CHAPTER 1: EXISTING SITE AND SURROUNDING AREA

CONTENTS

FIGURES

[This page is intentionally left blank]

1. EXISTING SITE AND SURROUNDING AREA

1.1 Introduction

1.1.1 This chapter provides an overview of the existing Hinkley Point C (HPC) development site and surrounding area which have the potential to be affected by the proposed new nuclear power station.

1.2 Location of the Hinkley Point C Development Site

1.2.1 The HPC development site is located on the coast of Somerset, 25km to the east of Minehead and 12km to the north-west of Bridgwater. The HPC development site falls within the parish of Stogursey in the district of West Somerset.

1.2.2 As illustrated in **Figure 1.1** the HPC development site is approximately centred on the National Grid Reference 320300, 145850 and occupies a total land-based area of 175.2 hectares (ha). The proposed area for the permanent land-based development will be approximately 67.5ha (the permanent development site).

1.2.3 Immediately to the east of the development site, the land is occupied by two nuclear power stations, Hinkley Point A and Hinkley Point B, which form the existing Hinkley Point Power Station Complex. Hinkley Point A operated between 1965 and 2000 and is currently undergoing decommissioning by the Nuclear Decommissioning Authority (NDA). Hinkley Point B, owned by EDF Energy, has operated since 1976 and is scheduled to continue generating until at least 2016.

1.2.4 The surrounding area is predominantly agricultural with scattered settlements, representative of the Vale of Taunton and Quantock Fringes National Character Area (NCA) including:

- Stolford approximately 2km to the east of the development site (as denoted by the red line boundary).
- Wick approximately 800m to the south east of the development site.
- Shurton adjacent to the south of the development site.
- Burton approximately 600m to the south-west of the development site.
- Stogursey approximately 1.5km to the south of the development site.
- Knighton approximately 500m to the west of the development site.

1.2.5 The villages of Combwich and Williton are located approximately 5km and 12km to the south-east and west of the site respectively. These villages have been identified as sites to accommodate the proposed off-site associated development. Further off-site, associated development will be located in the village of Cannington 8km to the south-east, at Bridgwater and in the vicinity of Junctions 23 and 24 of the M5.

1.2.6 The site is bounded to the north by the Bridgwater Bay, part of the Severn Estuary from which it is separated by a low cliff.

1.3 Hinkley Point C Development Site

1.3.1 As illustrated in **Figure 1.2**, the HPC development site is divided into three compartments for the purposes of the Environmental Impact Assessment (EIA) comprising:

- The Built Development Area East (BDAE) comprising land in the north-east part of the site, adjacent to the existing Hinkley Point Power Station Complex to be used for the built development and main construction works areas.
- The Built Development Area West (BDAW) located to the west and south of BDAE and which will be occupied by the built development and main construction works areas.
- The Southern Construction Phase Area (SCPA) located to the south of the Built Development Areas East and West and extends to the southern boundary. The northern part of this area between Green Lane and latitude 144750mN will accommodate areas for contractors, stockpiling, the on-site accommodation campus and other facilities throughout the construction period. The area south of 144750mN will accommodate early landscaping works, the emergency access road and a bridge over Bum Brook.

1.3.2 The majority of land within the development site is agricultural in nature and consists of a mix of arable and pasture fields, delineated by a mixture of fence lines and mature hedgerows. Five small broad-leaved woodlands are located within the coastal fields, with other woodland being limited to Branland Copse (on the western side of the existing Hinkley Point Power Station Complex) and a block of semi-natural plantation towards the southern boundary of the site.

1.3.3 The BDAE comprised predominantly agricultural land, until 1957 when a small sewage works was constructed towards the western boundary. A central part of this area was also subject to the deposition of spoil arising from the construction of the Hinkley Point A power station. The deposited spoil formed the large, double humped mound still present on site. During construction of the Hinkley Point B power station, a campus and fabrication area with associated electrical substations were developed on the southern section of the BDAE. These have since been removed. More recently, the north western part of this area was used as a temporary stockpile for material arising from the construction of the new Intermediate Level Waste (ILW) store on the Hinkley Point A site.

1.3.4 During 2011 the development site was subject to a series of separate planning permissions as detailed in **Volume 1** including:

- the construction of new bat barn on the western boundary of the site to mitigate for the loss of potential bat roosts within three derelict barns located within Built Development Areas East and West during early site clearance; and
- site remediation of known contamination within the spoil mound and surrounding areas within BDAE. See **Figure 1.3**.

1.3.5 In addition, a replacement car-park serving Hinkley Point B power station was constructed on existing operational land within BDAE through permitted development rights under The Town and Country Planning General Permitted Development Order 1995.

1.3.6 The topography of the development site is typical of that in the wider locality comprising mostly open, gently rolling, mixed lowland farmland with a series of east-west trending ridges from the coast extending inland. **Figure 1.4** illustrates the general landform. In essence, land rises from the coast up to Green Lane and then drops down again into the Holford valley before rising again in similar fashion before falling towards Bum Brook and the village of Shurton.

1.3.7 There are no substantial waterbodies within the development site boundary, although there are a number of watercourses including Bum Brook and Holford Stream which run west-east under the C182 and connect to the watercourses in Wick Moor. To allow for a development platform to be created, Holford Stream will be culverted. Further details are provided within the **Construction Method Statement**.

1.3.8 A minor unnamed ditch (referred to as the Hinkley Point C drainage ditch) arises to the west of the site and runs through Built Development Areas West and East before discharging to the intertidal zone.

1.3.9 Smaller standing water is also limited in extent, with a scrub-encroached pool towards the north-western edge of the site boundary, and further small pools to the south of the plant sewage works and near Pixies Mound to the east of the development site.

1.3.10 The development site is well served by a network of public footpaths and bridleways, including:

- part of the West Somerset Coast Path which links the River Parrett Trail at Steart in Bridgwater Bay with the South West Coast Path National Trail at Minehead;
- Green Lane, as described in 1.3.6 above; and
- a number of smaller, interconnecting footpaths running north-south and east-west.

1.3.11 The development site is bounded to the north by Bridgwater Bay, part of the Severn Estuary from which it is separated by a low cliff, between around five and ten metres in height. At low tide, the shore adjacent to the site comprises a relatively narrow platform of rock, cobbles and pebbles, interspersed with and fringed by muddy sand. Intertidal areas to the west include more extensive areas of mobile sand, while to the east, adjacent to the built nuclear power stations, the intertidal rock platforms, mud and sand extend up to 500m from the upper shore at low water. The Severn Estuary is recognised for its international and national nature conservation importance. Further details are provided below in section 1.4.

1.3.12 The Severn Estuary is a typical outer estuarine area that experiences a moderate variation in salinity regime throughout the tidal cycle. However, due to its extremely high tidal range, it is in most other respects atypical. Turbidity levels (the amount of fine silt suspended in the water) are extremely high. A significant feature is associated with the neap/spring tidal cycle, where some of these fine silts are deposited widely across the rock platform and in subtidal areas during the more extreme neap tides and remobilised at higher tidal ranges. This is a distinctive feature of Bridgwater Bay and the extreme turbidity and tidal regimes both have a significant influence on ecology and water quality. Another significant influence on water quality is the nearby Parrett Estuary, a large sub-estuary of the Severn, especially during extremes of river run-off when the freshwater plume can extend for some distance off-shore.

1.4 Designated Sites

1.4.1 As illustrated in **Figure 1.5** there are a number of designated sites in proximity to the HPC development site. The Severn Estuary is recognised for its international and national nature conservation importance and designated as:

- a Ramsar site under the Ramsar Convention on Wetlands of International Importance;
- the Severn Estuary Special Protected Area (SPA) under the EC Directive (79/409/EEC) on the Conservation of Wild Birds; and
- the Severn Estuary Special Area of Conservation (SAC), under the EC Directive (92/43/EEC) on the Conservation of Natural Habitats and of Wild Flora and Fauna.

1.4.2 The Severn Estuary SPA and Ramsar Sites covers all intertidal and inshore marine habitat adjacent to the northern boundary of the Built Development Areas and also extends inland and includes Wick and North Moor to the east.

1.4.3 Bridgwater Bay SSSI, which includes Bridgwater Bay National Nature Reserve (NNR), lies to the east of the site, south of the existing Hinkley Point Power Station Complex and comprises a succession of habitats ranging from mudflats, saltmarsh, shingle beach, and grazing marsh. It supports internationally and nationally important numbers of wintering and passage wildfowl and is an integral part of the Severn Estuary eco-system, as well as forming a link to the Somerset Levels.

1.4.4 A relatively extensive area of land on the southern side and small areas of ground to the east and west of the existing Hinkley Point Power Station Complex have been subject to land management and are non-statutorily designated for their conservation value as a County Wildlife Site (Hinkley CWS). Approximately 60% of the designation is within the BDAE.

1.4.5 Further details on the sites designated for the nature conservation value are provided within **Chapters 19** and **Chapter 20** of this Volume on Marine and Terrestrial Ecology, respectively.

1.4.6 Adjacent to the western boundary of the BDAW frontage, lies the ‘Blue Anchor to Lilstock’ SSSI which is designated for the unique cliff stratigraphy which comprises interbedded limestones, shale and mudstones of the Lower Blue Lias units. The exposed strata are considered to be amongst the best examples of the Blue Lias outcrop in Europe. Furthermore, the SSSI also has a geomorphological designation for the exposed limestone rock pavement on the foreshore.

1.4.7 There are no local landscape designations within the site, however, a Historic Landscape, Green Wedge, Historic Parks and Gardens and a Conservation Area are present within the wider study area. Within 5km of Hinkley Point there are three Scheduled Monuments (Wick Barrow Pixies Mound, Stogursey Castle and Village Cross) and three historic Parks and Gardens (Fairfield, St. Audries House and Crowcombe Courts). The presence of these features indicates historic activity in the area immediately surrounding the development site, and also immediately off-shore. As such the area is likely to be considered as being of high archaeological importance.

1.4.8 Located within 5km of the development site, to the west and south west, is the Quantock Hills Area of Outstanding Natural Beauty (AONB), which covers an area of 99km^2, from the vale of Taunton Deane to the Bristol Channel Coast. The AONB contains large areas of heathland, oak woodlands, ancient parklands and agricultural land. The existing Hinkley Point Power Station complex is visible from parts of this nationally designated landscape. Exmoor National Park and Mendip Hills AONB are also located within 20km of the development site.

1.5 Access to the Hinkley Point C Development Site

1.5.1 The main access road serving the existing Hinkley Point Power Station Complex is the C182 which is a single carriageway road passing from Hinkley Point south-east to the village of Cannington. The C182 routes to the east of Shurton and to the west of Combwich and passes through the centre of Cannington to join the A39 to the south of the village.

1.5.2 The A39 runs westwards towards Williton and Minehead and south-eastwards towards Bridgwater and then eastward to Glastonbury.

1.5.3 The A38 routes through Bridgwater on a predominantly north - south alignment. The A38 provides access to Bristol to the north and Taunton to the south. The M5 motorway bypasses Bridgwater to the east of the town with two interchanges at Junctions 23 and 24. Junction 23 is located north of Bridgwater and Junction 24 south east of the town.

1.6 Highway Improvements

1.6.1 A range of improvement works will be implemented across the highway network in the early stages of construction. The works will be located on the main transport routes to the HPC development and comprise two principal types, being modifications to existing road alignments or junction/roundabout arrangements or enhanced safety measures at the following locations:

- A38 Bristol Road/The Drove Junction, Bridgwater.
- A39 Broadway/A38 Taunton Road Junction, Bridgwater.
- A38 Bristol Road/Wylds Road Junction, Bridgwater.
- Wylds Road/The Drove Junction, Bridgwater.
- A39 New Road/B3339 Sandford Hill Roundabout.
- M5 Junction 23 Roundabout.
- Washford Cross Roundabout.
- Claylands Corner Junction.
- C182 Farringdon Hill Lane, Horse Crossing.

- Cannington Traffic Calming Measures.
- Huntworth Roundabout.

1.6.2 All works will be of a limited spatial scale and the baseline environment for each of the sites is described where relevant in the technical assessment chapters in this volume.

CHAPTER 2: DESCRIPTION OF PROPOSED DEVELOPMENT

CONTENTS

TABLES

FIGURES

APPENDICES

2. DESCRIPTION OF PROPOSED DEVELOPMENT

2.1 Introduction

2.1.1 Part 1, 17 (a) of the Infrastructure Planning (Environmental Impact Assessment) Regulations 2009 requires that a "description of the physical characteristics of the whole development" is provided.

2.1.2 This chapter describes the permanent Hinkley Point C (HPC) development, the landscaping proposals and the off-site highway improvements. It provides an overview of the physical characteristics and functions of the components of the development. Further details on the operation of HPC, together with commissioning activities, are provided in **Chapter 4** of this volume.

2.2 Permanent Site Layout

2.2.1 The permanent HPC built development and building layout, located in the north part of the HPC development site, is shown in **Figure 2.1**. The rest of the land within the HPC development site would be landscaped following completion of the construction works.

2.2.2 HPC will comprise a range of buildings as well as seabed and sub-surface structures and related facilities including:

- Two Nuclear Islands each comprising a UK EPR reactor and associated buildings.
- Two Conventional Islands, each including a Turbine Hall, located adjacent to the Nuclear Islands.
- A Cooling Water Pumphouse for each UK EPR reactor unit with related infrastructure.
- Sea bed cooling water intakes and outfall structures together with tunnels connecting these to the cooling water pumphouses and turbine halls.
- Fuel and waste management facilities, transmission infrastructure including the National Grid 400kV substation, staff facilities, administration, storage facilities and other plant.
- A Public Information Centre (PIC) to provide education and public information facilities.
- A Sea Wall incorporating a public footpath.
- Access and parking facilities for workers, visitors and deliveries for the main power station and the National Grid 400kV substation.

2.2.3 The permanent built development will be distributed over level platforms generally at 14m and 20m AOD. Elsewhere, the permanent landform will be in accordance with the topography presented in the landscape restoration proposals detailed later in this chapter. Illustrative cross-sections of the HPC development are provided in **Figures 2.2a – 2.2b.**

2.2.4 The main development platform will accommodate the Nuclear Islands, Conventional Islands, onshore cooling water infrastructure and other ancillary and storage buildings. This platform will have an elevation of 14m AOD, which will be attained above a slope behind the sea wall ranging in width from 11 to 29m along the site frontage.

2.2.5 Details on the layout and design of specific development components are provided in the sections below.

2.3 HPC Buildings and Structures

2.3.1 HPC will comprise two UK EPR reactor units each with its own reactor buildings; the dimensions of essential buildings and infrastructure are described below. Detailed plans and elevations are provided for each building in the **Application Plans**. As described in **Volume 1, Chapter 7,** although detailed permission is being sought for the majority of buildings**,** some uncertainties are likely to remain up to the point of commencing construction of individual buildings. Thus there is a necessity to allow for some flexibility in the plans and elevations.

2.3.2 The Environmental Statement (ES) has assessed HPC as detailed in the submitted drawings. These provide both detailed designs and alternative maximum and minimum parameters for some structures as shown in **Figure 2.3**. The potential need for flexibility is not anticipated to generate any major change in the characteristics of the development or to have a significant impact on any of the assessment topics. Where appropriate the technical assessments have undertaken a sensitivity analysis to demonstrate this.

2.3.3 **Table 2.1** and **Plate 2.1** provides the maximum dimensions and heights of buildings and structures, where applicable. The dimensions and heights provided are the overall external dimensions of buildings or structures. Dimensions are at ground level, where the length and width are based on the largest dimension in either direction. The height is based on the measurement from the ground level to the highest point of the building or structure. It should be noted that projections, such as heating and ventilation plant are not included.

2.3.4 A number of facilities are shared between the two UK EPR units. In the table below these are denoted “shared facilities”.

Table 2.1: Maximum Dimensions and Heights of Buildings and Structures

Building and Structures	Number	Maximum Dimensions (m)	Maximum Height (m) from the Appropriate Platform Level
Nuclear Island			
Reactor Building	One per unit	57 x 57	64
Fuel Building	One per unit	See **Plate 2.1**	36
Safeguard Building West	One per unit		38
Safeguard Building East	One per unit	See **Plate 2.1**	38
Safeguard Buildings	Two per unit		35
Nuclear Auxiliary Building	One per unit		35

Building and Structures	Number	Maximum Dimensions (m)	Maximum Height (m) from the Appropriate Platform Level
			(stack height 70m)
Access Tower	One per unit		27
Fuel Building Hall	One per unit		14
Boron Storage	One per unit		8
Radioactive Waste Storage Building (Unit 1)	Shared facility	26 x 33	17
Radioactive Waste Process Building (Unit 1)	Shared facility	37 x 39	14
Radioactive Waste Treatment Building (Unit 2)	One (Unit 2)	22 x 29	13
Hot Laundry (Unit 1)	Shared facility	39 x 19	12
Hot Workshop, Hot Warehouse, Facilities for Decontamination (Unit 1)	Shared facility	98 x 24	16
Effluent Tanks (Unit 1)	Shared facility	28 x 25	16
Emergency Diesel Generator	Two per unit	46 x 26	28
Conventional Island			
Turbine Hall	One per unit	123 x 64	46
Sky Bridges	One per unit	49 x 44	21
Non-Classified Electrical Building	One per unit	39 x 33	21
Gas Insulated Switchgear	One per unit	32 x 13	15
Main Transformer	One per unit	37 x 16	15
Unit Transformer	One pair per unit	13 x 8 (each)	12
Auxiliary Transformer	One per unit	13 x 8	12
Hydrazine and Ammonia Storage	One per unit	27 x 11	5
Auxiliary Feedwater Storage	One per unit	25 x 20	13
Operations			
Operational Service Centre	Shared facility	83 x 67	36
Cooling Water Pumphouse and Associated Buildings			
Cooling Water Pumphouse	One per unit	84 x 57	19
Forebay	One per unit	79 x 41	4
Outfall Pond (Surge Chamber)	One per unit	47 x 43	11
Filtering Debris Recovery Pit	One per unit	27 x 9	2
Fire-Fighting Water Building	One per unit	46 x 31	7
Remaining Balance of Plant and Other Plant			
Attenuation Pond	Shared facility	17 x 11	3
Demineralisation Station	Shared facility	39 x 32	14
Auxiliary Boilers	Shared facility	26 x 24	18
Hydrogen Storage	One per unit	45 x 14	4

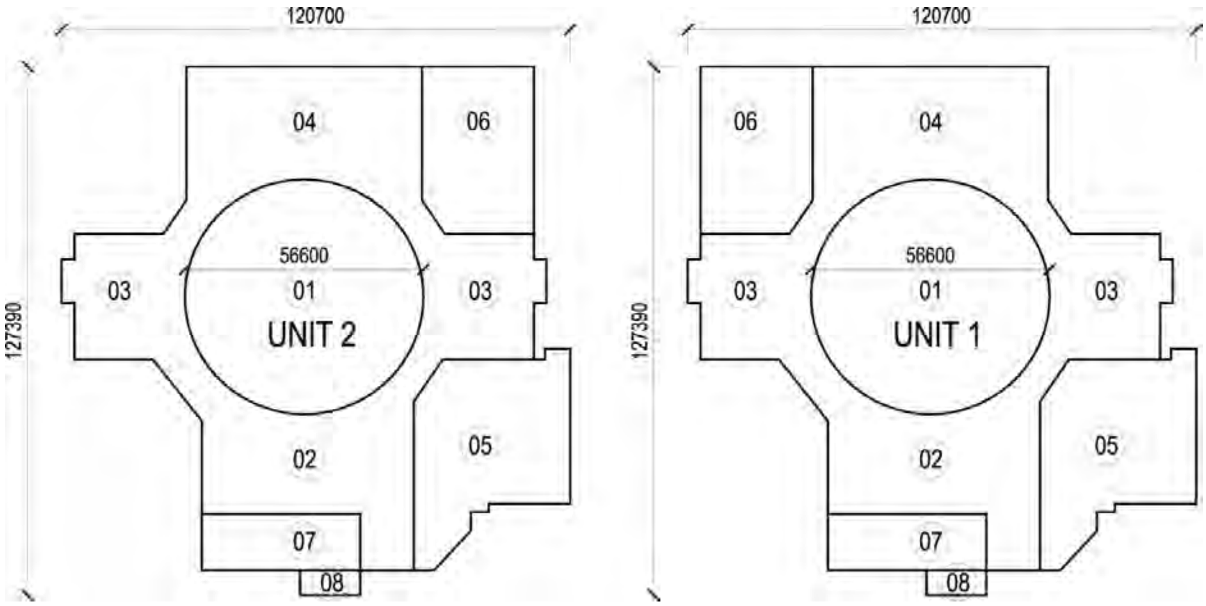
Building and Structures	Number	Maximum Dimensions (m)	Maximum Height (m) from the Appropriate Platform Level
Oxygen Storage	One per unit	14 x 4	4
Chemical Products Storage	Shared facility	30 x 26	7
Sewage Treatment Plant	Shared facility	8 x 4	3
Conventional Island Water Storage Tank (x2)	Shared facility	38 x 38	20
Nuclear Island Water Storage Tank	Shared facility	12 x 12	13
Fuel and Waste Storage			
Interim Spent Fuel Store	Shared facility	150 x 65	25 (stack height 55m)
Access Control Building	Shared facility	29 x 17	5
Intermediate Level Waste Interim Storage Facility	Shared facility	137 x 37	16 (stack height 20m)
Ancillary , Office and Storage			
Main Access Control Building	Shared facility	39 x 36	6
Entry Relay Building	Shared facility	39 x 17	6
Off-Site Vehicle Search Area	Shared facility	7 x 6	4
Auxiliary Administration Centre	Shared facility	38 x 29	15
Medical Centre	Shared facility	41 x 38	5
EDF Site Offices	Shared facility	65 x 65	10
Garage for Handling Facilities	Shared facility	56 x 23	8
Oil and Grease Storage and Oil Ancillary Building	Shared facility	38 x 29	10
AREVA Warehouse	Shared facility	80 x 44	14
Raw Water and Potable Water Supply	Shared facility	n/a	Underground
Meteorological Station	Shared facility	11 x 11	5
Outage Access Control Building	Shared facility	29 x 17	4
Contaminated Tools Storage (x2)	Shared facility	65 x 29	13
Conventional Waste Storage	Shared facility	59 x 38	7 (Hardstanding-Height of canopy)
Transit Area for Very Low Level Waste and Low Level Waste	Shared facility	45 x 23	4 (Hardstanding-fenced area)
Public and Training			
Simulator Building/Training Centre	Shared facility	99 x 40	11
Public Information Centre	Shared facility	32 x 31	19
National Grid Substation			
National Grid Substation GIS Hall and Annex	Shared facility	90 x 25	15

Building and Structures	Number	Maximum Dimensions (m)	Maximum Height (m) from the Appropriate Platform Level
Amenity Building	Shared facility	11 x 13	4
Other Site Structures			
Helipad	Shared facility	49 x 27	0 (Hardstanding)
Sea Wall (incorporating Coastal Path)	Shared facility	760 (length)	
Car Parks	Shared facility	n/a	n/a
Meteorological Station Mast	Shared facility	3 x 3	50
EDF Energy Pylons	Shared facility	Various	Various

Notes: A 'shared facility' is a building or structure shared between both UK EPR Reactor units

- *All dimensions are rounded up to the nearest metre.*
- *For precise dimensions of the proposed buildings/structures, please refer to the relevant application plans.*

Plate 2.1: Maximum Dimensions of the Reactor and Associated Buildings



2.4 Nuclear Island

2.4.1 Each of the two Nuclear Islands will comprise a reactor building surrounded by its associated safeguard buildings and fuel building. Each of the two Nuclear Islands will be shaped like a cross, with the reactor building at its centre and surrounded by the fuel building and safeguard buildings.

2.4.2 Other structures within the Nuclear Island associated with each reactor include the:

- Nuclear Auxiliary Building.
- Fuel Building Hall.
- Boron Storage.
- Hot Laundry (shared facility adjoining Unit 1).
- Hot Workshop, Hot Warehouse, Facilities for Decontamination (shared facility adjoining Unit 1).
- Effluent Tanks (shared facility adjoining Unit 1).
- Emergency Diesel Generator Buildings.
- Radioactive Waste Storage and Process Buildings (shared facility adjoining Unit 1).
- Radioactive Waste Treatment Building (Unit 2); and
- Access Tower.

2.4.2 The following sub-sections describe these structures in more detail.

a) The Reactor Building

2.4.3 There will be a reactor building housing a UK EPR reactor in the centre of each of the two Nuclear Islands. The reactor building will also contain the main components of the Nuclear Steam Supply System. The reactor building is cylindrical in shape with an ellipsoidal dome approximately 64m in height above platform level.

2.4.4 The reactor comprises a steel pressure vessel containing the nuclear fuel (reactor core) and four cooling loops, each consisting of a reactor coolant pump and a steam generator together with interconnecting pipework. One loop is connected to a pressuriser vessel.

2.4.5 Other components of the reactor buildings include:

- safety systems and equipment;
- a refuelling water storage reservoir;
- an area for the chemical and volume control system;
- a steam-generator blowdown system;
- main steam lines and main feedwater lines; and
- access to the containment inter-space.

2.4.6 **Figure 2.4** illustrates the southern elevation of the Reactor Building for Unit 2.

b) Fuel Building and Fuel Building Hall

2.4.7 Each UK EPR reactor unit will have a Fuel Building which houses a fuel storage pool for new and spent fuel and associated fuel handling equipment. Adjoining the Fuel Building is the Fuel Building Hall which will be used for the reception of new fuel and dispatch of casks containing spent fuel.

c) Safeguard Buildings

2.4.8 The major safety system consists of four sub-systems or 'trains' to provide quadruple redundancy. The purpose of the safety train is to control and remove residual heat from the reactor in the event of abnormal operation. Each train is capable of performing all of the necessary safety functions independently. There will be four safeguard buildings per UK EPR reactor unit, each with one train. The four safeguard buildings will be physically separated to prevent simultaneous common-mode failure of the trains. Access by personnel to these buildings will be strictly controlled.

d) Nuclear Auxiliary Building

2.4.9 The Nuclear Auxiliary Building will be built next to the Fuel Building for each UK EPR reactor unit. This will house the nuclear operation support systems and the maintenance areas. The main systems installed in the Nuclear Auxiliary Building are the following:

- the treatment system for primary effluents;
- the pool-water treatment system;
- the gaseous effluent treatment system;
- part of the steam generator blow-down treatment and cooling system; and
- the operational ventilation and chilled water systems of the nuclear auxiliary building.

2.4.10 All air exhausts from the radiological controlled areas are routed, collected, controlled and monitored within the Nuclear Auxiliary Building prior to release through a vent stack 70m high.

e) The Access Tower

2.4.11 The main function of the access tower on each unit is to enable controlled access to the Nuclear Island. The building will contain a number of operational and technical rooms.

f) Boron Storage

2.4.12 Each UK EPR reactor unit will have a boron preparation and storage area, located to the south of the Fuel Building. Boric acid will be stored and prepared before dosing the primary circuit water to control the reactivity of the core.

g) Radioactive Waste Storage, Process and Treatment Buildings

2.4.13 The waste buildings, collectively termed the effluent treatment building (ETB), will serve both UK EPR reactor units and will be used for the collection, storage, treatment and disposal of liquid and solid radioactive waste. The ETB is adjacent to the Nuclear Auxiliary Building for Unit 1. A waste treatment facility is provided at Unit 2.

2.4.14 The waste buildings, which are made of reinforced concrete, will be divided into two sections; one for the storage of solid waste and the other for liquid effluent and solid waste treatment.

h) Hot Laundry

2.4.15 The Hot Laundry is used to launder radiologically contaminated garments or potentially contaminated garments; that is the protective clothing worn by employees when working in contamination controlled areas.

i) Hot Workshop, Hot Warehouse, Facilities for Decontamination

2.4.16 The Hot Workshop, Hot Warehouse and Decontamination Facilities are encompassed in a single structure adjacent to the Hot Laundry.

2.4.17 The Hot Workshop is the facility for engineering work on radiologically activated or contaminated plant components such as valves, pipes and pumps.

2.4.18 The Hot Warehouse is designed to store activated or contaminated tools and components such as the multi-stud tensioner or spare reactor coolant pump motors.

2.4.19 The Decontamination Facility is designed to reduce or remove radioactive contamination of tools, components or wastes. Decontamination of equipment enables reuse of tools and minimisation of the volume of radioactive materials requiring disposal.

j) Effluent Tanks

2.4.20 The Effluent Tanks for the various liquid effluent systems adjoin the Unit 1 Waste Processing Building. Liquid effluent undergoes different treatment depending on its source; primary effluent treatment, spent effluent treatment or turbine hall drainage water treatment. The different types of effluent are sent to three specific types of tank for temporary storage and checking before discharge.

k) Emergency Diesel Generator Buildings

2.4.21 There will be two Emergency Diesel Generator buildings (EDGs) associated with each reactor. Each diesel building houses two main diesel generators and a station black out diesel generator. Each main diesel generator is dedicated to one of the safeguard trains in the event of a loss of off-site electrical power. The purpose of the blackout diesel generator is to provide a short duration back up to the main diesel generators. EDGs are located on either side of the reactor structures.

2.4.22 **Figure 2.5** illustrates the southern elevation of an Emergency Diesel Generator building.

2.5 Conventional Island

2.5.1 The Conventional Islands for each UK EPR reactor unit will comprise a Turbine Hall, Non-Classified Electrical Building, power transmission platform, Hydrazine and Ammonia Storage, and Auxiliary Feedwater Storage, as described below.

a) Turbine Hall

2.5.2 Each Turbine Hall is located adjacent to the Reactor Building for each UK EPR reactor unit, and contains components which form part of the steam-condensate-feedwater cycle, including the turbine and generator set (turbo-generator) and the main condensers.

2.5.3 **Figures 2.6** and **2.7** illustrate the east and west elevations of the turbine hall respectively.

b) Non-classified Electrical Building

2.5.4 The Conventional Island's electrical plant building (one per unit) houses electrical distribution panels, which provide the permanent power supplies to the Nuclear Island and the Conventional Island systems, together with the instrumentation and control system which monitors and manages these systems.

c) Power Transmission Platform

2.5.5 The function of the power transmission platform (one per unit) is to process and transmit the electrical power generated to the National Grid Substation. The power transmission platform is located adjacent to the Turbine Hall and houses the following key plant items:

- gas insulated switchgear.
- a main transformer;
- a unit transformer; and
- an auxiliary transformer;

2.5.6 Electricity generated from the turbo-generator is stepped up to 400kV via the main generator transformer and this power is then transferred to the National Grid 400kV substation via overhead lines and towers (pylons).

d) Hydrazine and Ammonia Storage

2.5.7 Bulk storage of hydrazine and ammonia is provided for adding to the secondary circuit water to achieve the correct pH and oxygen level to minimise corrosion.

e) Auxiliary Feedwater Storage

2.5.8 Additional feedwater storage tanks and an associated process building are provided to accommodate changes in the secondary circuit water inventory, particularly during start-up and shut-down of the turbine.

2.6 Cooling Water Pumphouse and Associated Buildings

2.6.1 The key components of the open circuit cooling water infrastructure are illustrated in **Figure 2.8** and described in more detail below.

a) Cooling Water Intake Tunnels, Intake Headworks and Associated Fish Deterrent System

2.6.2 Seawater for cooling will be abstracted from Bridgwater Bay via a series of seabed intake structures and tunnels. Each UK EPR reactor unit will have a single dedicated intake tunnel with two dedicated seabed intakes. At either end of the tunnels there will be vertical shafts that provide connection on the landward side to the onshore cooling water infrastructure and at the seaward end to the seawater intake heads. The tunnels extend approximately 3.5km and 3.4km from the foreshore high water mark for the Unit 1 and Unit 2 intakes respectively (see **Figure 2.9**) and at a depth of approximately 20m below the seabed. At their seaward extent, the two intake tunnels will be some 480m apart. The two seabed intake heads associated with each intake tunnel will be separated by approximately 200m.

2.6.3 Each intake head will comprise a main rectangular structure with a length of 35.5m, a width of 10m and a depth of 2.8m. Tapered sections (4.2m long) will be provided at either end of the rectangular structure to deflect tidal flows (see **Figures 2.10** and **2.11**).

b) Acoustic Fish Deterrence System

2.6.4 An Acoustic Fish Deterrent (AFD) system will be associated with each intake head. The AFD acts as a behavioural deterrent which would provoke an avoidance reaction amongst certain groups of fish. The AFD will compromise two modular sound projector arrays, one at each end of the structure. A series of amplifiers with associated sound projectors will be built into each module. Each module will incorporate a number of sound projectors. Piles will provide a means both of securing the modules in the appropriate positions and depths at each end of the intakes, and for their ready removal and replacement. The projectors will be positioned at the same level as the mid point of the intake head (see **Figure 2.12**).

2.6.5 The AFD modules will be streamlined and will also incorporate cowled tidal turbines that will provide power for the sound projectors.

c) Forebay

2.6.6 There will be one Forebay for each UK EPR reactor unit. The forebays will receive water from the intake tunnels and will be located to the north of the cooling water pumphouses. Each Forebay will have a depth of 29m. The front of each Forebay will be formed by a reinforced concrete wall. A single cooling water intake tunnel will feed directly into each open Forebay. Two underground tunnels of 2.5m diameter will run inland of the sea wall parallel with the shoreline and link the forebays of the two units; these are referred to as 'forebay link tunnels' (see **Figure 2.8**).

d) Cooling Water Pumphouse

2.6.7 There will be two cooling water pumphouses (one for each UK EPR reactor unit) that will draw water from the forebays. The cooling water pumphouses will contain equipment supplying seawater as coolant for:

- the Nuclear and Conventional Islands' auxiliary cooling water systems; and
- the condenser cooling system that cools the turbine exhaust steam and condenses it to liquid water for reuse as feed water within the secondary cycle.

2.6.8 Each Cooling Water Pumphouse will be divided into four distinct trains or channels fed with water from the forebay (detailed below). Each Pumphouse will thus be served by a separate sub-seabed cooling water intake tunnel linking it to two off-shore seabed intake structures.

2.6.9 Each Pumphouse will incorporate screening systems (including drumscreens and band screens) specifically designed in order to prevent the blockage of key elements of plant further downstream, primarily the heat exchangers and main condensers.

2.6.10 **Figure 2.13** illustrates the north and south elevations of the cooling water pumphouse, forebay, outfall pond and filtering debris recovery pit.

i. Cooling Water Supply Channels

2.6.11 Each Cooling Water Pumphouse has four distinct trains:

- Two central trains each separated into four waterways (narrow passages), which then recombine before feeding to the two main drum screens, which will primarily supply the essential service-water systems and the condenser cooling water.
- Two lateral trains each including a single waterway, each fitted with a band screen, which will supply the essential service-water systems and the conventional auxiliary cooling water systems.

2.6.12 Each waterway, leading both to the drum screens and band screens, will incorporate a fixed vertical coarse screen with spacings of 50mm in order to block larger elements of debris. Each will be maintained by a timer/pressure differential-driven trash rake. Sluice gates within the system may be closed within these waterways in order to isolate downstream elements of the cooling water system for maintenance purposes.

ii. Drum Screens

2.6.13 Each of the two cooling water pumphouses will have a rotating drum screen to remove finer debris from a flow of approximately 30m^3/sec prior to passage through the main cooling water pumps and the fine bore condenser and other heat exchanger tubing that follows.

2.6.14 Each drum screen will be made up of a horizontal axis drum whose outer circumference will be made up of panels of a smooth ('fish friendly') fine (<6mm) mesh. Aligned with the inner circumference of each drum screen are elevator ledges or 'buckets', which lift debris and marine organisms including fish clear of the seawater surface. Continuous wash-water sprays will then flush the collected material and organisms to collection troughs from which they will then be flushed to a gully. In normal operation the drum screens will rotate at a slow speed but if there is any indication of blockage both the rate of rotation and the flow rate of wash-water will be increased.

iii. Band Screens

2.6.15 Each of the two pumping stations will also have a rotating band screen to remove finer debris.

2.6.16 The screen is made up of a continuous belt of linked mesh plates which are rotated around two horizontal rollers, one positioned at the foot of the waterway and one above, and similarly aligned with a catch bucket and gully.

e) Filtering Debris Recovery Pit

2.6.17 A plant for managing screen debris is positioned next to each Cooling Water Pumphouse. It consists of a pre-discharge section and a pre-discharge basin. The pre-discharge section involves the continuation of the series of washwater gullies that will run from the drum and band screens to collect the fish and other marine organisms directed from the screens, together with materials from the raking screens.

2.6.18 The bottom of the basin will be at around 7m AOD in order to maintain a minimum water depth of 0.5m within the structure. The fall height of water from the channels into the basin will be less than 1m. The basin will be designed so as to channel fish to the base of an Archimedean screw pump system as illustrated in **Figure 2.14**.

2.6.19 A culvert will transfer the returning volume from the discharge basin at the top of the Archimedean screw pumps to a centrally located chamber prior to discharge to the dedicated FRR return tunnel.

f) Fish Recovery and Return System

2.6.20 A Fish Recovery and Return (FRR) system will be provided as a component of the open circuit cooling water infrastructure to recover and return fish and crustaceans drawn in with the cooling water and caught on the screens.

2.6.21 The general principles applied to the design of the system will be in accordance with general guidance published by the Environment Agency (Ref. 2.1 and 2.2) The overall arrangement of the FRR system is illustrated in the sectional drawing provided in **Figure 2.15**.

g) Return Tunnel

2.6.22 The return tunnel will be approximately 500m long from the shore. The tunnel will extend to a location which ensures that the outfall remains underwater at all times i.e. where the seabed is below the level of the Lowest Astronomical Tide of -6.1m OD. The tunnel will have an internal diameter of approximately 0.8m. Any bends in the tunnel will have a radius of 3m or greater.

h) Cooling Water Outfalls and Associated Tunnels

2.6.23 The single outfall tunnel associated with HPC will have a diameter of 7m and will be located approximately 1.8km off-shore at a depth of approximately 10m below OD. See **Figure 2.9.** The headworks will be aligned at 75 m intervals.

i) Fire-fighting Water Building

2.6.24 The fire-fighting water buildings, one for each unit, provide the fire fighting water supply, and also houses an emergency water provision for Nuclear Island facilities' cooling.

