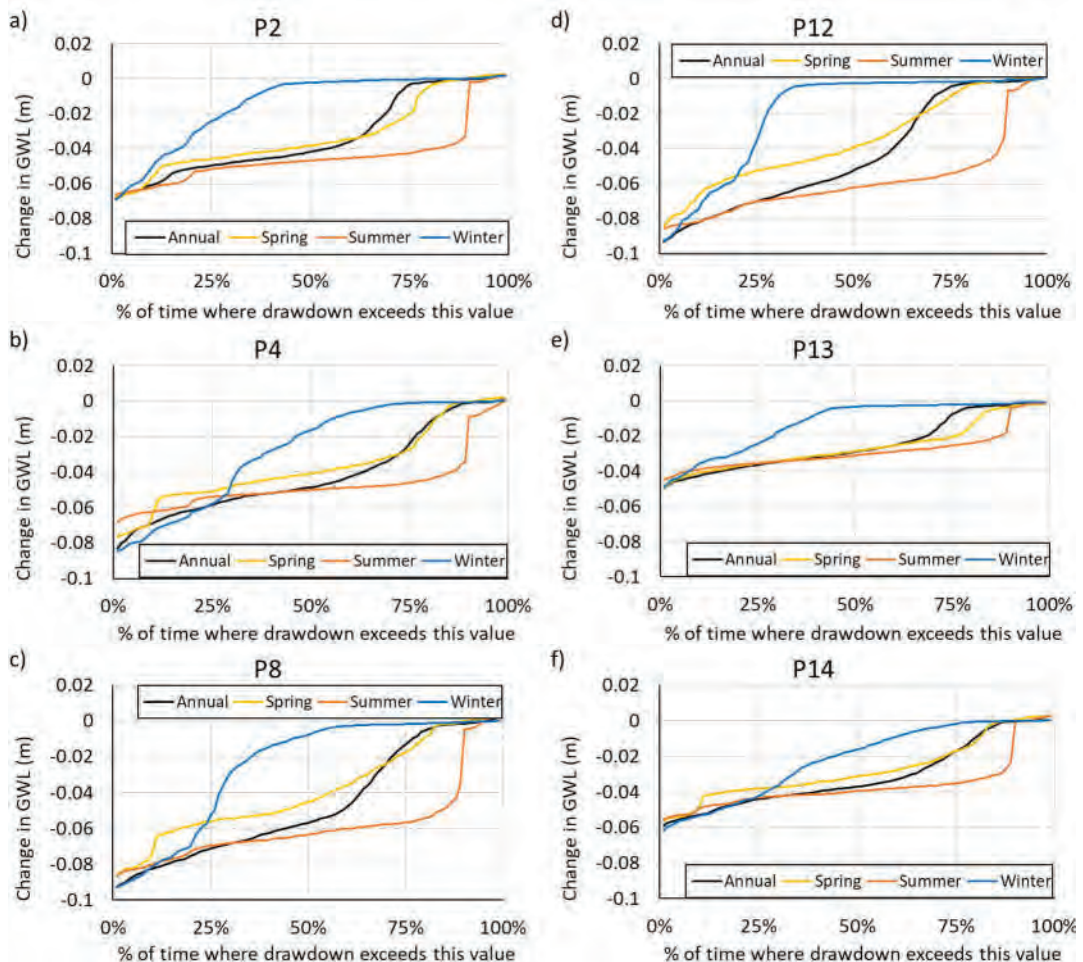

- 5.1.13. On higher ground, in the north and west of the Main Development Site, differences between the wet and dry scenario are more pronounced, progressively increasing to up to 50 cm in some piezometers by 2040.
- 5.1.14. Projected differences in stream stage, flow and flow duration are shown in Figures 19A.82 to 19A.84 respectively. These differences are most clearly seen in the flow duration curves in Figure 19A.84; periods of high flow in particular are substantially reduced in the dry scenario, relative to intermediate and wet conditions.

b) Comparison of development and baseline – dry scenario

- 5.1.15. Projected groundwater levels in the Peat for the dry scenario under baseline and construction conditions are shown in Figure 19A.85, while hydrographs showing the projected differences in groundwater levels are provided in Figure 19A.86. Notwithstanding the projected differences within the proposed footprint of development, the largest changes from construction manifest as an 11 cm reduction in groundwater levels in late 2024. Following the initial phase of dewatering (see Plate 4.3), the maximum projected drawdown in the majority of Peat piezometers is 7-8 cm, typically during summer.
- 5.1.16. Maximum drawdown contours for the water table aquifer during the dry scenario are shown in Figure 19A.87. This maximum projected drawdown, which occurs on 12 December 2024, is less than 10 cm across most of the Sizewell Marshes; areas of greater drawdown occur within 50 m of the platform and in localised parts of the wetland, away from drainage channels.
- 5.1.17. Small areas exceeding 10 cm of drawdown are present in the far south of the MWHM SSSI. Based on the change hydrograph for P13 nearby, these exceedances are projected to occur for only a limited duration towards the end of 2024/early 2025.
- 5.1.18. Mounding of groundwater is apparent around the Borrow Pits at this time, driven by the relatively low permeability of backfill material in this area, compared to that of the Crag material in the baseline model (see Section 4.3a)vi). The local topography, shown in Figure 19A.4, suggests that recharge occurring in this area would naturally flow southwards and the projected drawdown in this area reflects the reduction in this component of flow.

- 5.1.19. As discussed in Sections 3.2e) and 3.2i), reduced water table elevations lead to a reduction in the saturation of the subsurface and hence, lower hydraulic conductivity values. The area of drawdown to the south of the Borrow Pits therefore appears to restrict flow from the higher ground to the south-west, leading to localised groundwater mounding in this area.
- 5.1.20. The exact nature of backfill material in the Borrow Pits is uncertain at this stage, such that its permeability and recharge characteristics may differ substantially from that assumed in the model. As such, projected groundwater levels in this area are subject to greater uncertainty than other areas of the model, where the existing or design properties of the subsurface are better constrained.
- 5.1.21. Groundwater level change duration curves for selected piezometers within the Peat are shown in Plate 5.2. These piezometers were chosen based on their proximity to the platform, where dewatering is proposed, and the grade of fen meadow vegetation where the piezometer is located, as defined by Arcadis (2017). As stated by Arcadis (2017), the system is most vulnerable to changes in water levels during spring, summer and winter.
- 5.1.22. The maximum reduction in water level does not exceed 10 cm in any of these piezometers. Projected reductions in water level are less than 5 cm for the majority of each season in P2, P4, P13 and P14. Projected reductions in water level are less than 7 cm for the majority of the summer in P8 and P12 and less than 5 cm for the majority of spring and winter.
- 5.1.23. The step change to much smaller drawdown for 10% of the construction period (between the 90th and 100th percentiles) reflects the absence of dewatering in the first year of the construction period (see Plate 4.4).
- 5.1.24. Hydrographs and maximum drawdown contours for the shallow part of the Crag are shown in Figures 19A.88 to 19A.90. Due to the planned depth of construction dewatering adjacent to the Crag (although separated by a cut-off wall and sheet-piling) and the high permeability of this stratum, drawdown contours are more extensive, with less mitigating influence from surface water drainage.

Plate 5.2: Groundwater level change duration curves in selected Peat piezometers during the 2022-2032 construction period (construction minus baseline levels: dry scenario)

5.1.25. The differential hydrographs for the Peat and Crag indicate no overall change in groundwater storage after 2035 as a result of the proposed development. This is also evident from the transient groundwater balance for Sizewell Marshes in Plate 5.3.

5.1.26. The lowering of water levels from construction dewatering manifests in Plate 5.3 as a slight reduction in the magnitude of storage increases relative to current conditions, although this disparity between baseline and construction storage is no longer apparent towards the end of the construction period. The maximum storage loss relative to baseline conditions is approximately 20 ML, which is equivalent to an average difference in groundwater levels of approximately 5 cm across the Sizewell Marshes SSSI (based on an areal extent of approximately 1.75 km² and an assumed specific yield (drainable porosity) of 0.25).

- 5.1.27. The model indicates a slight reduction in recharge in the construction scenario, which can be linked to changes in land use in the Aldhurst Farm HCS from 2015 onwards and impermeable ground cover in the platform area from 2022.
- 5.1.28. The impacts of construction dewatering can be seen from 2023 onwards, when there is a reduction in groundwater inflows from the Crag relative to baseline conditions. This loss in flow reaches a maximum of 109 ML per year and is close to 100 ML per year from 2024 onwards.
- 5.1.29. Lower construction water levels around this time, as shown by Figures 19A.85 to 19A.90, leads to reduced evapotranspiration rates and reduced outflows to streams. The reduction in baseflow reaches a maximum of 102 ML per year (approximately 0.003 m³/s), compared to projected average stream flows at gauging station G1 of 0.049 m³/s in the baseline scenario over the construction period (see Figures 19A.92 and 19A.93).
- 5.1.30. A slight but persistent reduction in evapotranspiration following recovery of water levels can be linked to the presence of the platform area and the associated reduction in the overall area of the Sizewell Marshes.

Plate 5.3: Modelled transient groundwater balance in Sizewell Marshes under baseline and construction conditions in the dry scenario (2015-2040)

5.1.31. Projected stream stage, flow and flow duration curves for the baseline and construction simulations are shown in Figures 19A.91 to 19A.93 respectively. Differences between the two simulations appear minimal, with the exception of G6, where under dry baseline conditions, there is projected to be minimal flow throughout the year. In the construction scenario, the presence of surface water discharges and infiltration basins nearby (see Section 4.3a)ix) leads to higher peak flows. From Figure 19A.87, the presence of impermeable ground cover nearby and the associated reduction in recharge appears to contribute to localised drawdown near G6; this is likely to contribute to the negative (upstream) flow simulated during the early stages of construction dewatering.