2.7 Permanent Drainage System

2.7.1 HPC would be provided with a number of permanent drainage systems comprising:

- surface water drainage;
- plant drainage;
- foul drainage; and
- groundwater drainage.

2.7.2 Surface water drainage would be removed by two separate systems, one dedicated to removal of roof water which is of high quality and the other to remove runoff from roads and paved areas. Surface water and plant drainage systems would be routed to the attenuation pond for treatment as required. Waste water (black and grey water) drainage would be removed by a foul water drainage system for treatment at a sewage treatment plant.

2.7.3 There will be penetrations in the Sea Wall to the foreshore to discharge the cooling water forebay overflow.

2.7.4 Groundwater levels would be controlled through a passive groundwater collection gallery that would extend around the southern and western boundary of the main development platform. The gallery would collect groundwater at a level of about 8m AOD, i.e. 6m below the surface of the main development platform and route it to the forebay prior to discharge with the cooling water.

2.7.5 Further details on drainage are provided in the **Hinkley Point C Site Drainage Strategy**. See **Appendix 2A**)

2.8 Remaining Balance of Plant and Other Plant

a) Attenuation Pond

2.8.1 The attenuation pond, located between the two pumphouses, collects and processes the waste water on the permanent development site and is shared between the two units. This will include a containment tank, and a settler/oil separator. This pond will ensure that any polluted effluent, including that generated from accidental spillages, is not discharged to the environment without prior treatment. The containment tank will permit time for analysis and treatment of the effluent before discharge. The function of the settler/oil separator will be to isolate and separate any oil from oil-contaminated water, before discharging only treated water to the effluent water discharge system.

b) Demineralisation Station

2.8.2 A demineralisation station will be provided on site to process raw water delivered via the local water company mains. This demineralised water will be used in the UK EPR reactor for cooling purposes.

c) Auxiliary Boilers

2.8.3 The Auxiliary Boilers will provide steam for heating the deaerator and turbine gland sealing for startup for both UK EPR reactor units and would be located in a single building adjacent to Unit 1.

d) Hydrogen, Oxygen and Chemical Products Storage

2.8.4 Within the site there will be gas storage compounds for hydrogen, nitrogen, oxygen and other process gases, and a chemical products storage building. These will all be separate from the Nuclear and Conventional Islands.

e) Sewage Treatment Plant

2.8.5 On the site there will be a facility to process domestic effluents. The Sewage Treatment Plant is located near to the Cooling Water Pumphouse of Unit 1.

f) Nuclear Island Water Storage Tank and Conventional Island Water Storage Tanks

2.8.6 The Nuclear Island Water storage tank stores treated water which is required for use in the Nuclear Island. There are two Conventional Island water storage tanks, which house treated water used in the steam cycle which power the turbines.

2.9 Fuel and Waste Storage

a) Interim Spent Fuel Store and Access Control Building

2.9.1 The Interim Spent Fuel Store (ISFS) is a facility that will provide long term safe and secure underwater storage for irradiated (spent) fuel assemblies that have been transferred from the Fuel Building until they are removed from site. The ISFS will be designed for a life of up to at least 100 years and the design will be such that this lifetime could be extended through fabric and plant refurbishment, if required. The building contains facilities for receipt, storage and retrieval of spent fuel, together with water supply and clean-up systems and heat removal systems.

2.9.2 The location of the ISFS will be adjacent to the Intermediate Level Waste Interim Storage Facility (ILW) building in order to facilitate security zoning during the station operation and after station decommissioning.

2.9.3 The ISFS and associated Access Control Building are at an early stage of design and the appearance and layout details are not fixed. Parameter plans have been provided for the ISFS and associated Access Control Building which indicate the minimum and maximum dimensions for these structures.

2.9.4 The ISFS envelope consists of the Interim Spent Fuel Store itself, protection shell, a gaseous discharge stack (footprint within envelope) and ancillary plant including air-water heat exchangers and a potential requirement for diesel unit(s), although it remains to be determined whether the ISFS will require dedicated diesel units.

However, provision has been made for this in the design. The ISFS building would be a strong building that protects it from external hazards (for example, aircraft crash) and this is contained within the envelope. The stack is defined as 55m in height based on dispersion modelling carried out to date. The final height will be determined following detailed dispersion modelling but it is not expected that it will be above 55m. The requirements for the ISFS, and similarly the Access Control Building, will be contained within the parameters provided.

2.9.5 The Access Control Building is sized based on the requirement to contain the security and access functions and is similar in size to the Outage Access Control Building.

b) Intermediate Level Waste Interim Storage Facility (ILWISF)

2.9.6 ILW generated during the operational phase will be placed in the ILWISF which will be designed for a life of about 100 years. Further details on the management of spent fuel and radioactive waste are provided in **Chapter 7** of this volume.

2.10 Remaining Buildings on Site

2.10.1 There are a number of ancillary buildings located across HPC required for security s, training, office and storage purposes. These are summarised in **Table 2.2** below.

Table 2.2: Summary of Remaining Buildings

Building Type	Building(s)	Description
Operations	Operational Service Centre	Multi-purpose building that is the operational service centre for the power station. It accommodates access areas to the Nuclear Island, storage areas, workshops and storerooms, laboratories, offices, a data centre, and associated support and welfare facilities, including the staff restaurant.
Ancillary, Office and Storage	Main Access Control Building	Primary access and control of daily entrance and exit of personnel and visitors, and vehicles on-site.
	Entry Relay Store	Facility for receiving small packages or deliveries. The building is positioned near the site entrance and straddles the perimeter fence so as to enable deliveries to be made without entering the power station site.
	Off-Site Vehicle Search Area	Building will be used to control the movement of all vehicles on Wick Moor Drove approaching or leaving the site.
	Auxiliary Administration Centre	Multifunctional building that includes ancillary facilities for operational staff and administration.
	Medical Centre	Building to be used to monitor the health and well-being of the workforce during construction and the operational lifespan of the nuclear power station.
	EDF Site Offices	Office facilities for site personnel during the construction period and continued usage during operation, including during outage periods. The EDF Site Offices are located to allow easy access to and from the site.
	Garage for Handling Facilities	Building used for the garaging of special handling equipment and vehicles throughout the operational

Building Type	Building(s)	Description
		period.
Ancillary, Office and Storage	Oil and Grease Storage and Oil Ancillary Building	Building for the storage of oil and grease during operation. The building will also accommodate the vehicles for the transfer of the oil to the required locations.
	AREVA Warehouse	Warehouse to be used by AREVA during the construction phase. After the construction phase, it is proposed to be retained for office, storage and workshop facilities.
	Raw Water and Potable Water Supply	Facility which provides a balancing (buffer) tank for the raw water supply from the local water company and will also supply raw water to downstream users.
	Meteorological station	Facility for housing environmental monitoring and recording equipment.
	Outage Access Control Building	A security facility for access to and from the site during construction and as a secondary access point during outages.
	Contaminated Tools Storage (x2)	Store for contaminated tools.
	Conventional Waste Storage	Store for conventional waste.
	Transit Area for Very Low Level Waste and Low Level Waste	Buffer stores for sorting and interim storage before collection and removal off-site.
Public and Training	Simulator Building/ Training Centre	An ancillary building which provides specialist training facilities.
	Public Information Centre (PIC)	Facility to help inform the general public and other interested parties about the nuclear process of producing electricity and its infrastructure. The PIC is located outside the perimeter fence, but inside the site boundary.
National Grid Substation	National Grid 400kV Substation	Facility to connect the nuclear power station to the national grid high voltage transmission system. Further details provided in **Section 2.13** below.
Other Site Structures	Helipad	Helipad for operational safety or security usage.
	Sea Wall	Incorporating the coastal footpath, the sea wall extends the length of the permanent development site. Further details provided in **Section 2.14** below.
	Car parking	Facilities for site personnel and visitors. Further details provided in **Section 2.15** below.
	Meteorological Station Mast	A meteorological instrumentation mast is provided to the north of the meteorological station to carry instruments to measure environmental conditions such as wind speed, direction and air temperature.
	EDF Pylons	Pylons are provided on-site to transport the power from the generators via the power transmission platform and along lines to the National Grid Substation.

2.10.2 In addition to these structures, there is a network of underground service tunnels across the site, which enable cabling, pipework and other services between buildings and plant and which also enable plant and personnel access. Maintenance access to these service tunnels would be obtained via the above ground surface Service Access Buildings.

2.11 Fencing

2.11.1 A perimeter fence will enclose the majority of the permanent development site as illustrated in **Figure 2.1**. This excludes the car parks, the National Grid substation, the Public Information Centre (PIC), and the Simulator Building/Training Centre. Additional High Security Area (HSA) fencing will be provided within the permanent development area around the Nuclear Island and ISFS facility and Access Control Building. A separate fence is provided for the National Grid substation. An illustrative fencing plan is shown in **Figure 2.16**. [

2.12 Lighting

2.12.1 External lighting will be provided for the permanent development site with lighting levels generally at the minimum necessary to enable safe operation. Lighting levels will vary from 5 lux for roads and paths to task lighting of up to 100 lux for limited areas. The security fence areas will be lit to the required security standards. Further detail is provided in the Operational Lighting Strategy (see **Appendix 2B)**.

2.13 Transmission Infrastructure

2.13.1 A new National Grid 400,000 Volt (400kV) Gas Insulated Switchgear (GIS) substation is required to connect the Hinkley Point C power station to the national grid high voltage transmission system. The substation will be installed to the south-east of the permanent development site. As illustrated in **Figures 2.17** and **2.18** this substation compound will comprise:

- GIS switch hall with an annex.
- Amenity building.
- Earth store.
- Workshop.
- Diesel generator building.

2.13.2 An internal tarmac roadway will extend around the periphery of the compound along the eastern, northern and western sides to facilitate vehicular access for delivery, removal and maintenance of plant and equipment. Car parking within the compound will be provided in designated spaces for six vehicles.

2.13.3 The substation will normally be unmanned, being controlled and monitored remotely by National Grid from their Electricity National Control Centre, other than when plant maintenance is undertaken.

a) Connection to the National Grid High Voltage Transmission System

2.13.4 Four overhead line gantries will be sited along the southern side of the substation compound to facilitate the transition from overhead line to gas insulated busbar and subsequent through wall entry into the switchgear building as indicated on **Figures 2.1** and **2.18**. These four line entries will form connections to the main interconnected transmission system at Taunton and Bridgwater-Melksham. Two further overhead line gantries will be sited along the eastern boundary of the substation compound and will form the overhead line interconnection with the existing Hinkley Point B 400kV Air Insulated Switchgear substation.

2.13.5 All proposed National Grid overhead lines and towers, including the terminal towers and substation connecting downleads, will be subject to a separate DCO application by National Grid following public consultation.

2.13.6 On the northern side of the compound will be two overhead line landing gantries to transfer EDF Energy overhead line connections between the power transmission platform and the substation and two EDF Energy underground cable circuits to connect the Auxiliary Transformers to the substation.

2.14 Sea Wall

2.14.1 The Sea Wall will be approximately 760m in length (see **Figure 2.19**) and will comprise:

- In-situ cast, non-reinforced, gravity mass concrete wall orientated along the alignment of the existing cliffs in order to protect the proposed new nuclear development site from coastal erosion.
- A pre-cast reinforced wave return wall on top of the mass concrete wall.
- Rock protection at the foot of the sea wall in order to absorb wave impact during storm events and thus protect the foundation of that structure from scour and consequent beach down-cutting.
- 50m long secant piled return walls at the eastern and western extent of the wall;
- Two stepped pedestrian access points to the foreshore.
- A maintenance vehicle access point.
- A parapet located at the crest of the sea wall to provide a further increment of protection against wave overtopping to the coastal footpath lying immediately behind. This will include a handrail or other similar safety-related feature.

a) Integration with Existing Sea Wall and Topography

2.14.2 As illustrated in **Figure 2.20**, the Sea Wall will have a crest height of 13.5m AOD. The ground level behind the wall will range from 12.3 to 12.4m AOD compared with the main power station development platform which will be 14m AOD.

2.14.3 At its western and eastern ends, the wall will turn inland and run for approximately 50m at the design crest level of 13.5m AOD. The retain sections of wall will comprise reinforced concrete piles constructed to form continuous walls.

b) Toe Scour Protection

2.14.4 Scour protection will be needed at the toe of the Sea Wall in order to absorb the impact of storm waves. The design in **Figure 2.20** illustrates a typical rock toe cross-section. This protection will be provided in the form of two layers of rock armour that will rest within a narrow excavated area of the foreshore immediately in front of the sea wall. These two layers will have a total thickness of approximately 2.5m along the 760m length of the wall. The armour will also be extended for a distance of 50m past the western end of the wall to provide increased erosion protection to the base of the natural cliff in that area. The armour will comprise rocks with a nominal diameter of 1.35m.

c) Maintenance Vehicle Access Ramp

2.14.5 At the western end of the Sea Wall, an access ramp will be provided for maintenance vehicle access to the foreshore (see **Figure 2.21**).

d) Pedestrian Access

2.14.6 Although there is no formal public access to the foreshore from the footpath along the cliff at present, the design of the HPC Sea Wall will allow for safe access once the structure is complete. As illustrated in **Figure 2.22**, steps will be provided at locations 250m and 510m from the eastern end of the wall. They will be accessed at these points via breaks in the crest of the wall to ensure that the upper step platforms (set at 12.3m AOD) are level with the coastal footpath (Public Right of Way WL 23/95).

e) Drainage

2.14.7 Drainage of the backfill will be achieved by the provision of 150mm diameter drainage pipes extending through the wall at spacings of one hole per 10 linear metres. The holes will have an invert level of between 4.5 to 5.5m AOD at the rear face of the wall and the outlets at the front of the wall will be 0.5m lower than the landward side. The pipes will ensure that groundwater does not exceed the 6m AOD sea wall design level.

2.14.8 To the rear of the pipes there will be a 1.5m deep imported fill drainage layer separated from the permeable backfill above by a geotextile layer which will prevent the washing in of fine material that could otherwise cause blockage. Both ends of the drainage pipes will be fitted with a metal grille to prevent blocking by debris.

2.15 Access and Parking

a) Access Arrangements

i. Site Access

2.15.1 The existing access road into the Hinkley Point Power Station Complex will also be the main access for the proposed development. As illustrated in **Figure 2.1** two roundabouts are proposed along this route. The first to the east of the HPC permanent development site will provide access to site personnel and deliveries. The second, to the south-east of the site, will provide access to the southern part of the HPC development site during the construction phase, and during the operational phase will provide visitor access to the Public Information Centre (PIC) and Simulator Building/Training Centre (STC) and as an alternative means of access to HPC.

ii. Emergency Access Road and Junction onto Existing Highway

2.15.2 In addition, it is proposed to construct an emergency access road from the south of the HPC development site as an alternative means of accessing HPC. This is only required for use in exceptional circumstances such as for the emergency services to respond to an incident at the power station. It is not intended to be used during the construction period.

2.15.3 The design of the road will have a load capacity sufficient for the largest/heaviest emergency vehicles and will have sufficient passing places to allow incoming and outgoing emergency vehicles to pass. The roadway will be of low-maintenance design, suitable for occasional use and compatible with the proposed landscaping of the surrounding area. There is no requirement for kerbs, footpaths or lighting along the road, but the design will provide adequate indication of the edges of the road and the location of passing places. The elevation of the road will be no less than 10m AOD and sufficient land drainage shall be provided to preclude the possibility of flooding making the road impassable.

2.15.4 There will be locked gates at the ends of the access road where it joins roads open to general use, to prevent unauthorised access of motor vehicles. Separate provision is made for pedestrian access.

iii. Bum Brook Bridge

2.15.5 Where the emergency access road crosses Bum Brook, a bridge will be provided sufficient to allow the largest/heaviest emergency vehicle to cross. The design of the bridge, as illustrated in **Figure 2.23**, would present minimal resistance to floodwater flow in order to avoid exacerbating the flooding potential of Bum Brook.

iv. Internal Road Layout

2.15.6 The main road access within the HPC site is provided by a ring road around the major buildings (the main circulatory road). This would be supplemented by additional roads within the power station site to service the ancillary buildings and secondary roads for vehicle access to buildings, as necessary.

v. Car Parking

2.15.7 A car park for operational staff would be located to the south-east of the HPC site, adjacent to the substation. This would comprise 505 vehicle parking spaces for operational staff and staff from the existing Hinkley point Power Station Complex.

2.15.8 In addition, a second permanent car park would be located to south of the site (south of the PIC and STC) and would comprise a total of 508 parking spaces for additional workers who would be required during the planned ‘outages’ (i.e. maintenance periods), and car and coach parking for visitors to the PIC and the Simulator Building/Training Centre.

2.15.9 A further smaller car park, comprising 180 spaces, will be provided to the east of the site to replace the existing Hinkley Point Power Station Complex overflow car park. Disabled parking will be included within the car parking provision.

2.16 Public Rights of Way and Bridleways

2.16.1 The restored landscape has been designed to provide a network of public rights of way (PRoW) and permissive paths to link with the surrounding network.

2.16.2 Green Lane would be stopped up during construction for safety reasons. At the completion of construction, the section of Green Lane that crosses the HPC development site would be upgraded to a bridleway. The coastal footpath would be closed for a maximum of three years during construction. The coastal footpath adjacent to Hinkley Point C will be incorporated into the Sea Wall. A new permissive footpath would be created along Bum Brook during construction to provide access for streamside walks. This would be retained once the station becomes operational.

2.16.3 All footpaths will be well managed, kept clear of vegetation and clearly signposted. The proposals for the PRoW and permissive paths consider the needs of less able people. Self-closing bridle gates are proposed rather than stiles, to avoid creating barriers.

2.17 Landscape Proposals

2.17.1 When the construction of HPC permanent development is complete, the wider HPC development site would no longer be required for construction purposes. The landscape proposals for this wider site are presented in **Figure 2.24** and summarised below.

a) Land Form

2.17.2 The landscape scheme would build up existing ridges and valleys to a maximum height of 35m AOD, have smooth transitions at the edges, and use characteristic shapes and gradients typical of the local landscape character. The landform would extend around the HPC permanent development site.

b) Landscaping Plan

2.17.3 The landscaping plan for the HPC development site would comprise:

- Retention of the majority of the Green Lane ridge and hedgerows, together with the majority of site boundary hedgerows.
- The landscape would be structured with an angular field pattern defined by hedgerow field boundaries. The pattern would be based on existing field patterns adapted to site requirements, linking to the surrounding hedgerow network. Additional hedgerows would be added to replace some of those lost due to changes in agricultural practices.
- Three extensive woodlands – Haysgrove Brake on the coastal slopes, and Bishops Wood and Shurton Wood on the inland ridge – would be arranged within the angular field boundary pattern, and would represent a substantial increase in extent of woodland on the site.
- Extensive wildflower meadows would include south facing calcareous grassland to the south of Green Lane, lowland meadows and wet meadows in Holford Valley and along Bum Brook.
- Five wildlife friendly ponds with marginal planting would increase wetland on site.
- Areas of coastal scrub on the coastal slopes and hedgerow/scrub woodland edges inland would provide an increase in this habitat.
- A wide palette of native or naturalised plant species. **Table 2.3** provides a summary of proposed land uses and habitat types.

Table 2.3: Summary of Proposed Land Uses and Habitat Types

Areas	Existing	At Restoration
Broad-leaved woodland	3.5 ha	39.7 ha
Plantation woodland	3.5 ha	n/a
Scrub (including scrub/hedges)	1.1 ha	0.9 ha
Calcareous Grassland (*including Bishop's Wood)	*3.5 ha	17.7 ha
Improved Grassland	30.6 ha	n/a
Species-poor semi-improved grassland	16.1 ha	n/a
Semi-improved grassland/ Species rich hay meadow	n/a	30.9 ha
Arable (**Farmland Birds Annual Cover Crop)	97.6 ha	**3.8 ha
Wetland (including ponds)	<0.01 ha	0.43 ha
Linear Features		
Native Species-rich Hedgerow	7.74 km	13.10 km
Species-poor Hedgerow	3.40 km	n/a
Watercourses (excluding Bum Brook and including Holford Valley ditches)	2.02 km	1.2 km

c) Holford Stream Culvert

2.17.4 The Holford Stream culvert would be retained after the construction phase to allow for excess material from the ground terracing and construction phase to be retained on-site and used within the landscaping area to the west of the permanent development site.

2.18 Off-site Highway Improvements

2.18.1 A range of improvements will be implemented across the highway network which may be influenced by construction traffic related to the HPC Project, as illustrated in **Figure 2.25**. These improvements will be permanent, that is, they will not be decommissioned and removed following completion of construction of HPC. All improvements will generally be of a limited spatial scale and the majority would be carried out within the existing highway boundary.

2.18.2 A physical description of each of the highway improvements proposed is provided below. The justification for each of the improvements is set out in the **Transport Assessment**.

2.18.3 The improvements are of two principal types, including:

- modifications to existing road alignments or junction/roundabout arrangements; and
- enhanced safety measures.

2.18.4 Details of the individual works elements are presented in **Figures 2.26 – 2.35** and described in more detail below.

a) A38 Bristol Road/The Drove Junction, Bridgwater

2.18.5 As illustrated in **Figure 2.26** the proposed works at the A38 Bristol Road/The Drove junction comprise a very small increase in the width of the highway to improve the operation of the junction, through increasing the width of the right turn lane from Bristol Road into the Drove and to reduce queuing.

b) A39 Broadway/A38 Taunton Road Junction, Bridgwater

2.18.6 As illustrated in **Figure 2.27** there would be signal improvements at the A39 Broadway/A38 Taunton Road junction, which would include very minor works including the modification and possible replacement of the traffic signals and their associated control equipment, to improve the operation of the junction and reduce queuing.

2.18.7 These works would also include improvements to pedestrian facilities at the junction of the A39 Broadway and the A38 Taunton Road to the north-east of the existing Morrisons store. These works would comprise:

- various new tactile paving;
- minor carriageway realignment to the southern, western and eastern junction approaches;
- minor curb realignment; and
- minor changes to pedestrian islands.

c) A38 Bristol Road/Wylds Road Junction, Bridgwater

2.18.8 As illustrated in **Figure 2.28**, the proposed works at the A38 Bristol Road/Wylds Road junction comprise an increase in the width of the carriageway to increase the width of the right turn lane and provide for thee lanes, each 3.5m wide. The works also include an improvement to cycle routes along Bristol Road.

d) Wylds Road/The Drove Junction, Bridgwater

2.18.9 As illustrated in **Figure 2.29**, the proposed works at the Wylds Road/The Drove junction relate to various improvements to improve the operation of this junction and would comprise:

- provision of a left-turn slip road from Western Way into Wylds Road;
- new tactile paving; and
- realignment of existing pedestrian islands.

e) A39 New Road/B3339 Sandford Hill Roundabout

2.18.10 As illustrated in **Figure 2.30**, these proposals comprise a new four-arm roundabout at the junction of Quantock Road, Charlynch Lane, Sandford Hill and New Road, approximately 1km to the south-east of Cannington and would comprise:

- minor realignment of existing carriageway;
- provision of new four-arm roundabout;

- Some vegetation clearance to south west of Sandford Hill to achieve satisfactory visibility splays;
- provision of new signage and road markings;
- provision of new street lighting; and
- surface to be tarmacked with new kerbing.

f) M5 Junction 23 Roundabout

2.18.11 As illustrated in **Figure 2.31**, the M5 Junction 23 roundabout proposals relate to minor physical works required to facilitate partial signalisation of the junction. The proposals would be entirely within the existing carriageway and would comprise:

- minor carriageway widening;
- installation of traffic signals including signal control loops in approach carriageways;
- application of anti-skid coatings, road markings and additional signage; and
- provision of new street lighting.

2.18.12 These works also include minor improvements to the lane markings at Dunball Roundabout which will improve links to J23 of the M5, although these do not comprise physical works and therefore are not included as part of the DCO application. They have however been assumed to be part of the package of highway improvements for the purposes of the **Transport Assessment**.

g) Washford Cross Roundabout

2.18.13 As illustrated in **Figure 2.32**, the proposals provide for a new, four-arm roundabout at the existing junction of the B3190 and A39, approximately 1.5km to the west of Williton. These proposals would comprise:

- realignment of existing carriageway and creation of a new, four-arm roundabout;
- new full-depth carriageway constructed off the line of the existing road;
- existing carriageway to be broken out and area grassed or landscaped at eastern approach;
- existing carriageway at northern, southern and western approaches to be resurfaced;
- clearance of existing vegetation and removal of hedgerows;
- extension of field access to new boundary at northern approach;
- provision of new signage and road markings; and
- provision of new street lighting.

h) Claylands Corner Junction

2.18.14 As illustrated in **Figure 2.33**, there would be minor junction realignment works at Claylands Corner, approximately 500m east of Hillside Farm and 2km to the east of Stogursey. The works would comprise:

- minor widening at eastern edge of carriageway opposite junction;
- relocation of existing give-way line, approximately 2m to east;
- minor relocation of kerb line to western edge of carriageway by approximately 1m;
- widened carriageway strip to be finished in tarmac to match existing;
- finish with new edging strip; and
- provision of various new signage.

i) C182 Farringdon Hill Lane, Horse Crossing

2.18.15 As illustrated in **Figure 2.34**, there is a proposal for a new horse crossing at the junction of the C182 and Farringdon Hill Lane, to the east of Shurton, approximately 1.5km south of the HPC development site. The proposals would comprise the following works:

- existing trees and vegetation to be cleared to accommodate horse holding area;
- existing surfacing material to be removed within holding area and replaced with hard surfacing;
- push buttons to activate equestrian crossing warning sign to be located 10m back from edge of C182 to north and south;
- equestrian crossing warning signs adjacent to each side of carriageway on C182, before approach to horse holding area; and
- hedgerow to be removed or cut back along C182 to achieve necessary visibility splays.

j) Cannington Traffic Calming Measures

2.18.16 As illustrated in **Figure 2.35**, there around be improvements to pedestrian facilities and minor physical works to implement highway safety improvements, including a 20mph speed restriction, within the existing highway in Cannington.

2.18.17 The proposals would comprise the following works:

- a new footway to the northern edge of High Street, opposite Clifford Park;
- provision of skid-resistant surfacing;
- revised parking and waiting restrictions;
- a new puffin crossing at High Street;
- provision of tactile paving and widening of existing uncontrolled crossing at junction of Church Street and High Street;
- new speed restriction signs enforcing existing speed restrictions;
- new zebra crossing on Rodway before junction with Toll House Road; and
- tactile paving at junction of Rodway and Toll House Road.

2.18.18 In addition to these physical works, Somerset County Council are also proposing to implement two Traffic Regulation Orders to enforce parking controls and speed limits on the C182. These do not comprise physical work, other than signage and road markings, and therefore are not included as part of the DCO application. They have however been assumed to be part of the package of highway improvements for the purposes of the **Transport Assessment**.

k) Huntworth Roundabout

2.18.19 As illustrated in **Figure 2.36** the proposals for the Huntworth Roundabout comprise minor carriageway widening to reduce queuing at the junction and improve pedestrian crossing facilities. The proposals would be entirely within the existing carriageway and would comprise:

- widening of carriageway at eastern arm of roundabout;
- removal of part of existing verge and trimming back vegetation as necessary;
- provision of 2m wide footway between eastern and southern arms of roundabout;
- reconfiguration of existing traffic splitter island, including improved pedestrian crossing;
- adjustment of footway to north of eastern arm; and
- revision of white lining as appropriate.

CHAPTER 3: CONSTRUCTION

CONTENTS

TABLES

PLATE

FIGURES

[This page is intentionally left blank]

3. CONSTRUCTION

3.1.1 This chapter provides information on the construction of Hinkley Point C. It sets out the following:

- the HPC construction programme; and
- summary of construction land use and physical parameters.

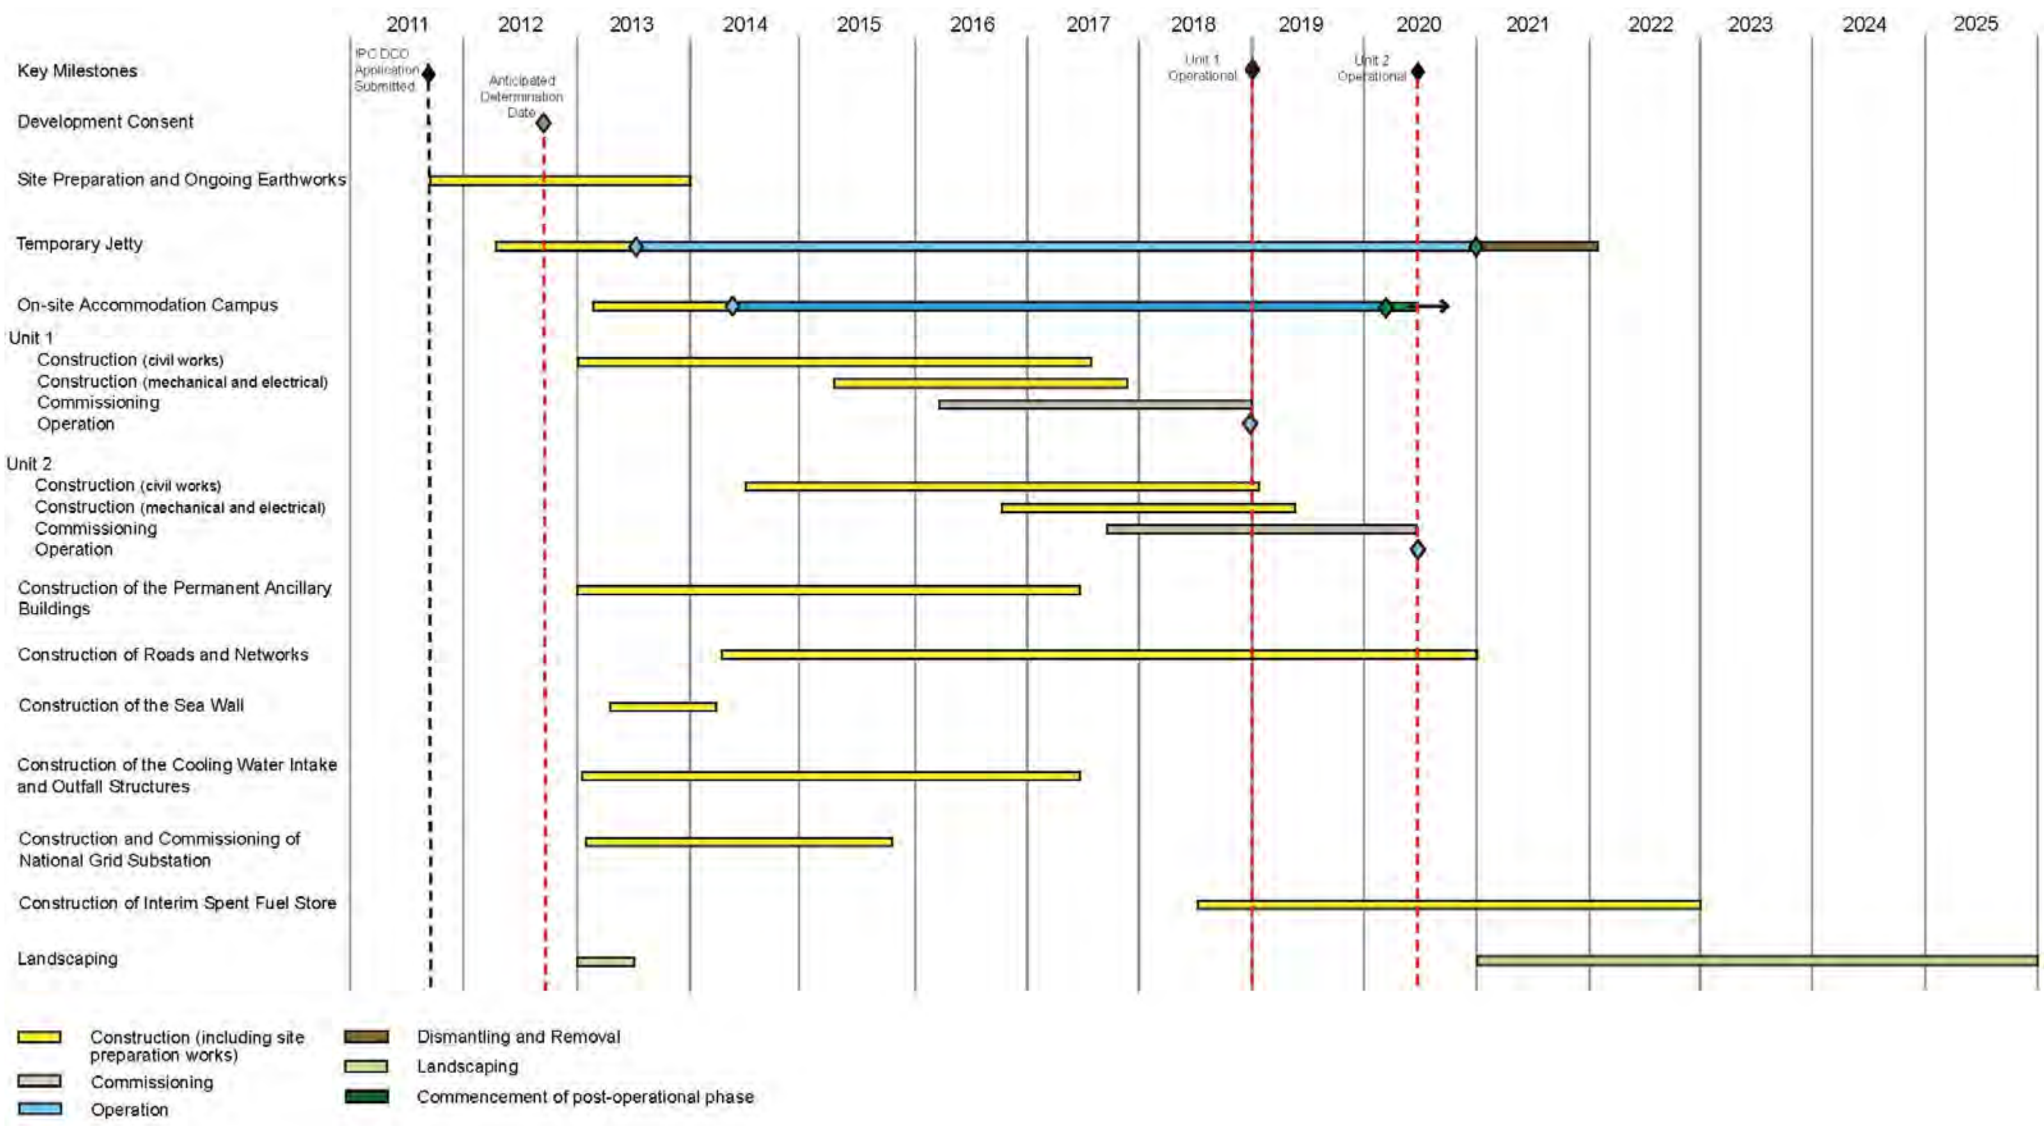
3.1.2 A description of construction activities and indicative phasing of work is provided in the **Construction Method Statement**. See **Annex 2**.

3.2 HPC Project Construction Programme

3.2.1 The HPC construction programme is anticipated to commence with the site preparation works in late 2011, followed by the main construction in early 2013, through the Development Consent granted by the IPC. The overall construction phase is anticipated to take approximately nine years, with the first UK EPR reactor unit operational in 2019, and the second UK EPR reactor unit operational approximately 18 months later. However, completion of the spent fuel store will extend some two years beyond initial operation of Unit 2. Some landscaping works to the south of the southern construction area will be undertaken early in the construction phase. The final landscape works will commence once the construction phase is complete and HPC is operational.

.

Plate 3.1: Hinkley Point C Indicative Construction Programme



3.3 Summary of Construction Land Use and Physical Parameters

a) Land Use

3.3.1 This section sets out construction land use and describes the physical characteristics of the development across the site.

3.3.2 The layout of the site will vary over the construction period but, taking this into account, the anticipated principal uses of the overall land area at the peak phase of construction, in 2016, are presented in **Table 3.1** below.

Table 3.1: Proposed Areas of Land Use during the Peak Phase of Construction

Land Use	Area (ha)
Final permanent power station area	67.5
Construction contractor accommodation, working and storage	28.4
Landscape screening and protected areas/reserves	27.5
Construction site entrance and access roads	20.6
Stockpile of material for re-use	13.3
Topsoil storage	9.7
On-site accommodation campus	3.7
Low-lying land unsuitable for construction use	2.8
Sea wall foreshore construction area	1.7
Total	**175.2**

b) Physical Parameters

3.3.3 The height of the temporary buildings and structures will vary across the HPC development site depending on specific requirements. **Figures 3.1** and **Figure 3.2** show in plan and cross-section the height limits for various areas of the development site.

3.3.4 Zone 1 is the area where the main power station buildings and structures would be located, and includes the area immediately to the west which would be used by the main construction contractors. Zone 2 is within Zone 1 and includes the Nuclear Island buildings, Conventional Island buildings and the areas immediately to the south and west where liner fabrication would be undertaken. Zone 2 is where very large mobile cranes (including a polar crane) would be used for installation of the liner roof and main exhaust stack.

3.3.5 Zone 3 includes the area to the west of Zone 1 where aggregates, sand and cement brought in by the jetty would be stored and the main construction contractors would site their storage and prefabrication facilities. Zone 3 also includes the area south of Zone 1 where the platform level is +20m AOD and various ancillary power station buildings would be constructed. It also includes an area where the main nuclear steam supply systems contractor would be based.