5.1.32. Short periods of negative flow at late time can be attributed to flow reversals caused by sea level rise, which becomes more pronounced in the 2030s. This effect is most clearly seen in G1 and G6, which lie closest to the coast.

c) Comparison of development and baseline – wet scenario

5.1.33. As shown in Figures 19A.94 and 19A.95, the magnitude and duration of projected drawdown in the Peat are similar to those modelled for the dry scenario, with drawdown of up to 10 cm in several piezometers during the winter of 2024/2025. The extent of the projected maximum drawdown contours, which occur on 26 December 2024 (Figure 19A.96), is also similar to that shown for the dry scenario, with the maximum drawdown occurring close to the platform and beneath impermeable area 2 and localised groundwater mounding and drawdown near the Borrow Pits, as discussed in Section 5.1b). The greater volume of water discharging to the WMZs in this scenario (see Appendix E) leads to notable groundwater mounding in these areas.

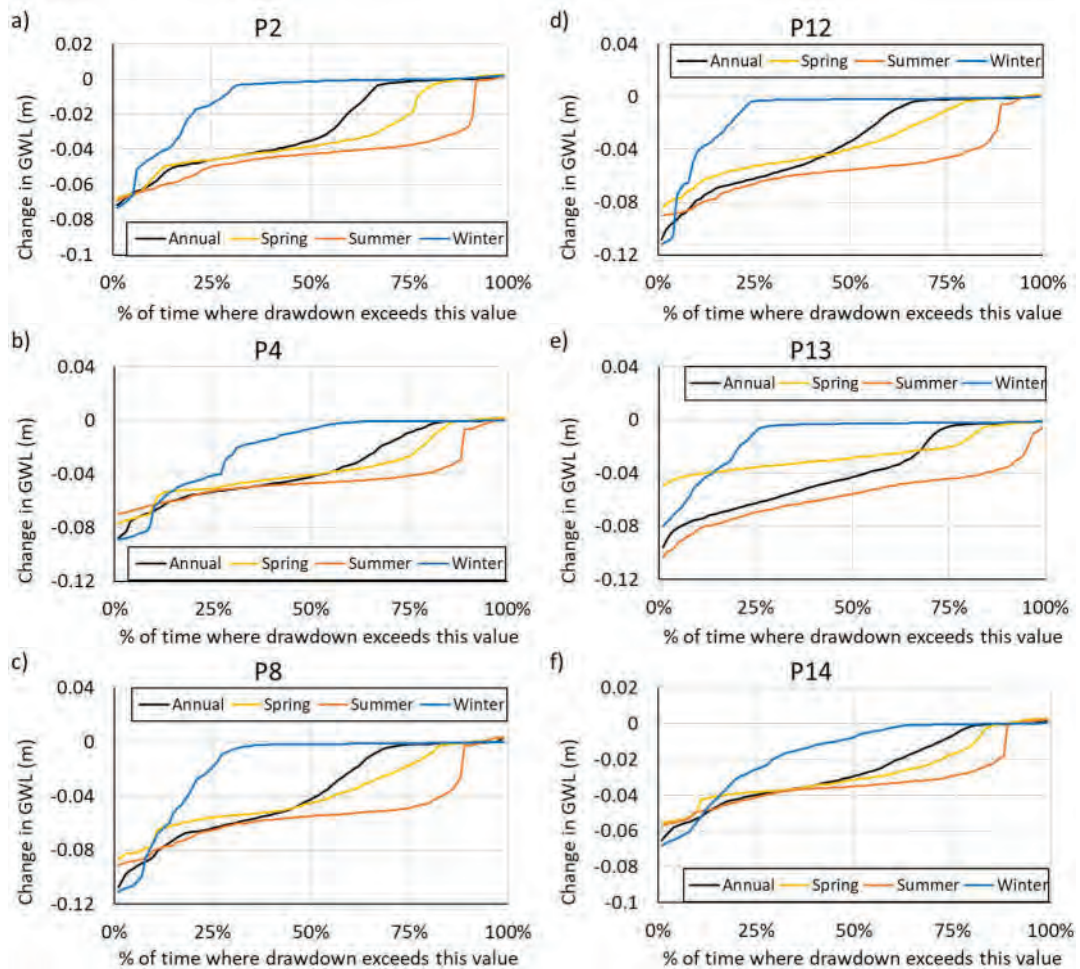

5.1.34. The groundwater level change duration curves in Plate 5.4 provide further detail on the seasonality and magnitude of projected drawdown in selected piezometers within the Peat.

5.1.35. The maximum projected drawdown typically occurs in winter, reaching 11 cm in P8 and P12, and between 7 cm and 9 cm in P2, P4, P13 and P14. These impacts are fairly short-lived, however, with projected winter drawdown exceeding 4 cm for less than 20% of the time in most piezometers.

5.1.36. Projected drawdown in summer reaches a maximum of 10 cm in P13 and exceeds 8 cm in P8, P12 and P13 for roughly 10% of the time. Projected summer drawdown in the other locations does not exceed 7 cm.

- 5.1.37. The step change to much smaller drawdown for 10% of the construction period (between the 90th and 100th percentiles) reflects the absence of dewatering in the first year of the construction period (see Plate 4.4).
- 5.1.38. Projected spring drawdown reaches a maximum value of approximately 8 cm in P4, P8 and P12, with smaller values in the other locations.

Plate 5.4: Groundwater level change duration curves in selected Peat piezometers (wet scenario)

- 5.1.39. The magnitude, duration and extent of drawdown in the shallow parts of the Crag (Figures 19A.97 to 19A.99) are also comparable to those modelled for the dry scenario, suggesting that impacts are not particularly sensitive to climatic conditions.
- 5.1.40. The differential hydrographs for the Peat and Crag indicate no overall change in groundwater storage after 2035 as a result of the proposed development.

5.1.41. Projected differences in the annual water balance for Sizewell Marshes as a result of construction during the wet scenario are shown in Plate 5.5. A slight reduction in recharge can be seen from 2015 onwards, due to land use changes in the Aldhurst Farm HCS; this discrepancy increases slightly in 2022 following the installation of the cut-off wall (see Table 4.1) and the effective removal of the platform area from the Sizewell Marshes water balance.

Plate 5.5: Modelled transient groundwater balance in Sizewell Marshes under baseline and construction conditions in the wet scenario (2015-2040)

5.1.42. Following the onset of construction dewatering in 2023, reduced inflows of groundwater from the underlying Crag are apparent, along with reduced outflows to streams (both from reductions in baseflow sent to the MIKE11 model and a reduced rate of groundwater seepages).

5.1.43. The maximum reduction in flows from the Crag is 120 ML per year, while the reduction in baseflow reaches a maximum of 100 ML per year (approximately 0.003 m³/s), compared to projected average stream flows at gauging station G1 of 0.055 m³/s in the baseline scenario over the construction period (see Figures 19A.101 and 19A.102).

5.1.44. A reduction in losses to evapotranspiration can also be seen during the construction period, which can be partly related to a lowering of the water table. A slight but persistent reduction in evapotranspiration following

recovery of water levels can be linked to the presence of the platform area and the associated reduction in the overall area of the Sizewell Marshes.

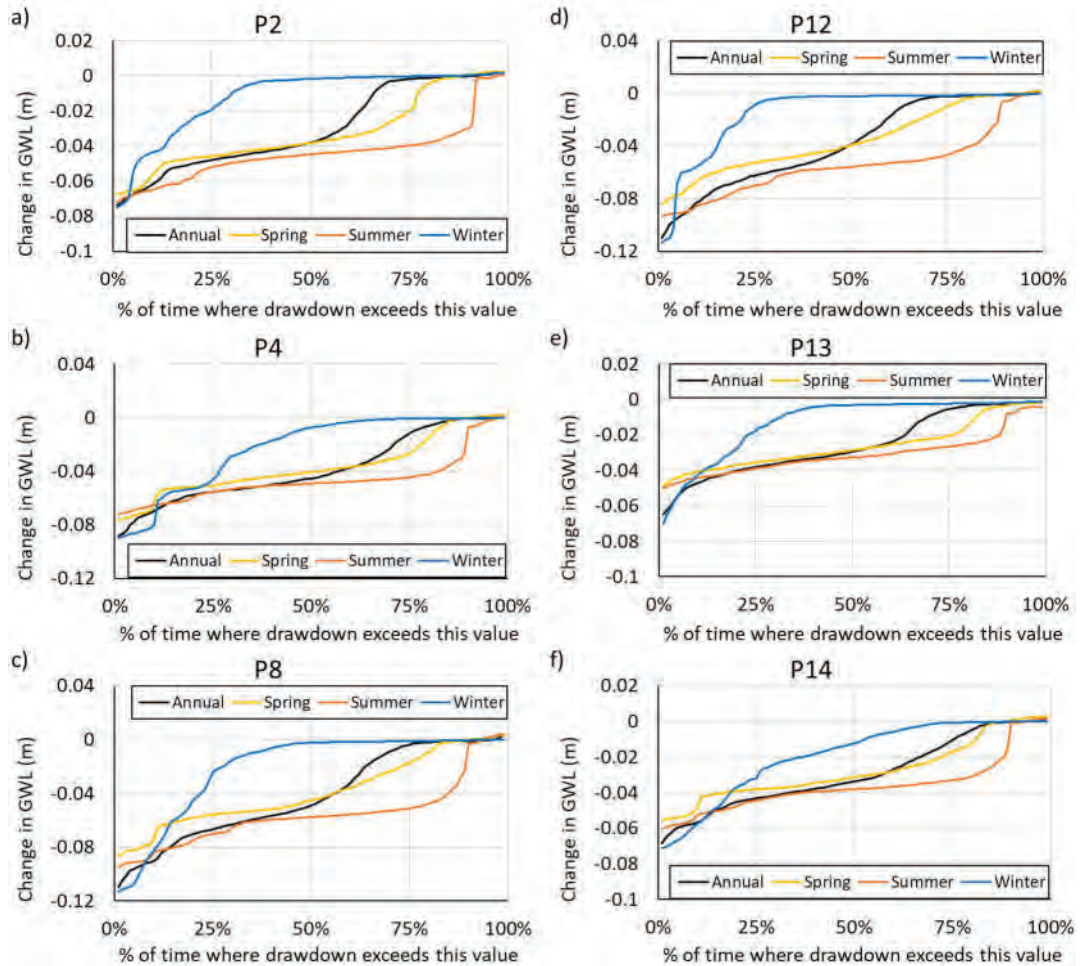

- 5.1.45. The lowering of water levels from construction dewatering, which is evident in Figure 19A.95, manifests in Plate 5.5 as a slight reduction in the magnitude of storage increases relative to current conditions, although this disparity between baseline and construction storage is no longer apparent towards the end of the construction period. The maximum storage loss relative to baseline conditions is approximately 20 ML, which is equivalent to an average difference in groundwater levels of approximately 5 cm across the Sizewell Marshes SSSI (based on an areal extent of approximately 1.75 km² and an assumed specific yield (drainable porosity) of 0.25).
- 5.1.46. Projected stream stage, flow and flow duration curves for the baseline and construction simulations are shown in Figures 19A.100 to 19A.102 respectively. Again, differences between the two simulations appear minimal, with the exception of G6, which lies close to proposed areas of impermeable ground, as well as infiltration basins and controlled discharges to surface water (see Section 4.3a)ix).
- 5.1.47. Short periods of negative flow in the construction model (Figure 19A.101) reflect a reversal in flow direction. In G4, this represents southward, rather than northward, flow in response to surface water discharges from the TCAs. Minor flow reversals are also apparent at G1 in both the baseline and construction models. These are most prevalent in the 2030s, due to the effects of sea level rise driving flow inland.

d) Comparison of development and baseline – intermediate scenario

- 5.1.48. As shown in Figure 19A.103, Figure 19A.104 and Plate 5.6, the magnitude and duration of projected drawdown in the Peat are similar to those modelled for the dry and wet scenarios, with drawdown of up to 11 cm in several piezometers during the winter of 2024/2025, followed by spring and summer drawdown of up to 7-8 cm in these piezometers during the remainder of construction dewatering.
- 5.1.49. Seasonal drawdown is projected to be less than 8 cm for at least 80% of the construction period in all piezometers, although winter drawdown is projected to be substantially less, with drawdown of less than 5 cm for 80% of the time.
- 5.1.50. Projected summer drawdown typically exceeds 3 cm (for at least 75% of the time in all piezometers except P13). The step change to much smaller drawdown for 10% of the construction period (between the 90th and 100th

percentiles) reflects the absence of dewatering in the first year of the construction period (see Plate 4.4).

Plate 5.6: Groundwater level change duration curves in selected Peat piezometers (intermediate scenario)

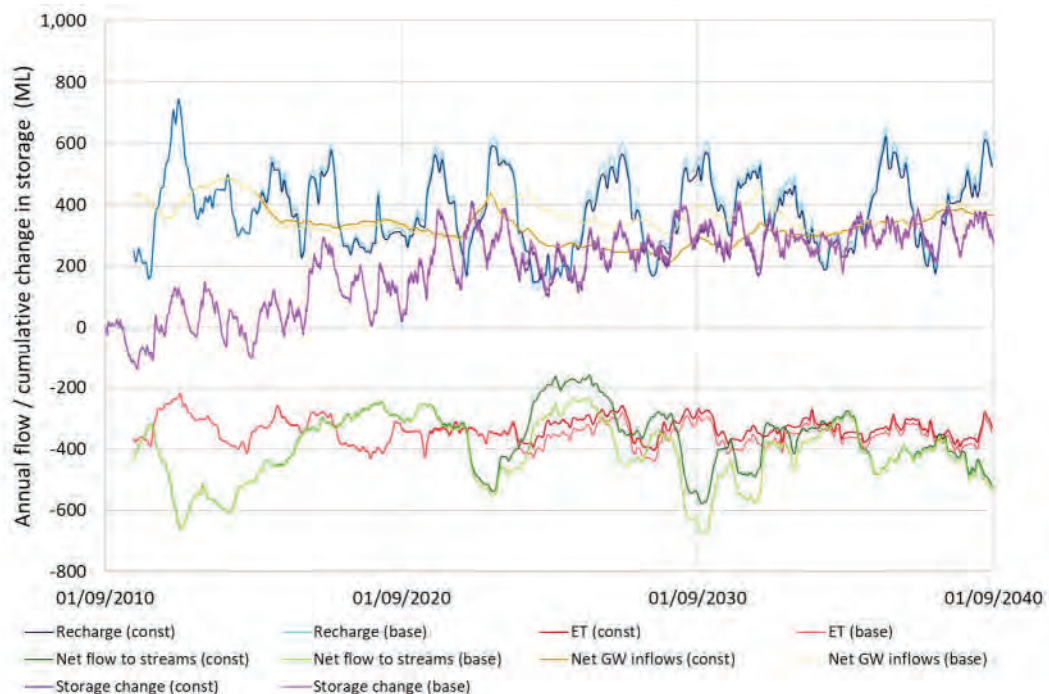

5.1.51. The extent of the projected maximum water table drawdown contours, which occur on 26 December 2024 (Figure 19A.105), is similar to that shown for the dry and wet scenarios, with the maximum drawdown occurring close to the platform and beneath impermeable area 2 and localised groundwater mounding and drawdown near the Borrow Pits, as discussed in Section 5.1b). In common with the wet scenario, groundwater mounding is also apparent in the vicinity of the WMZs.

5.1.52. The magnitude, duration and extent of drawdown in the shallow parts of the Crag (Figures 19A.106 to 19A.108) are also comparable to those modelled for the other scenarios; this supports the view that impacts are not particularly sensitive to climatic conditions.

- 5.1.53. The differential hydrographs for the Peat and Crag indicate no overall change in groundwater storage after 2035 as a result of the proposed development.
- 5.1.54. Projected differences in the annual water balance for Sizewell Marshes as a result of construction during the intermediate scenario are shown in Plate 5.7. A slight reduction in recharge can be seen from 2015 onwards, due to land use changes in the Aldhurst Farm HCS, although this is offset by increased inflows of groundwater, leading to relatively minor reductions in overall storage.

Plate 5.7: Modelled transient groundwater balance in Sizewell Marshes under baseline and construction conditions in the intermediate scenario (2015-2040)

- 5.1.55. There is a slightly greater reduction in recharge relative to baseline conditions following the installation of the cut-off wall in 2022 (see Table 4.1) and the effective removal of the platform area from the Sizewell Marshes water balance.
- 5.1.56. Following the onset of construction dewatering in 2023, reduced inflows of groundwater from the underlying Crag are apparent, along with reduced outflows to streams (both from reductions in baseflow sent to the MIKE11 model and a reduced rate of groundwater seepages).

- 5.1.57. The loss of flow from the Crag reaches a maximum of 123 ML per year and is close to 100 ML per year for most of the construction period from 2024 onwards. The reduction in baseflow reaches a maximum of 107 ML per year during the construction period (approximately 0.003 m³/s), compared to projected average stream flows at gauging station G1 of 0.054 m³/s in the baseline scenario over this period (see Figures 19A.110 and 19A.111). The average projected reduction in baseflow from Sizewell Marshes over the construction period is 71 ML per year, although surface water discharges from the TCAs lead to a projected average flow at G1 in the construction model of 0.055 m³/s, which slightly exceeds the projected baseline value.
- 5.1.58. A reduction in losses to evapotranspiration can also be seen during the construction period, which can be partly related to a lowering of the water table.
- 5.1.59. Differences in groundwater storage between the baseline and construction simulations are consistent with the patterns of drawdown shown in Figure 19A.104, with storage losses of up to 20 ML during the construction period and no discernible differences relative to baseline by the late 2030s. Based on an areal extent of approximately 1.75 km² and an assumed specific yield (drainable porosity) of 0.25, storage losses of 20 ML are equivalent to an average difference in groundwater levels of approximately 5 cm across the Sizewell Marshes SSSI.
- 5.1.60. Small but persistent reductions in net sources (recharge and groundwater inflows) and sinks (evapotranspiration and flows to streams) of water can be linked to the slight reduction in the overall extent of the Sizewell Marshes, due to the presence of the platform area. The similarity in storage changes in each scenario confirms that the reduced outflows are offset by a reduction in inflows, such that the model does not indicate any discernible long-term difference in water levels in the Marshes. This is consistent with the hydrographs shown in Figures 19A.104 and 19A.107.
- 5.1.61. Projected stream stage, flow and flow duration curves for the baseline and construction simulations are shown in Figures 19A.109 to 19A.111 respectively. Again, differences between the two simulations appear minimal, with the exception of G6 and to a lesser extent, G7. These gauging stations lie close to proposed areas of impermeable ground in the TCA, as well as infiltration basins and controlled discharges to surface water (see Section 4.3a)ix).
- 5.1.62. Short periods of negative flow at late time can be attributed to flow reversals due to sea level rise, which becomes more pronounced in the 2030s. This effect is most clearly seen in G1 and G6, which lie closest to the coast.

5.1.63. In G4, the negative values represent southward, rather than northward, flow in response to surface water discharges from the TCAs.

5.2 Sensitivity analysis

a) Higher permeability cut-off wall

i. Overview

5.2.1. A further simulation has been completed to assess the potential impacts of doubling the assumed hydraulic conductivity of the cut-off wall. Ecological impacts are likely to be greatest when natural groundwater levels are low, and as such, this sensitivity analysis incorporates recharge and evapotranspiration rates applied to the dry scenario.