3.3.6 Zone 4 is the area of the National Grid substation at +14m AOD and includes the temporary works area for the National Grid contractors.

3.3.7 Zone 5 is the area where the main mechanical and electrical installation contractors would be based. During the early construction works, this area may also be used by the main civil works contractor for laydown and storage.

Table 3.2 summarises the heights and uses applicable to each of the zones.

Table 3.2: Construction Zones and Height Parameters

Construction Zone	Explanation of Parameter	Construction Zone Parameter (Max. Height)[1]
Zone 1: Construction of the main nuclear island, conventional island, balance of plant and ancillary buildings.	Working envelope for main building construction requirements. Structures to include: temporary buildings, construction warehousing and storage buildings; and tower cranes, mobile cranes and other specialised lifting equipment.	140m AOD
Zone 2: Construction of the main nuclear island and conventional island - Exceptional Structures	Working envelope for exceptional structures that are required for the lifting and installation of reactor domes and other time limited activities that require specialised cranes or lifting equipment that go above the height parameters set out in Construction Zone 1. Typically these would include large mobile cranes for installation of the dome associated with the two reactor units.	175m AOD
Zone 3: Contractor areas to the north of green lane.	Working envelope for liner fabrication facilities, workshops, storage buildings, offices and mess facilities, concrete batching plants and associated aggregates stockpiles, covered stockpiles and cement/pulverised fuel ash silos.	75m AOD
Zone 4: National Grid sub-station area.	Working envelope for substation construction, transmission tower erection, workshops, storage buildings, offices and mess facilities.	80m AOD
Zone 5: Contractor areas to the south of green lane.	Working envelope for workshops, storage buildings, offices, mess facilities and fixed cranes.	55m AOD
Zone 5: Contractor areas to the south of green lane - Exceptional Structures	Working envelope for exceptional structures in Zone 5, such as mobile cranes.	75m AOD
Zone 6: On-site accommodation campus	Working envelope for the onsite accommodation campus.	32m AOD
Zone 6: On-site accommodation campus - Exceptional Structures	Working envelope for exceptional structures in Zone 6, such as mobile cranes.	55m AOD

Note: Exceptional buildings and structures comprise very large cranes and similar equipment which will be used for relatively short periods during the construction works for specific activities, such as lifting in the reactor building liner dome roof, and will then be removed.

[1] Figures quoted are height above ordnance datum level

3.3.8 Zone 6 includes the southern site entrance, the on-site accommodation campus and an area for offices and laydown/storage. Maximum heights within this area would be limited in order to minimise the visual impact on the village of Shurton.

c) HPC Accommodation Campus

3.3.9 A workers accommodation campus is proposed within the HPC development site. The location of the campus and general layout arrangement is shown in **Figure 3.1** and cross section BB in **Figure 3.2** illustrates the heights of key structures in relation to the landform.

3.3.10 The primary function of the campus is to provide living accommodation and facilities for the workforce involved in the construction of the power station. It would consist of the following:

- 15 three-storey accommodation buildings housing up to 510 workers;
- a two-storey multi-purpose amenity building;
- car parking for 319 cars, including accessible parking bays and motorcycle parking;
- external recreational space consisting of two, all-weather, 5-a-side football pitches surrounded by a fenced enclosure;
- single-storey plant and utilities enclosures and refuse compounds; and
- soft and hard landscaped areas providing both functional and amenity spaces.

3.3.11 The proposed Masterplan of the campus is shown in **Figure 3.3**.

3.3.12 Upon completion of construction, the campus will be removed and the land will be landscaped in accordance with the site wide Landscape Restoration Plan as described in **Chapter 2** of this volume.

CHAPTER 4: OPERATION

CONTENTS

PLATES

APPENDICES

[This page is intentionally left blank]

4. OPERATION

4.1 Introduction

4.1.1 This chapter provides a description of the operation of HPC which will have a design life of 60 years. Unit 1 is scheduled to commence operation in 2019 and Unit 2 18 months later in 2020. A summary of the process of electricity generation is presented together with a description of the sources and characteristics of liquid discharges and gaseous emissions during normal operation and plant commissioning. The anticipated workforce and visitor profile during the operational phase is described along with vehicle parking arrangements for staff and visitors.

4.2 Electricity Generation

4.2.1 Electricity will be generated at HPC from heat energy produced from the two UK EPR reactors. The heat will be used to raise steam which will then be utilised to power turbines to generate electricity. The expected electrical output of HPC will be approximately 1,630 megawatts (MW) per unit giving a total site capacity of 3,260MW net of the electricity used on the site by plant such as the reactor coolant pumps.

4.2.2 Electricity generated in the two turbine halls (one for each UK EPR reactor) will be converted by transformers to high voltage (400kV), before being exported by two EDF Energy overhead lines connected to the National Grid 400kV substation. Connections to the 400kV main interconnected national grid transmission system will be made via six overhead line gantries and three overhead line terminal towers (pylons). These will be situated along the southern and eastern sides of the National Grid substation. Details of the proposed National Grid substation and associated infrastructure are provided in **Chapter 2** of this volume.

a) Heat Energy Generation

4.2.3 A UK EPR reactor is capable of producing approximately 4,500MW of heat from nuclear fission which takes place in the reactor core. The core is contained within a thick-walled steel pressure vessel which is approximately 10m high and 5.5m in diameter. Diverse systems are installed for the safe shutdown of the reactor in the event of any faults. Within the core of each UK EPR reactor there will be 241 fuel assemblies each containing a 17 by 17 array of fuel rods comprising uranium dioxide pellets in a sealed cladding tube. The uranium is enriched in the fissile isotope Uranium-235 (U-235) from its naturally occurring level of 0.7% up to 5%. A fissile isotope is an isotope where, when it collides with a low energy neutron, its nucleus splits (“fissions”) into smaller fragments (“fission products”) and releases further neutrons together with energy. In a nuclear reactor, these neutrons are slowed down (“moderated”) to the point where they can cause a further nucleus to fission which results in a sustained chain reaction and the release of nuclear energy as heat.

4.2.4 The UK EPR design is such that once the fuel is loaded in the reactor core the reactor can operate at full power continuously in a ‘fuel cycle’ of up to 18 months. Spent fuel removed from the reactor core will undergo 10 years of storage to cool in the pools inside the plant before transfer to the Interim Spent Fuel Store (ISFS).

b) Refuelling and Maintenance Outages

4.2.5 During the 60 year operational life HPC will undergo refuelling and maintenance shutdowns (otherwise known as 'outages') at regular intervals. The length of these outages will vary according to the maintenance and inspections required.

i. Refuelling Outage

4.2.6 During each refuelling outage all fuel assemblies will be temporarily offloaded into the fuel storage pool (one for each reactor). When returned to the core, a proportion of the fuel assemblies, normally a quarter to a third, will be replaced with new fuel. Thus, each fuel assembly will normally spend three 18 month cycles in the reactor before being replaced. Refuelling outages will take place approximately every 18 months.

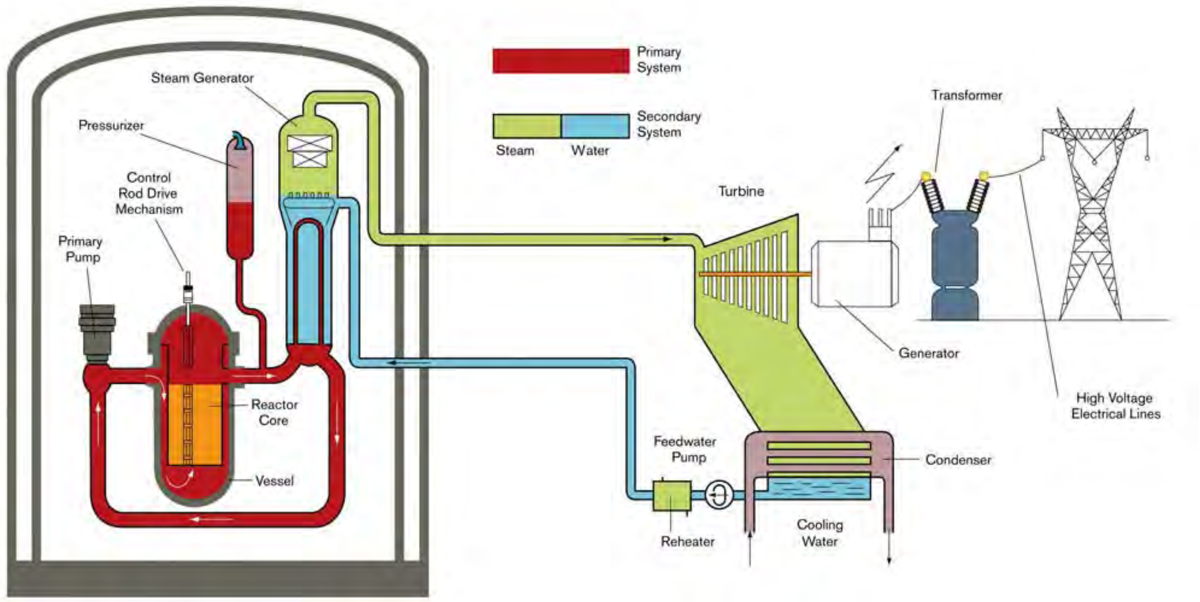
ii. Maintenance Outage

4.2.7 Maintenance outages will include 'preventative maintenance' incorporating inspections, tests, maintenance, repairs and replacements of equipment in order to comply with the Nuclear Site Licence and other regulatory requirements. The aim is to ensure that, throughout the installation's service life, the objectives of nuclear and industrial safety, environmental protection, and security are achieved. Maintenance outages will normally be undertaken in conjunction with refuelling outages. The length of the maintenance outage will vary depending on the scope of the work required.

4.3 Cooling Systems

4.3.1 For the UK EPR reactors at Hinkley Point there will be three cooling systems, comprising primary, secondary and open circuit systems. These are shown schematically in below.

Plate 4.1: Schematic Illustration of the Functioning of the UK EPR reactor



a) Primary System

4.3.2 The primary system, housed in the reactor building, is a closed water-filled pressurised system which enables the heat produced by the nuclear fission reaction inside the fuel assemblies in the reactor core to be extracted. The system comprises the reactor pressure vessel and four separate cooling loops, each containing a reactor coolant pump and a steam generator. The high pressure conditions of the system, which are controlled by a single pressuriser, prevent the cooling water from boiling even though the temperature of the water is around 330°C. The water within the system, which is heated by the fission occurring in the reactor, passes through tubes within the steam generators. The generators act as heat exchangers whereby heat is transferred through the tube walls into the water of the separate secondary system which flows outside and between the tubes. The primary coolant water, having passed through the steam generators is then pumped back to the reactor vessel. The metal cladding of the fuel assemblies, the reactor vessel and primary circuit and the containment building all form barriers to the potential release of radioactivity.

4.3.3 The water in the primary circuit also slows down (moderates) the neutrons released in the nuclear fission process, which is necessary to sustain the fission reaction. Control is achieved by inserting control rods from the top of the reactor and through changing the concentration of boron in the primary coolant. Both the control rods and the boron absorb neutrons and therefore reduce the rate of fission.

b) Secondary System

4.3.4 The secondary system is a closed system which is independent of the primary system and it operates at a lower pressure. Consequently, when heated by the primary system in the steam generators, the water in the secondary system boils to produce saturated steam. The steam is first dried inside the steam generators and then delivered to the turbine halls (one turbine hall for each UK EPR reactor unit). Here it powers a single large turbine rotating at 1,500 revolutions per minute (rpm). The turbine is coupled to the generator which produces electricity. After leaving the turbine, the steam is cooled and condensed back to liquid water in the condenser. It is then returned as feedwater to the steam generators.

c) Open Circuit System

4.3.5 The open circuit cooling system is independent of the primary and secondary systems and draws water directly from the sea. It absorbs heat from the secondary system in the condenser and the heated water is then discharged back to the sea.

4.3.6 Sea water will be supplied through the two off-shore intake tunnels, each of which has two intake heads. The relative positions of the intake heads associated with the two tunnels will ensure that no two intakes would abstract sea water from the same tidal streamlines, on either ebb or flood tide.

4.3.7 Each intake head will be designed to abstract 32.5m^3/sec of sea water (a flow rate that will, in practice, vary according to tidal state because of the consequent change in head at the cooling water pumps). The two intake heads for each tunnel and reactor unit will therefore provide for a combined flow of approximately 62.5m^3/sec of cooling water.

4.3.8 At its onshore end, each intake tunnel feeds directly into the forebays (one for each reactor unit). The intake cooling water will contain a high degree of suspended solids, which may accumulate to some extent in the forebays. It is common practice in the UK power industry at coastal sites to undertake periodic desilting of the forebays. Should desilting be required at HPC, the preferred option will be to return the sediment to the cooling water system for discharge back to the Bristol Channel.

4.3.9 The intake water is filtered as it is drawn from each forebay into an adjacent pumping station (which supplies the cooling water for one UK EPR reactor unit) in order to prevent the blockage of key elements of plant further downstream, primarily the main condensers and other allied heat exchangers. Coarse raking screens within the intake channels directly downstream of the forebay remove debris and larger marine organisms which will be routed to the filtering debris recovery pit which is periodically lifted and emptied. Further screening of material is then achieved using rotating coarse (drum) screens and fine (band) screens. The drum screens provide for the capture (impingement) and retrieval of fish, smaller marine organisms and remaining debris before being channelled to a pre-discharge basin, lifted above the level of the perimeter of the pumping station by Archimedean screw, and then returned to sea via the dedicated fish return tunnel under the seawall and intertidal shore.

4.3.10 The filtered cooling water from the pumping station is pumped through underground pipes routed in galleries to the turbine hall and Nuclear Island. The cooling water pipework is divided between different galleries based on the segregation requirements of the safety systems. Once the cooling water has served its heat removal function and passed through the condensers or other heat exchangers it is returned to the sea via two outfall ponds (also referred to as ‘surge chambers’). The outfall ponds serve to regulate the water level and control the pressure head on the discharge side of the Cooling Water Outfall Tunnel. The outfall ponds also receive waste water and effluents from different systems around the site after they have received any treatment that may be required.

4.3.11 Two onshore discharge culverts carry the water from the outfall ponds towards the head of a common discharge tunnel which extends approximately 1.8km offshore. The water is discharged offshore via two outfall structures, or ‘headworks’ which will be located approximately 75m apart at the end of the offshore outfall tunnel.

4.4 Operational Liquid Discharges

4.4.1 In normal operation all liquid effluents will be discharged to the sea in Bridgwater Bay via the outfall ponds and the cooling water outfall infrastructure. Sources and characteristics of liquid effluents which will be generated and discharged with the cooling water are described below and details are presented in **Appendix 4A**.

a) Production of Demineralised Water

4.4.2 The primary and secondary circuits both require a feed of fresh demineralised water. Demineralised water would be produced from mains water using a combination of membrane technology and ion exchange resins. This process will be undertaken in the Demineralisation Plant and will generate effluents characterised by either high acidity or alkalinity as a result of the use of sulphuric acid and sodium hydroxide to regenerate the resins and membranes. Batch treatment of these effluents using acids and alkalis would result in a neutral pH.

4.4.3 No further treatment of demineralisation effluents is proposed and the discharge will contain dissolved solids removed from the mains water as well as substances such as sulphates, sodium and chlorides.

b) Primary Cooling System and Other Radioactive Liquid Effluents

4.4.4 Increases in the boron concentration for controlling fission in the reactor core are achieved by dosing the primary coolant with boric acid. To counteract any changes in pH, the primary coolant is also dosed with small amounts of lithium hydroxide. Decreases in the boron concentration are achieved by topping up the primary coolant with low concentration borated water and releasing primary coolant to a coolant storage and treatment system.

4.4.5 There are also a number of corrosion products associated with the primary circuit including iron, nickel, cobalt, chromium, manganese, antimony and silver. These corrosion products are minimised at source through the careful selection of materials that are used to make the reactor systems and those components in contact with the primary coolant. The corrosion products can become activated by neutrons as they pass through the reactor in the primary circuit. Treatment prior to discharge will be undertaken to minimise the amount of corrosion products discharged.

4.4.6 Some further radioactive elements may be generated in the primary coolant by activation or fission processes. Measures are taken to minimise the generation of these radioactive elements at source. Once generated, abatement systems are used to minimise the amount of radioactive effluent discharged. Note that in addition to the primary circuit, radioactive effluents may also be generated from the fuel pool purification systems, the operation of a radioactive laundry facility and washings from plant decontamination. Techniques are applied to minimise the amount of radioactivity produced. In each case, the plant is designed and will be operated taking all reasonably practicable steps to minimise the generation and discharge of radioactive materials, in accordance with the environmental permits granted by the Environment Agency.

4.4.7 There are three main systems which remove contaminants from the water in the primary circuit and to treat effluents prior to discharge:

- Chemical and volume control system – this maintains the chemistry of the primary coolant by taking some of the primary coolant, known as let-down, cleaning it and returning it back to the system. Water is treated by the use of ion exchange resins and filters. Boric acid and lithium chemistry can be modified as required to meet the prescribed conditions in the reactor. This system also provides volume control for the primary coolant and contains any leaks from reactor coolant pump seals.
- Coolant storage and treatment system – this treats the liquid effluent from the primary circuit. The purpose of treatment is that, as far as possible, the boron and water may be recycled through the primary reactor circuit. Treatment for recycling involves demineralisation by ion exchange resins and filtration, evaporation and degassing. The evaporator is used to recover the enriched boric acid for re-use within the reactor coolant system.
- Liquid waste processing system - this is designed to ensure optimisation of the management of effluents by enabling treatment through a variety of techniques,

such as filtration, ion exchange and evaporation. The system allows effluents to be retreated and pass through different treatment techniques before being sampled and monitored and, if acceptable, discharged.

- After treatment to reduce the radioactive content of the effluent, it is sampled and monitored prior to final discharge with the cooling water.

c) Secondary Cooling System

4.4.8 A small proportion of the condensed water is bled continuously from the secondary circuit and replaced with fresh demineralised water. This is to prevent saturation of the secondary circuit with dissolved salts and to prevent the formation of foams or solids in the system that would make it difficult to dry the steam before it enters the turbine, which is required to prevent damage to the turbine. The water bled out of the system is known as 'blowdown' which is largely made up of demineralised feedwater.

4.4.9 The secondary circuit may also be dosed with hydrazine, ammonia, morpholine and ethanolamine which would be added to prevent corrosion and control the pH in the secondary circuit, as follows:

- Ammonia, morpholine and ethanolamine may be added to control pH, which helps to prevent corrosion; and
- Hydrazine would be added, as it is a very effective oxygen scavenger and therefore prevents corrosion associated with oxidation of metals in the steam generator (i.e. rusting). During shutdown, hydrazine may also be used to condition the steam generators.

4.4.10 The blowdown water from the steam generators will be processed and treated to remove non-radioactive corrosion products and dissolved salts before the water is recycled in the secondary circuit. Treatment involves filtration and the use of ion exchange resins.

4.4.11 As with the primary system the non-recyclable blowdown effluent would be transferred to a separate system which monitors and further processes effluents where required, before discharge. If necessary, this would be subject to hydrazine destruction; the method for hydrazine destruction would be determined during detailed design of the plant.

d) Oily Water Drainage System

4.4.12 There are a number of areas on the site where oils or hydrocarbon fuels will be used and stored, including the following:

- Back-up diesel generators.
- HPC and National Grid transformer compounds.
- Electrical substations.
- Oil and grease store.
- Oil and hydrocarbon fuel offloading areas.
- Workshops.

4.4.13 The drainage infrastructure (see also **Site Drainage Strategy**) in these areas will be segregated from other drainage, preventing the contamination of other effluents and clean surface water runoff. Any oily water in the segregated drainage system will be routed via a settling tank located in the Attenuation pond building. Once the tank reaches a predetermined level the contents would be pumped to an oil/water separator, following which the oil would be pumped to a mobile container and disposed of off-site at an appropriately licensed waste management facility. The treated effluent will have a hydrocarbon content of < 5 mg/l and will be discharged via the outfall pond.

e) Sanitary Effluent Treatment

4.4.14 The on-site workforce would generate sanitary effluent which would be treated in a Sewage Treatment Plant before being discharged. The Sewage Treatment Plant will be designed and sized to accommodate peak numbers of people on-site, for example during a major outage (shutdown for maintenance purposes), as well as operating effectively to treat effluent from the lower numbers of people expected during normal operations. The foul water drainage network would send effluent to the Sewage Treatment Plant where it would be treated a before being discharged via the Outfall Pond.

4.4.15 The sewage system will typically collect black and grey wastewater from lavatories. After treatment in the Sewage Treatment Plant; the discharge would typically be characterised by a relatively high five-day Biochemical Oxygen Demand (BOD_5 - a measure of the quantity of dissolved oxygen required to break down the residual organic material in the water) when compared to the other effluent streams generated at the site.

f) Surface Water

4.4.16 As described in **Chapter 2** of this volume (and the **Site Drainage Strategy**), there will be a surface water drainage system which will comprise two separate elements, one dedicated to the collection and removal of uncontaminated rainwater gathered from the roofs of buildings and the other to remove runoff from roads and paved areas. No treatment of drainage generated from roofs will be undertaken under normal circumstances although the retention and treatment of such drainage in the HXO building prior to discharge to the outfall pond will be possible. The drainage infrastructure for roads and car parks will be provided locally with oil/water separators for the higher risk areas where minor spills and leaks (principally from road vehicles) could occur. Again retention and treatment within the HXO building will be possible under abnormal conditions.

g) Groundwater

4.4.17 To prevent excessive groundwater pressure building up upon the sub-surface structures and foundations, groundwater levels would be controlled through a passive groundwater collection gallery that would extend around the southern and western boundary of the main development platform. The culvert would collect groundwater at an appropriate level (around 8m AOD) and route it to the Forebay of Unit 2 and then to the outfall pond. No treatment of groundwater is expected to be required prior to discharge. If this proves to be necessary, retention and treatment would be undertaken in the building.

h) Cooling Water Discharge

4.4.18 Operational requirements determine that at full operating load the cooling water will be discharged at 10 to 12.5°C above the intake water temperature, and the combined cooling water volume for both UK EPR units will be approximately 125 m^3/s. In practice, both the temperature and volume would vary tidally due to variable load on the cooling water pumps themselves: where pumping rates are reduced there is a corresponding increase in discharge temperature. For the purpose of the EIA, the twin outfall headworks discharging a flow rate varying tidally between 116m^3/s and 134m^3/s during normal operation has been assumed.

4.4.19 In addition to the substances associated with the effluents described above, the returned cooling water may also contain residual biocides arising from low-level chlorination (if a need is found to control biological fouling) of that cooling water stream.

4.4.20 Low level chlorination is one of the most commonly used and effective means of preventing untoward biological growth within cooling water circuits. The biocide may be introduced either in the form of sodium hypochlorite solution, or produced *in situ* by electrolysis of seawater. It is possible that the routine operation of HPC will not require chlorination because of the prevailing conditions in the Bristol Channel, and in particular the extreme turbidity regime which will limit the growth of biofouling organisms. The required elements of a chlorination system will none the less be fitted in case the need arises.

4.5 Commissioning and Associated Liquid Discharges

4.5.1 Prior to full operation, commissioning tests will be undertaken to demonstrate that HPC is capable of performing in accordance with its design specification and safety and environmental requirements.

4.5.2 Commissioning activities at HPC are anticipated to commence during the construction phase in 2015 and continue until the two units are operational. Early commissioning activities include the commissioning of the demineralisation plant and cooling water system, with commissioning of the reactor units anticipated to commence in 2017 and 2019 for reactor Units 1 and 2 respectively. The commissioning of the reactor units comprises two key phases including:

- Non-active commissioning, which will start with demonstration of equipment functionality and gradually build up to tests of the integrated function of the plant focusing on safety related systems and components. This stage includes hot functional testing, where the plant and equipment is put through its design envelope up to and including full temperature and pressure conditions, as far as practicable without nuclear fuel being in place. These tests are completed before fuel is loaded into the reactor and therefore no radioactive effluents are generated as a result of these activities; and
- Active commissioning which commences with fuel delivery and active commissioning of the reactor components e.g. testing the fuel storage systems before fuel loading, loading of fuel into the reactor vessel, initial criticality and power ascension testing, where the reactor is progressively increased in power and the operational and safety performance is verified.

a) Non-active Commissioning Discharges

4.5.3 With regards to discharges, the non-active commissioning of HPC can be broken down into two distinct phases, i.e. cold testing and hot functional testing (HFT).

i. Cold Testing

4.5.4 Cold testing involves the cleaning and initial preparation of various plant components. The main activity in this phase is cold flushing of pipe work (using demineralised water) to remove surface deposits and residual debris from installation including rust.

4.5.5 The discharges from this phase will primarily comprise water containing suspended solids and iron oxide (rust) and small quantities of conditioning chemicals including:

- Ammonia.
- Ethanolamine.
- Hydrazine.
- Phosphate.

4.5.6 During this phase of commissioning for Unit 1, the cooling water pumps will not have been commissioned therefore the cooling water system will not be available as a discharge route of these effluents (the cooling water system will be static (no significant flow) and unsuitable for receiving effluent for discharge through the cooling water outfall). This means that that discharges will be made via the temporary discharge route to the Foreshore Outfall following the necessary treatment to meet the relevant Environmental Quality Standards at point of discharge. Treatment may be required for ammonia, ethanolamine, hydrazine, phosphate, iron oxide and iron. Hydrazine will not be discharged during commissioning until the cooling water system and outfall tunnel is available as a discharge route. During the cold testing phase for Unit 1 hydrazine will be routed to a specific storage tank; storage will enable the hydrazine to decompose before being discharged via the outfall to the intertidal area.

4.5.7 The maximum combined cold-flush commissioning discharge will be 267m^3 per day (11.13m^3/h).

4.5.8 When Unit 2 undergoes cold testing, the cooling water system for Unit 1 and the common outfall tunnel will be available, and therefore the Unit 2 discharges will be routed through the Cooling Water outfall tunnel and not via the Foreshore outfall.

ii. Hot Functional Testing

4.5.9 HFT is a process whereby the UK EPR reactor is tested under high temperature and pressure prior to the loading of nuclear fuel into the reactor. The HFT phase of commissioning begins following the successful completion of the cleaning/flushing and cold performance tests and when the required equipment and functional units are deemed to be available.

4.5.10 The chemical substances discharged during the HFT phase of commissioning will be the same as those discharged during the normal operation of HPC. There will not be any radioactive effluents produced during non-active commissioning. However, HFT is an important step in passivating the primary circuit. This contributes to the minimisation of subsequent radioactive discharges over the lifetime of the facility.

4.5.11 Once HFT has been completed the primary circuit must be fully drained prior to refuelling with borated water. The steam generators are then either drained and placed in dry lay-up or wet lay-up (depending on the duration of preservation required). This is the only part of HFT that will be outside the normal operating envelope. During this period, operational discharge limits as defined by the appropriate Environmental Permit, will be respected and adhered to. This will involve careful planning to ensure that the effluent drained from the primary circuit is directed to appropriate storage tanks; sampled and subjected to appropriate analysis; and then discharged to the cooling water system. If analysis shows that discharge of this effluent would cause operational discharge limits to be breached, appropriate treatment would be applied to bring the effluent within specified limits. Failing this, disposal through an appropriately permitted off-site method would be arranged.

4.5.12 It is important to note that during the HFT phase, the cooling water system would be operational and therefore available to receive effluents and apply adequate dilution.

b) Active Commissioning Discharges

4.5.13 Discharges of chemical (non-radioactive) effluents during the active commissioning phase will be bounded by the limits described in the water discharge activity Environmental Permit. Discharges of radioactive liquid effluents will be bounded by the limits in the RSR Environmental Permit.

c) Sanitary Effluent Treatment During Commissioning

4.5.14 During the commissioning phase, HPC would continue to produce routine sewage effluent, which would be treated and discharged with sewage effluent associated with the construction works. Once the permanent Sewage Treatment Plant and cooling water infrastructure is available, then the sewage effluent associated with HPC would be rerouted and discharged via the cooling water outfall tunnel.

4.6 Operational Gaseous Emissions

4.6.1 The potential operational emissions to air arising from the operation of HPC would primarily include:

- Formaldehyde (H_2CO), that may in turn produce carbon monoxide (CO), emitted by the thermal decomposition of insulation material during reactor return to operation following maintenance outages.
- Ammonia (NH_3) discharged as the temperature rises in the steam generators during start-up following a maintenance outage.
- Sulphur dioxide and nitrogen oxides (SO_2 and NO_x), carbon monoxide (CO) and particulate matter (PM_{10} and $PM_{2.5}$) in the exhaust gases from engines of back-up diesel generators during periodic testing.
- SO_2, NO_x, CO, PM_{10} and $PM_{2.5}$ from plant including; fire fighting and hydrant diesel pumps, domestic heating boilers, and small diesel engines associated with the Interim Spent Fuel Store (ISFS).
- Discharge of radioactive gaseous effluents arising from the degassing of primary coolant and maintenance and operations in building areas containing radioactivity.

a) Start-up of the Reactor Plant

4.6.2 During the return to operation following a maintenance outage (approximately every 18 months), thermal decomposition of plant piping insulation material will result in the release of steam containing formaldehyde (H_2CO) that may in turn produce carbon monoxide (CO). It is estimated that during return to operation following maintenance, the operating time required to evacuate these emissions would be eight hours at normal flow and 42 hours at low flow. These gases would be captured by the ventilation extraction system and discharged to atmosphere via the main stack, which would be approximately 70m in height and have a flow rate of approximately 224 to 290 m^3/h. Two installation restarts are assumed per year during routine operation.

4.6.3 Start-up following a maintenance outage may also result in the production and emission of ammonia (NH_3). Depending on the type of maintenance planned during an outage, the steam generators may need to be filled with demineralised water and corrosion inhibitors to prevent their fabric corroding and also provide a biological barrier (a water shield). Once the outage is over, the rise in temperature in the steam generators generates gaseous ammonia partly from this wet lay-up solution, and partly from the steam generators emergency feedwater system. These emissions would be discharged via four steam relief valves associated with each unit. For the purpose of this ES, it has been assumed that the NH_3 emissions from one steam generator would be released during a period of 83 hours per restart. Two installation restarts are assumed per year.

b) Periodic Testing of the Back-up Diesel Generators

4.6.4 In order to ensure power is always available to the site (even in the event of loss of connection/supply to the National Grid), there would be a number of back-up diesel generators.

4.6.5 For each unit there are four main backup Essential Diesel Generators (EDGs) each with a thermal input of 18.5MW_{th}, and electrical output of around 7.9MWe. There would also be two emergency back-up generator per unit, referred to as Station Black Outs (SBOs) each with a thermal input of 7.0MW_{th}, and electrical output rated at around 2.9MWe.

4.6.6 These back-up generators would routinely operate during periodic tests, which represent an estimated 60 hours per year for each of the EDGs and SBO generators. This is a conservative assumption and in reality it is expected that running hours would be much lower.

4.6.7 These emissions would be discharged via exhaust stacks (one per generator), approximately 30m above ground level and have a flow rate of approximately 27.5 m^3/s (EDGs) and 7.9 m^3/s (SBOs), located on the roof of the diesel generator buildings. Each diesel generator building would house two EDGs and one SBO; thus there would be two diesel generator buildings per unit.

c) Other Gaseous Emissions

4.6.8 Domestic heating boilers would be routinely used around the site (particularly during periods of cold weather). Fire fighting diesel pumps located around the site would only be used for short periods in the event of an emergency or during periodic tests. Small diesel engines would also be used to provide backup power supply to the

ISFS. Emissions from these sources would be discharged to air via their own flue gas vents and likely to comprise SO_2, NO_x, CO, PM_{10} and $PM_{2.5}$.

4.6.9 Stack parameters and emission rates for EDGs, SBOs and non-diesel generator emissions to air are presented in **Appendix 4B.**

d) Radioactive Gaseous Emissions

4.6.10 Operation of the reactors and other radioactive facilities on site (such as the ISFS) produce radioactive gaseous effluent from the degassing of the primary cooling circuit and ventilation of potentially contaminated areas. Gaseous radioactive emissions are filtered and treated and only very small quantities are permitted to be discharged. These discharges into the environment will use the discharge stack and other authorised outlets, in accordance with the RSR Environmental Permit. The discharges are continuously sampled and monitored.

4.7 Gaseous Emissions associated with Commissioning

4.7.1 During commissioning there will be a number of emissions to air, including:

- Formaldehyde (H_2CO), that may in turn produce carbon monoxide (CO), emitted by the thermal decomposition of insulation material during reactor plant start-up (commissioning);
- Ammonia (NH_3) discharged as the temperature rises in the steam generators during start-up (commissioning):
- Sulphur dioxide and nitrogen oxides (SO_2 and NO_x), carbon monoxide (CO) and particulate matter (PM_{10} and $PM_{2.5}$) in the exhaust gases from engines of back-up diesel generators during periodic testing.

a) Start-up of the Reactor Plant

4.7.2 During start-up (commissioning) of the reactor building or return to operation following an outage (approximately every 18 to 22 months), thermal decomposition of plant piping insulation material results in the release of steam containing formaldehyde (H_2CO), that may in turn produce carbon monoxide (CO). Assuming the worst-case with respect to emissions (i.e. the shortest period over which the emissions may occur) It is estimated that during commissioning it would take 10 hours to evacuate these gases at normal flow rates, and 52 hours at low flow rates. As with operational discharges, these gases would be captured by the ventilation extraction system and discharged to atmosphere via the main stack.

b) Commissioning of Back-up Diesel Generators

4.7.3 During commissioning it is not anticipated that more than one EDG or SBO would be in operation at any one time. Each EDG and SBO will be operated for approximately 245 hours during its testing period. It should be noted that some of the hours needed for commissioning the SBOs will involve tests that can be carried out before the engines are brought to site. The commissioning hours presented therefore represent a conservative estimate of the time for which plant may be run on-site during this phase.

4.7.4 As for the operational testing of the diesel generators, these emissions would be discharged via exhaust stacks located on the roof of the diesel generator buildings.

4.8 Workforce and Visitors

4.8.1 The operational workforce would gradually build up during the commissioning phase and it is anticipated that the operational workforce of approximately 700 permanent staff would be employed on-site during normal operations. Approximately 180 staff would be employed in professional and managerial positions, 60 would be in clerical/administrative positions and 460 would be in industrial positions. There would also be up to an additional 200 contract staff.

4.8.2 It is anticipated that the majority of the operational staff would travel from the three local districts of Sedgemoor, West Somerset and Taunton Deane.

4.8.3 During the maintenance and refuelling outages, it is anticipated that a further 600-1000 staff would be required, with the number depending upon the extent of the maintenance planned for the outage, and that a large number would be located in the Operational Service Centre.

a) Working Hours

4.8.4 A number of operational staff will work shift patterns. Up to 100 operational staff will work shifts to cover the 24 hour day operational requirements. The remaining 800 staff would be likely to work day shifts (08:00 – 16:30).

4.8.5 The outage workforce would work day and night shifts with approx 60% of the workforce working a day shift and 40% a night shift. During an outage, the south car park will be made available to the additional staff.

b) Visitors

4.8.6 Business visitors will be limited in number and it is assumed for the EIA that in numerical terms they would replace members of the workforce who are working away from site at the time.

4.8.7 Visitors to the Public Information Centre (PIC) would reach a maximum of 1,360 in a single day. There are expected to be a maximum of four groups of visitors to the PIC during a day with a maximum of 340 people in a group to ensure that the maximum occupancy of the building is not exceeded. It is anticipated that there would be around seven staff working at the PIC.

c) Transport and Parking Arrangements

4.8.8 It is anticipated that the majority of the 700 permanent staff and 200 contract staff on-site will travel from the three local districts of Sedgemoor, West Somerset and Taunton Deane.

4.8.9 As described in **Chapter 2** of this volume, on-site car parking that would be available during the operational phase would comprise:

- 505 spaces in the south-east car park;
- 180 spaces in the east car park. Disabled parking will be included within the car parking provision; and
- 508 parking spaces in the south car park for additional workers who will be required during the planned ‘outages’ (i.e. maintenance periods), and car and coach parking for visitors to the PIC.

4.8.10 Of these car parking spaces approximately 430 would be available in the south-east car park for operational staff; equating to a ratio of one space per 1.9 workers present. It is assumed that these spaces would be occupied by workers’ cars using a car share ratio of 1.6. A Framework Travel Plan has been produced as part of the Transport Assessment which sets out the approach which will be adopted to travel planning during construction and operation of HPC.

CHAPTER 5: DECOMMISSIONING

CONTENTS

TABLES

[This page is intentionally left blank]

5. DECOMMISSIONING

5.1 Introduction

5.1.1 Following the 60 year operational phase, Hinkley Point C (HPC) will be decommissioned. This chapter outlines EDF Energy's overall approach to the decommissioning of the proposed UK EPR reactor units and the associated buildings and infrastructure based upon experience gained from decommissioning of other nuclear power stations and taking into account the UK EPR design and the site-specific conditions which apply at HPC.

5.1.2 The chapter also provides a summary of the relevant legislation and describes the required funding arrangements for decommissioning. An outline of the environmental effects that may be associated with the decommissioning process is presented.

5.1.3 Before decommissioning can take place, there is a requirement for the operator to obtain consent from the Office for Nuclear Regulation (ONR) under the Nuclear Reactors (Environmental Impact Assessment for Decommissioning) Regulations 1999 (EIADR 99) (Ref. 5.1). This requires the submission of an (ES) following an Environmental Impact Assessment (EIA) and a period of public consultation. For the HPC UK EPR reactor units the preparation and submission of the (EIA) will take place in the years leading up to End of Generation (EoG). The EIA performed at that time would take full account of the environmental impacts of decommissioning.