5.2.2. This scenario considers changes to the overall permeability of the cut-off wall, rather than localised defects. The presence of localised defects within the cut-off wall would potentially lead to increased drawdown within a more localised area and suitable monitoring would be required to identify these impacts at an early stage. Further, there is scope to address localised defects through mitigation measures, such as targeted grout injection, which would not be viable if the whole cut-off wall had a higher permeability.

ii. Results

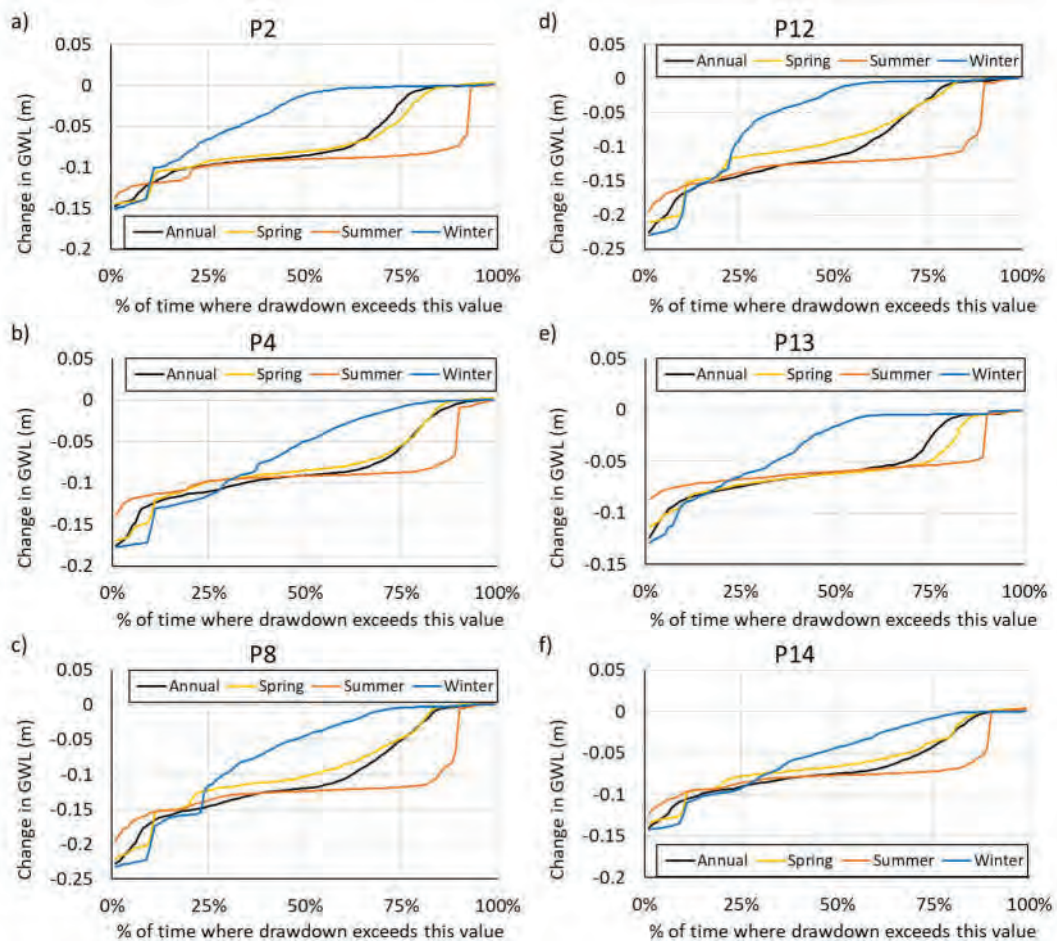

5.2.3. Hydrographs showing projected differences in groundwater levels across the Peat are shown in Figure 19A.112, comprising changes in groundwater level relative to baseline conditions for both the standard and higher permeability cut-off walls.

5.2.4. A doubling of hydraulic conductivity in the cut-off wall leads to a projected doubling of drawdown during construction. Notwithstanding hydrographs within the footprint of proposed excavation works, nearby piezometers are projected to show a maximum reduction in groundwater levels of more than 20 cm in late 2024. Following the initial phase of dewatering (see Plate 4.4), the maximum projected drawdown in the majority of Peat piezometers is approximately 10-15 cm.

5.2.5. Figure 19A.113 shows the maximum extent of drawdown in the water table aquifer during this scenario (occurring on 9 January 2025), alongside contours produced for the standard cut-off wall for the same date. Beyond the cut-off wall, the area experiencing a maximum drawdown of more than 20 cm is approximately doubled in this scenario, while approximately half of the Sizewell Marshes is projected to experience more than 10 cm drawdown at this time.

- 5.2.6. As shown in Plate 5.8, the largest effects are typically projected to occur in summertime, with the smallest effects in winter throughout most of the construction period.
- 5.2.7. The step change to much smaller summer drawdown for 10% of the construction period (between the 90th and 100th percentiles) reflects the absence of dewatering in the first year of the construction period (see Plate 4.4).
- 5.2.8. Similar changes can be seen in the shallow parts of the Crag, which is projected to experience an approximate doubling of the magnitude and extent of drawdown (Figures 19A.114 and 19A.115).

Plate 5.8: Groundwater level change duration curves in selected Peat piezometers (higher permeability cut-off wall)

- 5.2.9. The projected impact of a higher permeability cut-off wall is also apparent in the water balance of the Sizewell Marshes (Plate 5.9). The additional drawdown shown in Figures 19A.112 to 19A.115 manifests as an additional reduction in upward flow from the underlying Crag of approximately 50%

during most of the construction period and an additional reduction in outflows to streams of approximately 60-80 ML per year (approximately 0.002 m³/s on average), compared to projected average stream flows at gauging station G1 of 0.046 m³/s during construction with the standard cut-off wall and 0.047 m³/s in the baseline scenario over this period (see Figures 19A.117 and 19A.118).

Plate 5.9: Modelled transient groundwater balance in Sizewell Marshes under dry baseline and construction conditions, assuming standard and higher permeability cut-off walls (2020-2040)

- 5.2.10. Despite the projected changes in groundwater level in this scenario, the impacts are not apparent in the stream stage, flow and flow duration hydrographs in Figures 19A.116 to 19A.118.
- 5.2.11. However, the results in Figures 19A.112 to 19A.115 indicate a near-linear relationship between cut-off wall permeability and resulting drawdown in the adjacent groundwater system. This highlights the importance of ensuring that an effective, low-permeability barrier is installed and maintained throughout the construction period.

b) Natural recharge in TCAs

i. Overview

- 5.2.12. The model projections in Section 5.1 assume substantial areas of hardstanding will be present in the TCAs, alongside infiltration basins and

discharges to surface water to manage the associated run-off following heavy rainfall (see Section 4.3a)ix).

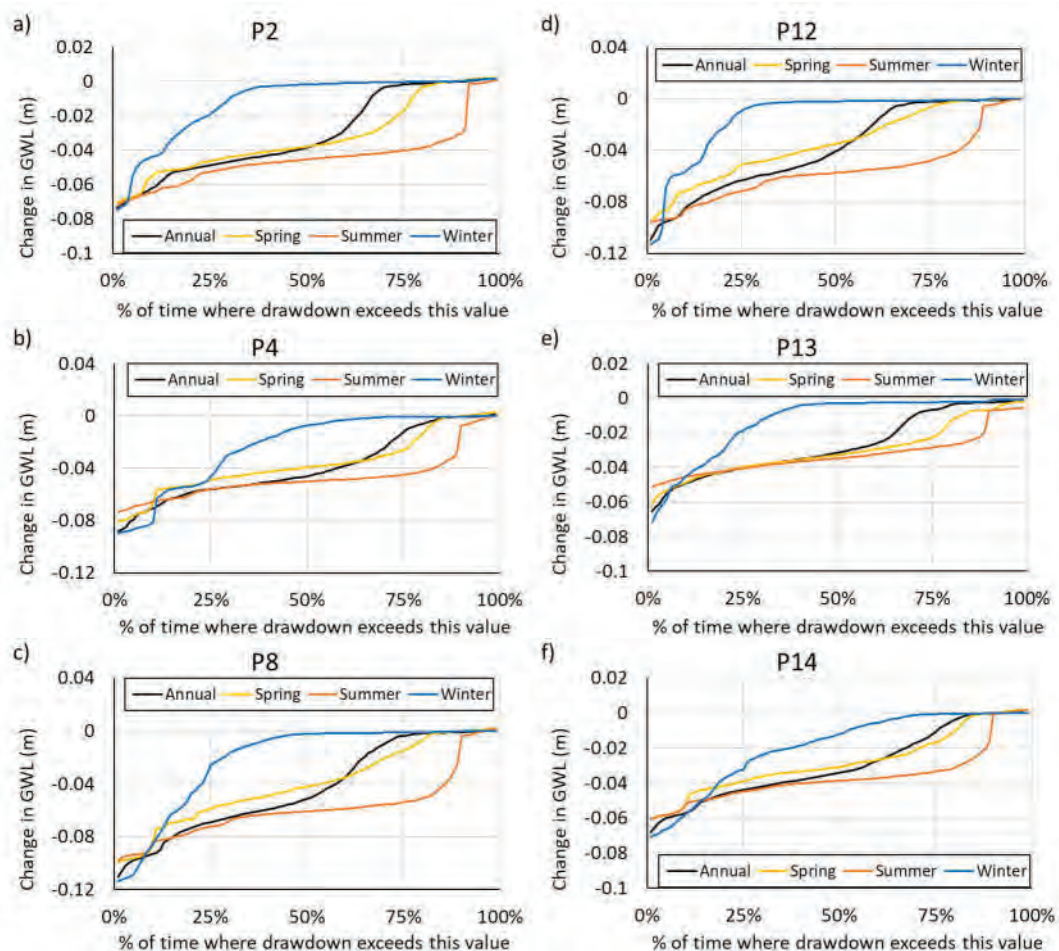

- 5.2.13. The final design of the site may incorporate more permeable surfaces in these areas, to minimise any changes to natural recharge and run-off.
- 5.2.14. A sensitivity analysis has been completed to assess groundwater and surface water behaviour during the construction period, assuming that natural recharge persists throughout the TCAs, with no associated infiltration basins or surface water discharges. The car park, which is proposed to exist throughout plant operation, has been maintained as an impermeable feature, with no recharge.
- 5.2.15. Recharge and evapotranspiration rates from the intermediate scenario were applied during this sensitivity analysis.

ii. Results

- 5.2.16. Hydrographs showing projected differences in groundwater levels across the Peat in this scenario are shown in Figure 19A.119, comprising changes in groundwater level relative to intermediate baseline conditions for both modified and natural intermediate recharge in the TCAs during the construction period, from 2022-2032.
- 5.2.17. Changes to the management of recharge and run-off in these areas produce no discernible change in the modelled Peat hydrographs, which continue to show a maximum drawdown of up to 11 cm in several piezometers during the winter of 2024/2025, followed by spring and summer drawdown of 7-8 cm in these piezometers during the remainder of construction dewatering (see Plate 5.10).
- 5.2.18. Figure 19A.120 shows the maximum extent of drawdown in the water table during this scenario (occurring on 26 December 2024), alongside contours produced for the same date when impermeable areas, infiltration basins and surface water discharges are present. Groundwater mounding around the water management zones is no longer present and there is less drawdown near impermeable area 2, which has been removed.
- 5.2.19. There is little discernible change in water levels within Sizewell Marshes, although the extent of the 0.1 m drawdown contour near Nursery Covert is slightly larger in the absence of infiltration basins and surface water discharges, and small areas of drawdown are apparent to the south and east of WMZ2, close to the surface discharge point from this catchment (shown in Figures 19A.73 and 19A.74). Mounding near WMZ6, which is apparent in Figure 19A.105 for the main simulation at the western edge of Sizewell Marshes, has also disappeared.

- 5.2.20. Projected changes in groundwater level still occur in the vicinity of the borrow pits, due to changes in recharge and hydraulic properties of the shallow subsurface, as discussed in Section 5.1b).
- 5.2.21. The magnitude and duration of changes in groundwater level for selected piezometers within the Peat are shown in Plate 5.10.
- 5.2.22. The results are comparable to those shown in Plate 5.6 for the main intermediate scenario, with maximum drawdown of close to 11 cm projected in P8 and P12, and maximum drawdown of 7-9 cm in the other piezometers. The largest effects are typically projected to occur in summertime, with the smallest effects in winter throughout most of the construction period.

Plate 5.10: Groundwater level change duration curves in selected Peat piezometers (natural recharge in TCAs)

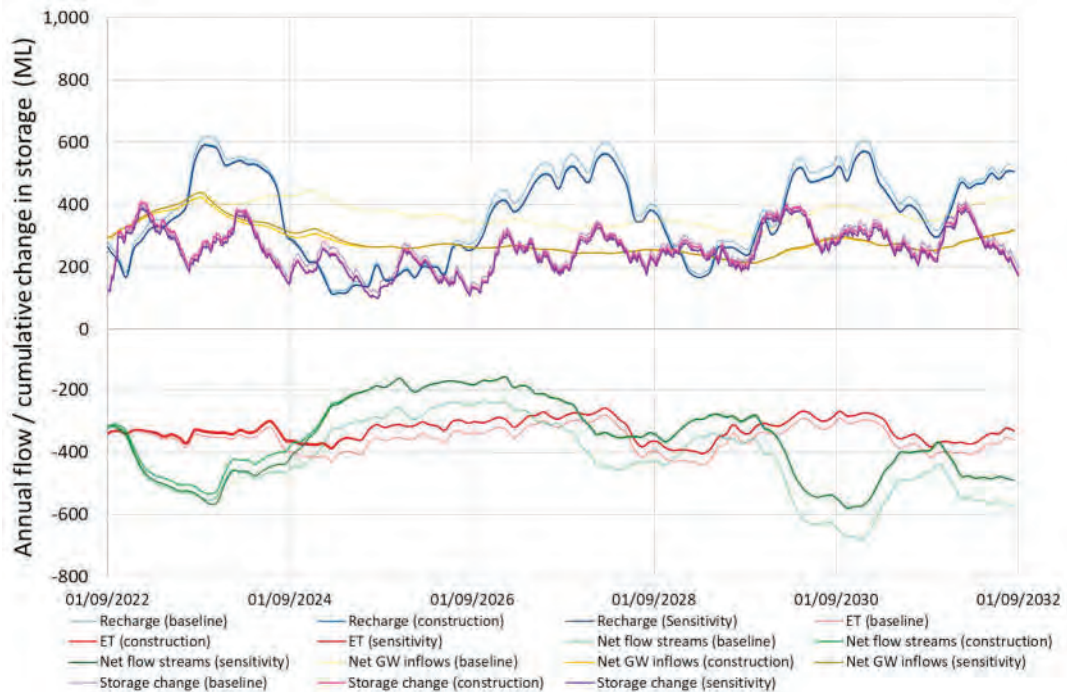

- 5.2.23. Seasonal drawdown is projected to be less than 8 cm for at least 80% of the construction period in all piezometers, although winter drawdown is

projected to be substantially less, with drawdown of less than 5 cm for 80% of the time.

- 5.2.24. Projected summer drawdown typically exceeds 3 cm (for at least 75% of the time in all piezometers). The step change to much smaller drawdown for 10% of the construction period (between the 90th and 100th percentiles) reflects the absence of dewatering in the first year of the construction period (see Plate 4.4).
- 5.2.25. Hydrographs showing projected differences in groundwater levels across the shallow Crag in this scenario are shown in Figure 19A.121. The hydrographs show similar trends to those observed in the main construction scenario; however, the response to rainfall events appears markedly less flashy in the northern part of the Main Development Site. This is consistent with natural behaviour in the unsaturated zone, where evapotranspiration in the shallow subsurface and the presence of soil moisture deficits (see Section 3.2d)ii) attenuates recharge, while the absence of impermeable areas and WMZs leads to recharge being more evenly distributed across the TCA.
- 5.2.26. The contours presented in Figure 19A.122 show similar drawdown in the shallow part of the Crag across both scenarios. The sensitivity analysis produces slightly greater projected drawdown in the far northern part of Sizewell Marshes (near WMZ2 in the main construction model), where there are no longer controlled discharges to the local surface water system. There is a noticeable reduction in projected drawdown in the northern part of the Main Development Site, which can be attributed to the presence of recharge beneath areas that were impermeable in the main construction model.
- 5.2.27. The water balance for the Sizewell Marshes in this scenario (shown in Plate 5.11) is comparable to that for the main intermediate construction simulation. The only discrepancies between the two simulations comprise a slight increase in flow to streams at the beginning of the construction period, along with a slight reduction in storage at this time.

Plate 5.11: Modelled transient groundwater balance in Sizewell Marshes under intermediate baseline and construction conditions, assuming natural and modified recharge in the TCAs (2022-2032)

- 5.2.28. The increased flow from Sizewell Marshes to the drainage channels, relative to the main construction model, reaches a maximum of 34 ML per year in late 2023 and is no longer discernible by the end of 2024. This maximum increase in flow, equivalent to $0.001 \text{ m}^3/\text{s}$, compares to projected average stream flows at gauging station G1 of $0.054 \text{ m}^3/\text{s}$ in the baseline model during the construction period and $0.055 \text{ m}^3/\text{s}$ in the main construction model.
- 5.2.29. This increased flow at early time can be attributed to slower relay of water from the TCAs, which in this scenario do not incorporate infiltration basins or surface water discharges. This in turn leads to slightly lower stream stage, driving additional baseflow from the surrounding wetlands. As this effect represents a delay in flow from the TCAs, as opposed to a net loss of water, the discrepancy between the two simulations is short-lived.
- 5.2.30. The short-term reduction in stage near the surface discharge points can be seen as a slight reduction in peak stage at G6 and G7 in late 2023/early 2024 (see Figure 19A.123).
- 5.2.31. The associated storage losses between 2022 and 2024, relative to the main construction model, reach a maximum of 20 ML, with no discernible differences relative to baseline by the end of 2024. Based on an areal

extent of approximately 1.75 km² and an assumed specific yield (drainable porosity) of 0.25, storage losses of 20 ML are equivalent to an average difference in groundwater levels of approximately 5 cm across the Sizewell Marshes SSSI.

5.2.32. Comparison of drawdown contours in Figures 19A.105 and 19A.120 suggests that these storage losses manifest close to the proposed locations of WMZ2 and WMZ6, which are inactive in the sensitivity analysis.

5.2.33. As shown in Figures 19A.124 and 19A.125, there is little discernible difference in projected stream flows at each gauging station, with the exception of G4, which no longer displays negative flows in early 2023. As discussed in Section 5.1d), the negative flows at G4 in the main construction model simply reflect a reversal in flow direction, southwards rather than northwards, which can be attributed to the addition of water from surface water discharges. The absence of these negative flows in the sensitivity analysis confirms this as the likely cause.

c) **Extreme drought in early construction phase (2022-2025)**

i. **Overview**

5.2.34. The recharge projections described in Section 4.2 allow potential impacts from construction to be assessed under a wide range of climatic conditions.

5.2.35. However, these projections do not necessarily account for extreme droughts in the near future, which may reflect climatic variability, as opposed to the longer-term trends associated with climate change.

5.2.36. To assess the vulnerability of the Sizewell Marshes and MWHM SSSIs to dewatering during extreme drought conditions, the model was run with three dry years in a row at the start of the construction period.

5.2.37. Based on model years, which run from the 1st September, rainfall and evapotranspiration from the three driest years during the period from 1st September 1981 to 31st August 2010 were used to produce recharge estimates in the SMBM (see Section 3.2d).

5.2.38. The fourth driest year during this period (from 1st September 1988 to 31st August 1989) was run twice in succession through the SMBM to generate an appropriate soil moisture deficit, with which to calculate recharge from 2022 onwards.

5.2.39. Average rainfall and net recharge (including the effects of evapotranspiration from saturated ground in wetland areas) applied to the model domain over the period of the sensitivity analysis are shown in Table 5.1.