5.1.4 At this time, it is difficult to predict the specific characteristics of the environmental baseline conditions that will apply at the end of the operational life of HPC. New infrastructure may be built; local communities may change in size and character; a national geological disposal facility (GDF) for radioactive waste should exist but the location is not currently known; new technologies for waste treatment may be developed; and appropriate site reuse options would need to be considered. These issues represent substantial uncertainties with respect to the outcome of the assessment of impacts that can be undertaken at present. These uncertainties necessitate that the EIA for decommissioning will need to be completed nearer to the time when work will commence.

5.2 Legislation, Policy and Guidance

5.2.1 This section presents an outline of the regulatory framework specific to the decommissioning of nuclear sites.

5.2.2 In 1995, the Government produced a Review of Radioactive Waste Management Policy (White Paper CM2919) (Ref. 5.2). This set out the policy for decommissioning of nuclear sites and was updated following public consultation (Ref. 5.3). A further update was published in September 2004 "The Decommissioning of the UK Nuclear Industry's Facilities" (Ref. 5.4) and the 2008 White Paper "Meeting the Energy Challenge" (Ref. 5.5). Key aspects of the policy now in place include:

- each operator is expected to produce and maintain a decommissioning strategy and plans for its site(s);

- decommissioning operations should be carried out as soon as reasonably practicable, taking all relevant factors into account as provided for in the relevant operator's strategy and plan;
- sites of decommissioned nuclear facilities may represent a potentially valuable resource. The future use of the site, once decommissioning operations have been safely completed, could therefore be a significant factor in determining decommissioning operations;
- the use of Best Available Techniques (BAT) to minimise the volumes of radioactive wastes which are created, particularly the volume of Intermediate Level Waste (ILW). Wherever possible wastes should not be created during decommissioning until an appropriate management solution is, or would shortly be, available for use; and
- any new facility covered by this policy should be designed and built so as to minimise decommissioning and associated waste management operations and costs.

5.2.3 Regulation of the decommissioning of a nuclear facility is carried out under essentially the same arrangements as apply to construction and operation. Under the Nuclear Installations Act 1965, the ONR grants a licence for the purpose of installing, operating and subsequently decommissioning any commercial nuclear power station. Attached to the licence are conditions which require the operator to make and implement adequate arrangements relevant to safety. Site Licence Condition 35 specifically applies to decommissioning and requires that when a nuclear facility reaches the end of its operational life it is decommissioned in a safe and controlled manner and not left to pose a hazard for current and future generations. The purpose of the Licence Condition is therefore to require the licensee to have adequate arrangements for the safe decommissioning of its facilities. These arrangements include the preparation of a decommissioning plan and schedule for the site.

5.2.4 The precursor of the ONR, the Nuclear Installations Inspectorate, published its Safety Assessment Principles which apply to decommissioning and which the operator's site licence arrangements are required to meet (Ref. 5.6).

5.2.5 Disposal of radioactive wastes from decommissioning will be regulated by environmental permitting regulations where the application of BAT is expected to remain a key principle.

5.3 Funding of Decommissioning

5.3.1 The costs of decommissioning, waste and spent fuel management (post EoG) and disposal of all higher activity waste would be funded through a Funded Decommissioning Programme (FDP), approved by the Secretary of State, which the current draft guidance (Ref. 5.7) requires to have been approved before 'construction work on buildings with nuclear safety significance' commences. Under these arrangements, EDF Energy will ensure that it sets aside funds over the operating life of the power station to cover these costs in full.

5.3.2 A legal framework that implements this policy has been established through the Energy Act 2008 (Ref. 5.8) and the Nuclear Decommissioning and Waste Handling (Finance and Fees) Regulations 2011 (Ref. 5.9). Government has also published two consultations on draft FDP guidance, one in February 2008 (Ref. 5.7) and a second in December 2010 (Ref. 5.10), providing further detail on what an FDP should contain. In March 2010, Government published a further consultation on the arrangements for taking title and liability to waste and spent fuel, and the mechanism for setting a fixed price for waste disposal (Ref. 5.11) with an updated consultation document issued in December 2010 (Ref. 5.12).

5.3.3 The UK Government has created the independent Nuclear Liabilities Financing Assurance Board (NLFAB) to provide impartial scrutiny and advice on the suitability of the FDP submitted by operators of new nuclear power stations. NLFAB would advise the Secretary of State on the financial arrangements that operators submit for approval, and on the regular review and on-going scrutiny of funding.

5.3.4 Final guidance on the FDP and Waste Transfer Contract is now awaited from Government.

5.4 Design for Decommissioning

5.4.1 The UK EPR has been designed with maintenance and decommissioning in mind, enabling radiation doses to workers and radioactive waste quantities to be minimised when decommissioning takes place. The design incorporates a number of features to achieve this objective including:

- **choice of construction materials** – where practicable materials will be selected, to minimise the activation of certain elements which give rise to high levels of radiation, including cobalt, silver, and antimony;
- **optimisation of neutron shielding** – neutron shielding is utilised between the core and reactor vessel. This will reduce the depth of irradiation of the concrete of the reactor compartment;
- **optimisation of access routes to nuclear areas** – the layout of the primary circuit plant takes account of the handling and access routes for decommissioning;
- **reactor systems design** – systems are designed to minimise activation products and circuit contamination;
- **removal of major process components** – major components can be removed as a single item for size reduction in purpose built facilities;
- **submerged disassembly of reactor pressure vessel** – the design of the reactor compartment facilitates the flooding of the compartment for underwater dismantling of the reactor vessel;
- **modular thermal insulation** – the design facilitates easy removal minimising worker dose;
- **fuel cladding integrity** – improved fuel clad reduces contamination of the circuit with fission products;
- **primary circuit** – careful control of primary circuit chemistry should minimise level of activity in the primary circuit;

- **plant design** – design facilitates decontamination during decommissioning;
- **prevention of contamination spread** – containment, ventilation and segregation are utilised to prevent contamination spread; and
- **minimisation of hazardous materials** – the use of materials which would result in the creation of hazardous waste during decommissioning is minimised as far as possible.

5.4.2 In summary, the design of the UK EPR includes measures which would:

- minimise the activity level of irradiated components;
- reduce worker dose during decommissioning;
- permit decontamination;
- minimise the spread of contamination;
- facilitate the access of personnel and machines for decommissioning and the removal of waste from the reactor building;
- minimise the volume of radioactive waste;
- reduce the operator intervention time; and
- minimise the chemical toxicity of the waste.

5.5 Decommissioning Strategy

5.5.1 The decommissioning strategy to be employed for HPC is early site clearance. This strategy means that decommissioning would commence as soon as practicable after EoG and would proceed without significant delay to complete the process of decommissioning of the site. The decommissioning plan for HPC estimates that the decommissioning of the site, with the exception of the Interim Spent Fuel Store (ISFS), could be achieved approximately 20yrs after the EoG.

5.5.2 The process of decommissioning would be divided into a number of activities leading to the complete decommissioning of the site. For the UK EPR these are as follows:

- Activity 0: Pre-Closure Preparatory Work.
- Activity 1: Spent Fuel Management.
- Activity 2: Site Operation and Plant Preparation.
- Activity 3: Management of Operational Wastes.
- Activity 4: Plant Decommissioning.
- Activity 5: Site Clearance and Release for Re-use.

5.5.3 In many cases the activities overlap significantly in time, and are not necessarily sequential. The following sections outline each of the activities.

5.5.4 It is important to note that it is currently assumed that for this two UK EPR reactor unit site at HPC, Unit 2 would cease generation approximately 18 months after Unit 1.

5.6 Decommissioning Activities

a) Activity 0: Pre-closure Preparatory Work

5.6.1 Several years before the planned closure date for a reactor unit, a programme of preparatory work would be initiated to ensure that there is no delay to commencement of decommissioning following EoG and to ensure that the site is decommissioned as efficiently and economically as possible. This phase is anticipated to include the following:

- introduction of a final fuel cycle to maximise the utilisation of the nuclear fuel;
- preparation of a detailed decommissioning plan;
- preparation of an Article 37 submission (required to determine the acceptability of the radiological impact of decommissioning HPC on other EU member states);
- undertaking an EIA and preparation of an ES for commencement of decommissioning;
- preparation of further arrangements for compliance with Nuclear Site Licence Condition 35 to ensure safe and controlled decommissioning of the site;
- preparation of a decommissioning schedule;
- revisions to outage management;
- revisions to the requirements for maintenance, inspection and testing of systems and equipment;
- revisions to Radioactive Substances Regulation Environmental Permit for waste discharge and disposal; and
- revisions to site safety management arrangements.

5.6.2 Some of the activities listed above will require formal approval by regulatory bodies, therefore the preparation of these submissions will need to be commenced up to five years before the planned EoG.

b) Activity 1: Spent Fuel Management (Defuelling)

5.6.3 The first major activity following EoG would be the defuelling of the reactors. Defuelling would proceed as soon as practicable following reactor shutdown. The process would be undertaken using the existing fuel handling equipment, safety case and operational procedures.

5.6.4 Fuel would be removed from the reactor core within a few weeks of EoG. The fuel would be transferred to the reactor fuel pools and remain in storage in the reactor fuel storage pools for a period of cooling (approximately three years) before the spent fuel is transferred to the ISFS.

5.6.5 It has been determined that the final load of spent fuel would need to remain in storage within the ISFS for a period of approximately 50yrs after removal from the reactor (see **Chapter 7** of this volume for further details on spent fuel management). As a consequence there would be a need for periodic refurbishment and replacement of plant and equipment of the facility. In addition, during operation of the site a number of services are provided from the power station itself, (e.g. a secure electrical supply, waste treatment facilities and liquid effluent discharge). Each of these would need to be secured via an alternative arrangement to support the ISFS after decommissioning of the power station.

c) Activity 2: Site Operation and Plant Preparation

5.6.6 This section describes the "operation" of the site during decommissioning and management of the fuel and wastes. The scope of activities includes:

- safe operation of the plant after EoG, including resources for fuel and operational waste management;
- making plant and equipment safe for subsequent dismantling;
- Post Operational Clean Out including the removal of hazardous chemicals and clean up of radioactive materials;
- new liquid effluent discharge arrangements; and
- new alternative services (e.g. electrical supply).

5.6.7 As defuelling, operational waste management and other decommissioning work proceed, various systems are required to remain operational to maintain the safe operation of the plant. These systems would continue to be operated by experienced site staff employing the same or very similar procedures to those utilised during the operational life of the plant.

5.6.8 Following final shutdown of the reactor, plant systems, electrical equipment which are not required for safety reasons would become progressively redundant. Redundant electrical systems would be isolated and made safe. Redundant mechanical plant and systems would be taken out of service and isolated, drained and purged or flushed and vented to make them safe, and potentially hazardous materials would be removed from site as soon as is reasonably practicable.

5.6.9 To facilitate decommissioning, and the removal of some of the services, alternative services need to be installed. These include, for example, a new site electrical supply and distribution system and alternative liquid effluent discharge arrangements. These would enable the decommissioning of the existing high voltage electrical systems and of the cooling water system at the appropriate time.

d) Activity 3: Management of Operational Wastes

5.6.10 How radioactive waste is managed depends to a large extent on how radioactive it is. There are three main categories of radioactive waste defined in UK legislation; these are defined in **Table 5.1**.

5.6.11 Some waste which contains very little radioactivity is exempted from regulation by an Exemption Order currently issued under the Radioactive Substances Act 1993[1]. Exempt waste does not need require a specific permit for disposal.

Table 5.1: Radioactive Waste Categories

Waste Type	Description
Low Level Waste (LLW)	This comprises materials from routine operations and decommissioning with primarily low concentrations of beta/gamma contamination, but may include small amounts of alpha contaminated material. In the UK LLW may be treated and disposed of through a variety of routes including the national LLW Repository (the LLWR), via commercial incinerators, other treatment facilities, or in certain cases to specific approved landfill (see below). Some LLW which is not suitable for disposal within the LLWR would be stored until the national Geological Disposal Facility (GDF) is available. In the UK, LLW is defined as waste with a radioactive content exceeding 400kBq in any $0.1m^3$ and 40kBq per article (unless the activity is due to carbon-14 or tritium, in which case the limits are a factor of ten greater) but not exceeding 4GBq/te of alpha radioactivity or 12GBq/te of beta/gamma radioactivity.
Very Low Level Waste (VLLW)	A sub-set of LLW is categorised as VLLW which consists of the least radioactive component of the LLW category and may therefore be suitable for alternative disposal or treatment routes. VLLW from nuclear power stations would be classed as High-volume VLLW and could be disposed of to specified approved landfill sites. The waste would be subject to controls on its disposal which would be specified by the Environment Agency.
Intermediate Level Waste (ILW)	Waste containing higher concentrations of beta/gamma contamination and sometimes alpha emitters. There is little heat output from this category of waste. These wastes usually require remote handling. Such waste comes from routine power station maintenance operations, for example used ion exchange resin and filter cartridges. ILW generated during power station operations would be stored in purpose built facilities which may if necessary incorporate shielding to protect operators from radiation. Some ILW is treated as it arises to put it into a more inert, passively safe, form. This is known as conditioning. In the UK, ILW is defined as waste with a radioactive content exceeding that of LLW but which does not require heat dissipation to be taken into account in the design of storage or disposal facilities.
High Level Waste (HLW)	Waste containing high concentrations of alpha/beta/gamma emitting radionuclides. HLW only arises from nuclear fuel reprocessing operations and therefore would not be generated during operations at HPC. HLW generated during reprocessing of spent fuel requires remote handling (due to the radiation levels) and cooling (due to the heat produced) for many years. In the UK, HLW is defined as waste in which the temperature may rise significantly as energy is released by radioactive decay, so this factor has to be taken into account in designing storage or disposal facilities.

[1] The exemption orders are currently being revised and in the future will be implemented under the Environmental Permitting Regulations.

5.6.12 Operational wastes held in the operational vessels (e.g. ion exchange beds and filters utilised in effluent treatment), will need to be retrieved and processed after the EoG. Additionally there would be some operational type wastes that continue to be produced after the EoG as some essential systems would remain in service for a short period after EoG. These operational wastes would be retrieved and processed at the earliest practicable opportunity after EoG.

5.6.13 It is assumed that the GDF will be available to take these wastes at EoG, so the packaged waste arising from the ILW processing plants would be consigned directly to the GDF with no requirement to transfer packages to the on-site ILW Interim Storage Facility (ILWISF). Further it is also assumed that the packaged waste in storage can be retrieved from the ILWISF and despatched to the GDF for disposal at this time.

5.6.14 The Radioactive Waste Management Directorate (RWMD) of the Nuclear Decommissioning Authority (NDA) has indicated in its 2010 document "Geological Disposal – Steps towards implementation March 2010" (Ref. 5.13), that a UK GDF could be available to accept ILW for disposal by 2040. More recently in June 2011, Charles Hendry, the Energy Minister, has said that he would like to "*Set a goal of putting the first waste into a geological disposal facility by the end of 2029. I have tasked the Nuclear Decommissioning Authority to look at opportunities for accelerating progress to meet this aim.*" Given that these dates are for the disposal of existing legacy waste, it is considered that it is highly improbable that by the time EDF Energy would begin disposal of waste to the facility (some 40yrs after the proposed start of legacy ILW disposal) there will be no UK GDF available to accept the waste.

5.6.15 For the purposes of decommissioning planning it is assumed that the scheduling of transfer waste to the GDF can be optimised to allow transfer of packaged ILW during the main site decommissioning phase. However if optimisation requires a further period of interim storage the life of the on-site ILWISF may need to be extended until the GDF is available.

5.6.16 The strategy for the remaining operational low level waste (LLW) is identical to that for waste generated throughout electricity generation operations (i.e. it would be disposed of as soon as reasonably practicable following treatment to minimise volumes in line with the HPC Integrated Waste Strategy).

5.6.17 As with LLW, EDF Energy expect the ILW remaining in operational vessels at EoG would be processed in the same manner as ILW managed during the nuclear power plant operations subject to demonstrating this remains BAT. ILW would be retrieved and processed to ensure the waste is in a passively safe final form to be transferred from the site to the GDF.

5.6.18 Further detail on the management and disposal of operational radioactive waste is set out in the Radioactive Waste and Spent Fuel Management section of the ES (**Chapter 7** of this volume).

e) Activity 4: Plant Decommissioning

5.6.19 This activity covers the complete decommissioning of all plant, equipment, buildings and facilities at the power station site, and the management of the wastes arising from decommissioning activities. The activity includes the removal of all permanent buildings and facilities on the site with the exception of the ISFS and its supporting infrastructure.

5.6.20 The scope of this activity includes the decommissioning of the reactor and primary circuit and all other plant and equipment in the 'Nuclear Island', as described in **Chapter 2** of this volume, the processing of the wastes arising, and their packaging for disposal or recycling as appropriate.

5.6.21 The decommissioning of the 'Conventional Island' includes all power generation plant, ancillary plant and offices and welfare facilities. It is envisaged that the offshore structures would be demolished and removed to sea bed levels and on shore sections of the cooling water tunnels would be made safe.

5.6.22 All structures including roads, hard standings, cable and pipe trenches would be removed to 1m below ground. Basements would be adapted to permit free flow of groundwater, and would be backfilled with suitable infill material originated on-site from the demolition of buildings, supplemented, if necessary, with imported material.

f) Management of Decommissioning Wastes

5.6.23 Estimates of the volume and characteristics of radioactive waste generated during decommissioning have been developed as a basis for the development of the site decommissioning plan and the costs that will need to be covered by the FDP. The types of wastes expected to be generated during decommissioning are presented in **Table 5.2**.

5.6.24 During decommissioning, waste would be generated as a result of removing plant, equipment and structures, buildings and facilities at the power station site. The largest volume of this waste would be non-radioactive and suitable for reuse, recycling or disposal at suitably authorised sites. LLW generated during the decommissioning process would be disposed of to a suitably authorised site, this may include disposal of VLLW to an authorised landfill where this represents BAT.

5.6.25 The full range of waste minimisation methods will be used to reduce the amount of waste produced during decommissioning to as low a level as practicable, including decontamination, volume and size reduction and appropriate segregation of the waste to enable:

- the maximisation of materials recycling;
- minimal production of waste which is difficult to dispose of, particularly, long-lived, high activity waste and chemically hazardous wastes;
- minimal production of 'secondary' waste (equipment and materials used for the decommissioning); and
- maximum use of safe, radiologically exempt and chemically inert crushed and graded demolition material, such as brick and concrete, for backfilling voids, thus minimising the import of clean backfill material onto the site, subject to an appropriate waste disposal license.

g) Management of Radioactive Wastes during Decommissioning

Table 5.2: Types of Wastes Generated during Decommissioning

Waste Type	Description
Activated Waste	Activated products are created when stable chemical elements are bombarded by neutrons and turned into radioactive versions (isotopes) of the element. Typically these are produced from elements, such as cobalt, which are incorporated in the steel structure of nuclear reactors.
Contaminated Waste	Radioactive contamination is caused by radioactive material being deposited on the surface of, or within, objects. The radioactivity may be deposited from gaseous sources, from liquid sources, or from physical contact. Radioactive contamination is generally located on or near the surface of materials like metal or high-density concrete or painted walls. Radioactive contamination can usually be removed from surfaces by washing, scrubbing, spraying, or by removing the outer surface of the contaminated objects.
Primary Waste	Primary decommissioning waste refers to waste generated during dismantling activities. Primary waste will include plant system components; such as the pressure vessel and associated internal components, primary circuits, steam generators and the concrete shield that surround the vessels. Typically, primary waste consists of construction materials, such as steel and reinforced concrete.
Secondary Waste	Secondary waste refers to waste generated during various decontamination and dismantling activities (e.g. decontamination of metallic components or flushing of systems to reduce the amount of primary waste). Secondary waste consists of liquid waste, spent ion exchange resins, spent filters, and dry active waste.

5.6.26 ILW and LLW generated during decommissioning would consist of primary and secondary wastes. Primary waste varies widely in terms of type, activity, size and volume, and consists of both activated and contaminated components. Estimates of the quantities and characteristics of decommissioning ILW have been developed based on modelling of the neutron flux (a measure of the radiation field within the reactor capable of causing activation), the projected power history, and material composition data for the core of a UK EPR reactor unit. Activated components would have both short lived and long lived radionuclides resulting from the activation of the reactor material.

5.6.27 In addition to the activated waste, some surfaces, including building materials and process equipment and components would be contaminated by radioactive deposits. These deposits result from the transport of activated corrosion products, which occurs to a small extent in normal operation, and of fission products which may, in exceptional circumstances, be released from the fuel assemblies during reactor operation.

5.6.28 The strategy for the main components of the primary circuit, such as steam generators and pressurisers, is to remove them intact from their operational location, and to cut them up and package the wastes in a dedicated facility. This facility will also process, assay and package the other radioactive decommissioning wastes arising from the decommissioning of both reactor units. This facility is the Decommissioning Waste Management Facility (DWMF).

5.6.29 Following deplanting and backfilling of Unit 1 turbine hall, it would be converted into the DWMF for:

- processing of primary circuit and other large components requiring radiological precautions;
- receipt and buffer storage of raw LLW and ILW;
- further processing of LLW and ILW as necessary; and
- assay, packaging and buffer storage of packaged waste for disposal.

5.6.30 Other wastes would be generated during various decontamination and dismantling activities (e.g. decontamination of metallic components or flushing of systems to reduce the amount of primary waste). This waste would consist of liquid waste, spent ion exchange resins, spent filters, and dry active waste such as personal protective equipment, paper, and plastic. This waste will be managed and processed through the existing HPC waste management facilities or through the DWMF.

5.6.31 **Table 5.3** presents an estimate of the amount of waste produced by the two UK EPRs proposed at Hinkley Point C during decommissioning, based on an operational life of approximately 60yrs and a decommissioning strategy of early site clearance (Note these figures do not include waste arising from the decommissioning of the ISFS).

Table 5.3: Estimated HPC Decommissioning Waste Quantities (Based on two UK EPR Units)

	ILW (t)	LLW (t)	VLLW (t)
Primary Nuclear Island decommissioning waste	1,559	8,885	14,438
Clean-up waste (secondary waste from the decontamination, decommissioning and clean-up of the plant)	129	320	1,966
Process waste (filters and ion exchange resins arising from decommissioning activities)		642	
Induced waste (waste produced by equipment and material used in decommissioning)			1,642
Technological waste (waste plant and equipment used in decommissioning)		532	4,790
Total (t)	**1,688**	**10,379**	**22,836**

5.6.32 Surface treatment of contaminated materials can substantially reduce the amount of waste which has to be sentenced for final disposal as radioactive waste. In particular, the use of chemical cleaning or blasting of the surface and melting of metallic material can increase the amount of material suitable for unrestricted or restricted release. The use of these methods will be balanced against possible liquid and gaseous discharges arising from their use.

5.6.33 Appropriate segregation and decontamination procedures would be implemented to reduce, as far as is reasonably practicable, the volume of radioactive materials requiring treatment or disposal.

h) Disposal of ILW Generated During Decommissioning

5.6.34 As part of the ongoing Generic Design Assessment process, the views of the Nuclear Decommissioning Authority RWMD were sought on the likely acceptability for disposal in a GDF of packaged primary ILW generated during decommissioning of the UK EPRs. RWMD indicated that, in principle, any of the proposed waste packages would be acceptable for disposal. EDF Energy would continue to work with RWMD to ensure that packaged ILW from HPC would be acceptable for disposal in a GDF (Ref. 5.14).

5.6.35 ILW arising during decommissioning from decontamination and dismantling activities (i.e. secondary waste, would have similar characteristics to those wastes generated during the operation of HPC), therefore EDF Energy is confident that all wastes would be acceptable for disposal. EDF Energy is developing its decommissioning plans with due consideration of the potential disposability of any waste produced.

i) Management of Non-radioactive Waste During Decommissioning

5.6.36 Decommissioning activities would inevitably create large quantities of non-radioactive wastes during the deplanting and demolition of the non-radioactive and ancillary buildings and during final site clearance. It is anticipated that clean concrete and brick rubble from demolition of building structures would be crushed and retained on-site. It is planned to re-use as much of this material as possible on-site as infill for basement voids. This would minimise the environmental impact by reducing the amount of waste that has to be transported off-site for reuse, recycling or disposal to a landfill site.

5.6.37 Other non-radioactive wastes would be segregated and sent off-site for reuse or recycling (e.g. steelwork from building structures and redundant plant would be segregated and may be sold for recycling if a route is available). Materials unable to be reused or recycled would be disposed of to landfill.

5.6.38 Hazardous wastes would similarly be identified, segregated and securely stored on-site before transfer to permitted treatment or disposal facilities.

5.6.39 During the preparatory work stage, hydrocarbon fuels, refrigerants, oil and other chemical systems would be drained down and tanks emptied. Where possible these materials would be reused on-site, or sent off-site for re-use or recycling.

j) Final Decommissioning of Interim Spent Fuel Store (ISFS)

5.6.40 The ISFS would be utilised on the site to store the full operational lifetime arisings of spent fuel from the reactors. The current assumptions regarding availability of a GDF for spent fuel, and the length of cooling time before the fuel is suitable for disposal mean that a period of storage on the site would be required after the decommissioning of the reactors and other facilities.

5.6.41 It has been assumed that the date for start of transfer of spent fuel from the HPC site to a GDF is 2128. The process of transfer from the site could be completed in about 8.5yrs therefore all fuel could be removed from the site by 2136. Further detail on the management and disposal of spent fuel is set out in the Radioactive Waste and Spent Fuel Management section of this document (**Chapter 7** of this volume). On completion of transfer of the spent fuel from site for disposal, the ISFS would be decommissioned.

5.6.42 The decommissioning of the ISFS would be a relatively simple project. The techniques for decommissioning of wet spent fuel storage facilities, including pool clean up, are well developed internationally. The decommissioning process is anticipated to include:

- drainage and decontamination of the fuel storage pool;
- dismantling of the fuel storage racks and other pool furniture;
- dismantling of the fuel handling facilities;
- decontamination, drainage and dismantling of the pool water treatment plant;
- dismantling of the ventilation systems;
- decontamination and radiological clearance monitoring of the storage facility; and
- demolition of the storage facility and remediation of the site.

5.6.43 Appropriate radiological precautions would be employed throughout the process to minimise the spread of contamination and the quantities of radioactive waste, so as to ensure the safety of the public and workforce. All radiological and hazardous wastes would be packaged and disposed of appropriately, with clean non-radioactive waste reused or recycled wherever possible. Clean demolition rubble from decommissioning of the ISFS would be utilised to backfill ISFS basement areas.

k) Activity 5: Site Clearance and Release for Re-use

5.6.44 The current assumption for completion of the decommissioning process is the complete radiological clearance and de-licensing of the site.

5.6.45 Site clearance monitoring, remediation, landscaping and de-licensing would be undertaken in two phases. The first and largest phase would be undertaken following completion of the decommissioning of the power station plant and ILWISF. At this stage the ISFS would still be operational. The second phase would be undertaken on completion of emptying and decommissioning of the ISFS.

5.6.46 It is assumed that the original site licence and licensed area would be reduced to that required for the ISFS during the first phase of decommissioning. For the area to be cleared and de-licensed in the first phase a radiological and chemical survey would be undertaken and any necessary remediation carried out. On completion of this the site would be clearance monitored to check that all radioactive materials of regulatory concern have been removed from the site. Subject to the ONR being satisfied that there is no danger from any radioactivity on site, it would then be de-licensed. Upon completion of spent fuel transfer and decommissioning of the ISFS a further radiological and chemical survey would be undertaken and any necessary remediation carried out followed by de-licensing of the ISFS land.

5.6.47 The final stage of decommissioning would be the removal of the nuclear licensing requirements from the site. The ONR has published a policy statement setting out its criteria for de-licensing (Ref. 5.15). A licensee's period of responsibility does not end until there is no longer any danger from radioactivity on the site. Therefore, in seeking to end the licensee's period of responsibility, a safety submission would need to be made for the ONR's agreement. To de-license the site the ONR would establish that the site represents no danger to future site users from:

- licensee's evidence;
- ONR's own independent assessment; and
- evidence provided by the Environment Agency.

5.6.48 Once the criteria for "no danger" set by the ONR is met, the ONR would be able to de-license all or part of the site, thus ending the licensee's period of responsibility.

5.6.49 An important factor in site clearance would be the demonstration that the site has been cleared of all man-made sources of radioactivity originating from the operation of the reactors on the site to below an appropriate risk level.

5.6.50 The decommissioning EIA process would require significant consultation with statutory and non statutory bodies and their views would need to be considered before reinstatement proposals can be finalised.

5.6.51 For planning purposes it is assumed that the site is reused for industrial purposes but it is also assumed that landscaping of the site and return to grassland will be an interim measure.

5.7 Environmental Assessment of Decommissioning

5.7.1 As stated previously, in order to decommission a nuclear reactor it is necessary to obtain consent from the ONR under the Nuclear Reactors (Environmental Impact Assessment for Decommissioning) Regulations 1999 (EIADR99) (Ref. 5.1). This would require the submission of an ES and a period of public consultation prior to gaining approval for the commencement of decommissioning. A full EIA would be carried out as part of the process of obtaining consent to decommission HPC at the EoG, indicatively 60yrs after the start of operations.

5.7.2 The EIA would determine and describe the baseline conditions for the decommissioning works as they exist at the relevant time. This would be informed by any specialist surveys that may be necessary. The EIA would identify changes to the baseline conditions that would occur as a result of the decommissioning works and determine the scope, duration, magnitude and significance of the resultant impacts. The EIA would consider the relevant legislation in place at that time.

5.7.3 There are substantial uncertainties with respect to the characteristics of the future baseline conditions. In addition the technology which may be available to assist with the decommissioning works may change relative to current knowledge and capability. The location of the GDF is also not known at present and thus off-site impacts relating to the transportation of waste materials that may be disposed at the GDF cannot be fully assessed. Despite these uncertainties the types of environmental impacts that may occur during decommissioning and their broad scope have been identified and summarised below. The summary is based on the assumption that the decommissioning activities would largely be confined within the boundaries of the HPC permanent development site.

5.7.4 At the end of the decommissioning phase there would be a significant reduction in the amount of land occupied by buildings and other structures. The end state of the land following decommissioning is not certain at present, but is currently assumed to be re-used for industrial purposes with return to grassland as an interim measure.

a) Socio-economics

5.7.5 There will be a run down in workforce numbers from the operational phase to decommissioning after EoG and this will be the main socio-economic impact. The manner in which the run down in workforce numbers will take place is not fully known at present.

5.7.6 There will, however, be an increase in direct employment for contractors completing decommissioning activities. The services of specialist technology providers will also be required and their input will contribute to the knowledge economy of the area.

5.7.7 There may be a demand for local accommodation for out of the area workers although the use of local workers will be encouraged. There will also be expenditures during the decommissioning activities for material, plant and equipment supplies and by the decommissioning workforce personnel.

5.7.8 The assessment would determine the social and economic impacts related to the works and the deployment of the workforce. Requirements for worker accommodation and the need for support services such as health care and education would be evaluated relative to the provisions available in the local area at the time.

b) Transport

5.7.9 With the change in the workforce profile there will be a change in the pattern of worker trips to and from the site. It is likely that the decommissioning workforce numbers will be substantially less than the construction workforce. There will also be a change in the pattern of worker journeys to and from the site relative to the operational phase.

5.7.10 There will be an increase in traffic movements relative to the operational phase associated with the delivery of materials, plant and equipment required to facilitate the decommissioning works and the export of certain waste arisings. Vehicle trip generation is likely be substantially less than for the construction phase.

5.7.11 The transport assessment would determine the scope, magnitude and significance of impacts on the highway network and users of the network by applying the additional traffic related to decommissioning to the baseline traffic flows that apply at the time the works are scheduled to be carried out.

c) Noise and Vibration

5.7.12 Noise levels may be temporarily increased at the nearest sensitive receptors during the decommissioning phase relative to the operational phase. Noise levels will vary according to the particular activities being undertaken at any given time. There may be short-term peaks in noise levels associated with certain activities such as demolition of above ground structures.

5.7.13 As stated in Paragraph 5.7.3, decommissioning activities will be largely confined to the northern part of the HPC development site. It is considered that the noise impacts to local residents from decommissioning are likely to be of lower magnitude than during construction due to the substantial separation distance between the activities and residential dwellings.

5.7.14 The assessment would predict noise levels at sensitive receptors (principally residential dwellings) resulting from the decommissioning works on-site using appropriate predictive techniques. It is likely that noise modelling would be undertaken. In addition assessment would be undertaken of noise related to traffic associated with the works.

d) Air Quality

5.7.15 Air emissions during decommissioning will primarily comprise emissions from vehicles on the highway network and dust from demolition and site clearance activities.

5.7.16 Dust emissions will be controlled through the implementation of best construction practices. Since decommissioning activities will be focussed on the power station buildings and infrastructure it is not anticipated that dust generation will be a significant issue to off-site receptors (particularly residential receptors to the south of the HPC development site).

5.7.17 The assessment will provide predictions of air pollutant concentrations at sensitive receptor locations and will determine the scope, magnitude and significance of impacts on this basis. It is likely that air quality modelling would be undertaken.

e) Soils and Land Use

5.7.18 Soils and land use impacts will be limited to any areas of the HPC development site that may be temporarily required for decommissioning activities. The spatial extent of potential impacts would be much reduced compared to that related to the construction phase of HPC. Areas which are subject to impact during the works would be subject to appropriate restoration to enable use after completion of decommissioning. No significant adverse impacts on soils and land use are anticipated.

f) Geology, Land Contamination and Groundwater

5.7.19 Decommissioning may require some excavations to be undertaken adjacent to the below ground structures but these excavations will not result in significant impacts upon geological resources. Uncontaminated debris generated from demolition and clearance of above ground structures may be used to infill excavations. Material required for the backfilling of voids will be generated on-site as far as is practical.

5.7.20 The topography of the HPC site will have been modified during construction and landscape restoration post construction. The decommissioned site will be contoured after completion of works in accordance with requirements for the identified future use. It is likely that limited only regrading would be undertaken irrespective of future use.

5.7.21 It is not anticipated that contaminated soils will be present on site or that contaminated groundwater will be encountered during decommissioning works Monitoring of soil and groundwater contaminations status will continue during the operational phase of HPC and this information would be used to establish the baseline conditions prior to the commencement of decommissioning. In the unlikely event that contamination is identified it will be subject to appropriate management prior to commencement or during the execution of the works.

5.7.22 It is unlikely that groundwater dewatering will be required during decommissioning therefore no significant impact on groundwater behaviour is anticipated. Following completion of the works, the operational phase groundwater level control system is likely to become redundant. This will allow groundwater levels to equilibrate to a more natural state.

g) Surface Water

5.7.23 When the operational site's cooling water outfall and associated infrastructure are no longer available during decommissioning, the surface water runoff that flows into the outfall would need to be managed as necessary in the interim period during the works by diverting flows to suitable discharge locations which may include surface watercourses and/or to the intertidal zone.

5.7.24 Best practices will be implemented during the works to avoid the discharge of sediment laden water off-site into surface watercourses. Due to the distance of the decommissioning area from the site boundary, there would sufficient land area to allow effective management of runoff to ensure that sediment release does not occur.

5.7.25 No significant impacts on surface water receptors are anticipated as a result of the decommissioning works.

h) Terrestrial and Marine Ecology

5.7.26 During decommissioning the need for cooling water discharge from the reactors to the marine environment will cease and hence no impacts related to thermal discharges will occur. The generation of operational effluents will end thus the discharge of chemical and radiological substances will reduce over time. The cessation of cooling water intake will result in positive impacts with respect to a reduction of the entrainment of fish and other marine organisms.

5.7.27 It is not proposed to remove the HPC sea wall and thus there should be no requirement for significant decommissioning works in the intertidal area and hence no significant adverse impact on ecological receptors in this area or in the offshore areas is anticipated.

5.7.28 It is proposed to remove the intake and outfall structures but these works will be very limited in spatial scale and of limited duration. No significant impacts upon marine ecology receptors are anticipated as a result of these works.

5.7.29 Nevertheless, care will be taken through the design and execution of the works to avoid adverse effects on protected habitats such as Sites of Special Scientific Interest (SSI), National Nature Reserves (NNR), Special Protection Areas (SPA), Special Areas of Conservation (SAC) and County Wildlife Sites (CWS). The nearby protected habitats which are currently afforded protection are described in detail in **Volume 2**, **Chapters 19** and **20** of this ES.

i) Landscape and Visual

5.7.30 There will be some visual impacts due to the presence of construction plant and equipment during the decommissioning phase. However, the impacts will be temporary and after the decommissioning is complete all above ground structures will be removed. The landscape setting will differ from both the present baseline and the baseline at the EoG when both HPA and HPB are likely to have completed decommissioning. It is expected that there would be an interim period while the ISFS is still present in the north-east of the HPC development site before the site is totally cleared.

j) Amenity and Recreation

5.7.31 Dependant on the chosen end state of the site, there is the potential for the provision of new Public Rights of Way or other amenity uses.

5.8 Conclusions

5.8.1 This chapter has set out the anticipated approach to decommissioning for HPC and has outlined how it would meet Government policy and regulatory requirements.

5.8.2 Decommissioning plans for HPC estimate that the decommissioning of the site would be achieved approximately 20yrs after the EoG. At the end of this stage all buildings on the site will have been removed with the exception of the ISFS which will continue to operate until a GDF is available and the spent fuel is able to be disposed. Final decommissioning of the ISFS is planned to be completed by approximately 2140.

5.8.3 The types of environmental impacts anticipated to occur during decommissioning have been identified as far as can be determined at this point in time, however the decommissioning would be subject to an EIA under the decommissioning EIA regulations. Other regulatory requirements including the need to renew, and where necessary amend Environmental Permits will also be addressed.