Table 5.1: Assumed recharge and projected recharge during extreme drought simulation

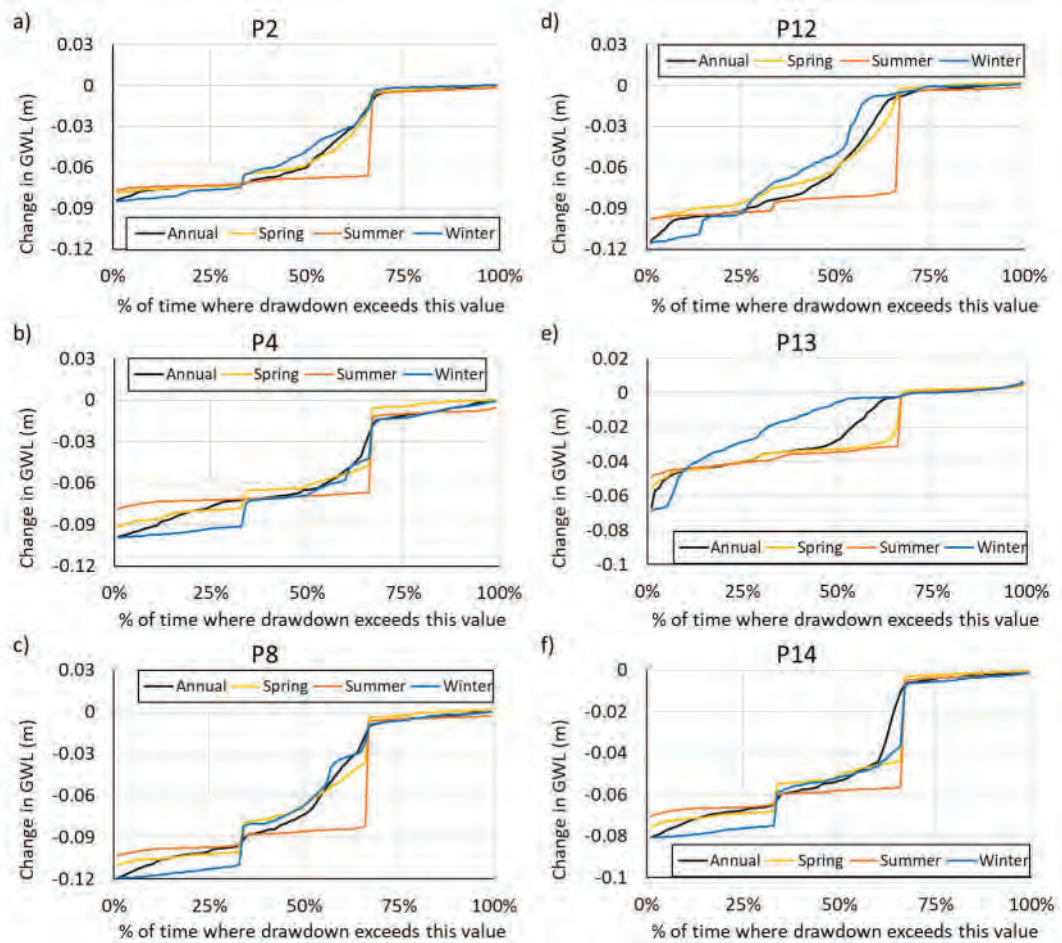

Model year (historical year)	Rainfall (mm)	Rainfall relative to average during model calibration period	Net recharge (mm/yr)	Change relative to model calibration period (mm/yr)
2021-2022 (1988-1989)	491.2	76.2%	N/A	N/A
2022-2023 (1996-1997)	455.6	70.6%	-6.5	-75.1
2023-2024 (1989-1990)	447.1	69.3%	-6.2	-74.8
2024-2025 (1995-1996)	418.3	64.9%	-8.8	-77.4

ii. Results

5.2.40. Projected drawdown in the Peat for individual monitoring boreholes (shown in Figure 19A.126) is similar to that shown in Figure 19A.86 for the start of construction during the dry scenario.

5.2.41. However, comparison of Plates 5.2 and 5.12 suggests that maximum drawdown in the Peat exceeds that projected for the dry scenario by approximately 2 cm in each piezometer. During extreme drought, projected maximum drawdown is close to 12 cm in P8 and P12, and 7-10 cm in the other piezometers. It should be noted that the focus of this simulation on the early part of construction, when dewatering is expected to be most intense, exaggerates the maximum drawdown impacts in terms of percentage duration.

Plate 5.12: Groundwater level change duration curves in selected Peat piezometers (extreme drought)

5.2.42. Step changes are apparent in the seasonal curves, which reflect the different phases of dewatering during the early construction period. As shown in Plate 4.4, there is assumed to be no dewatering during the first year of the construction period, leading to minimal drawdown for about a third of this simulation. The period of maximum dewatering in the platform area has a duration of approximately 18 months; this translates to relatively large drawdown for approximately a third (one year) of the simulation period, with less drawdown at the start of this period in the Marshes as water levels equilibrate and following the end of this period as water levels in the platform area recover from -18.9 to -11 m AOD.

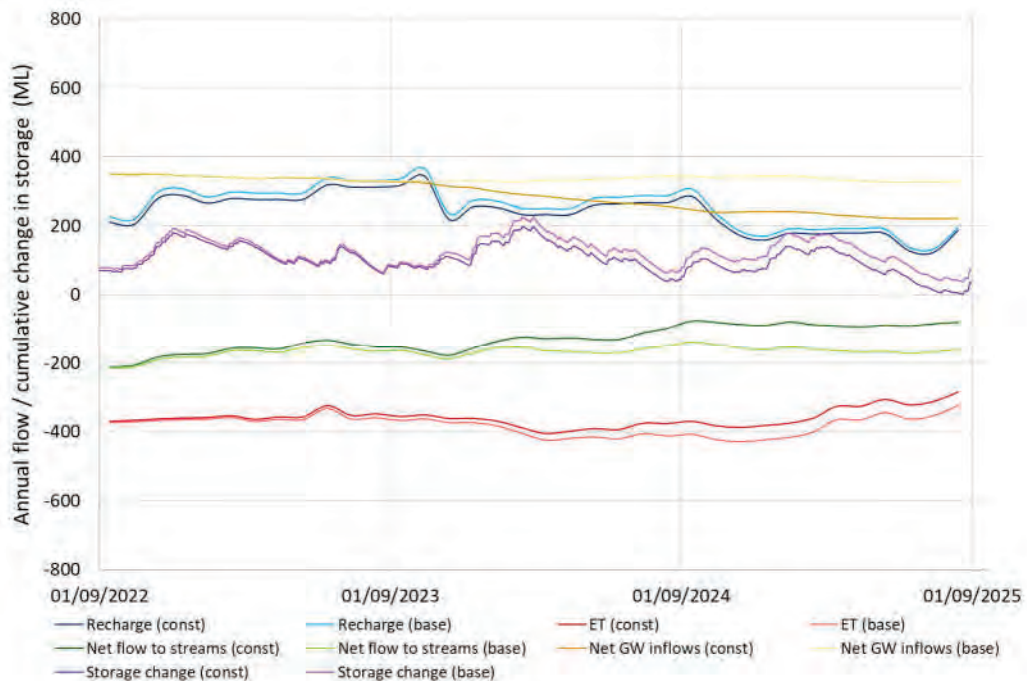

5.2.43. Outside the period of maximum dewatering, seasonal drawdown is projected to be less than 9 cm in all piezometers.

5.2.44. The transient water balance for Sizewell Marshes during extreme drought under baseline and construction conditions is shown in Plate 5.13. As no assumptions have been made in this scenario regarding climatic conditions

beyond the first three years of the construction period, the water balance is shown until September 2025 only.

- 5.2.45. There is a clear reduction in all components of the water balance attributable to development in this scenario, including a 37 ML reduction in storage, almost double that projected in the dry scenario (see Section 5.1b). Based on an areal extent of approximately 1.75 km² and an assumed specific yield (drainable porosity) of 0.25, storage losses of 20 ML are equivalent to an average difference in groundwater levels of approximately 8 cm across the Sizewell Marshes SSSI.

Plate 5.13: Modelled transient groundwater balance in Sizewell Marshes under baseline and construction conditions during extreme drought (2022-2025)

- 5.2.46. Close inspection of the maximum drawdown contours for this and the dry scenario show only minor differences in drawdown extent in the shallow part of the Peat, where the water table lies (Figures 19A.87 and 19A.127), although notable changes can be seen in the Aldhurst Farm HCS and immediately to the south of impermeable area 2. The projections indicate that the western edge of the Sizewell Marshes may be more vulnerable to extreme drought following land use changes in the Aldhurst Farm area.
- 5.2.47. The increased drawdown beneath the western part of the Marshes in this scenario is emphasised by the change hydrographs for the shallow Crag in Figure 19A.128. Although the magnitude of drawdown by the end of August

2025 is similar to the dry scenario (see Figure 19A.89) for most monitoring boreholes, there is a notable increase in drawdown in GW3, which is the most westerly monitoring point.

5.2.48. These differences in drawdown extent within the shallow Crag can also be seen in Figure 19A.129, which shows the 0.1 m drawdown contour extending around 40 m further west from the platform than in the dry scenario (Figure 19A.90). This suggests that much of the projected storage losses shown in Plate 5.13 occur in the deeper part of Sizewell Marshes.

5.2.49. The pattern of drier conditions in the western part of Sizewell Marshes is also apparent in Figures 19A.130 to 19A.132, which show reduced stage and flow in G4 and G5, but minimal changes at downstream gauging locations G1, G3 and G6.

d) Reduced stream bed conductance

i. Overview

5.2.50. Based on the results of the historical sensitivity analysis in Section 3.5, stream bed conductance may be substantially lower than what has been represented in the main simulations.

5.2.51. As enhanced leakage from streams has the potential to mitigate drawdown induced by dewatering, a reduced connection to the streams during construction may lead to substantially greater impacts on water levels in Sizewell Marshes and the MWHM SSSI.