CHAPTER 6: ALTERNATIVES

CONTENTS

TABLES

FIGURES

[This page is intentionally left blank]

6. ALTERNATIVES

6.1 Introduction

6.1.1 This chapter presents the principal alternatives that have been addressed in the context of the design of the Hinkley Point C (HPC) development. The scope of the alternatives which have been considered during the evolving design process range from localised siting arrangements for the HPC power station and related infrastructure, to specific aspects of the power station design and proposals for the landscape restoration of the HPC Development Site upon completion of construction works. The alternatives which are described in this chapter have been included as they concern issues of relevance to the environmental impacts for the HPC Development Site and surrounding area.

6.2 Local Site Selection for HPC

6.2.1 One of the principal determining factors in the selection of the most appropriate site for HPC has been the presence of the existing Hinkley Point Power Station Complex. It is preferable to site a new nuclear power station as near to an existing power station as possible to minimise the landscape and visual impacts as the physical characteristics of HPC will be similar to the existing adjacent development. This would not be the case for an equivalent development within a greenfield setting. Co-locating alongside existing facilities provides other benefits including the ability to use existing infrastructure, for example access roads and power transmission lines.

6.2.2 Given the requirement for large volumes of cooling water for the operation of HPC and the prohibitive cost and significant energy consumption requirements associated with pumping water inland, HPC needs to be sited near to the coast. In terms of land use in relation to the existing nuclear complex and in view of the need to take advantage of existing infrastructure a location either directly east or west of the existing plant would be the best option.

6.2.3 The proposed siting of HPC was subject to consideration at the pre-application Stage 1 consultation in 2009. The areas which were considered at that time are shown in **Figure 6.1**. Following an evaluation of the land available, the area to the west of the Hinkley Point A station (the Hinkley Point C development site) was considered to be the most suitable for new nuclear development. The principal issues considered during the site selection process are outlined in **Table 6.1**.

Table 6.1: Hinkley Point Nuclear Power Station Location Assessment

Local Siting Criteria	East of the Existing Power Station Complex	West of the Existing Power Station Complex
Environmental Designations – International and National	The site is located within the Severn Estuary Special Protection Area (SPA), Severn Estuary Ramsar Site and Sites of Special Scientific Interest within Bridgwater Bay. The site lies adjacent to a number of designated sites of ecological importance including: Severn Estuary Special Area of Conservation (SAC) and Bridgwater Bay National Nature Reserve (NNR).	The majority of the site is undesignated. However, construction works will be necessary along the foreshore and these works lie within the Severn Estuary SPA; Severn Estuary Ramsar Site; Severn Estuary SAC; Sites of Special Scientific Interest within Bridgwater Bay and Bridgwater Bay NNR.
Flood Risk	The site lies within Environment Agency Flood Zone 3. The area would require substantial raising of existing ground levels to accommodate a new nuclear power station.	The site is suitable for development as a development platform can be readily created above the flood risk zone at 14m Above Ordnance Datum (AOD).
Landscape and Visual Impact	Ground raising is likely to have a significant impact on landscape character.	The existing topography of the land particularly the presence of the ridge line occupied by Green Lane will help assimilate the built development structures which will be to the north of ridge line into the surrounding landscape.
Access	Access is required to the site around the existing Hinkley Point Power Station Complex which would have landscape and ecology impacts.	The existing access road (Wick Moor Drove) lies adjacent to the eastern boundary of the site. This will help to limit the requirement for new primary access routes and reduce the impact of constructing new access roads into the site.
Existing Land Use	Low lying pasture land undisturbed by development.	Primarily agriculture with isolated derelict farm buildings. The north-eastern part of the site is used for car parking and training by the existing Hinkley Point Power Station Complex.
Cultural Heritage	The site has no Scheduled Monuments or Listed Buildings. Archaeological detail is not known. However, the area has not been disturbed by major development.	Site is near to Pixie's Mound Scheduled Monument.

6.3 Land Use

6.3.1 Public and statutory consultee responses to the Stage 1 consultation did not indicate concerns with respect to the suitability of the proposed site for HPC. Furthermore, the overall positioning and layout of the permanent power station buildings and infrastructure within the HPC development site have not been subject to significant debate. **Figure 2.1** within **Volume 2**, **Chapter 2** of the ES illustrates the location of the main power station structures including the reactor buildings, turbine halls and pump houses. These development elements remain largely unchanged from the locations shown in the Stage 1 consultation submission.

6.3.2 The principal focus of attention since Stage 1 has been on the use of land for construction purposes, particularly in the southern areas of the site which are closest to residential properties. Land use allocation within the site during the construction phase has predominantly been driven by the requirement for the creation of development and construction platforms to provide the necessary areas for construction activities and permanent buildings and infrastructure. The proposed extent of site levelling and terracing has evolved as a result of the need to minimise the volumes of material to be excavated whilst providing the necessary construction working areas and permanent development platforms. The excavation and terracing will require the management of approximately four million cubic metres of material in total, including topsoil, subsoil, material suitable for re-use in the power station construction (engineering fill principally comprising excavated rock) and material which is required to create the final restoration landform. To avoid road vehicle journeys, it is intended that the excavated material will be retained on site and therefore significant areas are required for interim materials stockpiling and storage prior to re-use. EDF Energy has addressed the requirements and available options for the siting of the following land uses during the site preparation works and subsequent construction phases:

- stockpiling of excavated rock for re-use as engineering backfill;
- subsoil and topsoil storage;
- contractors' working areas; and
- construction workers' accommodation campus.

6.3.3 In addition to assessing responses to Stage 1 consultation, EDF Energy has held specific discussions with the residents of Shurton and other surrounding villages in April and June 2010 on the proposed land uses within the HPC development site and the extent of the areas of land required for specific construction activities within the site. As a result of these discussions, EDF Energy reached an agreement with local residents that the main construction site fence would extend only as far south as Ordnance Survey Gridline 144750mN throughout construction of the power station thus limiting the main construction activities to the north of this line. This provision allows for an increased distance buffer between the southern extent of the principal construction activities and the closest residential properties as the 144750nM boundary lies to the north of the construction site boundary proposed at Stage 1. Some construction work will, however, need to be undertaken to the south of the main construction fence. These works include the construction of an emergency access road with an associated bridge crossing over Bum Brook, a water management zone(s) relating to surface water drainage and early landscaping, which will provide additional screening to occupiers of residential properties located to the south of the site from the main construction activities.

6.3.4 The proposed land uses within the HPC development site throughout the site preparation works and subsequent construction works are summarised in **Chapter 3**, **Volume 2** and illustrated further in the Construction Method Statement. See **Annex 5.3**.

6.4 Landscaping

6.4.1 Design of the landscape restoration of the HPC development site following completion of construction works commenced in 2009. At this time options for restoration were informed by the following requirements:

- retention of all excavated material within the site to avoid the need for removal, by road vehicles, of material which is not required for engineering purposes;
- retention of most of Green Lane due to its ecological, landscape and heritage value;
- final landform and interim materials stockpiling not to exceed the height of Green Lane;
- restoration of Holford Stream within the final landscape scheme in order to address the Environment Agency's policy which requires that culverting of watercourses should be avoided where possible; and
- provision of a mosaic of land uses including agricultural land and new wildlife habitat.

6.4.2 At this early stage, the design included proposals for the restoration of Holford Stream following completion of construction works for HPC. However, the volumes of excavated material which needed to be retained on-site post construction increased as engineering studies relating to earthworks progressed. The increased volume of material to be retained on-site resulted in the requirement to accommodate material permanently within the Holford Stream Valley. Therefore, the restoration of the valley profile to its baseline condition was not a viable option and the retention of Holford Stream in a permanent culvert became an essential engineering requirement. The requirement to retain the culvert was discussed and agreed with the Environment Agency and the Internal Drainage Board with decision making being informed through the provision of a culvert justification report by EDF Energy (Ref. 6.1).

6.4.3 Following the decision to retain the Holford Stream in culvert, the landscape restoration design progressed through a number of further iterations which focussed primarily on:

- the selection of the most appropriate profile for the restored landform to achieve compatibility with the character of the landscape in the locality of the HPC development site;
- treatment of boundaries around the perimeter of the site to provide screening of the construction works and the permanent built development through landforming and planting;
- creation of internal field boundaries in the restored landscape to reflect the typical pattern of field boundaries in the locality of the site; and
- provision of the appropriate proportions of different land uses in the restored landscape.

6.4.4 These design iterations were influenced by both formal consultation and dialogue with the following stakeholders:

- English Heritage;
- Natural England;
- Environment Agency;
- Somerset County Council;
- West Somerset Council;
- Sedgemoor District Council;
- Fairfield Estate;
- Commission for Architecture and the Built Environment; and
- Somerset Wildlife Trust.

6.4.5 The decision to increase the separation distance between the main construction works and the residential properties to the south of the HPC development site through the establishment of a buffer zone to the south of Ordnance Survey Gridline 144750mN provided opportunities for early planting and landforming to enable additional screening of the construction works and the permanent development to be achieved.

6.4.6 With the support of local residents, planting of a screening belt of vegetation including native tree species and shrubs has already been undertaken (March 2011) in order for this to have the longest possible time to mature prior to the commencement of construction of HPC. Additional planting of a hedgerow around Doggetts Farm is proposed in the winter planting season (2011).

6.4.7 Further to this, EDF Energy has considered alternative design options with respect to additional screening of the construction works and permanent development from the south. The Stage 2 Update consultation proposed early landscaping and ecological habitat creation to the south of main construction fence line. The design of this early landscaping has considered alternatives with respect to the most appropriate landform, plant species selection and planting layout to ensure the maximum screening benefit whilst meeting the objective of providing landscaping in keeping with the existing landscape character of the locality. The landform will result in the building up of the levels of the existing slope in the southern part of the HPC development site to provide visual screening whilst achieving smooth transitions in slopes from the adjacent land. The planting includes 3-6m high feathered trees to provide a high level of screening from the start of the construction phase. The early landscaping proposals were discussed with local residents and other consultees and include provisions for circular routes for walking together with bridleways for horse riding.

6.4.8 Extensive consultation has also taken place with the Fairfield Estate and other consultees to agree the screening landform and planting along the north-western boundary of the site and a range of alternative designs have been prepared for discussion and agreement with stakeholders in this context.

6.4.9 The final landscape scheme following construction of HPC has also been subject to design iteration and again alternative designs with respect to landform, planting and habitat creation have been prepared and discussed with stakeholders in order to ensure that the landscape design principles and objectives are met. From the outset, site landscape design was informed by the requirement to provide significant biodiversity gain relative to the existing baseline situation through the creation of extensive areas of new wildlife habitat. The principles with respect to the creation of new habitats were established at a very early stage. Specific features such as woodland and ponds have been included in the restoration design in response to consultee suggestions.

6.4.10 In response to consultee comments, habitat protection and creation proposals have been extended during the construction phase during the design process. Additional areas for habitat retention during the site preparation works phase have been identified and off-site planting of woodland and hedgerow on Fairfield Estate and , as part of site preparation wildflower meadow creation on nearby off-site agricultural land have been included in addition to the early landscaping of land south of the main construction fence line at latitude 144750nM.

6.5 Alternative Designs for Power Station Elements

a) Introduction

6.5.1 The design of the reactor and main elements of the Nuclear Islands are largely determined by generic EPR design requirements. However, for the HPC, elements of the associated power station infrastructure have undergone an iterative design process which has taken into account site-specific conditions and environmental, health and safety, and nuclear safety considerations. This section outlines where alternative designs have been considered for associated infrastructure that has significance with respect to potential environmental impacts and explains why the final design choices were made. Key alternative designs for the associated infrastructure are outlined below.

b) Alternatives for Cooling

i. Selection of Cooling Option

6.5.2 A number of potential alternative means of cooling the water used to condense steam after it has passed through power station turbines exist for new nuclear power stations in the UK. These alternatives have been reviewed by the Environment Agency (Ref. 6.2). An understanding of the alternatives and their respective benefits and drawbacks was fundamental to informing the EDF Energy and British Energy (BE) submissions to the Strategic Siting Assessment and EDF Energy's decision to proceed with an application for nuclear new build development at Hinkley Point.

6.5.3 There are three principal cooling options:

- air cooling (closed circuit) utilises an extensive array of radiators across which air is forced at high volume to effect heat loss directly to the atmosphere;
- tower cooling (again closed circuit) involves the dispersion and cooling of water in direct contact with incoming air, within a large tower (or towers), involving some evaporative heat loss from the cooling water circuit and the need to make-up for this loss; and

- direct cooling (open circuit) involves the transfer of heat directly from the condensers to a large volume of water which is typically abstracted from the sea or a major river by passing the water once through the condensers before returning it to the environment.

6.5.4 The development of the cooling infrastructure (heat sink) design for HPC has taken account of site-specific considerations and the substantial experience directly available to EDF Energy from the following sources:

- EDF SA's design for the heat sink for the Flamanville 3 EPR (FA3);
- EDF SA's operation of the heat sink plant for a fleet of 58 pressurised water reactors (PWRs) at 19 sites within France including four coastal locations (Gravelines, Paluel, Penly and Flamanville) and at an estuarine location (Blayais);
- BE's operation of the heat sink plant at the Hinkley Point B (HPB) site and at six other advanced gas cooled reactor (AGR) stations around the UK coast; and
- BE's operation of the heat sink plant at the Sizewell B PWR.

6.5.5 The experience of other nuclear plant operators (UK and worldwide) has also been considered, including that of Magnox who manage the adjoining Hinkley Point A (HPA) site and several other sites around the UK coast.

6.5.6 In addition to the local data already available from the operation of HPA and HPB, the following issues were considered to inform the development of the HPC heat sink design:

- bathymetry (i.e. sea water depth);
- sedimentology;
- geology;
- air temperature and humidity data;
- water temperature data;
- sea water composition (including turbidity and salinity);
- high and low water levels including astronomical tides, surge and wave heights;
- ship collision; and
- clogging potential from marine organisms, ice and other water-borne debris.

6.5.7 Feasibility studies were undertaken in 2008 to assess the key heat sink design options and in particular to compare the relative merits of open and closed circuit systems (and combinations of these). EDF SA's considerable experience in the use of closed circuit heat sink designs at inland sites was supplemented by meetings with closed circuit technology companies in order to assess the implications of using the turbid, saline water available from the Bristol Channel for use at HPC as make-up water for a closed circuit cooling system. The feasibility of each option was assessed for:

- nuclear safety, including:
  - protection against hazards (integrity, redundancy, segregation and diversity);
  - reliability and availability;

- environmental impact, including visual impact, noise and effects on flora and fauna;
- technical feasibility and proven performance;
- operability;
- inspection and maintenance requirements; and
- cost (capital and operating).

6.5.8 EDF Energy then undertook a major technical review of the heat sink option studies in December 2008 from which it was decided that the optimum design for the HPC heat sink would be an open circuit system drawing water through long offshore intake tunnels into one onshore forebay for each UK EPR reactor unit. The main factors which led to this decision were:

- A closed circuit design with cooling towers would be likely to have a significant visual and noise impact.
- A closed circuit design with sea water make-up would require a large-scale onshore water treatment facility to reduce sediment load and to undertake desalination because of the turbid, saline water available from the Bristol Channel for cooling at HPC. The disposal of large quantities of water treatment residue would pose operational and environmental challenges.
- A closed circuit design with sea water make-up would require on-site trials covering a full range of weather conditions to prove the operability and availability of the cooling towers, particularly if more basic water treatment options were considered.
- The site footprint of cooling towers and the associated water treatment facility and reserve basins would be large and necssitate a larger land area to be used for the power station.
- The availability of a closed circuit system with cooling towers would tend to be more vulnerable to extreme weather events than an open circuit system.
- At coastal sites, there is a far more operating experience using open circuits than closed circuits. All of the coastal nuclear power stations in the UK and France have open circuit heat sink designs.

6.5.9 The following issues related to open circuit design were recognised as requiring resolution, but operating experience and the design provisions developed for FA3 indicated that these were surmountable and not as substantive as the challenges presented by closed circuit designs:

- increased vulnerability of offshore cooling water infrastructure to marine hazards including clogging and ship collision;
- fish capture with cooling water intake;
- the discharge of cooling water at elevated temperature into the marine environment (thermal plume); and
- possible chemical dosing requirements to control marine biofouling.

6.5.10 During 2009, the concept design of the open circuit water intake and discharge progressed in conjunction with several supporting studies including initial assessment of the seismic integrity of the intake structures and the concept design of the intake heads (see on the next page).

ii. Length and Location of Cooling Water Intake and Outfall Tunnels

6.5.11 Aside from engineering practicability there are two primary considerations for the appropriate positioning of cooling water intake and outfall structures – the need for safe and efficient operation including the requirement to incorporate redundancy against hazards into the design, and the consideration of environmental sensitivities. To serve both requirements a detailed understanding of the physical conditions of the local marine environment is required, together with that of the dynamic processes that would govern the behaviour of the resultant cooling water plume.

6.5.12 The business and environmental risk associated with cooling water intake and outfall selection is high as, once built, subsequent alterations to infrastructure and specific items of plant would be exceedingly costly. As a result considerable care has been taken to obtain sufficient high quality data on the local marine environment in the vicinity of Hinkley Point and to develop the appropriate predictive tools to assess a series of potential alternative solutions.

6.5.13 Different levels of uncertainty exist within an assessment process of this kind and each is dealt with in turn by application of best practice. To describe the physical environment involved a sufficiency of data is required, both current and historical, and this is combined with an understanding of both likely forward trends of environmental change and a consideration of the range of possible future scenarios that might result, whether driven by deliberate management policy and associated infrastructure development or otherwise. For example, for HPC there has been a consideration of both the advice of UK government advisers on the likely effects of climate change, including the impact on sea level rise, and the use of expert groups of advisers in order to develop an understanding of a series of plausible alternative scenarios of coastal process change that could lead to changes in coastal geomorphology, sedimentation and bathymetry.

6.5.14 A key tool within this process is the use of predictive numerical hydrodynamic models. The models allow an understanding of the dispersion of a cooling water plume in the marine environment and its spatial extent relative to the locations of sensitive environmental receptors. In addition the models enable the interaction between cooling water intake and outfall locations to be determined both with respect to the proposed HPC infrastructure and the existing HPB infrastructure. Avoidance of recirculation of discharged cooling water is a fundamental requirement to ensure that the efficiency of the cooling water circuits for the existing HPB and proposed HPC power stations is maintained. Such models can be developed with a very high level of sophistication, based on the physical data acquired locally, and can be both validated with and calibrated against elements of that same data set. They nonetheless provide outputs which are only estimates, and when called upon to extrapolate a prediction for a situation for which there is little or no current data – such as a future coastal change scenario or indeed a new discharge location – there is, again, a degree of uncertainty involved. Best practice in this situation, if the cost is justified by the level of business and environmental risk, is to use a suite of differently designed numerical models independently constructed but subject to uniform standards of data quality input and peer review – this is termed 'ensemble' modelling. The secondary advantage of this approach is that, whilst allowing a cross-check between outputs and thus a reduction in uncertainty, such different models also provide a greater range of predictive and descriptive capability.

6.5.15 For HPC, two models have been used and some detail of this is provided in the Chapters on Coastal Hydrodynamics and Geomorphology, Marine Water and Sediment Quality and Marine Ecology (**Volume 2, Chapters 17**, **18** and **19**). These models were first used to test a series of alternative intake and outfall configurations for HPC in support of the heat sink design process and then to refine understandings of detail based upon a preferred option, in discussion with the regulatory authorities concerned.

iii. Cooling Water Intake Structure

6.5.16 On the basis of the numerical modelling work described above, and due to the extensive coastal modifications that would have been needed to secure a cross-shore intake given the extreme tidal range, an offshore intake position has been selected as the preferred option.

6.5.17 The requirements of such a structure are several: it must be sufficiently robust to function for the longer-term (60 years of power station operation) in the harsh physical environment concerned, with very limited opportunity for maintenance; it must abstract at a sufficient depth so as not to draw in air during extreme tidal conditions or in wave troughs; it must avoid interactions with bed sediment transport in order to avoid entraining solids that might accumulate within and block the cooling water system; and it must seek to limit the number of fish that could potentially be entrained (caught) with the water intake.

6.5.18 The engineering design solution that most recently evolved to meet the needs of nuclear site development in the UK was the ‘velocity capped’ intake design currently deployed at the Sizewell B power station. This intake stands proud of the seabed and abstracts water from within the lower water column from below an upper horizontal cap, designed to prevent water (or air) being drawn downwards from the sea surface. Through commissioning trials this intake structure and its relative offshore location was shown to reduce the rate of fish catch per unit water intake volume when compared to the catches of the adjacent Sizewell A power station.

6.5.19 With respect to the design of HPC the opportunity has been taken to revisit the velocity cap design, whose primary disadvantage in fish protection terms is that the intake port velocity varies with tidal condition. A conceptual design that had arisen through historic Central Electricity Generating Board (CEGB) research has been developed with the aim of achieving low intake port velocities throughout all tidal conditions, despite the very high tidal velocities concerned off Hinkley Point. Expert advice on the behavioural basis for fish exclusion at such structures has been employed in the development of this approach, which accords with the Environment Agency guidance (Ref. 6.2). The proposed intake head design enables a water intake velocity of not greater than 0.3m/s to be achieved which will minimise the entrainment of fish.

iv. Fish Deterrence, Recovery and Return

6.5.20 In addition to the limitation of water intake velocity at the intake heads, additional measures to limit the magnitude of fish entrainment have been considered following extensive consultation with the relevant regulatory bodies. In order to comply with BAT and in response to consultation, an Acoustic Fish Deterrence (AFD) system is proposed to further limit entrainment.

6.5.21 The recovery of fish that become entrained with the cooling water has also been considered and the decision making with respect to the most practical and efficient means of recovering entrained fish has been subject to engineering and environmental appraisal. The recovery of fish was deemed to be optimised at the point where the fish are caught (impinged) by the cooling water filtration systems. Several configurations of filtration recovery were considered along with the methods of collection and transfer of fish back to the marine environment. In particular, a range of methods was considered for the raising of fish from the filtration infrastructure to a sufficient height to allow gravity discharge back to the marine environment.

6.5.22 Various options have been considered for the return of fish and other marine organisms back into the marine environment. The main design requirement which applies in this context is the need to ensure that fish are returned into a sufficient depth of water at all tidal states. It is also necessary to ensure that returned fish are not entrained into the HPB cooling water intake.

6.5.23 Open and enclosed channels cut into the rock of the foreshore were considered. An open channel was rejected on the grounds of health and safety and the potential for the channel to be attractive to predators and for recreational angling. Although a closed rock cut channel would avoid these issues, it would lead to the requirement for significant construction works on the foreshore and thus the increased potential for environmental impact on sensitive ecological receptors in the intertidal zone.

6.5.24 A tunnel option was selected as it avoids the need for construction on the foreshore and provides a means of returning fish continually to the sea at all stages of the tide.

6.5.25 Four alignment options for the fish return tunnel (**Figure 6.2**) were assessed with respect to the following factors:

- potential for fish to be entrained in the intake water for HPB;
- tunnel length (abrasion and pressure issues which might affect fish survival prior to discharge);
- predation from sea birds;
- predation from fish and sea mammals;
- the requirement for the tunnel outfall to remain unblocked by sediment;
- sustainability of the outfall location given projected trends in relative sea level; and
- avoidance of the HPB thermal plume.

6.5.26 All four options have discharge locations that are below -6mODN which means that they would be covered by water during all tidal states. However, Options A and B would discharge into water depths of less than 1m at low tide and as a result returned fish are likely to suffer from significant predation by birds. Options C and D would discharge into a greater water depths (approximately 2m and 3m at low tide, respectively) which renders returned fish more likely to fall prey to other fish and sea mammals, however these forms of predation are considered less significant than predation by birds.

6.5.27 A predictive modelling study found Option C to be the most favourable in terms of minimisation of entrainment of returned fish in the intake water of HPB, as well as being the least likely to be affected by the thermal plume from HPB.

6.5.28 Option C would be the longest tunnel, but tunnel length was not considered to be important in terms of fish survival.

6.5.29 When the physical and topographical conditions at location of the outfalls were assessed, in particular with regard to the possibility of sedimentation and subsequent blocking of the fish return tunnel, Option D was found to be the best option because it is located within a relatively extensive area of scoured rock.

6.5.30 When all aspects are considered together, Option D is considered the most favourable option as it combines most of the favourable characteristics of Option C in terms of fish survival, with having the most favourable discharge location in terms of reduced sedimentation.

6.5.31 Option D is, therefore, the chosen alignment option for the fish return tunnel (**Figure 6.2**). This option would have an outfall that would discharge at 1m below the Lowest Astronomical Tide (LAT) mark and the tunnel would have a length of approximately 500m north of the shore.

v. Surface Water Drainage

6.5.32 In parrallel with the design of the earthworks and excavations required for the construction of HPC, considerable thought was given to requirements with respect to the management of surface water drainage during the construction phase, The existing topogarphy and proposed construction and development platforms to the north of Green Lane necessitate that surface water runoff within this area is discharged to Bridgwater Bay.

6.5.33 The rock platform within the intertidal area immediately to the north of the HPC Development Site contains open channels which support *Corallina sp* (a red algal species). EDF Energy recognised that discharge of surface water across the intertidal area under low tide conditions could impact the *Corallina* habitat and that engineering design should therefore consider options with respect to the location of the discharge in order to minimise such impact.

6.5.34 The evolving drainage design for the area of the HPC Development Site to the north of Green Lane resulted in proposals to collect surface water runoff into a series of three north/south orientated “spine drains”. In engineering terms the simplest arranagement would be to allow discharge of water from each of these spine drains directly to the intertidal area. However, this would result in surface water runoff being directed over *Corallina* habitat, the extent of which has been accurately mapped during detailed ecological surveys undertaken for EDF Energy.

6.5.35 As a result of the environmental sensitivity related to *Corallina,* options were explored to determine the most appropriate arrangement for the discharge to minimise the impact on Corallina habitat. Three discharge arrangements were considered as follows:

- **Option 1 –** Three Discharge Outfall options. This option would comprise three spine drains discharging directly to the shore through separate outfall structures at an elevation of 9m AOD at the cliff face.
- **Option 2 –** Single Outfall - for this option the spine drains would be in the same positions as Option 1 but they would be connected to the landward side of the cliff by a collector drain running parrallel to the cliff line. The collector drain would then discharge to the shore at an elevation of 7.5m AOD at the location of the former dry dock (graving dock) which was used during the construction of the existing Hinkley Point Power Station Complex.
- **Option 3 –** Single Outfall - this option would be similar to Option 2 but with the single outfall located at an elevation of 7.5m AOD in the vicinity of the Hinkley Point C Drainage Ditch discharge onto the shore. The location of the three options are shown in **Figure 6.3**.

6.5.36 These were assessed with the aid of a predictive hydraulic model which was used to identify the spatial extent and depth of the discharged water within the intertidal area. The 1 in 30 and 1 in 2.33 year flood events (3.33% and 43% Annual Exceedence Probability (AEP) events respectively) were modelled with respect to surface water runoff.

6.5.37 The modelling demonstrated that Option 2 with a single discharge point at Location A (former graving dock for HPA and HPB) was the most suitable. This is due to the fact that water discharged at this outfall point would be confined across the intertidal shore and would not migrate to a significnt extent laterally. Most importantly significant spillage of discharged water into the natural longshore drainage routes (channels) associated with *Corallina* would not occur.

6.5.38 Further consideration of the impacts upon the ecology of the intertidal environment associated with discharges to the shore is given in **Volume 2**, **Chapter 19:** Marine Ecology.

vi. Interim Storage of Spent Fuel

6.5.39 EDF Energy has reviewed the alternatives that are available for on-site interim storage of spent fuel at the HPC site prior to its disposal within a Geological Disposal Facility (GDF) (Ref 6.3). The length of time for which storage will be required is dependent upon the availability of the GDF which is yet to be constructed and the length of time required for the fuel to cool sufficiently before it meets the required conditions for disposal.

6.5.40 The alternative technological solutions that were subject to consideration by EDF Energy included those identified by the ONR under the GDA process together with the outcome of the work initiated by British Energy (prior to acquisition by EDF) which had already examined options for providing additional spent fuel storage at Sizewell B.

6.5.41 Assessment of the alternatives was conducted using a Multi-Attribute Decision Analysis (MADA) process, the findings of which were analysed using expert engineering judgement to determine the most appropriate solution for HPC.

6.5.42 The following spent fuel storage options were included within the MADA process:

- Pool storage (wet storage);
- Metal cask storage (dry storage);
- Vault storage (dry storage); and
- Canister storage (dry storage).

6.5.43 These options were considered as they have been used successfully internationally and all are judged to be capable of meeting the high safety and environmental standards which are required to permit their use in the UK. Each of the technologies was assessed with respect to attributes applicable to four evaluation categories:

- health and safety;
- technical performance, safety and practicability;
- environmental; and
- economic.

6.5.44 The MADA process involved the scoring of the different options against each of the attributes and also weighting the importance of each attribute. EDF Energy's review placed a high level of importance on safety and environmental performance. However, because all options studied were assessed as being capable of meeting stringent UK criteria, the selection of the preferred option was linked to other performance issues where the different attributes of each technology proved to be more discriminating. The key areas were:

- protecting long term flexibility with respect to possible development in fuel technology;
- ease of inspection of spent fuel thus enabling review of fuel condition against GDF waste acceptance criteria;
- reducing financial risks; and
- maximising the benefits from retaining consistency in design with other EDF EPRs.

6.5.45 In reaching its proposed spent fuel storage decision, EDF Energy has considered the possible future developments and determined that, for the site-specific circumstances at HPC, interim storage within an engineered pool (wet storage) is the chosen approach. The proposed spent fuel management strategy for HPC is detailed within **Volume 2**, **Chapter 7**. EDF Energy has concluded that, whilst its preferred option will deliver a safe and secure solution, there may be alternative options available in the long-term that mean spent fuel does not need to be stored for long periods on UK EPR reactor power station sites. The pool (wet storage) option proposed for HPC is one that is flexible enough to be adapted to such future changes, should they occur.

6.6 Delivery of Bulk Materials and Design of the Temporary Jetty

6.6.1 The construction of HPC will require a total of approximately two million tonnes of bulk construction materials (including aggregates, sand and cement) for concrete production. Concrete could be imported directly to the site (e.g. as pre-cast concrete units and/or ready mix concrete) or as raw materials for on-site concrete batching and on-site pre-casting. In order to avoid significant risk to the construction programme that would result from a lack of materials available for production due to, for example, adverse weather conditions EDF Energy determined that bulk materials should be stockpiled in sufficient quantities on-site to allow continuous concrete production to occur.

6.6.2 Three main alternatives have been considered for the delivery of the bulk materials required for concrete production to site including; sea, road and rail transportation routes.

6.6.3 EDF Energy has evaluated the option for a direct rail link to the HPC site. However, the nearest point of connectivity to the existing rail network lies some 10km from HPC and construction of the link would be a major civil engineering undertaking with substantive environmental impacts. A rail link has been discounted on economic and environmental grounds.

6.6.4 The estimated HGV movements would place a significant burden on the capacity of the road network and account for a very high proportion of HPC development related traffic during the construction phase. Importation by road would also lead to adverse environmental impacts, with noise and air quality being of particular significance in this context.

6.6.5 With respect to transportation by sea, the following five options were identified for the delivery of bulk construction materials and Abnormal Indivisible Loads (AILs):

- new temporary jetty facility at Hinkley Point;
- new temporary foreshore facility at Hinkley Point;
- new permanent foreshore facility at Hinkley Point;
- refurbishment of the existing facility at Combwich Wharf; and
- redevelopment of the existing facility at Combwich Wharf.

6.6.6 The options were assessed for the separate delivery of both AILs and bulk construction materials with the exception of the temporary jetty which was only considered for bulk construction materials. The assessment included consideration of transport options including some consideration of potential environmental impacts associated with the available options based upon the knowledge available at that time.

6.6.7 EDF Energy identified a temporary jetty as the preferred option for the importation of bulk materials to Hinkley Point because it would have the least effect on local communities and would not require the transfer of materials from Combwich Wharf to the HPC site by road. Upgrading of the wharf facility was the preferred option for the delivery of AILs.

6.6.8 A range of design options and locations was considered for the temporary jetty. Cross-shore facilities were considered including solid concrete wharf designs on the shore, with and without a shore access channel cut into the rock pavement, but an open-piered jetty design was eventually selected. The potential sensitivity of the intertidal environment in terms of its conservation interest was a consideration as was the need to ensure navigational access across a wide range of tidal conditions. An open-piered structure also has the advantage of being largely transparent to meteorological, tidal and wave forces; lending itself both to greater engineering efficiency and an avoidance of potential environmental impacts. Lastly, the design selected permitted a modular approach to construction and decommissioning.

6.6.9 Once on open-piered jetty structure had been selected, two options were considered for the location of the jetty, one at the east and one at the west of the HPC site. The options are similar with the exception that the eastern option extends further (by approximately 70m) offshore in order to reach a water depth of -2mCD which is the minimum depth necessary for navigational access for the vessels which will use the jetty.

6.6.10 The two options were then subject to a comparative assessment which included considerations with respect to navigational safety, the disposition of land based reception facilities for the bulk materials and environmental sensitivities in the intertidal and subtidal areas. Environmental survey (as described in **Chapter 19** of the ES on Marine Ecology) found the near subtidal area to be clear of particular ecological sensitivities for both options. The preferred option (western location) was selected principally because it is shorter and thus would be less costly and require less time to construct. The western jetty routing acknowledges the presence of certain ecological interests on the shore and that a high level of care will be required in protecting these interests during both construction and decommissioning.

7. SPENT FUEL AND RADIOACTIVE WASTE MANAGEMENT

7.1 Introduction

7.1.1 This chapter considers the management of spent fuel and radioactive waste which will arise throughout the operation and decommissioning of Hinkley Point C (HPC).

7.1.2 Radioactive waste is designated as any waste material contaminated with or incorporating radioactivity above certain thresholds defined in legislation, and for which no further use is envisaged.

7.1.3 Spent fuel from nuclear power stations is not categorised as waste because it still contains uranium and plutonium which could potentially be separated out through reprocessing and used to make new fuel.

7.1.4 The management of spent fuel and radioactive waste would be carried out in accordance with relevant legislation, policy and guidance as detailed in **Appendix 7A**.

7.2 Spent Fuel and Radioactive Waste Management Strategy

a) HPC Integrated Waste Strategy

7.2.1 Strategic planning of waste management is a regulatory requirement and would be implemented at HPC through the development and production of an Integrated Waste Strategy (IWS) which will be reviewed and updated throughout the lifecycle of the HPC development. The IWS would set out the logic behind the development of individual waste strategies and how their integration results in the effective management of all the wastes generated by HPC.

7.2.2 The principal objective of the IWS is to ensure that waste management throughout the lifecycle of HPC is robust, consistent with UK policy and protects people and the environment. The IWS provides a framework to be utilised when taking decisions on waste management issues. The IWS will also be used to enable the site to demonstrate compliance with environmental protection principles for all waste types, including materials such as spent fuel that may become waste in the future. The IWS recognises that the design of the power station can have an impact on waste management strategy and is therefore taken into account in the design. The IWS aims to ensure that, during the construction, operation and decommissioning of the installation, workers, the public and the environment are protected and that radiation doses are as low as reasonably practicable (ALARP). These objectives are achieved by minimising discharges of radioactivity to the environment through the application of the waste hierarchy and best available techniques (BAT). Definitions of ALARP and BAT are set out in **Table 7.1** on the following page.

Table 7.1: Minimisation of Dose, Discharges and Radioactive Waste

Technique	Definition
ALARP	As Low As Reasonably Practicable is an expression used in risk reduction to define a standard or point at which the implementation of additional risk reduction measures would be grossly disproportionate to the benefits achieved.
BAT	Best Available Techniques describe the most effective economically and technically viable technology and methods designed to prevent, and where this is not practicable to reduce, emissions and their impacts on the environment as a whole.
Waste hierarchy	This concept proposes that minimisation of the creation of waste is the best way to reduce waste, re-use the second best option, followed by recovery (e.g. recycling) and as a last resort disposal.

7.2.3 The key factors in demonstrating the minimisation of the production of radioactive waste are:

- **Design of fuel, including containment** – the fuel is designed and handled to retain as much of the actinides and fission products as possible. This ensures that the radioactivity is removed with the fuel and does not enter the primary circuit or cooling pond water. The fuel cladding material has been chosen due to its resistance to corrosion, its impermeability to fission and activation products and the lower degree of activation. The manufacturing process minimises the presence of trace uranium on the outer surface which can release fission products into the primary circuit;
- **Efficiency of fuel use** – maximising the efficiency of fuel use, when coupled with fuel design and manufacture, will ensure that the minimum amount of spent fuel is created per unit of electricity generated. A combination of the UK EPR core design and the enrichment selected for the fuel is expected to deliver higher burn-up of the fuel which means that less fuel will be required. This will also reduce the secondary waste arisings from spent fuel management;
- **Detection and management of failed fuel** – the reactor is operated in such a way as to minimise the risk of fuel failure and the subsequent transfer of actinides and fission products to the primary circuit. EDF Energy continuously reviews operational experience and is engaged in exhaustive research and development programmes in this field. The condition of the fuel is assessed by monitoring the primary coolant activity levels. This allows any failures to be detected and managed;
- **Materials of construction for the reactor and cooling circuits** – the specification of any structural materials will include a requirement to replace or reduce those substances that are particularly susceptible to activation. This specification will also apply to materials that are susceptible to erosion, wear and corrosion to limit the potential for activation of any particulate matter that will pass through the reactor core with the primary coolant. Materials for the primary and secondary circuits will be specified to prevent leaks, to minimise the potential for corrosion and thus prevent the spread of radioactivity to lower contamination areas;
- **Primary coolant chemistry** – managing the primary coolant chemistry contributes to maintaining the integrity of the fuel cladding and the primary circuit by reducing corrosion. This, in turn, reduces the presence of activated corrosion

products in the cooling circuit and therefore minimises secondary waste from cooling water treatment. Chemistry management also includes the control of primary coolant gases and helps to minimise the production of tritium. The coolant management system allows the chemistry to be modified to reflect specific requirements at different phases of reactor operation; and

- **Commissioning, start-up and shutdown procedures** – a number of approaches have been developed to reduce the risk of generating corrosion products, which could subsequently become activated, during these key stages of reactor operation. Commissioning includes the creation of a tight and protective oxide layer on surfaces in the primary circuit. The primary circuit is degassed and purified during start-up to remove impurities that encourage corrosion. Cold shutdown procedures include a controlled release of corrosion products accumulated on surfaces. This allows them to be collected without the risk of activation in the neutron flux.

7.2.4 The features set out above will minimise the generation of radioactive waste and will, therefore, make a significant contribution to minimising the activity of the waste that will be discharged or disposed of.

b) Management and Storage of Wastes from Other Nuclear Sites

7.2.5 EDF Energy has no plans to receive, process or store spent fuel or radioactive waste from other nuclear sites. EDF Energy has no plans to reprocess spent fuel at the HPC site and has set out a baseline strategy that assumes interim storage followed by disposal. The facilities provided at HPC have been designed and sized to manage and store the spent fuel and waste from the HPC site only.

c) High-level Strategy for HPC Radioactive Wastes

7.2.6 This section provides a description of EDF Energy's preferred options for management of radioactive waste from HPC. Any implemented options will ultimately depend on regulatory agreement, and may therefore differ in some ways from those described within the following sections.

i. Solid Radioactive Waste and Spent Fuel Management Strategy

7.2.7 The strategy for solid radioactive wastes is these are to be disposed of as soon as reasonably practicable where a viable disposal route is available. ILW and spent fuel for which there are as yet no available disposal routes would be accumulated and safely stored on-site in compliance with the requirements of the NSL and HPC Radioactive Substances Regulation (RSR) Environmental Permit until a suitable disposal route or an alternative management route becomes available.

7.2.8 The design of the UK EPR incorporates a number of measures aimed at minimising the amount of solid wastes by facilitating the segregation and volume reduction of solid wastes, taking account of the review of the performance and operating experience of existing reactors.

ii. Liquid Radioactive Discharge Strategy

7.2.9 The overall strategy for the management of liquid radioactive discharges from the two UK EPR reactor units planned for HPC is based on the Reference Case presented in the Generic Design Assessment (GDA) for the UK EPR (Ref. 7.1) and the information presented within the RSR Permit Submission for HPC (Ref. 7.2) is:

- minimising the production of liquid effluents at source;
- partitioning of radionuclides where appropriate to minimise the environmental risks and impacts;
- optimum use of segregation and effluent treatment systems to afford greatest flexibility in their management;
- abatement to capture, concentrate and contain radionuclides, where appropriate, through the use of demineralisation, evaporation and filtration. The treatment of liquid effluent will exclude where reasonably practicable entrained solids, gases and non-aqueous liquids from the discharges;
- optimum use of suitable storage systems for the site, taking advantage of any delay and radioactive decay that may arise;
- assessment and sentencing of liquid effluents prior to discharge to confirm that these are in line with permitted levels;
- where radioactive effluent is discharged into the environment, optimising the manner and timing of any release to minimise the impacts on the environment and members of the public; and
- carrying out routine surveys of the environment to establish that the impact is acceptable.

7.2.10 The management strategy to limit radioactive liquid discharges from the operating activities of the UK EPR is based on the design of the plant and the operational practices to be implemented.

7.2.11 The design features use BAT to minimise liquid discharges at source and to minimise the impacts of discharges by means of abatement and discharge plant. EDF Energy will balance worker doses, costs and the accumulation on-site of additional solid waste incurred as a result of treatment in the plant with any potential reduction in public doses from discharges. Systems and plant are managed and used in a manner so as to minimise, so far as reasonably practicable, the environmental impacts of discharges and to ensure that all discharges are monitored and recorded to demonstrate that they fall within the permitted limits.

iii. Gaseous Radioactive Discharge Strategy

7.2.12 The overall strategy for the management of gaseous radioactive discharges from the two planned UK EPR reactor units at HPC is based on the Reference Case presented in the GDA (Ref. 7.1) and the information presented within the HPC RSR Permit Submission for Hinkley Point C (Ref. 7.2) is:

- minimising the production of gaseous effluents at source;
- partitioning of radionuclides where appropriate to minimise the environmental risks and impacts;
- abatement of gaseous discharge streams through the use of carbon delay beds to capture noble gases and carbon traps to capture isotopes of iodine and HEPA filters to trap particulate activity;

- monitoring of gaseous effluent prior to discharge;
- where radioactivity is discharged into the environment ensuring the design of the stacks is optimised such that they minimise the impacts on the environment and members of the public; and
- carrying out an agreed environmental survey programme to confirm that off-site impacts are acceptably small.

7.2.13 As with liquid discharges, the management strategy to limit radioactive gaseous discharges from the operating activities of the UK EPR is based on the design of the plant and the operational practices to be implemented. The design features use BAT to minimise gaseous discharges at source and to minimise the impacts of discharges by means of abatement and discharge plant, and also balance worker doses and costs together with the accumulation on-site of additional solid waste incurred as a result of treatment in the plant with any potential reduction of public doses from discharges. Systems and plant are managed and used in a manner so as to minimise so far as reasonably practicable the environmental impacts of discharges, and to ensure all discharges are monitored and recorded to demonstrate that they fall within the permitted limits.

7.3 Low-Level Wastes (LLW)

a) Management of LLW Generated During the Operation of the HPC UK EPR

7.3.1 The precise volume of solid LLW produced by HPC is dependent on the future management of the various systems associated with the operation of the nuclear power station. **Table 7.2** provides the annual estimated production of raw (untreated) LLW for two UK EPR reactor units based on the information presented in the UK EPR GDA submission (Ref. 7.1) and the HPC RSR Permit Submission for Hinkley Point C (Ref. 7.2). The volume and activity of LLW requiring disposal from HPC would be minimised by the use of the waste hierarchy and the application of BAT.

7.3.2 **Table 7.3** provides a description of the LLW that would be generated from the operation of the HPC reactors and auxiliary facilities. These can be grouped in two broad categories:

- LLW generated through operation of systems and processes used to ensure safe operation of the power station or to minimise discharges of radioactivity to the environment; and
- LLW generated during maintenance and refuelling operations.

Table 7.2: LLW Generation and Proposed Management Strategy for the HPC UK EPRs (Two EPR Units)

Waste Type		Estimated Raw Waste Volume Annual from Two UK EPRs (m^3)	Preferred Waste Arrangement[1]	Alternative Waste Arrangement
Steam Generator Blowdown System APG (SGBS) ion-exchange resins		15	Package as required to meet CfA and transfer for disposal as VLLW	Transfer for incineration Direct disposal to LLWR
Wet sludge (from sumps, tanks)		1	Condition/package as required to meet CfA and transfer for disposal to LLWR	
LLW cartridge filters from auxiliary circuit treatment		0.10	Condition/package as required to meet CfA and transfer for disposal to LLWR	
Evaporator concentrates		6	Condition/package as required to meet CfA and transfer for disposal to LLWR	
Air and water filters		8	Transfer for Incineration (water filters) Transfer for high force compaction (air filters) and onward disposal to LLWR	Direct disposal to LLWR
Dry active wastes (excluding metals)	Non-combustible	25	Transfer for high force compaction and onward disposal to LLWR	Direct disposal to LLWR
	Combustible	75	Package and transfer for off-site incineration	Direct disposal to LLWR
Waste oils and solvents		4	Package and transfer for off-site incineration	
Metal scraps and metallic waste		12	Package and transfer for metals treatment	Direct disposal to LLWR

[1] Note these disposal routes represent the preferred option for LLW management and disposal based on the anticipated waste characteristics. Alternative routes may be utilised in the future if they can be demonstrated to represent BAT or if the above disposal routes are found to be unavailable.

Table 7.3: Categories of LLW that would be Generated at HPC

Waste Type	Waste Description
Steam generator blowdown system (SGBS) ion-exchange resins	Ion-exchange beds are utilised in the SGBS to trap activation and fission products from the primary coolant circuit. In recycling the SGBS blowdown water from the UK EPR secondary circuit, the blowdown water is purified by the use of two parallel filters for the removal of suspended solids and two parallel demineralisation lines which use ion-exchange resins to perform the demineralisation.
LLW wet sludge	During the operation of the HPC UK EPR reactor units, particulates would settle as sludges in various buffer and storage tanks associated with the auxiliary water circuits (e.g. liquid waste processing system). These are likely to be contaminated with small quantities of fission and activated corrosion products. This sludge is periodically cleaned out and removed for treatment prior to disposal as LLW.
LLW cartridge filters from auxiliary circuit treatment	Filters are used to capture particulate material in the UK EPR water auxiliary circuits. Spent filter cartridges arise from the treatment lines of the following water auxiliary circuits: Chemical and volumetric control system, boron recycle system, liquid waste treatment system, and the spent fuel storage compartment treatment system. Water filters are withdrawn from operation on the basis of clogging and/or dose rate and then treated as waste. The physical form of this waste stream consists of filter cartridges that are composed principally of stainless steel supports with glass fibre filter media and some organic materials. The amount of particulate radioactive material (principally metallic oxides) trapped on each filter can vary. The majority of waste within this category is anticipated to be ILW at the point of generation but some LLW is expected.
Evaporator concentrates	The UK EPR proposes to make use of evaporation for the minimisation of non-recyclable radioactive liquid effluents arising from the liquid waste treatment system. Evaporation would be used to minimise the discharge of active aqueous effluents to the environment. Evaporation of effluents results in the production of a sludge-like concentrate that would contain the bulk of the radioactivity initially present in aqueous effluent streams as activated metal oxides.
Air filters	All radiation controlled areas of the nuclear auxiliary building, fuel building, safeguards buildings, reactor building, operational production centre, access building and effluent treatment building are served by dedicated ventilation systems. The extract from these systems is subject to a number of airborne activity abatement techniques, including the use of high efficiency particulate air (HEPA) filtration, before discharge to the environment. The HEPA filters remove particulate material to ensure doses to workers are ALARP and discharges to the environment are minimised. This also ensures that the doses to members of the public from airborne discharges are minimised. The abatement systems would produce a number of spent LLW HEPA filters over the course of reactor operations.
Water filters	Water filters may arise from filtering of the low active effluent (from the gaseous waste processing system, liquid waste treatment system, steam generator blowdown system). The physical form of this waste stream consists of filter cartridges that are composed principally of stainless steel supports with glass fibre filter media and some organic materials. The amount of particulate radioactive material (principally metallic oxides) trapped on each filter can vary.
Dry active wastes (DAW)	DAW comprise the combustible and non-combustible LLW generated through routine and maintenance operations in the UK EPR Nuclear Island and consist of contaminated personal protection equipment, monitoring swabs, plastic, clothing, contaminated tools, segregated pieces of metal, glassware and other process consumables. These wastes mainly arise during outages.

Waste Type	Waste Description
Oils and solvents	Oils are used in the lubrication of various components such as circulators and process pumps and have the potential to become radiologically contaminated during normal service. Contaminated liquids such as chemical cleaning solutions and solvents used as decontamination agents also arise and would be included within this waste stream.
Metal scraps and other metallic wastes (Dose rate < 2 mSv/h)	Metal wastes arise during maintenance operations from the replacement of engineering components. The redundant metal components or equipment used during the maintenance operations in the nuclear island may become contaminated and require disposal as radioactive waste.

b) Arrangements for Site LLW Management

7.3.3 Detailed arrangements for radioactive waste management would be covered in the EDF Energy operating procedures required to demonstrate compliance with NSL and RSR requirements. For LLW, these instructions are anticipated to cover minimisation, segregation, characterisation/assessment, packaging, labelling, record keeping and consignment for transfer/disposal.

7.3.4 The design of the UK EPR incorporates a number of measures aimed at minimising the amount of solid wastes by facilitating segregation and volume reduction of solid wastes, taking account of the performance and operating experience of existing reactors. Examples include:

- The composition of the primary circuit component materials has a direct impact on the radioactive inventory in the primary coolant, especially on the activation of corrosion products. Therefore, chemistry and radiochemistry are optimised in the UK EPR design to reduce the primary circuit radioactive inventory and lower the dose rate levels, which in turn would minimise the activity of corrosion products which contribute to solid waste arisings.
- Improved efficiency of recycling (e.g. coolant) and effluent processing systems to reduce solid waste volumes associated with the treatment of coolant and effluents.
- Zoning of rooms and controlled areas to maximise the segregation of radioactive and non-radioactive wastes and thus minimise radioactive waste arisings.

c) Facilities to be Provided for Site LLW Management

7.3.5 LLW generated during the operational period from both the reactors and the associated auxiliary plant would be transferred to the effluent treatment building (ETB) of UK EPR reactor Unit 1 (Unit 1). This facility is designed to manage waste through segregation and application of suitable treatments in preparation for disposal. LLW would be processed and packaged as required to meet the conditions for acceptance (CfA) of the appropriate off-site disposal facility.

7.3.6 LLW would be safely transferred from different locations in the radiation controlled area to the ETB. Waste would be collected and stored according to waste activity categorisation at dedicated locations in the ETB and placed into a temporary buffer store prior to treatment. The waste would then be separated on the basis of the treatment method and would be stored in these areas until sufficient quantities have accumulated for a treatment campaign to start or for shipment off-site.

7.3.7 The treatment route for solid waste would be determined (once it has been monitored and assayed) by categorisation of the waste and by considering its physical and chemical characteristics.

7.3.8 Once categorised the waste would be packaged (and conditioned if necessary) and transferred off-site to the most appropriate facility for its treatment (e.g. such as super-compaction, metal treatment or incineration) or disposal.

i. Segregation

7.3.9 Solid wastes would, as far as practicable, be segregated and sorted at source to minimise secondary handling. Where waste streams generate mixed wastes these would be sorted in a dedicated unit within the ETB to optimise their subsequent management and disposal. If no further benefit can be obtained from further segregation then the waste would be transferred to the next stage. The benefits associated with the segregation of waste need to be balanced with the detriments associated with increased operator exposure.

7.3.10 The segregation of the waste into different waste groups would be carried out on the basis of different physical and chemical properties (e.g. combustible, non-combustible and compactable waste, and non-compactable waste).

ii. Shredding

7.3.11 Bulky solid combustible and compactable waste may be size reduced by shredding in the ETB prior to further treatment. The waste is size reduced by the use of a rotating blade assembly. The shredded material then falls through a duct into a compactable drum located directly below the shredder. Once full, the drum would be returned to the storage area and temporarily stored until a sufficient volume of waste for treatment or disposal is collected.

iii. Low Force Compaction

7.3.12 A low force compactor in the ETB could be used on-site to assist in the volume reduction of appropriate wastes prior to transfer off-site for disposal.

iv. Conditioning of LLW for Disposal

7.3.13 Some LLW (e.g. sludges and resin), may require processing within the ETB through a combination of dewatering, drying, and encapsulation in a mortar matrix within the waste disposal package prior to transfer from the site in order to meet the CfA for the proposed disposal site.

v. Handling and Transfer of Final Packages

7.3.14 Following treatment, the waste would be placed in an appropriate container for transport or disposal. After being sealed, the containers would be checked for the presence of external contamination prior to transfer out of the ETB. Waste containers awaiting transfer off-site would be placed in buffer stores and transferred into transportation containers prior to loading onto the transportation vehicle.

d) LLW Volume Estimates

7.3.15 The LLW volume estimate is based on a review of the waste arisings from existing French nuclear reactors of similar power rating to the UK EPR, performed as part of the GDA process (Ref. 7.1). It is assumed at present that HPC, with two UK EPR reactor units, would produce double the arisings predicted for one unit in the GDA, even though some facilities would be shared. The sharing of facilities, such as the waste treatment facilities, may result in some reduction of operational arisings. However, at this stage it is not possible to make precise predictions of reductions so the figures set out in **Table 7.1** are considered to present a best estimate of solid LLW arisings.

e) LLW Disposal Strategy

7.3.16 A key consideration of the choice of preferred disposal route has been the commitment to demonstrate best use of existing UK LLW management facilities. Therefore direct disposal to LLWR, in Cumbria, is seen as the least desirable option and where a reasonably practicable alternative disposal route exists (e.g. incineration or metal recycling, this has been chosen as the preferred option). This approach is consistent with the national strategy for LLW and EDF Energy will aim to utilise alternative disposal routes to the LLWR as available. This will contribute to the minimisation of the disposal of wastes to the LLWR and maximise its remaining operational lifetime.

7.3.17 The strategy for LLW is that waste generated throughout nuclear power plant operations and decommissioning would be disposed of as soon as reasonably practicable, following treatment to minimise volume and perform appropriate conditioning or packaging. The ultimate disposal of the wastes is expected to be via one of the following main routes depending on the radioactivity level of the waste produced, its physical characteristics and its chemical properties:

- off-site treatment of metals, ultimately for recycling, via commercially available routes subject to meeting the relevant CfA;
- off-site incineration of combustible wastes using commercially available routes subject to meeting relevant CfA. There would be no on-site incineration of wastes;
- use of an appropriate authorised off-site disposal facility for exempt and VLLW disposal (notably for soil, rubble and aggregates) where no reuse or recycling options are viable, subject to meeting relevant CfA;

- transfer of suitable LLW for super-compaction prior to disposal at the LLWR to minimise disposal volume; and
- disposal of LLW directly to LLWR would be utilised only where the above alternatives are not practicable.

7.3.18 For all LLW, with the exception of oils and solvents, acceptance for disposal has been agreed in principle with LLWR during the GDA process. This has now been updated for HPC's LLW/VLLW and disposability in principle has been confirmed by LLWR for the volume and activity levels presented within this document.

7.3.19 In order to demonstrate the acceptability of the potential non-LLWR disposal routes for HPC's LLW, disposability in principle for the appropriate waste streams was obtained for incineration, VLLW landfill, and the ancillary segregated waste services provided by the LLWR Ltd. (e.g. metal treatment and super compaction). The segregated waste services are provided by LLWR Ltd. to improve the availability of alternative waste management options and reduce the volume of waste disposed of to LLWR.

7.3.20 EDF Energy has reviewed the potential treatment and disposal options for LLW from HPC. The preferred options for management of LLW generated at HPC are set out diagrammatically in **Plate 7.1.** Conditions and limits would be set, by the Environment Agency, for the transfer of LLW in the HPC RSR Environmental Permit issued under the Environmental Permitting (England and Wales) Regulations 2010 (Ref. 7.2).

7.3.21 EDF Energy is aware that the LLWR has a current estimated lifetime shorter than the operation of Hinkley Point C. It is assumed that, as stated in Government policy and enshrined in Environmental Permitting Regulations 2010, (Ref. 7.2) that new disposal facilities (either at LLWR or elsewhere) will ultimately be provided by the NDA after the current LLWR has ceased to receive waste. However EDF Energy will apply the waste hierarchy and waste segregation to demonstrate best use of existing UK LLW management assets.

i. Off-site Metal Recycling Facility Operations

7.3.22 Where the metallic waste generated by operational maintenance work cannot be adequately decontaminated on-site, the waste would be transferred to an off-site commercial Metal Recycling Facility (MRF) (e.g. Studsvik Metal Recycling Facility at Lillyhall, Cumbria). The volume of metallic waste requiring disposal could be reduced by up to 95% using metal recycling techniques.

7.3.23 Once transferred to the MRF, a range of industrial cutting and cleaning techniques would be applied. The metallic waste is decontaminated and cleaned using methods such as dry grit blasting. The resulting materials can either be recycled in the UK or potentially sent to a facility for further cleaning by melting.

ii. Off-site Incineration Operations

7.3.24 LLW would be segregated within the ETB to separate combustible waste from non-combustible. Combustible waste suitable for incineration would be transferred to an off-site commercial incinerator and incinerated in a specially engineered kiln up to around 1000^{o}C. Any gases produced during incineration are treated and filtered prior to discharge into the atmosphere and would conform to international standards and national emissions regulations.

7.3.25 Incineration of combustible wastes is used as a treatment for both radioactive and conventional wastes in the UK. In the case of radioactive waste, incineration has been used for the treatment of LLW from nuclear power plants, fuel production facilities, research centres (such as biomedical research), the medical sector and other waste treatment facilities.

7.3.26 Modern incineration systems are well engineered and designed to burn the waste efficiently whilst producing minimum emissions. Ash remaining following incineration would be disposed of as appropriate.

iii. Off-site Super Compaction Facility Operations

7.3.27 Suitable LLW would be transferred off-site to a super compaction facility to minimise its volume. In this process drums or boxes of waste are compacted under high pressure of up to 2,000 tonnes per square metre. Following super compaction the drums would be transferred onward to LLWR, near Drigg, in Cumbria for disposal.

iv. LLWR Operations

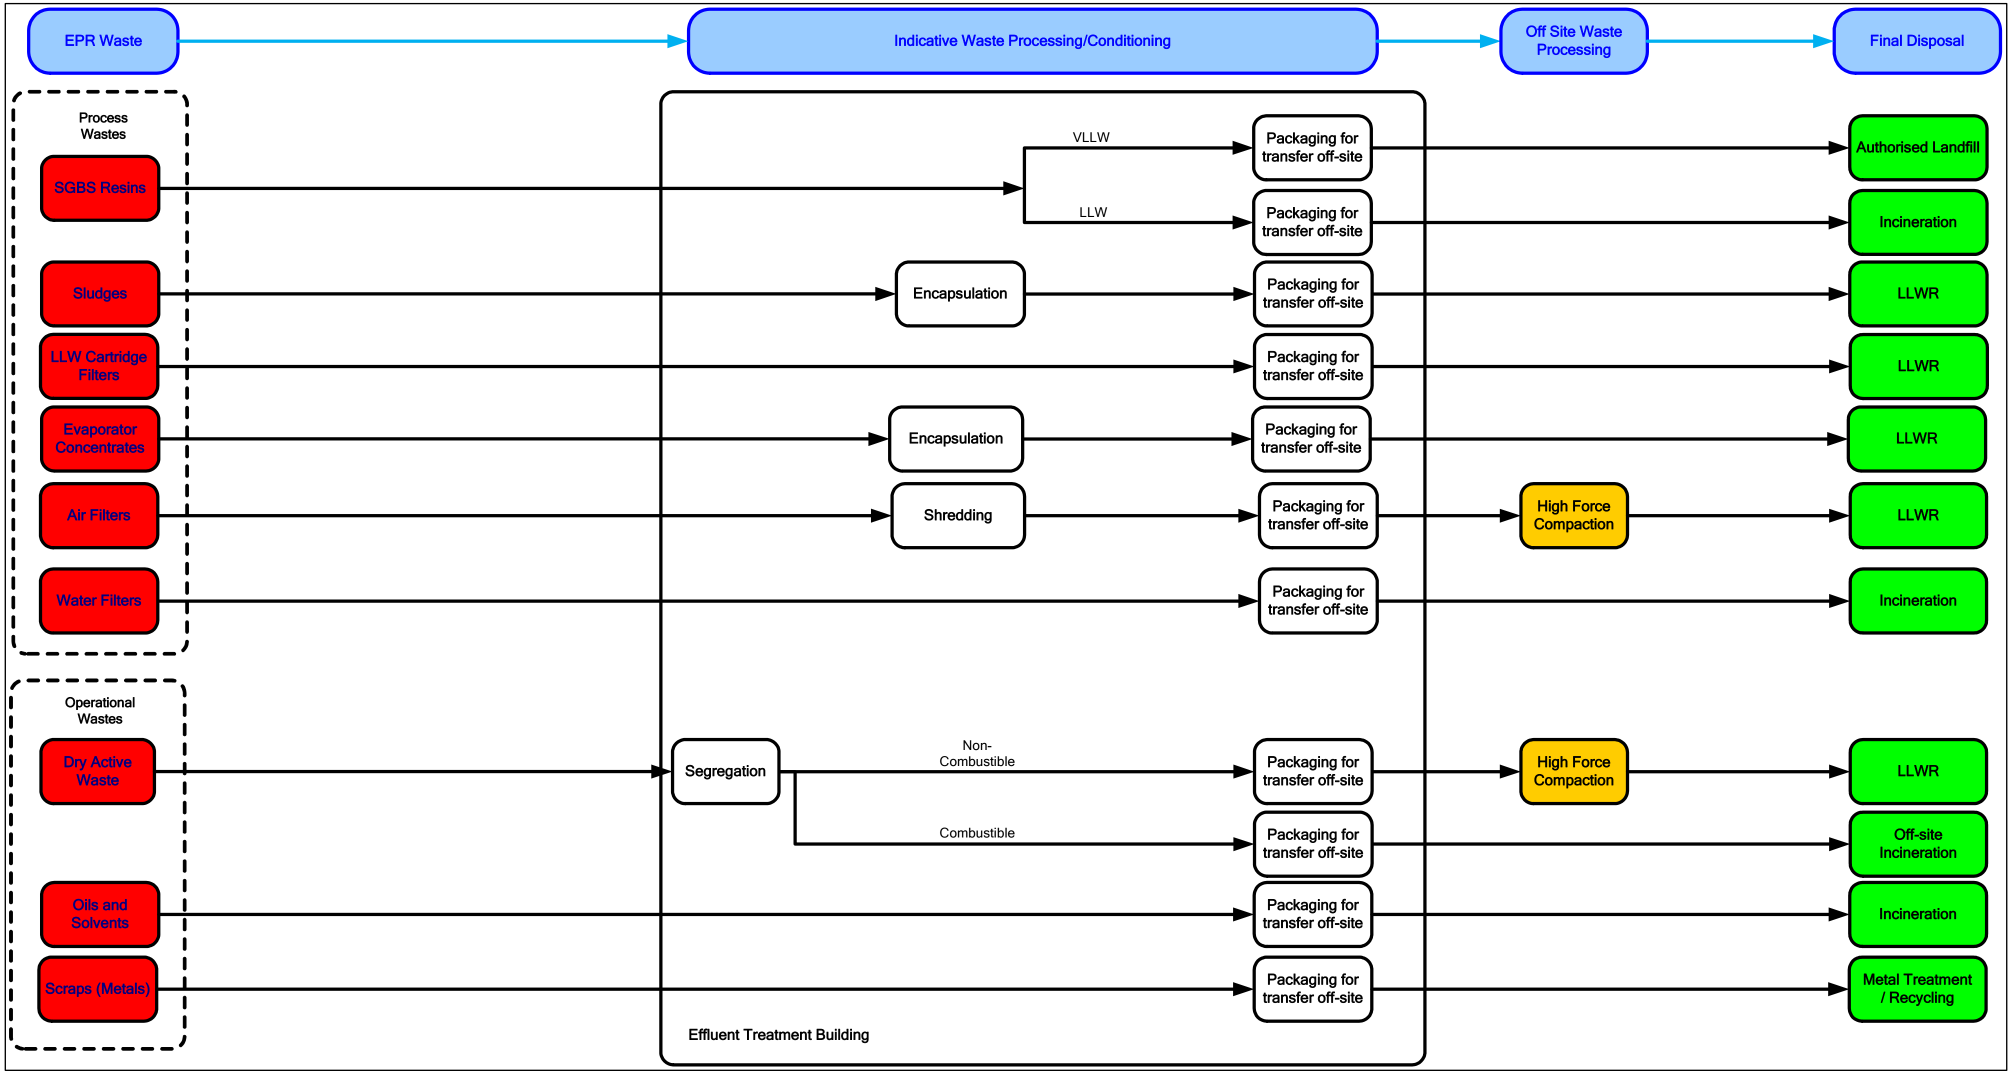
7.3.28 LLW unsuitable for disposal via the above disposal routes, but which meets the CfA for LLWR (Ref. 7.3), would be packaged on-site and transferred directly for disposal to LLWR in approved transport packages (e.g. Half Height ISO Containers (HHISO)).

v. VLLW Operations

7.3.29 High-volume VLLW could be disposed of to specified approved landfill sites. The waste would be subject to controls on its disposal which would be specified by the Environment Agency.

7.3.30 Wastes from HPC will be transferred to LLW disposal sites only if they have been demonstrated to represent BAT for the disposal of the waste and have been authorised by the UK regulatory bodies to accept the waste for disposal.

Plate 7.1: Indicative LLW Processing and Disposal Strategy



Note these disposal routes represent the preferred option for LLW management and disposal based on the anticipated waste characteristics. Alternative routes may be utilised in the future if they can be demonstrated to represent BAT or if the above disposal routes are found to be unavailable.

f) Transport Arrangements for LLW

7.3.31 All radioactive waste transferred from the site would need to comply with applicable UK and international legislation at the time of despatch, including the relevant requirements of the Carriage of Dangerous Goods and Use of Transportable Pressure Equipment Regulations 2009 (Ref. 7.3). Each consignment would undergo the required contamination checks and external radiation measurements before leaving the site.

7.3.32 Radioactive waste is transported in specially designed and approved packages. The packages provide protection to operators and members of the public and are required to be sufficiently robust to withstand a wide range of credible accident scenarios.

g) Timing of the Decommissioning of LLW Facilities

7.3.33 The LLW processing facilities would be utilised for the management of wastes throughout the operation of both of the HPC UK EPR reactor units. It is anticipated that the LLW processing facilities would be decommissioned in the final stages of the main decommissioning phase as set out in **Chapter 5** of this volume.

7.4 Intermediate Level Waste (ILW)

a) Management of ILW Generated during Operation of the HPC UK EPR

7.4.1 Routine operation of the HPC reactor units and their associated auxiliary systems would generate ILW. The majority of ILW would arise from the treatment of liquids and gases in order to reduce worker doses and discharges of radioactivity to the environment (e.g. ion exchange resins).

7.4.2 In addition to the process wastes, operational wastes may be generated as a result of maintenance work carried out during reactor operation and work performed during reactor outages.

7.4.3 The ILW streams that are anticipated to arise from normal operation and maintenance of the two UK EPR reactor units at HPC are set out in **Table 7.4** below.

Table 7.4: Categories of ILW that would be Generated at HPC

Waste Type	Waste Description
ILW ion exchange resins	Ion exchange beds are used to capture and minimise soluble radioactive material. This material results from corrosion in the primary circuit (mainly in the steam generators and activation of chemicals in the primary circuit) and in the following UK EPR water auxiliary circuits: • Chemical and volumetric control system; • Coolant purification system; and • Spent fuel storage compartment treatment system. The ion exchange resins in the beds are periodically changed to optimise their performance. Additional volumes of ILW ion exchange resins may arise from the maintenance of water quality and the abatement of liquid discharges from the Interim Spent Fuel Store (ISFS).
ILW cartridge filters	This waste consists of filters used in the clean-up of primary circuit water and water from the liquid waste and spent fuel pool treatment systems. There are several designs of filters depending on the abatement required. A proportion of the filters generated would fall into the ILW category.
ILW sludges	During the operation of the HPC UK EPR reactor units, particulates would settle as sludges in storage tanks associated with the auxiliary water circuits (e.g. liquid waste treatment system). These are variously contaminated with a range of fission and activated corrosion products. This sludge would be periodically cleaned out and removed for treatment prior to disposal. The waste is a sludge consisting of settled particulate. A proportion of the sludge generated would fall into the ILW category.
Operational wastes >2mSv/hr	This comprises a range of materials including contaminated metal, plastics, cloth, glassware, and rubble arising from operations during planned shutdown periods. Activated components with higher dose rates generated during maintenance operations may be temporarily placed into the reactor fuel pools to allow for a period of radioactive decay in order to minimise dose to workers.

b) ILW Management Strategy for HPC

7.4.4 The strategy is for ILW to be retrieved, conditioned and packaged on-site on a campaign basis throughout the operational phase. Waste processing would result in a passively safe package ready for interim storage. The passively safe packages would be stored in the ILW Interim Storage Facility (ILWISF) for the duration of operations. The stored ILW packages would be removed from the ILW store when a GDF is available to accept new build waste for final disposal. The assumed timescales for store emptying are discussed later in this chapter.

c) Decay Storage of Waste for Re-categorisation

7.4.5 The radioactivity of all radioactive waste diminishes with time (known as radioactive decay). All radionuclides have a characteristic half-life (the time it takes for any radionuclide to lose half of its radioactivity) and eventually all radioactive waste decays into non-radioactive elements. The process of waiting for a natural decline in the level of radioactivity to allow waste to be disposed of as a lower category of waste is known as decay storage.

7.4.6 The radioactivity of a proportion of the ILW that would be generated during operation of the HPC UK EPR reactor units would be dominated at the time of arising by relatively short lived radionuclides including cobalt-60 (half-life of 5.27yrs), caesium-137 (half-life of 30.2yrs) and iron-55 (half-life of 2.7yrs).

7.4.7 Waste identified as being suitable for decay storage will be packaged into suitably robust containers within the ETB and transferred into the ILWISF for a period of storage. Following the period of interim storage the radioactivity of the selected wastes would have reduced to such levels that the waste would no longer be classified as ILW. This waste would be removed from the ILWISF and managed as LLW.

d) Disposability of ILW from HPC

7.4.8 Before conditioning and packaging of ILW, regulatory guidance (Ref. 7.4) requires that sites produce an ILW conditioning proposal. This would include a demonstration that, following conditioning, the waste would be compatible with existing or future planned management and disposal options. This requires that a letter of compliance (LoC) is obtained for the packaging proposal. The LoC process is the mechanism that the NDA Radioactive Waste Management Directorate (RWMD) utilises to provide confidence that a waste package can be accepted at a future GDF.

7.4.9 The overall objective of the LoC assessment process is to give confidence to all stakeholders that the future management of waste packages has been taken into account as an integral part of their development and manufacture. This is achieved by the site operator working with RWMD to demonstrate that the waste packages produced by a proposed packaging process will be compliant with the generic waste package specification and compatible with plans for transportation and emplacement in the planned future geological repository.

7.4.10 In cases where the assessment has concluded that the waste package is compliant with the repository concept and underpinning assessments, RWMD is prepared to confirm this by the issue of the LoC.

7.4.11 As part of the GDA process, the opinion of the RWMD was sought on the likely acceptability for disposal in a GDF of packaged ILW generated by the UK EPR. RWMD was asked for its views on a number of different waste packages, including those that would be produced by implementing the GDA reference strategy for on-site ILW management. RWMD indicated that, in principle, any of the proposed waste packages would be acceptable for disposal. EDF Energy will continue to work with RWMD through the LoC process to ensure that packaged ILW from HPC would be acceptable for disposal in a GDF (Ref. 7.4).

e) HPC ILW Processing Strategy

7.4.12 The proposed strategy for ILW conditioning and packaging at HPC is termed the 'Reference Case'. It assumes that operational ILW would be conditioned and treated using the same procedures as applied during the operation of existing pressurised water reactors (PWR) in France with due consideration for UK specific requirements.

7.4.13 Under the Reference Case strategy, two types of cylindrical pre-cast concrete casks, designated C1 and C4, are the packages to be utilised for all operational ILW. Both of these casks can include internal mild steel shielding of varying thicknesses to provide shielding against different concentrations of gamma emitting radionuclides. The C1 cask is 1.4m in diameter, 1.3m high, and has a 0.15m thick concrete shield wall. The C4 cask has the same dimensions apart from the diameter which is 1.1m. In the Reference Case Scenario, the operational ILW would be immobilised within the casks using epoxy resin or cement grout prior to being placed into the on-site ILWISF.

f) Arrangements for Site ILW Management

7.4.14 Arrangements and requirements for radioactive waste management would cover minimisation, segregation, quantitative assessment, packaging, labelling, record keeping and consignment for transfer/disposal (Ref. 7.4).

7.4.15 Processes would be established and implemented for the packaging of radioactive wastes that encompass the whole lifetime of waste packages to ensure that packaged waste has the properties ascribed to it. These arrangements would be reviewed periodically and adequate records maintained.

7.4.16 The management arrangements would apply to all activities, interactions and aspects that can affect the quality of the waste package product, including:

- waste characterisation;
- container design;
- container manufacture;
- wasteform development;
- process development;
- plant specification and design;
- LoC submissions and advice actions;
- plant commissioning and operation;
- raw materials storage;

- waste package interim storage and monitoring;
- control of non-conforming packages;
- change control and continual improvement of waste package design, processing plant and interim storage; and
- package records and their long-term retention.

g) Facilities for Site ILW Management

7.4.17 ILW generated on the HPC site would require conditioning and packaging into an acceptable (passively safe) form prior to interim storage. This process is described in the following sections.

7.4.18 Based on current UK radioactive waste policy and strategy, the intention is that the final disposal location of packaged ILW from HPC would be in a GDF.

i. ILW Processing and Packaging

7.4.19 ILW generated during the operation of UK EPR reactor units at HPC would be conditioned in the ETB. The ETB is the primary interface for the processing of all radioactive operational waste materials that would be generated by the operation of the UK EPR reactor units and includes functions for safe handling, treatment, conditioning, buffer storage, packaging and monitoring of wastes prior to transfer of packages to the ILWISF. It is anticipated that some waste generated within the ISFS will be packaged and processed within the ISFS rather than being transferred to the ETB.

7.4.20 The key waste management functions are:

- treatment of radioactive wastewater and effluent;
- treatment of solid waste; and
- conditioning of solid/liquid waste (including cementation and resin encapsulation).

7.4.21 The conditioning process for the treatment of the waste would ensure the waste is in a passively safe form to be transferred from the ETB to the ILWISF and the waste package itself would be compliant with the requirements of RWMD.

ii. ILW Cementation

7.4.22 Cementation through the use of specially formulated grouts provides a means to immobilise radioactive material that is either solid or in various forms of sludges. At HPC, it is anticipated that all ILW wastes, other than ion-exchange resins, would be conditioned utilising a cementation process.