5.2.52. To assess the potential for any greater impacts to occur, the intermediate scenario was rerun, with stream bed conductance values reduced by an order of magnitude, from 0.1 d^{-1} to 0.01 d^{-1} .

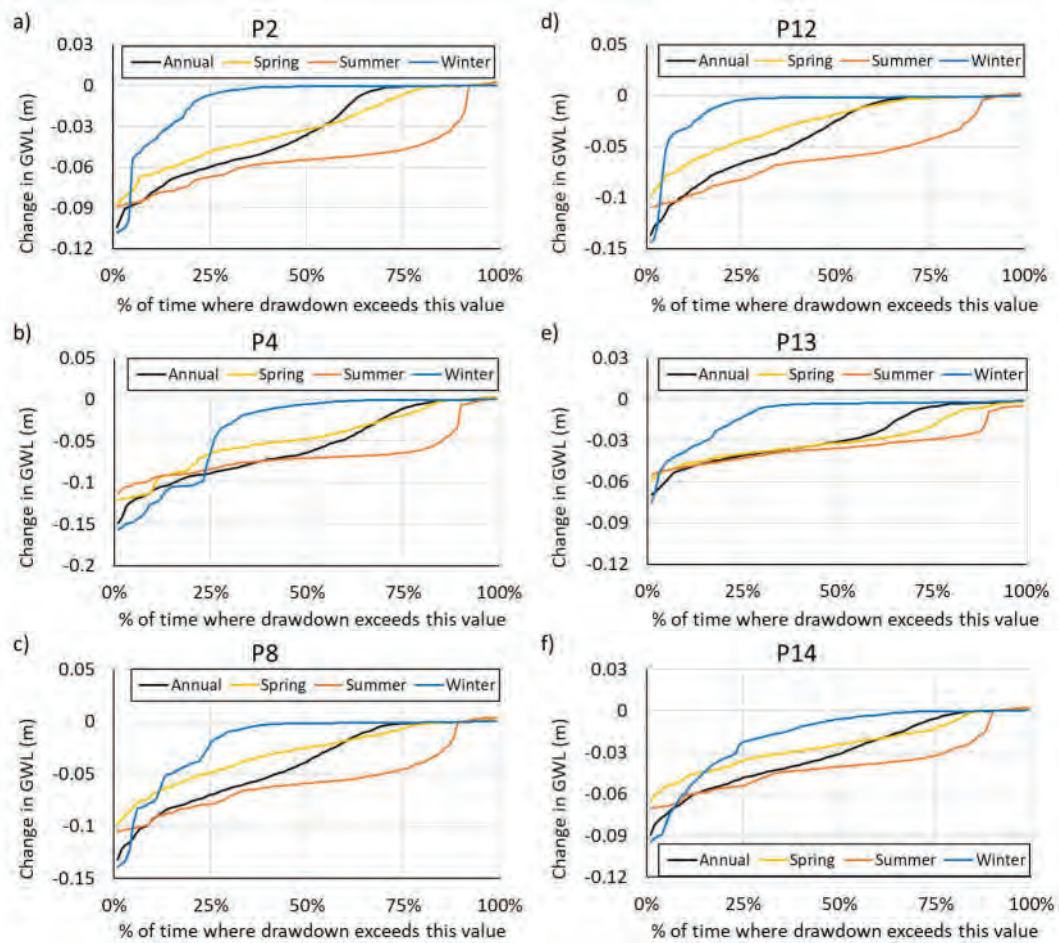

ii. Results

5.2.53. As shown in Figure 19A.133, projected drawdown in the Peat is similar in several piezometers to the main intermediate scenario. However, increased drawdown of 2-3 cm is apparent in boreholes P2, P4, P8, P9 and P12, which are the closest monitoring points to the Main Development Site.

5.2.54. This pattern can also be seen in the groundwater level change duration curves in Plate 5.14, which shows projected drawdown exceeding 10 cm for 10-15% of the time in P4, P8 and P12.

5.2.55. Consistent with the intermediate scenario, projected drawdown is typically greatest in summer and smallest in winter.

Plate 5.14: Groundwater level change duration curves in selected Peat piezometers (low stream bed conductance)

- 5.2.56. The water balance for the Sizewell Marshes in this scenario (shown in Plate 5.15) is comparable to that for the main intermediate construction simulation (Plate 5.7), with the same pattern of recharge.
- 5.2.57. As expected for this sensitivity analysis, the magnitude of outflows to streams in both baseline and construction simulations is lower and time-varying changes in baseflow are less pronounced. The projected maximum impacts of construction on baseflow are similar in both scenarios, with a maximum reduction of 107 ML per year during the construction period in this sensitivity analysis (approximately 0.003 m³/s), compared to 106 ML in the main simulation. However, the average reduction in baseflow with the lower stream bed conductance is 64 ML per year, as opposed to 71 ML per year in the main simulation.
- 5.2.58. The reduced losses to surface water are related to slightly higher water levels in both baseline and construction simulations, as shown by the larger

cumulative changes in storage throughout the construction period. These higher water levels drive slightly increased losses to evapotranspiration in both baseline and construction simulations.

- 5.2.59. Differences in groundwater storage between the baseline and construction simulations are greater than those that occur in the main projections for the intermediate scenario, with storage losses of up to 38 ML during the construction period (compared to maximum losses of 20 ML in the main projections). Based on an areal extent of approximately 1.75 km² and an assumed specific yield (drainable porosity) of 0.25, storage losses of 37 ML are equivalent to an average difference in groundwater levels of approximately 8 cm across the Sizewell Marshes SSSI.
- 5.2.60. The loss of flow from the Crag is similar to that in the main intermediate scenario, reaching a maximum of 122 ML per year during the construction period and remaining close to 100 ML per year from 2024 onwards.

Plate 5.15: Modelled transient groundwater balance in Sizewell Marshes under intermediate baseline and construction conditions, assuming low stream bed conductance (2022-2032)

- 5.2.61. The reduced ability for surface water to mitigate drawdown impacts can be seen in the maximum water table drawdown contours in Figure 19A.134 (showing projected drawdown on 26th December 2024), which extend further from the platform area and unlike in the main intermediate scenario, they are largely unaffected by the presence of drainage lines.

- 5.2.62. As shown in Figure 19A.135, projected drawdown in shallow Crag piezometers is similar to the intermediate scenario, although to the north of Sizewell Marshes, PZ19 and PZ20 exhibit substantially reduced impacts from dewatering and some evidence of groundwater mounding. This is consistent with infiltration from the WMZs and limited discharge to surface water.
- 5.2.63. Maximum drawdown contours for the shallow Crag, from 26th December 2024, are slightly greater in extent than in the main intermediate scenario, reflecting the reduced inflows from surface water, which would otherwise mitigate drawdown (Figure 19A.136).
- 5.2.64. Stream flow and stage, shown in Figures 19A.137 to 19A.139, are not discernibly affected by construction in this scenario, except at G1, which shows a reduction in maximum flow rates of up to 0.1 m³/s, although for flows below the 20th percentile, there appears to be no obvious reduction due to dewatering. There is a slight increase in flow during dry periods, which may be due to slight reductions in stage drawing more water from the upstream part of the drainage network.
- 5.2.65. There are also minor changes in the flow duration curve for G5, which shows higher peak flows and lower minimum flows, which can be attributed to the presence of wetlands in the Aldhurst Farm area in the construction scenario, which allow increased evaporation during summer and more readily accept recharge during winter.

6 SUMMARY AND CONCLUSIONS

6.1 Background and overview

- 6.1.1. A combined surface water and groundwater numerical model has been developed to understand the potential impacts from proposed construction of the Sizewell C Power Station in East Suffolk.
- 6.1.2. The projected impacts do not take proposed mitigation measures into account. As such, the results presented will be used to understand the likely locations and magnitudes of unmitigated impacts, to inform and refine the overall approach to monitoring, mitigation and betterment. This approach will be presented in the associated Monitoring and Mitigation Plan, which will form part of the DCO submission and be used to proactively assess the real-world changes to ensure no unacceptable impacts occur.
- 6.1.3. The numerical model is underpinned by a detailed conceptual understanding of the site, based on site investigation and monitoring data

collected over a period of several years, as well as publicly available information and literature sources.

- 6.1.4. The numerical model was calibrated to observed groundwater level, surface water stage and flow data to ensure it is representative of conditions at the site, including in the nearby Peat of the MWHM SSSIs, and in the underlying Crag aquifer, which would be subject to dewatering during the construction phase of the proposed development.
- 6.1.5. Key uncertainties in model parameterisation were assessed using a series of sensitivity analyses, which compared the results of these alternative parameterisations with observed data. Parameterisations that produced reasonable calibrations to the observed data were deemed to be plausible, and those with the potential to affect future projections of construction and operational impacts were considered in subsequent scenario modelling.
- 6.1.6. The calibrated model was used to simulate future conditions at the site, with respective model runs representing the system in the presence and absence of development.
- 6.1.7. These construction and baseline models were each run for three different projections of future climate; nominally dry, wet and intermediate conditions. This allows the model to capture potential impacts under a wide range of plausible conditions, so that monitoring and mitigation planning can be developed to cover these different eventualities.
- 6.1.8. Sensitivity analyses were also completed on the future scenario models, covering key aspects of the proposed design, as well as alternative parameterisations of the natural system that produced reasonable calibrations to historical observations, as indicated by the first phase of sensitivity analysis.

6.2 Summary of historical modelling

- 6.2.1. The calibrated model closely matches observed groundwater levels in the Peat of the SSSIs, typically with a difference of less than 10 cm throughout the year. The calibrated model also closely matches observed groundwater levels in the Crag. The model matches both absolute groundwater levels and the observed seasonal range in these values.
- 6.2.2. The model closely matches observed flow and stage at stream gauging locations, with stage in the upstream part of the model (at gauging station G5) the only notable exception to this. The discrepancy at this location is attributed to the build-up of silt in a nearby culvert downstream of this point and the presence of natural “dams” in the surface water drainage system, which are irregular in shape and potentially mobile.