7.4.23 In general the solid wastes would be placed into C1 or C4 containers. The grout is then added into this container and allowed to set. The container with the now monolithic block of concrete/waste is then suitable for storage and disposal.

7.4.24 Similarly in the case of sludges the current packaging assumption is that the waste would be placed in a C1 or C4 container and a grouting mix, in powder form, is added. The two are mixed inside the container and left to set leaving a similar type of product as in the case of solids, which can be disposed of in a similar way.

iii. ILW Epoxy Resin Encapsulation

7.4.25 Ion-exchange resins consist of small beads used to remove radioactivity from contaminated liquids. The radioactive ions in the liquid are absorbed onto the resin by the chemical process of ion exchange. The resins retain the activity and the cleaned liquids can then be safely disposed of. When the ability of the resins to absorb more radioactive ions is exhausted they become radioactive waste.

7.4.26 It is proposed that spent ion exchange resins would be processed by in-container solidification utilising a polymer solidification process. The process is already established as a technique for treating ILW ion exchange resins in the UK at the Magnox site at Trawsfynydd. At HPC, EDF Energy propose to utilise the same mobile processing units currently operating to manage the resin waste generated on the fleet of EDF Nuclear Power Plants in France.

h) Summary of ILW Strategy and Volumes

7.4.27 The baseline processing strategy for the HPC ILW streams is summarised in **Table 7.5**. The proposed baseline set out in the table is the Reference Case for ILW processing which has been used to demonstrate that a suitable strategy can be implemented to manage the waste streams.

7.4.28 The anticipated lifetime package numbers set out in the final column of **Table 7.5** provides an upper estimate which does not take into account ILW that would, following decay storage in the ILWISF, be suitable for re-categorisation as LLW. As the detailed proposals for decay storage of ILW at HPC are developed this figure is expected to be reduced as waste initially categorised as ILW is disposed of as LLW.

Table 7.5: Operational ILW Waste Generation and Proposed Management Strategy for the HPC UK EPR Reactor Units

ILW Stream	Waste Description	Anticipated Annual Raw Waste Volume from Two UK EPR Reactor Units (m^3)	Lifetime (60yr) Raw Waste Volume from Two UK EPR Reactor Units (m^3)	HPC Processing Strategy	Anticipated Lifetime (60yr) Package Numbers from Two UK EPR Reactor Units
ILW ion exchange resins	Organic resins that arise from the clean-up of primary circuit water, water from the effluent treatment systems and the reactor fuel pools.	6	360	Polymer immobilisation in Concrete C1 casks. Followed by interim storage on-site awaiting availability of a GDF.	900
ILW spent cartridge filters	Filters from the clean-up of primary circuit water and water from the Liquid Waste and Spent Fuel Treatment Systems. The filters consist of a stainless steel support, with a glass fibre or organic filter media.	5	300	Cement grouted in Concrete C1 casks. Followed by interim storage on-site awaiting availability of a GDF.	720
	Other designs of filters, typically with lower activity.	5	300	Cement grouted in Concrete C4 casks. Followed by interim storage on-site awaiting availability of a GDF.	1200
Operational wastes >2mSv/hr	A range of materials, including activated core components, contaminated metal, plastics, cloth, glassware and rubble arising from operations during planned shutdown periods.	2	120	Cement grouted in Concrete C1 casks. Followed by interim storage on-site awaiting availability of a GDF. Note: Activated core components with heat generation levels above the ILW categorisation would be transferred to the reactor fuel pools where they would be held for a period of delay storage before processing.	360

ILW Stream	Waste Description	Anticipated Annual Raw Waste Volume from Two UK EPR Reactor Units (m^3)	Lifetime (60yr) Raw Waste Volume from Two UK EPR Reactor Units (m^3)	HPC Processing Strategy	Anticipated Lifetime (60yr) Package Numbers from Two UK EPR Reactor Units
ILW wet sludge	Sludge arising from cleaning the bottoms of liquid waste treatment tanks and various sumps.	2	120	Cement grouted in Concrete C1 casks. Followed by interim storage on-site awaiting availability of a GDF.	480
Totals		**20m^3[(2)]**	**1200m^3**		**3660 Packages**

i) Interim On-site Storage of ILW

7.4.29 There is currently no ILW disposal facility in the UK. The GDF is not expected to be available for disposal of wastes for a number of years after start of HPC operations. The strategy for ILW management at HPC is, therefore, to process and store the waste on-site, according to the principles of passive safety (Ref. 7.5), pending availability of the GDF.

7.4.30 The key requirement of the ILWISF would be to provide protection for the waste packages from potential degradation which could have a long-term impact on the integrity of the package and eventual acceptance of the package at GDF. In terms of containment of radioactivity and prevention of releases which could impact upon the outside environment, a number of barriers and environmental controls are provided as listed below:

- the conditioned wasteform is the primary barrier (e.g. the cemented matrix);
- the waste container is the secondary barrier (e.g. the concrete package);
- control of the store environment is important in maintaining integrity of the waste container to ensure compliance with LoC requirements (e.g. humidity levels controlled by adequate ventilation); and
- the store structure is the final layer of weather protection for the waste package and also provides a role in the physical security of the waste.

[2] An additional volume of ILW may be generated during the operation of the ISFS. The design of the ISFS is ongoing and as such the abatement systems and waste volume generation has not yet been finalised. All waste resulting from the operation of the ISFS is expected to fall into the categories set out above, or the previously discussed LLW categories. The main solid waste streams are anticipated to be spent ion exchange resins and filters; these would be expected to be processed as above followed by interim storage on-site awaiting availability of a GDF.

7.4.31 The store would require appropriate maintenance and various levels of in-service refurbishment. As a condition of the NSL, the facilities on-site, including the ILWISF, would be subject to Periodic Review of the safety case throughout the operational life of the store, ensuring any necessary improvements would be made in a timely manner.

7.4.32 EDF Energy anticipate that the store would be emptied of waste and would be decommissioned within 20 years of EoG but its lifespan is considered to be capable of extension if necessary, through refurbishment or replacement of equipment and structures.

7.4.33 The facility is designed to receive and store packages of ILW waste arising from the planned 60 years of operation of the two UK EPR reactor units on the HPC site. The waste would be packaged into a passively safe state as described earlier, prior to being transferred to the ILWISF.

ii. Facility Design Description

7.4.34 The ILWISF would consist of areas performing the following functions:

- receipt and dispatch area;
- interim storage space for all operational ILW until a GDF becomes available;
- package inspection area; and
- facilities to manage ILW that would become LLW following a period of decay storage.

7.4.35 The facility would also require a number of auxiliary systems and plant, such as those providing electrical power, ventilation and maintenance facilities.

iii. Safety Aspects

7.4.36 The design and operation of the facility would be required to be compliant with the NSL with regard to the safety of workers and the public. The facility would be designed, constructed and operated to comply with the Ionising Radiation Regulations 1999. In order to minimise radiation doses to workers and the public, the facility would include the following safety functions:

- the facility would provide containment for radioactive material. In most instances the primary containment would be provided by the conditioning process and the waste packages and secondary containment by the facility structure;
- the facility would minimise the radiation exposure of workers and the public through the provision of shielding; and
- the facility would be maintained at a reduced pressure through the use of a filtered ventilation system to prevent any spread of contamination in the event of an incident at the facility.

7.4.37 Further measures would be implemented to prevent loss of containment by a waste package including:

- minimising waste package handling operations and when package movements cannot be avoided, minimising the lift height of packages where practicable;

- inspection and monitoring of the waste packages in the storage hall to allow early intervention if any package defect is identified; and
- the waste packages are designed to be robust against impact and or being dropped during movement.

7.5 Long-Term Management of ILW

a) Timing of Decommissioning of ILW Management Facilities

7.5.1 The ILW processing facilities would be utilised for the management of wastes throughout the operation of both of the HPC UK EPR reactor units. It is anticipated that the ILW processing facilities would be decommissioned in the final stages of the main decommissioning phase as set out in **Chapter 5** of this volume.

7.5.2 The ILWISF would be decommissioned following complete transfer of all waste from the store; the anticipated timing of transfer of ILW from the store is set out below.

b) Transport of ILW to GDF

7.5.3 At the end of the interim storage period it is the responsibility of the waste producers to ensure that the package is safe for export off-site and is compliant with transport regulations in force at that time. Assessments for the LoC process also address transportation, so that transport issues will necessarily have been addressed for packages that comply with a LoC.

7.5.4 All radioactive waste despatched from the site would need to comply with applicable UK and international legislation at the time of despatch, including the relevant requirements of the Carriage of Dangerous Goods and Use of Transportable Pressure Equipment Regulations 2009 (Ref. 7.3). Each consignment would undergo the required contamination monitoring and external radiation measurements before leaving the site.

7.5.5 Radioactive waste is transported in specially designed and approved packages. The packages provide protection to operators and members of the public and are required to be sufficiently robust to withstand a range of credible accident scenarios. The UK has more than 50 years of experience of transporting radioactive waste and other radioactive materials by road, rail and sea in accordance with international and national regulations that are designed to protect people, property and the environment. The transport of radioactive material and waste is a well established process that has a proven safety record.

c) Disposal of ILW to GDF

7.5.6 In planning the implementation of the national policy of geological disposal, the NDA has assessed that a UK facility could be operational for the disposal of legacy ILW by about 2040. Disposal of legacy waste is estimated to be completed by about 2130 and the Government's waste base case currently assumes that disposal of new build wastes would begin once disposal of legacy wastes is completed. This assumes that new build ILW is disposed of to the same facility as the UK legacy waste inventory which would require agreement with the host community through the MRWS process.

7.5.7 The proposed decommissioning strategy which would be employed at HPC is early site clearance. Fundamentally the strategy means that decommissioning would commence as soon as possible after EoG at the site, and would proceed without significant delay to complete the process of decommissioning of the reactors and auxiliary buildings. Therefore a reactor that begins generation in 2018, with a 60 year generating life, could have all ILW packaged and ready for transfer to GDF by approximately 2100 (i.e. significantly earlier than the current assumption regarding availability of the GDF).

7.5.8 The current scheduling for transfer of waste to the GDF has been devised by the NDA based on a design which has not been optimised for new build waste. Optimisation of the current scheduling programme for legacy ILW could allow disposal of new build ILW on earlier time scales than the 2130 date currently assumed. NDA is engaging with nuclear new build operators to determine whether it is feasible to establish an optimised baseline which would allow earlier disposal of ILW to the GDF.

7.5.9 For the purposes of decommissioning planning it is assumed that the GDF scheduling can be optimised to allow transfer of packaged ILW during the main site decommissioning phase. However if optimisation requires a further period of interim storage it is possible that the ILWISF may need refurbishment to extend its life until the GDF is available. Safety issues related to the design of the ILWISF and the extension of its life would be regulated outside of the planning regime, through nuclear site licensing.

7.5.10 The potential impact of the disposal of UK EPR operational and decommissioning ILW on the size of a GDF has been assessed by NDA RWMD. Although the impact depends to some extent on the type of package, it has been concluded that in all cases the volume increase is relatively small, corresponding to less than approximately 60m of disposal vault length for each UK EPR. This represents less than 1% of the area required for the UK legacy ILW, per reactor. This reflects the substantial reduction in waste arising per unit of electricity generated in the UK EPR compared with earlier designs.

7.6 Spent Fuel

a) The Quantity of Spent Fuel Generated During the Operation of HPC UK EPR

7.6.1 The UK EPR core contains the nuclear fuel in which the fission reaction occurs. The remainder of the core structure serves either to support the fuel, control the chain reaction or to channel the coolant.

7.6.2 The reactor core of a UK EPR consists of 241 fuel assemblies providing a controlled fission reaction and a heat source for electrical power production. Each fuel assembly is formed by a 17x17 array of Zircaloy M5 (or equivalent zirconium alloy) tubes, made up of 265 fuel rods and 24 guide thimbles. The fuel rods consist of uranium dioxide pellets stacked in a zirconium alloy cladding tube which is then plugged and seal welded.

7.6.3 It is currently assumed that a maximum of 90 spent fuel assemblies (SFA) would be removed every 18 months of operation from each UK EPR reactor unit. With time included for planned outages for maintenance over the anticipated 60yrs operation, a total of approximately 3,400 assemblies per UK EPR reactor unit are expected to be generated. Through the lifetime of HPC, which would have two UK EPR reactor units, a total of around 6,800 fuel assemblies would be generated.

7.6.4 The dimensions of one fuel assembly are 0.214m x 0.214m x 4.859m so the raw waste volume associated with the lifetime total of 6,800 fuel assemblies requiring interim on-site storage would be 1,513m^3. Each spent fuel assembly has a mass of 527.5kg of uranium; therefore a total inventory at EoG would be approximately 3,600 tonnes.

b) The Requirement for Interim On-site Storage of Spent Fuel

7.6.5 The Government has concluded that, in the absence of any proposals from industry for reprocessing, any new nuclear power stations that might be built in the UK should proceed on the basis that spent fuel would not be reprocessed and that plans for, and financing of, waste management should proceed on this basis.

7.6.6 Whilst there is a Government programme in place to develop a GDF, there is currently no disposal facility for spent fuel and the GDF will not be available until many years after the time when HPC would start generating spent fuel. The strategy for spent fuel management at HPC is, therefore, to store the spent fuel on-site pending availability of a GDF and this is consistent with the "base case" that Government has described in Section 4 of its 2008 Consultation on Funded Decommissioning Programme Guidance for New Nuclear Power Stations.

7.6.7 Although it is possible that over the life of the station alternative facilities could become available that might allow spent fuel to be transported off-site earlier, it is prudent to plan on the basis that sufficient capacity is provided on-site to store the lifetime arisings of spent fuel from the two UK EPR reactor units until it can be transported offsite for disposal in the GDF which is currently estimated as being around 2130.

c) Arrangements for Site Spent Fuel Management

7.6.8 The amount of heat generated from radioactive decay within spent fuel means that after it has been removed from a reactor it must be cooled for an initial period under water before its heat output reduces such that it can be placed into interim storage and eventually transported off-site for disposal. This initial cooling would take place in the reactor pool within the Fuel Buildings associated with each EPR unit. Fuel assemblies removed from the reactor would be cooled underwater in the on-site reactor fuel pool for up to 10 years. The reactor fuel pools are not designed for the full life-time arisings of spent fuel.

7.6.9 Following this initial storage period in the on-site reactor fuel pool, the spent fuel assemblies would be prepared for transfer to the separate on-site ISFS where they would be safely stored until the GDF is available and the spent fuel is in a condition suitable for final disposal.

7.6.10 This period of interim storage is assumed to last until around 2130 when on, current planning assumptions, the GDF will be available to receive spent fuel from new nuclear power stations and the spent fuel produced within the Hinkley Point EPRs will have cooled to a level compatible with its disposal.

7.6.11 The planning assumption is therefore that the ISFS would provide storage for spent fuel from the HPC UK EPR reactor units from around 10 years after the start up of Unit 1 until the spent fuel is transferred off-site for disposal at the GDF at around 2130. The ISFS would be designed for a life of at least 100 years and there would be a capability for this to be both achieved and extended, if necessary, through refurbishment or replacement. The ISFS will be designed so as to be capable of operating independently of other parts of the power station in recognition of the fact that it will have a lifetime that would, under current assumptions, extend beyond the decommissioning of the other facilities on the site.

7.6.12 The design of the ISFS must be capable of meeting the following requirements:

- ensuring safe operations (e.g. by preventing a fuel criticality, ensuring sufficient residual heat removal, and maintaining effective containment of radioactivity);
- providing radiological protection of the public, workers and the environment at all times in compliance with dose limits and ensuring that all doses are ALARP and that any discharges of radioactivity to the environment are demonstrated to be minimised in accordance with BAT;
- ensuring cooling and maintaining spent fuel in a condition appropriate for its eventual retrieval, transport and final disposal.

7.6.13 EDF Energy has reviewed the options available for on-site interim storage of spent fuel and determined that for the site specific circumstances at HPC, wet interim storage within an engineered pool is the best approach. The alternative technical options that have been considered and the factors leading to EDF Energy's choice are identified within **Chapter 6** of this volume.

7.6.14 Wet storage of spent fuel has been used widely in the UK and internationally (Ref. 7.6) and has been licensed previously. The use of wet interim storage of spent fuel is capable of providing HPC with a safe, secure and technically flexible solution until such time that the spent fuel is suitable for transfer and a UK GDF, or other off-site management facility, is available.

7.6.15 Although the ISFS is not required to be available until around 10 years after the first unit begins operation, it is the intention to build the facility as part of the main power station construction.

d) Key Safety and Operational Features Associated with the HPC ISFS

7.6.16 The ISFS design is under development and is currently at the conceptual stage. The proposed ISFS would have a range of safety features to maintain the safety of the facility and it would be required meet the requirements of the safety, security and environmental regulators.

7.6.17 A brief outline of some of the key safety and operational features of the proposed ISFS are summarised below:

- Even when containing its full loading of spent fuel, the volume of water within the pool will be large in comparison with the amount of heat generated within the stored spent fuel; this means that pool water temperature will only change slowly should there be an interruption to cooling systems;
- the spent fuel pool cooling systems will be designed such that they will be able to provide significant cooling even when operating in passive mode and this capability will be sufficient to ensure safety over very long periods even if all power supplies were lost. In addition, the design will be optimised to favour as much as possible passive operation of the facility;

- clean-up systems will be provided to maintain water quality and the water chemistry will be controlled to avoid corrosion of fuel assemblies;
- the facility will be designed to be resistant to a wide range of external events such as aircraft crashes or earthquakes;
- the spent fuel pool will be designed with high integrity and will have leak detection and collection systems;
- the water within the ISFS will not require to be dosed with a soluble neutron absorber to ensure protection from criticality; instead this will be achieved through structural materials surrounding the stored fuel assemblies;
- the design and operation of the ISFS will ensure that the amount of radioactivity discharged to air or to sea during operation of the facility will be extremely small.

e) Operations involved during the management of Spent Fuel on site

7.6.18 The operations involved in managing HPC spent fuel can be broken down into a number of steps:

- after an appropriate length of storage, spent fuel would be removed from the reactor fuel pool and packaged into a flask for transfer to the separate ISFS;
- on arrival at the ISFS, the flask would be submerged in the unloading pool;
- the flask lid would be opened and the flask prepared for unloading;
- the fuel assemblies would be unloaded one at a time and placed into mobile storage racks which would contain several assemblies;
- pool handling equipment would be used:
  - to place fuel within a storage rack (or remove it if necessary);
  - to move the racks from the loading position to the storage positions in the pool;
  - to move the racks during storage to optimise pool loading;
  - to move the racks from/to the stored position to permit fuel inspection; and
  - to move the racks from the stored positions to the unloading position (at the end of the interim storage period);
- throughout the operational life of the ISFS an inspection and monitoring regime would be implemented to ensure that fuel is stored safely
- When the time comes for the ISFS to be emptied, the spent fuel assemblies would be removed from the ISFS and loaded into transport flasks for transfer to an encapsulation (packaging) facility prior to transport to the GDF for disposal.

f) Management of Radioactive Waste and Discharges from the ISFS

7.6.19 Wet interim storage would result in the generation of small quantities of liquid, gaseous and solid radioactive wastes resulting from the requirement to maintain pool water quality, to ensure that doses to workers are ALARP, and to minimise discharges of radioactivity to the environment. These wastes would require management throughout the lifetime of the interim store.

7.6.20 The minimisation of wastes and discharges from ISFS operations, through the application of BAT, would need to be demonstrated in order for EDF Energy to fulfil the requirements of the RSR Environmental Permit.

7.6.21 While the UK EPR reactor units are operating it is anticipated that liquid discharges from the ISFS would be routed to the same discharge point as for other liquid discharges from both HPC UK EPR reactor units. The liquid discharges from the ISFS would be minor in comparison to the already small radioactive liquid discharges from the operation of both UK EPR reactor units. Following decommissioning of the EPR units at HPC an alternative liquid discharge arrangement would be required for the ISFS. It is anticipated that the gaseous releases of the ISFS would be discharged by a specific stack on the ISFS. Again, the gaseous discharges associated with spent fuel management would be much less than the already very small gaseous discharges associated with the UK EPR reactor units themselves.

7.6.22 During the period of reactor operations the treatment of radioactive waste generated from the ISFS would be carried out either within the ISFS itself or would be transferred to the ETB. Waste generated following the decommissioning of the reactors and auxiliary buildings, including the ETB, would require management within a new waste treatment facility within the ISFS. It is anticipated that these wastes would be transferred for disposal directly to GDF in the case of ILW, or to a suitable LLW disposal facility for LLW, without the need for interim storage on-site. In the event that disposal facilities are unavailable following decommissioning of the reactor site and auxiliary buildings an additional period of on-site interim storage for the ILW and LLW from spent fuel management may be required.

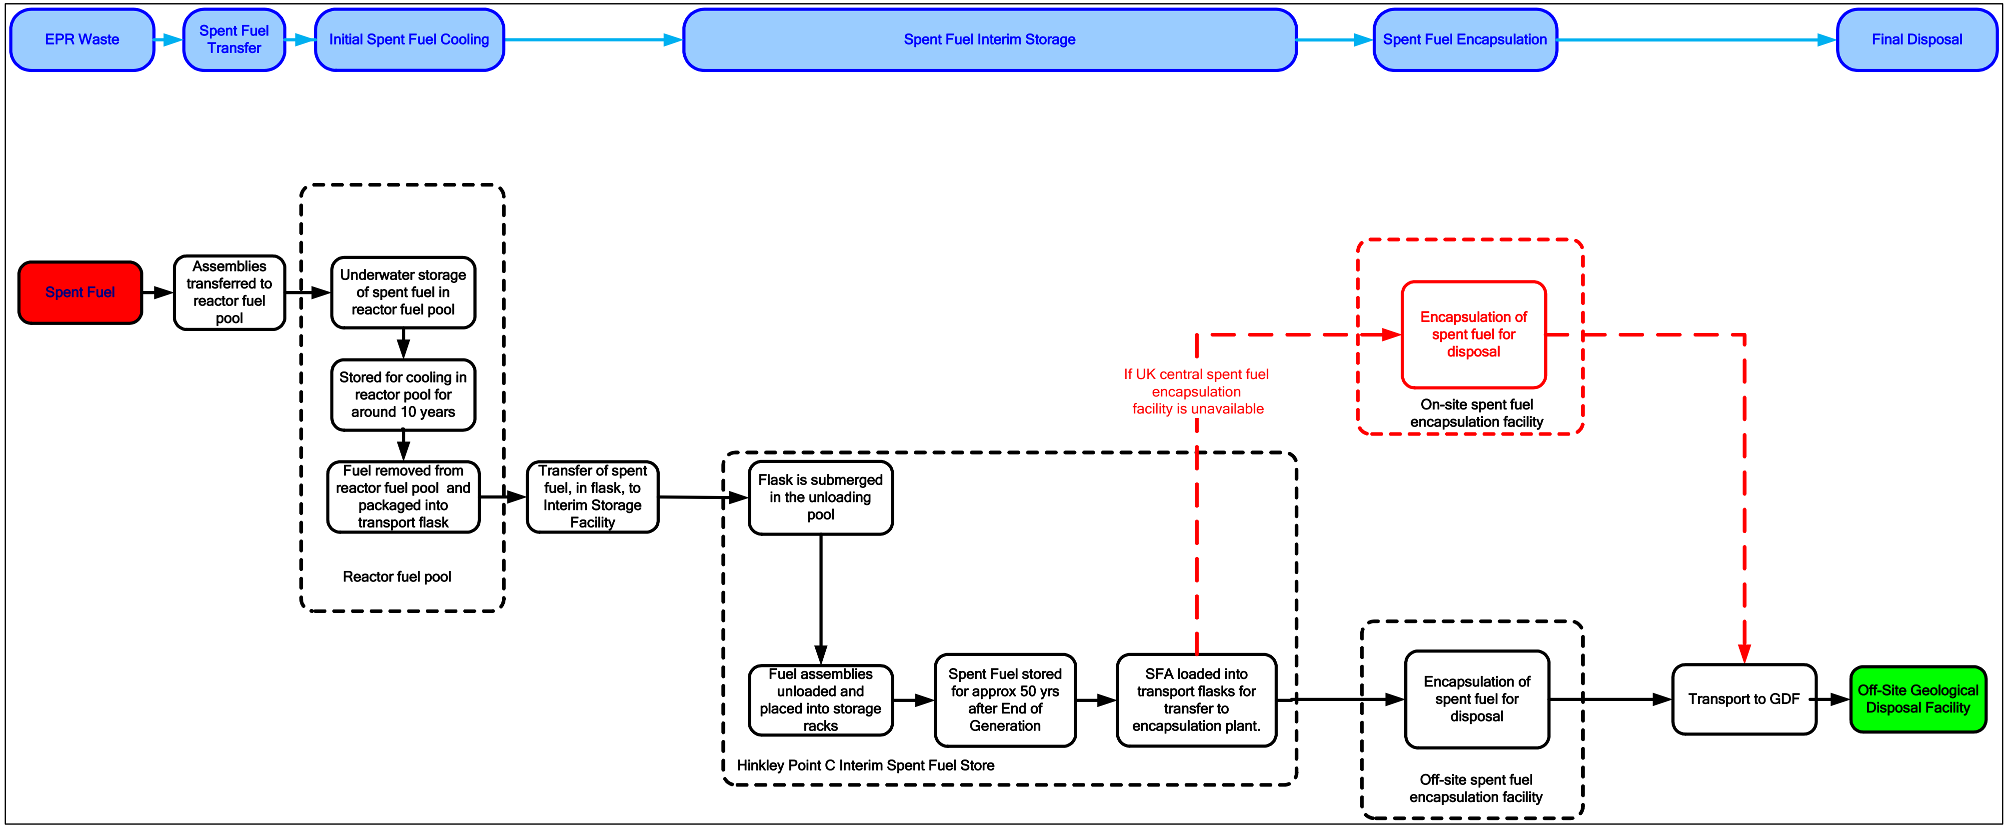
7.7 Long-Term Management of Spent Fuel

a) Spent Fuel Management Following Reactor Decommissioning

7.7.1 At the EoG (indicatively 2079 for Unit 1 and 2080 for Unit 2) all remaining spent fuel would be removed from the reactors and transferred to the ISFS, following the initial cooling period in the reactor storage pools. During the main site decommissioning phase the spent fuel would continue to be stored in the on-site ISFS and the store would be modified to allow it to be a stand alone facility after the rest of the site has been decommissioned.

7.7.2 Following the end of the main site decommissioning the spent fuel would remain within the ISFS. The facility would continue to be licensed as a nuclear site and a number of additional facilities would be provided to accommodate the requirements for a small workforce to operate the storage facility, ensure security of the site, and continue to maintain all safety and environmental obligations. The costs for these modifications and the continued operation of the facility would be funded through the EDF Energy FDP. The Spent Fuel Management Strategy (**Plate 7.2**) sets out the proposed spent fuel management baseline. Only when all the spent fuel has been removed from the ISFS, and decommissioning of the facility is completed, would this remaining part of the site be de-licensed and the land released for alternative use.

Plate 7.2: HPC Spent Fuel Management Strategy



b) Timing of Transfer of Spent Fuel to GDF

7.7.3 The time that would be required for the safe and secure on-site interim storage of spent fuel prior to disposal depends on a two key factors:

- the availability of a GDF; and
- the requirement that spent fuel characteristics are suitable to allow disposal to the GDF (i.e. the spent fuel has sufficiently cooled to allow disposal to GDF).

7.7.4 RWMD have published their plans and timescales for the expected implementation of the GDF (Ref. 7.7). This schedules the end of legacy spent fuel disposal to the GDF as approximately 2130.

7.7.5 NDA's disposability assessment for UK EPR spent fuel, performed during the GDA process, included the finding that if spent fuel is produced at the highest burn-up considered (65GWd/tU), spent fuel cooling (i.e. the time in interim storage) might be required for a period of up to 100 years before disposal to GDF (Ref. 7.7). It was acknowledged that this figure is conservative and the more recent work performed has resulted in a reduction of the expected storage time.

7.7.6 Recent work undertaken by RWMD on behalf of the NIA (Ref. 7.7) has concluded that the storage period to enable the spent fuel to cool sufficiently to allow disposal to the GDF could be around 50 years after the EoG.

7.7.7 It is therefore assumed that the date for start of transfer of spent fuel from the HPC site to a GDF, following encapsulation, is approximately 2128 (50 years after EoG). The process of transfer from the site could be completed in about 8.5 years (based on a transfer rate of 800 spent fuel assemblies per year) therefore all fuel could be removed from the site by 2136. On completion of transfer of the spent fuel from site for encapsulation and disposal, the ISFS would be decommissioned. The final stage of decommissioning would be to demonstrate that there is no longer any danger from radioactivity on the site, and that it can therefore be delicensed and the operator's period of responsibility brought to and end.

c) Alternative Scenarios for Long-term Interim Storage of Spent Fuel

7.7.8 There are a number of alternative scenarios which could result in spent fuel being transferred from the site significantly earlier, allowing earlier decommissioning of the ISFS and subsequent site de-licensing. For example:

- a change in spent fuel management strategy, for example the provision of a UK centralised spent fuel interim storage facility; or
- the optimisation of the GDF design to allow earlier disposal of new build spent fuel.

d) Packaging (Encapsulation) of Spent Fuel for Disposal

7.7.9 The RWMD is developing disposal concepts for HLW and spent fuel undertaking work on several related areas.

7.7.10 RWMD has developed a reference disposal concept based on the Swedish KBS-3V method. This concept is known as the UK Reference HLW and Spent Fuel

Repository Concept. The concept was developed in order to demonstrate the viability of geological disposal of HLW and spent fuel in the UK.

7.7.11 Under this concept, spent fuel would be over-packed before disposal into durable, corrosion resistant disposal canisters manufactured from suitable materials, which would provide long-term containment for the radionuclides contained within the spent fuel. This process is known as encapsulation.

7.7.12 Encapsulation of fuel under the UK reference strategy would require the construction of a complex and expensive facility. Whilst the Government's waste base case envisages on-site encapsulation of spent fuel, EDF Energy considers that a more realistic assumption would be for a single UK facility to be developed to encapsulate both legacy and new build spent fuel and HLW. Such a facility could be co-located with the eventual repository site.

7.7.13 In the event that a central facility for encapsulation of spent fuel is unavailable at the required time, an encapsulation facility to manage Hinkley Point spent fuel could be constructed on site. Such a facility would require planning consent and would be designed, constructed and operated in compliance with the NSL and RSR permit requirements with regard to safety and radioactive waste discharges.

e) Transport and Disposal of Spent Fuel to GDF

7.7.14 As part of the GDA of the UK EPR, RWMD has undertaken a Disposability Assessment for the spent fuel expected to arise from the operation of a UK EPR (Ref. 7.7). This assessed the implications of the disposal of the proposed spent fuel disposal packages against the waste package standards and specifications developed by RWMD and the supporting safety assessments for a GDF. The safety of transport operations, handling and emplacement at a GDF, and the longer term performance of the system have been considered, together with the implications for the size and design of a GDF.

7.7.15 On the basis of the GDA Disposability Assessment for the UK EPR, RWMD has concluded that, compared with existing spent fuel, no new issues arise that challenge the fundamental disposability of the spent fuel expected to arise from operation of such a reactor. This conclusion is supported by the similarity of the fuel to that expected to arise from the existing PWR at Sizewell B. Given a disposal site with suitable characteristics, the spent fuel from the UK EPR is expected to be disposable.

7.7.16 The assumed operating scenario for a single UK EPR reactor unit (60 years operation) gives rise to an estimated 900 disposal canisters. This has been calculated to require an area below ground of approximately 0.15km^2 for the associated disposal tunnels representing approximately 8% of the area required for legacy HLW and spent fuel. The spent fuel associated with the two HPC UK EPR reactor units would require an area of approximately 0.30km^2, excluding associated service facilities. This represents approximately 16% of the area required for legacy HLW and spent fuel.

8. CONVENTIONAL WASTE MANAGEMENT

8.1 Introduction

8.1.1 This chapter provides an assessment of the potential impact of conventional waste arisings associated with the construction and operation of Hinkley Point C, including the construction, operation and as far as reasonably practicable, the post-operational phase of the associated developments.

8.1.2 Spent fuel and radioactive waste which arise during the operation of HPC are discussed within **Chapter 7** of this volume, and the waste arisings associated with the decommissioning of the HPC nuclear power station are considered in **Chapter 5.**

8.1.3 The key phases which will generate waste associated with HPC and the associated developments are:

- **earthworks/construction** such as demolition/remedial wastes of any pre-existing structures; old formwork, steel off-cuts;
- **operational wastes** such as maintenance of pipes, equipment and control rooms at the HPC nuclear power station, and general waste produced from the workers at their offices/accommodation; and
- **post-operational waste** such as demolition waste and spoil, where applicable.

8.1.4 HPC will be constructed over a period of approximately nine years, and throughout this period waste will be produced. It is proposed that Unit 1 and Unit 2 would become fully operational in 2019 and 2020 respectively, and will operate for a period of 60 years prior to decommissioning.

8.1.5 The off-site associated developments will take up to two years to construct, with an approximate seven year operational phase, unless required to support the operational phase of HPC, as described in **Chapter 5** of each of **Volumes 3** to **10** of this ES. The potential post-operational uses differ for each proposed development as explained in the above chapter.

- **Bridgwater A -** Some infrastructure would be removed and some retained following cessation of use of the site by EDF Energy. A Post-Operational Scheme would be submitted to the Infrastructure Planning Commission (IPC) at the relevant time to approve which components of the development would be retained or removed, to facilitate re-use of the site in the longer term.
- **Bridgwater C -** The infrastructure would be retained, with the exception of some minor structures, following cessation of use by EDF Energy and would be transferred to a third party for use in connection with Bridgwater College.
- **Cannington Bypass -** The bypass would be retained to support the operational phase of the HPC power station and would be adopted by the highways authority for use as public highway.

- **Cannington Park and Ride -** All of the infrastructure would be removed and the land would be restored to agriculture.
- **Combwich -** The wharf would be retained to support the operational phase of the HPC power station. In terms of the freight laydown facility, all of the infrastructure would be removed and the land returned to agriculture.
- **Junction 23 -** The proposed development could be removed and the land restored to its existing use (agriculture) following cessation of use by EDF Energy. Alternatively, the site could be retained in part to allow for future use by third parties.
- **Junction 24 -** Appropriate measures would be carried out to allow the site to be available for storage/distribution purposes following cessation of use by EDF Energy.
- **Williton -** Appropriate measures would be carried out to allow the site to be available for use as a lorry park depot and storage area following cessation of use by EDF Energy.

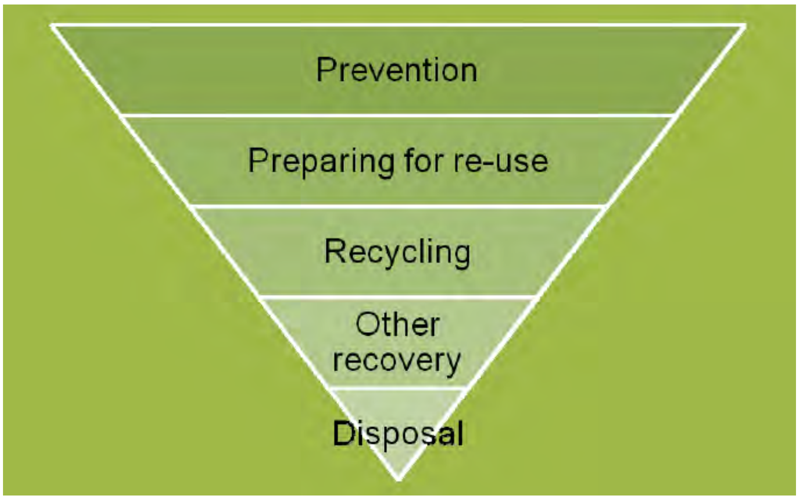
8.1.6 Further details of the mechanisms for the post-operational phase are described in the **Post-operational Strategy** appended to the **Environmental Statement.**

8.1.7 To facilitate the prevention and minimisation of waste in accordance with the waste hierarchy described below, EDF Energy has developed a Waste Management Implementation Strategy (WMIS) (see **Annex 5**) for waste generated during the construction and operation of the HPC Project, which includes the post-operational phases for each of the off-site associated developments.

8.1.8 The principal objective of sustainable waste management is to use material resources more efficiently, thereby reducing the amount of waste generated and minimising the quantity of residual waste requiring final disposal. Where there is residual waste, it would be managed in line with the principles of the waste hierarchy, applying the proximity principle to minimise environmental impacts and actively contribute to the social and economic goals of sustainable development.

8.1.9 The waste hierarchy requires prevention of waste generation in the first instance and reducing, as far as possible, the volume requiring disposal once the waste has been produced. The waste hierarchy gives an order of preference for waste management options to minimise the volume for disposal, as illustrated in **Plate 8.1**.

Plate 8.1: The Waste Hierarchy. Source: Defra.



8.1.10 Waste is defined as any substance or object which the holder discards, intends to discard or is required to discard, and has no specific proposed use at the time of its creation. Waste is generally subdivided into three broad categories, inert, non-hazardous and hazardous, as described below:

- **Inert waste** does not undergo any significant physical, chemical or biological transformations (e.g. brick, concrete and glass). Construction and demolition type waste will be the largest volume of inert waste produced from the project.
- **Non-hazardous waste** is reactive but not considered harmful to human health and/or the environment (e.g. organic matter in household waste).
- **Hazardous waste** has properties which are considered harmful to human health and/or the environment (e.g. some remedial waste, batteries and fluorescent tubes). Hazardous waste will comprise the smallest proportion of waste produced from the project.

8.2 Scope and Objectives of Assessment

a) Scope of Assessment

8.2.1 The scope of this chapter has been determined through the Stage 1 and 2 consultations, along with informal engagement with Somerset County Council (SCC), the Environment Agency (EA) and Somerset Waste Partnership (SWP).