- 6.2.3. Assigned flow at G5 matches observed values, while stage and flow at downstream gauging stations, closer to the area of maximum potential impacts from construction, also match the observed data. As such, underestimation of stage at G5 is not considered to be detrimental to the overall calibration of the coupled model.
- 6.2.4. The calibrated model was validated by comparing simulated and observed drawdown during a 2011 pumping test in the platform area of the Main Development Site. The model results closely match observed trends, with slight discrepancies attributable to differences of a few cm between modelled and observed water levels at the start of the test, as opposed to the magnitude of the test response itself.
- 6.2.5. Further validation of the model was conducted by comparing modelled and observed values following the end of the calibration period. This validation period runs from September 2015 until the end of 2017.
- 6.2.6. The quality of fit to the validation dataset is similar to that achieved during the calibration period, providing further confidence in the ability of the model to represent future conditions at this location.
- 6.2.7. Sensitivity analysis on the calibrated model comprised the following:
- variations in stream bed conductance;
 - variations in vertical hydraulic conductivity of Sizewell Marshes;
 - variations in evapotranspiration rates with depth in the Peat;
 - explicit inclusion of distributed surface run-off within the surface water (MIKE11) network, in addition to the upstream and downstream flow and stage boundary conditions that already incorporate both baseflow and run-off at these locations; and
 - explicit representation of floodplain inundation in the wetland areas, in which water levels can exist above the ground surface and influence flow to and from the underlying groundwater system (compared to the calibrated model, where water lying above the ground surface is removed in the model and treated as discharge to the surface water system in the associated water balance).
- 6.2.8. Variations in evapotranspiration with depth and changes in the vertical hydraulic conductivity of Sizewell Marshes produced significantly poorer fits to observed data, as did increasing the vertical conductance of stream beds. The results suggest that the values assigned to these parameters

during sensitivity analysis are not representative of the system, although the model is sensitive to changes in these parameters.

- 6.2.9. Applying surface run-off to the model does not change the modelled stream hydrographs significantly. As such, it appears that flow and stage within existing surface water channels are sufficiently constrained by the applied upstream and downstream boundary conditions (which are based on observed values that include both run-off and baseline components), that the modelled surface water results are insensitive to the explicit inclusion of run-off.
- 6.2.10. Sensitivity analyses in which stream bed conductance was lowered by an order of magnitude produced a good match to the observed groundwater and surface water data. As a result, the effects of reduced stream bed conductance were assessed further in the future model projections. reduced stream bed conductance has the potential to remove the mitigating effect on drawdown of leakages from surface water.
- 6.2.11. The inclusion of flood plain inundation produces a good match to observed groundwater levels and slightly reduces seasonal fluctuations in the Peat. As such, it provides a less conservative representation of the system's response to drier conditions (as might be experienced during proposed construction dewatering).
- 6.2.12. However, the inundation model produces a poor match to observed stream flows and stage. This may be attributed to difficulties in representing the locations and duration of ponding within the floodplain, which would increase evaporative losses substantially for most of the year and would lead to much lower discharges to the surface water channels than those simulated in the floodplain model. As such, this sensitivity analysis has not been carried forward to the future projections, although it should be noted that the periodic flooding of the wetlands may mitigate the effects of construction dewatering on the underlying groundwater system.

6.3 Summary of future projections

- 6.3.1. The future model results represent the projected response to construction activities under a wide range of climatic conditions.
- 6.3.2. Under baseline conditions (i.e. in the absence of development), groundwater storage in Sizewell Marshes is projected to increase in all three climatic scenarios between now and 2040, driven by a combination of increased recharge and rising sea levels.
- 6.3.3. The projected maximum difference in groundwater storage within Sizewell Marshes between the wet and dry baseline scenarios is equivalent to an average difference in groundwater level of approximately 14 cm across this

area. This highlights the level of uncertainty in future climatic conditions and the challenge for any monitoring, mitigation or management strategy to address potential changes from both development and climatic factors.

- 6.3.4. Projected impacts from construction, relative to natural baseline conditions, are similar in all three climatic scenarios, with maximum drawdown occurring around 16 months into the construction period (nominally in December 2024 or January 2025).
- 6.3.5. In each scenario, the maximum drawdown at this time is less than 10 cm across the majority of Sizewell Marshes, with greater drawdown to the north of the platform near a proposed impermeable area and in localised areas, around 100 m in diameter, away from drainage channels in the eastern and northernmost parts of the SSSI. A small area of more than 10 cm drawdown is also projected to occur up to 100 m north of the Main Development Site in the MWHM SSSI, at its eastern edge where it meets the shoreline.
- 6.3.6. Projected groundwater level change duration curves have been produced for selected monitoring borehole locations within the Peat, where drawdown is expected to be greatest. These curves suggest that the maximum drawdown for most of the construction period is likely to occur during summer, with the least drawdown typically occurring during wintertime.
- 6.3.7. The overall pattern of drawdown in groundwater level change duration curves and drawdown hydrographs mimics the inferred dewatering schedule, which requires the greatest drawdown 1-3 years into the construction period, with dewatering to shallower levels for up to 7 years subsequently.
- 6.3.8. The model projections show drawdown exceeding 7 cm for up to 25% of the construction period in any single monitoring borehole outside of excavated areas and exceeding 5 cm for less than 50% of the construction period in all of these monitoring boreholes during the wet and intermediate scenarios.
- 6.3.9. In the dry scenario, boreholes P8 and P12, which lie approximately 200 m from the north-west corner of the platform, show drawdown exceeding 6 cm for around 50% of the construction period, while the other monitoring boreholes outside of excavated areas all show less than 5 cm of drawdown for at least 50% of the construction period.
- 6.3.10. Transient water balance graphs for Sizewell Marshes were developed for each scenario over the period from 2015 until 2040, by which time projected hydrographs indicate full recovery in water levels following construction. In each climatic scenario, a reduction in flow from the

underlying Crag aquifer represents the largest single change to the water balance, with losses of up to 100 ML/yr during the construction period.

- 6.3.11. The reduction in upward flow from the Crag is offset by reduced flows of groundwater to drainage channels within the Marshes. Reductions in baseflow reach a maximum of around 100 ML/yr in each scenario, equivalent to around 6% of projected total flow at the G1 gauging station, which lies immediately downstream of the platform area.
- 6.3.12. Projected impacts on stream flow are insufficient to see any discernible change in stage or flow hydrographs in any of the scenarios.

6.4 Summary of future sensitivity analyses

- 6.4.1. Several sensitivity analyses have been conducted to assess changes or uncertainty in design parameters, impacts of construction during extreme drought and reduced stream bed conductance, which was found to be a key uncertainty during historical sensitivity analysis.
- 6.4.2. A doubling of the hydraulic conductivity of the cut-off wall, which surrounds the platform area of the Main Development Site leads to an approximate doubling of projected drawdown impacts within the adjacent Sizewell Marshes, with nearby piezometers showing a reduction in groundwater levels of up to 20 cm during the early part of the construction period.
- 6.4.3. The implementation of natural recharge in the temporary construction areas, as opposed to impermeable hardstanding, infiltration basins (known as water management zones) and discharges to surface water, produces no discernible change to projected drawdown within Sizewell Marshes. However, there is a notable decrease in groundwater mounding near the water management zones to the north of it.
- 6.4.4. Consecutive years of drought at the beginning of the construction period is projected to increase drawdown relative to the main construction scenario. In the extreme conditions modelled, this manifests as an increase in drawdown of approximately 2 cm in the majority of monitoring locations within the Peat. Although much of this drawdown can be attributed to dewatering within the platform area, there is also increased drawdown in the western part of Sizewell Marshes, linked to the creation of new wetlands in the Aldhurst Farm area, which may be susceptible to high rates of evapotranspiration during prolonged dry periods.
- 6.4.5. The lowering of stream bed conductance in the model leads to increases in projected maximum drawdown of up to 2-3 cm across Sizewell Marshes, with areas where maximum drawdown exceeds 10 cm covering a greater extent and showing greater connectivity, due to reduced inflows from overlying drainage channels.

- 6.4.6. The results of the sensitivity analysis highlight key uncertainties in the model and demonstrate the importance of ongoing monitoring and management of the wetland areas.

This chart shows that the SMD follows the water level throughout the modeled period as would be expected - both for the period where the derived water level is used (pre-December 2013) and afterwards where observed data is used.

Rainfall (mm)	Average stage (maod)
N.B. Average stage is taken from day and next day to account for any lag effects from rainfall late in the day

15 to 20	17.5	1.14
20 to 30	25	1.16

From this trendline:
 $stage = 0.0061 \times rain + 1.0064$
 This is relationship used to calculate flows for modelled time

This method uses an assumed velocity of 0.09 m/s unless rainfall is greater than 10mm then assumed velocity = 0.12 m/s

This method uses a baseflow on dry days, and then uses the rainfall-stage relationship on wet days

Stage = 0.0061*rainfall +1.0064
 stage in maod
 rainfall in mm/d

Datum
0.734 maod

Baseflow on consecutive dry days
 0.04 m3/s

Date	MORECS rainfall (mm)	Average 2 day rain	Assumed velocity (m/s)	V mean	Calculated stage (maod)	Converted stage (mad)	Calculated area (m2)	Calculated flow (m3/s)	Calculated flow using baseflow (m3/s) when average daily rain <0.5

Stage-area rating relationship (Hydro-Logic Services LLP, 2015)
 $A = 1.5207 \cdot h^4 - 5.3247 \cdot h^3 + 7.6867 \cdot h^2 - 0.5866 \cdot h + 0.0048$
 Velocity index rating:
 $V_{mean} = (1.397 \cdot V) + (0.191 \cdot h) - 0.027$

Date	MORECS rainfall (mm)	Average 2 day rain	Assumed velocity (m/s)	V mean	Calculated stage (maod)	Converted stage (mad)	Calculated area (m2)	Calculated flow (m3/s)	Calculated flow using baseflow (m3/s) when average daily rain <0.5