8.2.2 This assessment aims to:

- identify the main waste streams and predicted volumes likely to arise from the construction, operation and post-operational phases of the HPC Project;
- identify any potential impacts upon existing waste infrastructure;
- identify measures that would be implemented to prevent and minimise waste generation; and
- ensure that a sustainable waste management option is adopted.

8.2.3 The assessment of conventional waste generation arising from the HPC development site and the off-site associated developments has been undertaken adopting the methodologies described in Section 8.4.

8.2.4 The existing baseline conditions, against which the likely waste impacts are assessed, are described in Section 8.5. The baseline conditions have been identified as the existing waste management facilities within Somerset, in terms of their type, capacity and availability. In addition, baseline conditions for the HPC development site and each of the off-site associated developments have been determined, in terms of their current waste production.

8.2.5 The predicted waste types, volumes and schedule of waste production are outlined in Section 8.6. In Section 8.7, the predicted waste volumes have been compared against the existing baseline conditions. Appropriate mitigation measures aimed at reducing the impact of the waste generation are presented in Section 8.8.

b) Objectives of the Assessment

8.2.6 With regards to earthworks, construction and demolition waste resulting from the HPC Project, EDF Energy has set a target of re-using, recycling or recovering at least 90% of the waste. This is in addition to a target of re-using, as far as practicable, 100% of excavated clean soils.

8.2.7 In order to meet the above targets, the following objectives have been developed for waste management:

- prevent and reduce the volumes of waste produced through the application of the waste hierarchy;
- maximise re-use and recycling within the wider development;
- maximise re-use and recycling outside of the HPC Project; and
- minimise the impact upon the existing waste management infrastructure.

8.2.8 The practical implementation of these objectives across the HPC Project is summarised below.

i. Prevention

- EDF Energy will ensure careful design of earthworks, for example:
  - storage of topsoil and subsoil during construction and incorporation into the final landscape scheme;
  - re-use of deeper subsoil and rock to construct the main platform;
  - the reuse of excavated natural bedrock (where appropriate); and
  - recovery of secondary aggregates from excavated Made Ground.
- Construction activities and the ordering of materials during the construction phase will be planned to minimise waste including packaging.
- Use of modular units to reduce construction waste generation on-site. For example, the majority of the accommodation campus buildings will be modular. Consequently, these materials would be delivered as abnormal indivisible loads (AILs) to site.
- Adoption of best practice construction methods and consultation with the Waste and Resources Action Programme (WRAP) would ensure that the waste minimisation and resource efficiency targets are met.

ii. Preparation for Re-use

- Efforts will be made to re-use materials during construction, operation and reinstatement of the main site, and the post-operational phase for the associated developments (as applicable).
- EDF Energy will encourage re-use of material through a waste inventory, for example, whole units, materials, fabrics and components could potentially be resold locally.

iii. Recycling

- General waste (e.g. plastic and glass) produced from the operational phases of the accommodation campuses will be segregated prior to being sent to an appropriate recycling facility.

iv. Disposal

- Where not connected an existing system/discharge, sewage at the off-site associated development sites would be collected and sent to a foul sewer. At the HPC development site during construction, sewage would be tertiary treated prior to being discharged *via* the construction outfall to the foreshore.
- Only in the last instance would material be sent to landfill.

8.2.9 EDF Energy will ensure that suppliers comply with sustainability objectives through contractual mechanisms and will develop systems for monitoring and checking performance, with an aim of annual improvement. Furthermore, all workers involved with the HPC Project will be actively encouraged to recycle and this will be monitored accordingly.

8.3 Legislation, Policy and Guidance

8.3.1 The key pieces of legislation and guidance considered in developing a compliant WMIS are discussed below. A more detailed review of legislation, policy and guidance relating to waste is provided in the WMIS report.

8.3.2 **The Waste Strategy for England 2007** (Ref. 8.1) – This national strategy for waste sets out the government's views on waste management in England. The strategy commits to setting new national targets for the reduction of household waste through recycling and composting by at least 40% by 2010, 45% by 2015 and 50% by 2020, in comparison to 2000 levels. In addition, new national targets are expected for the reduction of commercial/industrial waste going to landfill; including a 20% reduction in material going to landfill by 2010 compared to 2004. This project aims to achieve a rate of <10% of construction, demolition and earthworks waste going to landfill.

8.3.3 **The Environmental Protection Act 1990** (Ref. 8.2) addresses areas of significant environmental concern including waste disposal. Waste Management issues are considered under Part II of the EPA. Controlled waste includes commercial, industrial (including agricultural waste from 2006) and household waste. Under the act, the deposition of waste to land without a licence or breaching licence conditions is an offence. The Act is also designed to prevent environmental pollution or harm to human health by prohibiting treatment, storage and disposal of controlled wastes without a licence or in breach of a licence

8.3.4 **The Site Waste Management Plans Regulations 2011** (Ref. 8.3) aim to make the construction industry more sustainable by ensuring that those responsible for development projects are aware of the waste being produced, so that it can be reduced. These regulations make it an offence to fail to prepare and implement a site waste management plan (SWMP) for certain construction projects that have an estimated cost of more than £300,000 (excluding VAT). Additional requirements are described in the Schedule for projects over £500,000.

8.3.5 **Environmental Permitting (England and Wales) Regulations (2010)** (Ref. 8.4) – These regulations introduce a new streamlined system of environmental permitting in England and Wales for certain installations, waste operations and mobile plants. Activities under these regimes will be covered by a single form of environmental permit governed by one set of regulations. This provides a system for environmental permits and exemptions for industrial activities, mobile plant, waste operations, mining waste operations, water discharge activities, groundwater activities and radioactive substances. It also sets out the powers, functions and duties of the regulators. Notably, the requirements of the Landfill Directive and Waste Management Licensing are applied under these regulations.

8.3.6 **Planning Policy Statement 10 (PPS10): Planning for Sustainable Waste Management (2005)** (Ref. 8.5) – PPS10 forms part of the national waste management plan for the UK. The main aim of the policy is to protect human health and the environment by producing less waste and by using it as a resource wherever possible. PPS10 sets out the key planning objectives for waste planning authorities.

8.3.7 The development falls within the south-west region of England and therefore **The Regional Waste Strategy for the South West 'From Rubbish to Resource' (2004-2020)** (Ref. 8.6) applies. This is a non-statutory Regional Waste Strategy which aims to ensure that by the year 2020 over 45% of waste is recycled and reused and less than 20% of waste produced in the region will be landfilled. One of the key areas for action is to adopt the waste hierarchy to reduce the amount of waste being produced, before considering reuse, recycling, recovery or disposal. The strategy's policies and actions address local authorities, the waste industry, non-governmental organisations and community groups as they are key partners to deliver the strategy.

8.3.8 **The Somerset Waste Local Plan (2001-2011) (adopted in February 2005)** (Ref. 8.7) sets out the broad land use framework for future waste management in Somerset. It covers all forms of waste including household, commercial, industrial and construction waste. The plan states that the most significant implication is the amount of waste disposed to landfill, which will have to be reduced in order to meet government disposal targets. In addition, most waste sent to landfill will require pre-treatment. The plan has a number of policies which provide commitment to sustainable waste management, including the waste hierarchy and the proximity principle, whereby waste is managed close to its sources of generation.

8.3.9 **Waste and Resources Action Programme (WRAP)** (Ref. 8.8) assists the UK government to meet national and international commitments and to support resource efficiency in the UK. This is achieved by helping businesses and individuals within the UK to benefit from reducing waste, develop sustainable products and use resources in an efficient way.

8.3.10 **Contaminated Land Applications in Real Environments (CL:AIRE)** (Ref. 8.9) is an independent, non-profit organisation that aims to encourage the sustainable remediation of contaminated land and groundwater throughout the UK, for effective social and economic use. This is achieved by increasing awareness and confidence in practical, sustainable remedial solutions.

8.4 Methodology

8.4.1 The methodology for assessing likely impacts associated with the generation of conventional waste at the HPC development site and the off-site associated developments is based upon an assessment of the quantity and types of waste that are likely to be produced during their construction, operational and post-operational phases (where relevant), and their impact upon the existing waste infrastructure. In order to identify any resultant impacts, the baseline conditions were determined, as per the methods described below.

a) Study Area

8.4.2 The study area for this assessment comprises the HPC development site and the off-site associated developments.

b) Baseline Description

8.4.3 To establish the baseline conditions for the waste assessment, the current levels of conventional waste production in Somerset have been determined together with the type, capacity, and availability of existing waste management infrastructure within the county.

8.4.4 Data for the current level of waste production and available waste handling, treatment and disposal facilities have been derived from publicly available government sources and through direct consultation with the relevant regulatory bodies, including SCC, the Environment Agency and SWP. An assessment of operational Materials Recovery Facilities (MRF) and Waste Transfer Plants within Somerset has been undertaken, using information provided in SCC's Mineral and Waste Development Framework (Ref. 8.10). The assessment was based on the annual tonnage capacity of each facility (as per the Environment Agency Public Register) and the distance of the facility from the HPC development site. Discussions included the feasibility of utilising existing waste infrastructure within Somerset and the surrounding counties over the duration of the project.

c) Assessment Methodology for Waste Volumes

i. HPC Nuclear Power Station

8.4.5 In order to calculate the anticipated waste volumes for the construction of the HPC nuclear power station, reference has been made to the construction of the Flamanville 3 nuclear power station in France. This is considered to be an appropriate reference as it used similar construction techniques and is likely to produce comparable waste types and quantities. As HPC will have two UK EPR reactor units and Flamanville has only one, the waste volumes from the Flamanville project have been doubled. An additional 10% has been added to the total calculated volume as a contingency measure.

8.4.6 The operational waste volumes for HPC nuclear power station were based upon typical arisings from the two other operating reactor units at Flamanville during 2006.

ii. Associated Developments

8.4.7 The anticipated construction waste volumes arising from the associated development sites were calculated as approximately 1% of the estimated material volumes required for construction. The percentage was considered appropriate based upon experience from other similarly scaled projects, combined with professional judgement. Furthermore, as a conservative measure, a 20% contingency has been assigned to the total numbers calculated. Where volumes have been provided in cubic metres, these have been converted to tonnes assuming a density of 2.0 tonnes per m^3. This conversion has been based upon a typical density of sand and gravel being 1.8 tonnes per m^3, plus a conservative allowance for bulking of material.

8.4.8 Waste is anticipated to arise at Bridgwater A and Bridgwater C from remediation of the sites. However, the final details of this remediation are to be defined. Consequently, conservative estimates of the potential remediation volumes have been incorporated into the overall waste volumes based on similarly scaled projects and professional judgement. More specifically, the volumes of remedial waste calculated for Bridgwater A were partly based on the volume of contaminated arisings produced through the redevelopment of a site in North-East Bridgwater.

8.4.9 The operational waste volumes estimated for the accommodation campuses were based upon national performance indicators for Sedgemoor residents, as provided by SWP. Furthermore, consideration was taken of British Standard 5906 (Ref. 8.11), which provides estimates of operational waste generation for various developments. The operational waste volumes for the non-accommodation sites were derived from experience of similarly scaled projects and professional judgement.

8.4.10 The post-operational waste volume estimates for the associated developments were determined as the estimated volume required for construction, minus the waste produced during construction (1%) and any infrastructure to remain on-site for its legacy use. Where volumes have been provided in cubic metres, these have been converted to tonnes assuming a density of 2.0 tonnes per m^3. A 20% contingency has been assigned to the total numbers as a conservative measure. The types of waste to be produced from the post-operational phases were assumed to be similar to the construction phase.

d) Methodology for Impact Assessment

8.4.11 The predicted waste volumes to be produced for each phase of development (i.e. construction, operational and post-operational) have been compared against the current baseline conditions at the HPC development site and each of the off-site associated developments. Secondly, the total predicted waste volumes for each phase of development have been compared against the baseline conditions in terms of the types and total volumes of waste managed and/or produced in Somerset annually.

e) Assumptions

8.4.12 For the purpose of this document, it is assumed that the Development Consent Order (DCO) would be granted in 2012, and EDF Energy's target for the first nuclear reactor becoming operational in 2019.

8.4.13 There would be some highway improvements proposed as part of the HPC Project, however, these works are assumed to be produce only negligible waste volumes and therefore are not considered further.

8.4.14 The future re-use option for the proposed park and ride facility and freight management facility at Junction 23 is undetermined at this stage. There are three potential options but for the purpose of this assessment, the most conservative scenario, of restoring the site to greenfield status (in full or part) has been assumed.

8.4.15 In the event that it is not possible to re-use soils on the site of origin or on other HPC Project sites, then it is assumed that surplus soils could be re-used on other sites within Somerset. For example, the use of the National Industrial Symbiosis Programme (NISP) (Ref. 8.12) could assist in the identification of companies/sites that may require large quantities of construction and demolition wastes, such as large scale housing developments. In addition, Taunton is to undergo regeneration, therefore there may be opportunities for re-use of materials from those developments.

8.5 Baseline Assessment

8.5.1 Baseline conditions have been established in order to clarify the present circumstances within Somerset in terms of the waste types and volumes currently produced, including the capacity and availability of waste management facilities. Furthermore, baseline conditions have been determined for the HPC development site and the off-site associated developments in terms of the waste types and volumes currently produced (if any).

a) Somerset Waste Production

8.5.2 It is reported by SCC in their Document Waste Management Need to 2028 (March 2011) (Ref. 8.13), that a total of 393,603 tonnes of waste was received at licensed facilities within Somerset during 2008. Details are presented in **Table 8.1** below:

Table 8.1: Construction/Demolition Waste Received in Somerset – 2008

Construction/Demolition Waste	Total (tonnes)
Inert	104,857
Non-inert	249,336
Other	39,410
TOTAL	**393,603**

8.5.3 Following consultation with SCC, it is evident that facilities in Somerset are either small-scale or recycle predominantly household type wastes. They, therefore, have limited capacity to manage large volumes of construction and demolition waste. According to SCC's document Waste Management Need to 2028 (March 2011) (Ref. 8.13), it is assumed that approximately 33,865 tonnes of hazardous waste is produced in Somerset annually.

8.5.4 In terms of municipal solid waste, 279,117 tonnes arose within Somerset during 2009/2010 (Ref. 8.13). Of this, 45% was recycled, 0.7% was treated and 54% was sent to landfill. The national performance indicators show that Sedgemoor residents generate for collection approximately 400kg per head per annum of wastes.

b) Waste Management Facilities in Somerset

8.5.5 **Table 8.2** details the various waste management facilities in Somerset along with their location, distance from the HPC development site and capacity for managing waste.

Table 8.2: Waste Facility Search for Somerset

Recycling Facility	Distance (miles)	Capacity (tonnes p/a)	Operator	Post Code
Material Recycling Facilities and Waste Transfer Stations				
Old Station Yard Scrap Metal	26.4	49,999	J C Thomas & Sons Ltd.	BA6 9LU

Notes: With Planning Permission; WPS Pyrolysis Plan at Heybridge, Wells; Anaerobic Digestion Plant (Viridor), Walpole. To open by 2014; Priorswood MRF Extension (Viridor), Taunton.

8.5.6 Examples of small-scale facilities which can accept construction and demolition wastes in Somerset include Wellington Waste Skips in Taunton, which can accept approximately 11,000 tonnes of per annum and Southwood Waste Transfer Station in Shepton Mallet, which can accept up to 9,000 tonnes. However, the capacity of these facilities is relatively small in comparison to the anticipated waste generation for the HPC Project.

8.5.7 There is a MRF at Priorswood, Taunton operated by waste management contractor Viridor which has a capacity of up to 25,000 tonnes and can receive co-mingled wastes, as well as individual specific waste streams such as glass. Residual wastes that are non-recyclable would currently be sent to the Walpole Landfill.

8.5.8 In addition, Viridor operate several household waste recycling centres on behalf of SCC (Bridgwater, Chard, Highbridge, Taunton and Williton) with individual capacities of up to 25,000 tonnes per annum.

8.5.9 There is a composting and wood shredding facility at Walpole landfill close to Junction 23 of the M5 which has a capacity of up to 75,000 tonnes per annum. Furthermore, there is an in-vessel/rotary composting facility, along with an open windrow composting facility at Dimmer Landfill near Castle Cary. These facilities accept 35,000 tonnes and 15,000 tonnes per annum respectively but are scheduled to close by 2014.

8.5.10 There is an anaerobic digestion plant operating in Cannington which has an annual capacity of up to 20,000 tonnes. It may be possible for this facility to accept food waste from the HPC Project. There are also proposals for a Mechanical Biological Treatment (MBT) and anaerobic digestion facility to be constructed to the north-east of Walpole Landfill. If this is developed then the facility will be operational by 2014 and would provide treatment of segregated organic waste to recover energy and compost from waste that currently goes to landfill. Waste that could be accepted includes vegetation and food.

8.5.11 Walpole landfill, as mentioned above, accepts construction and demolition waste. This landfill is permitted to accept up to 446,350 tonnes per annum. In addition, there are four other landfills located within Somerset which would be able to accept construction and demolition type waste.

8.5.12 The only facilities which can accept hazardous waste are landfill sites. Walpole landfill, which has been mentioned previously, can accept asbestos waste. However, the closest landfill sites to the HPC Project which can accept other types of hazardous waste are located outside of Somerset. Examples are Kingweston Landfill in Bristol and Parkgate Farm Hazardous Waste Landfill in Wiltshire.

c) Baseline Conditions – HPC Development Site

8.5.13 The HPC development sites is currently greenfield status except for the Built Development Area East, where part of the area is subject to a series of works including remediation of a spoil mound as described in **Volume 1**, **Chapter 6**. It is assumed for the purposes of this application that these works would have been completed prior to commencement of the bulk earthworks.

8.5.14 The site preparation works as resolved to be approved by West Somerset Council (WSC) are anticipated to commence in the third quarter of 2011, with the earthworks commencing in 2012. However it is intended that all material arising would be retained on-site for re-use throughout the HPC Project. Consequently, there would only very limited volumes of waste, such as some general waste produced from the construction workers.

8.5.15 Certain off-site associated developments are currently greenfield status. Consequently, current baseline waste volumes produced at these sites are considered to be negligible. Any minor quantities of waste produced would be likely to be organic and therefore re-used by the farmer. The off-site associated developments which are currently greenfield status are listed as follows:

- Combwich Wharf freight laydown facility.
- Cannington park and ride facility.
- Cannington bypass.
- Junction 23 park and ride, freight management and courier consolidation facilities and induction centre.

8.5.16 The Bridgwater A accommodation campus site currently comprises a derelict factory, giving rise to reasonable quantities of demolition waste.

8.5.17 The Bridgwater C accommodation campus site forms part of a rugby club and therefore some general waste and some green waste (e.g. from pitch maintenance) would be likely to be produced at present but only in small quantities (less than 20 tonnes per annum).

8.5.18 Combwich Wharf is only used occasionally by EDF Energy for the delivery of AILs which cannot be delivered to Hinkley Point by road due to their size or weight. As such, current waste volumes are not likely to exceed 70 tonnes of operational waste per annum.

8.5.19 The Junction 24 site comprises a storage/distribution facility and Williton park and ride comprises an existing lorry park. Consequently, current waste volumes are likely to be in the region of 85 tonnes per annum at these sites and will likely comprise some general waste and a small volume of hazardous waste.

8.6 Project Waste Generation Assessment

8.6.1 The predicted waste volumes for the earthworks/construction, operational and post-operational phases are displayed below in **Tables 8.3**, **8.4** and **8.5** respectively.

Table 8.3: Earthworks/Construction Phase Waste Quantity Estimates

Earthworks/Construction Waste (tonnes)	Inert	Non-Hazardous	Hazardous	TOTAL	TOTAL (Contingency = 10% HPC Power Station, 20% AD's)
HPC Development Site					
HPC power station	150,000	68,000	2,000	220,000	242,000

Earthworks/Construction Waste (tonnes)	Inert	Non-Hazardous	Hazardous	TOTAL	TOTAL (Contingency = 10% HPC Power Station, 20% AD's)
HPC accommodation campus	1,767	471	118	2,356	2,828
Off-Site Associated Development Sites					
Combwich Wharf refurbishment and extension	23,972	6,392	1,589	31,953	38,344
Combwich Wharf freight laydown facility	2,103	560	140	2,803	3,364
Bridgwater A accommodation campus (including remediation waste)	28,775	8,800	12,062	49,637	59,564
Bridgwater C accommodation campus (including any remediation waste)	1,592	608	1,766	3,966	4,760
Cannington bypass	40,364	10,764	2,691	53,819	64,583
Cannington park and ride	2,099	560	140	2,799	3,359
Junction 23	4,295	1,145	286	5,726	6,872
Junction 24	2,577	687	172	3,436	4,123

TOTAL	**259,817**	**98,593**	**21,116**	**379,526**	**433,433**

Table 8.4: Operational Phase Waste Quantity Estimates

Operational Waste (tonnes)	TOTAL (tonnes per annum)	TOTAL (over lifetime of development)
HPC Development Site		
HPC power station (non-radioactive waste)	1,140	68,400 (60 years)
Temporary jetty	0	0
HPC accommodation campus	168	1,008
Off-Site Associated Developments		
Combwich Wharf refurbishment and extension	0	0
Combwich Wharf freight laydown facility	75	487
Bridgwater A accommodation campus	280	1,820
Bridgwater C accommodation campus	50	325
Cannington bypass	0	0
Cannington park and ride	86	688
Junction 23	86	600
Junction 24	86	744
Williton park and ride	86	600

Table 8.5: Post-Operational Associated Development and Temporary Jetty Waste Quantity Estimates

Post-Operational Phase Waste (tonnes)	Inert (79%)	Non-Hazardous (20%)	Hazardous (1%)	TOTAL	TOTAL (Contingency = 20%)
HPC Development Site					
Temporary jetty	37,707	9,546	477	47,730	57,276
HPC accommodation campus	29,709	7,521	376	37,606	45,128
Off-Site Associated Development Sites					
Combwich Wharf freight laydown facility	265,756	67,280	3,364	336,400	403,680
Bridgwater A accommodation campus	61,523	15,576	778	77,877	93,453
Cannington park and ride	14,096	3,569	178	17,843	21,412
Junction 23	76,343	19,327	966	96,636	115,964
Junction 24	2,462	623	31	3,116	3,739
Williton park and ride	815	206	10	1,031	1,238
TOTAL	**488,411**	**123,648**	**6,180**	**618,239**	**741,890**

8.6.2 A peak in waste production would occur during mid-2013. This is because the majority of the associated developments would be under construction at this same time, along with the site preparation works and temporary jetty construction at HPC development site. The waste volumes would decrease in early 2015, owing to the onset of the operational phases of the associated developments, although the HPC construction continues. The volumes would remain relatively constant until mid-2020, when they will begin to increase significantly as the associated development post-operational phases commence. A significant peak occurs around 2021, particularly associated with the removal of the following:

- Temporary jetty.
- HPC accommodation campus.
- Bridgwater A accommodation campus.
- Combwich Wharf freight laydown facility.
- Cannington park and ride facility.
- Junction 23 park and ride facility, freight management facility, consolidation facility for postal courier deliveries and induction centre.

8.7 Assessment of Impacts

i. HPC Construction

8.7.1 Approximately 242,000 tonnes of waste would be produced from the site earthworks/construction phase of HPC, of which the majority would be suitable for re-use, recycling or recovery. As such, there would be a significant increase in the volume of waste currently produced at this site. It is reported by SCC in their Mineral and Waste Development Framework (March 2011) (Ref. 8.10) that 393,603 tonnes of construction/demolition waste was received by licensed facilities within Somerset during 2008. Consequently, in view that the total waste to be generated from the construction of HPC will be spread over a period of approximately ten years, it is expected that the waste management infrastructure within Somerset will be capable of managing the waste.

ii. Associated Developments – Construction Phase

8.7.2 The volumes of waste to be produced during the earthworks/construction phases of the associated developments would exceed the baseline volumes of waste currently produced at these sites.

8.7.3 It is anticipated that the waste to be produced from the earthworks/construction phases will be suitable for re-use, recycling or recovery. However, a small quantity of waste would require disposal at landfill (e.g. remedial wastes from Bridgwater A and Bridgwater C sites).

8.7.4 It is not expected that the total waste to be produced from the construction of the associated developments will exceed the annual baseline capacity of 393,603 tonnes of construction/demolition waste, which can be managed in Somerset (Ref. 8.10). Furthermore, the waste production would be spread over approximately two years. However, in order to comply with the waste hierarchy and to avoid exerting undue burden on the existing waste management infrastructure in Somerset, material would need to be re-used in the first instance (e.g. selling direct to market or re-using surplus soils from the site preparation phases on other non HPC Project sites within Somerset). Remaining material would then be managed effectively through use of a network of smaller MRF's within Somerset which are considered to have sufficient capacity to manage the waste produced. If necessary, waste management infrastructure in the surrounding counties will be utilised.

iii. Associated Developments – Operational Phase

8.7.5 The operational phases of the associated developments would exceed the current negligible baseline values, with the exceptions of Bridgwater A (which would be likely to produce lower volumes) and the Junction 24 site and Williton park and ride (which are predicted to produce the same volumes). In total, approximately 915 tonnes of waste would be produced from the associated developments each year, over an average period of approximately seven years. The majority of this waste would comprise general wastes suitable for re-use, recycling or recovery.

8.7.6 As the predicted annual operational waste volumes described above are only a fraction of the baseline value of 279,117 tonnes of the municipal solid waste managed in Somerset during 2009/2010, there should not be any significant additional pressure on the existing waste management facilities from the operational phases.

8.7.7 Notably, the waste produced during the operational phases of the associated developments would be generated during the construction of the HPC nuclear power station. As such, there will be cumulative, project-wide waste generation during this period.

iv. Associated Developments – Post-operational Phase

8.7.8 The post-operational phases of the associated developments would produce significant waste volumes, as detailed in **Table 8.5**. These volumes are significantly greater than the current negligible baseline values. Consequently, a significant volume of predominantly inert demolition waste would require management over a relatively short period of time (mid 2020-2022). As the baseline volume of inert construction/demolition waste managed in Somerset each year is reported to be 393,603 tonnes, the post operational phases may result in some strain on the existing waste infrastructure within Somerset. Hence, it would be necessary to re use material by selling these direct to market or to waste brokers in the first instance, and then use a network of smaller MRF's within Somerset and the surrounding counties. However, given the time period to the post operational phase, there would likely be some market changes. It is difficult at this stage to predict the future availability of waste management facilities, therefore this will be reviewed at the time.

v. HPC Operational Phase Waste

8.7.9 The operational phase of the HPC nuclear power station is estimated to generate approximately 1,140 tonnes of non-radioactive waste annually over a 60 year period of which 200 tonnes would comprise hazardous waste. Again, this would exceed the current baseline volume of waste produced at the site. As this total is a small fraction of the 279,117 tonnes of municipal solid waste which was managed during Somerset during 2009/2010, the 393,603 tonnes of construction/demolition type waste managed during 2008 and the 33,865 tonnes of hazardous waste produced annually within the county (Ref. 8.10), this should not present any significant additional pressure on the existing waste management facilities.

8.8 Mitigation of Impacts

8.8.1 All waste arisings would be managed in a responsible manner throughout all phases of the development with a clear intention to prevent and reduce waste streams in accordance with the waste hierarchy (see **Plate 8.1**). Most importantly, waste production would be prevented through careful design and management of materials during the construction phase. The existing waste infrastructure within Somerset will be used to manage sustainably the waste that would be produced. Furthermore, the proximity principle would be applied, whereby waste facilities located closest to the point of waste production are given preference over facilities located further away, where economically feasible.

8.8.2 Calculations based upon figures provided by SCC indicate that between 2011 and 2021, a total of 14,965 tonnes of earthworks material sourced from the HPC Project could be utilised in Bridgwater for the development of residential and commercial properties (excluding HPC and the off-site associated developments), if this was deemed appropriate as a mitigation measure.

8.8.3 During the construction and post-operational phases of the associated developments, each site will be subject to a **Site Waste Management Plan** (SWMP) as required by the Site Waste Management Plans Regulations 2011 (Ref. 8.3), whereby co-ordinated planning between the various sites will be encouraged.

8.8.4 During the operational phases of the associated developments there may be opportunities to engage with local waste management authorities and the supply chain on how best to manage the post-operational phase waste.

8.8.5 Following the operational phases of the associated developments, and prior to the post-operational phases (where relevant) there would be a review stage, whereby the proposed waste management methods would be re-assessed. This would take into account any new management methods or facilities available.

8.9 Conclusions

8.9.1 Overall, this assessment has demonstrated that impacts from the production of waste across the HPC Project would be mitigated through its management in order of the waste hierarchy (e.g. prevention, preparation for re-use, recycling, other recovery and disposal), seconded by the implementation of the proximity principle, whereby waste would be managed close to the point of origin. Essentially, it is intended for the production of waste to be prevented/reduced at source where possible through careful design and procurement.

8.9.2 The greatest volumes of waste production are predicted to arise during the early construction works for HPC and associated developments and post-operational phases of the associated developments. In general, the current baseline waste volumes produced at the primarily undeveloped HPC main site and associated development sites would increase during all phases of their development (construction and operation).

8.9.3 Despite the increase to the current baseline volumes of the HPC Project sites, it is anticipated that this waste would be managed effectively. Materials will be reused when possible (e.g. selling direct to market or re-using surplus soils from the site preparation phases on other non HPC Project sites within Somerset). Additional materials would then be managed through use of a network of smaller MRF's and recovery facilities within Somerset with capacity to manage the waste produced. Although it is the intention for waste to be managed in order of the waste hierarchy, there would inevitably be some waste which would require disposal to landfill. Waste management infrastructure in the surrounding counties would be utilised.

8.9.4 Given the time period to the post-operational phase of the associated developments (approximately ten years time), there are expected to be some market changes. It is therefore difficult to predict the future availability of waste management facilities. However, during the operational phases of the associated developments there may be opportunities to engage with local waste management authorities and the supply chain on the best methods to manage the post-operational phase waste. Furthermore, there will be a review stage prior to the post-operational phases whereby the proposed waste management methods will be reassessed.

Appendix 9F: Socio-Economic Technical Note 6: Community Cohesion

9. SOCIO-ECONOMICS

9.1 Introduction

9.1.1 This Chapter covers the socio-economic effects of the Hinkley Point C (HPC) Project including the proposed HPC nuclear power station and associated developments. The assessment considers the potential employment, economic, population and demographic effects on the wider study area (defined in section 9.4).

9.1.2 The construction of the HPC Project would take approximately nine years before both units are operational, and both units would be permanent, operating for a period of approximately 60 years after which they will be decommissioned. The associated developments are proposed to facilitate the construction of HPC and to mitigate potential transport impacts and socio-economic impacts, associated with workforce accommodation and journeys to and from the HPC development site.

9.2 Scope and Objectives of Assessment

9.2.1 The scope of the assessment has been determined through a formal Environmental Impact Assessment (EIA) scoping process undertaken with the Infrastructure Planning Commission (IPC). It has also been informed by ongoing consultation with statutory consultees (including Sedgemoor District Council (SDC), West Somerset Council (WSC) and Somerset County Council (SCC), the local community and the general public). The socio-economic assessment of the proposals for HPC has been integrated into EDF Energy's wider process of project development, collaborative working, and consultation. The scoping and production of the assessment has therefore been an ongoing "adaptive" process emerging from the stages of project development, both formal consultation and through ongoing engagement with local authorities and statutory bodies.

9.2.2 EDF Energy's approach to project development has followed the Infrastructure Planning Commission's (IPC) guidance promoting collaborative working (Advice Note 2, Working Together on Nationally Significant Infrastructure Projects (Ref. 9.1)). This has included the use of a Planning Performance Agreement (PPA) between EDF Energy (the applicant) and local authorities: WSC; SDC; and SCC, which has enabled cross boundary working across the study area, and addresses, amongst other issues, the following priorities:

- defining and delivery of the proposed low carbon business cluster;
- ensuring a long term employment and skills legacy for local people;
- recognition of the contribution made by the natural environment and built heritage to the local economy; and
- contributing to the County's image for inward investment and tourism.

9.2.3 A socio-economic workstream was established bringing together EDF Energy's technical assessment and implementation teams with the local authorities, their advisers and representatives of other statutory and partner organisations. **Technical Notes** on key assessment issues have been produced and considered with the local authorities and form the basis of key elements of this assessment. EDF Energy has used these assessments as the basis for discussions with service providers, through working groups, to identify the key mitigation and enhancement measures.

9.2.4 Accommodation and transport workstreams have been run in parallel and their work has fed into this assessment, including the assessment of accommodation baseline and impacts and the underlying assumptions about the spatial spread of impacts.

9.2.5 In parallel with this collaborative approach EDF Energy has also undertaken the formal statutory process of scoping and consultation as required by the IPC.

9.2.6 The **Scoping Opinion** was issued by the IPC in April 2010. It welcomes EDF Energy's intention to take a broad approach to the assessment and identifies a number of areas which should be covered. These are the cumulative impacts with the de-commissioning of the existing stations at Hinkley Point, and the impacts on agriculture and rural communities, and on Bridgwater.

9.2.7 The formal consultation process has included:

- preliminary consultation prior to the Stage 1 proposals;
- the Stage 1 Consultation Document and Environmental Status Report;
- the Stage 2 Consultation Documentation including the Socio-Economic Chapter of the Environmental Appraisal; and
- an updated workforce profile published as part of the Stage 2 Update Consultation.

9.2.8 The **Consultation Report** sets out the formal response to these consultations which includes comments on the scope or nature of the Socio-Economic Assessment. As a result of this process, and reference to the scope of assessments set out in the National Policy Statements (NPS) for Energy Infrastructure (see Section 9.3b) the objectives underlying the socio-economic impact assessment were:

- identification of the workforce required to construct and operate HPC and associated developments including phasing, skills requirements and labour supply – this underpins the remainder of the assessment;
- identification of the likely origins of workers, including a Construction Daily Commuting Zone (CDCZ) to identify the locations from which workers already living within the area will travel to HPC and the likely proportion of the workforce who will come from within that zone (home-based workers);
- identification of activities and measures to support training and recruitment of residents of the study area and region to work in the construction and operational phases at HPC, and to help businesses benefit from supply chain opportunities;
- identification of the likely proportion of non-home-based workers – those who will temporarily move to the area to work on the construction of the power station;
- identification of likely age and demographic profiles of the workforce and the extent to which non-home-based workers will bring families to the area;
- assessment of current accommodation capacity, likely accommodation preferences of workers (in the context of EDF Energy's proposed accommodation

strategy) and impacts of this on local accommodation supply and demand and locations in which workers are likely to live;

- assessment of consequent impacts on public services of likely workforce accommodation preferences and spatial spread, including education, health, policing and emergency services, and leisure and recreation provision and any mitigation measures required;
- assessment of likely impacts on community cohesion and wellbeing in locations in which there may be clusters of workers;
- assessment of likely wider economic impacts including expenditure and induced effects and impacts on the tourism and hospitality sector; and
- assessments of impacts on key equalities target groups as identified in the Equalities Act 2010 (Ref. 9.2).

9.2.9 The spatial spread of effects will vary depending on the different topic area. Consultation with the local authorities and others identified some key generic areas for consideration which include the CDCZ, the South West region, the County, and the three most local Districts (West Somerset in which HPC is located, Sedgemoor in which a number of associated development sites are located, and Taunton Deane).

9.2.10 More fine grained assessments are based on those locations/areas which may see some localised impacts based on assumptions about workers' locational preferences. Section 9.4a considers these issues in more detail.

9.2.11 A number of comments on socio-economic impacts and assessment raised through the consultation process by both public bodies and individual consultees have taken the form of comments or speculative statements. The authors of this assessment have sought to find evidence in relation to the full range of these issues. However in line with NPS Guidance, the assessment of socio-economic impacts has been limited in this document to those areas where likely effects can be considered, based on evidence. The assessment also identifies the need for mitigation arising from the socio-economic effects, and outline enhancements and the scale of residual effects.

9.2.12 The DCO application is accompanied by other documents, outside the Environmental Statement, for example the **Health Impact Assessment**, which seeks to identify and assess some of the more qualitative "wellbeing" impacts.

9.2.13 Cumulative socio-economic impacts arising from the proposed development with external plans and projects are identified and assessed in **Volume 11** of this ES.

9.3 Legislation, Policy and Guidance

9.3.1 There is a very large amount of policy and guidance relating to socio-economic issues, particularly at the national level. This section summarises that which is regarded as being of direct relevance to the assessment of the impacts of the HPC Project. This includes "process" guidance as to what should be included in such an assessment, as well as specific policies on issues on which there may be significant impacts.

9.3.2 The UK coalition Government, elected in May 2010 inherited a substantial amount of policy guidance across the various Government departments. In priority areas it has made explicit where it has abolished or intends to replace previous policies. In the area of planning for example, it is in the process of the abolition of Regional Spatial Strategies and consolidating guidance into a National Planning Policy Framework, which has been published in draft for consultation. In relation to education, the Department for Education website states that “All statutory guidance and legislation linked to/from this site continues to reflect the current legal position unless indicated otherwise, but may not reflect Government policy.”

9.3.3 This policy review seeks to identify the current policy position and those areas where policy is being reviewed and the direction of Government policy based on public statements and business plans.

9.3.4 As stated in **Volume 1**, **Chapter 4**, the Overarching National Policy Statement (NPS) for Energy (NPS EN-1) when combined with the NPS for Nuclear Power Generation (NPS EN-6) provides the primary basis for decisions by the IPC on applications for nuclear power generation developments that fall within the scope of the NPSs.

9.3.5 Notwithstanding this, the IPC may consider other matters that are both important and relevant to its decision-making. This could include Planning Policy Statements (PPSs), Planning Policy Guidance Notes (PPGs), regional and local policy documents, although, if there is a conflict between these and the NPS, the NPS prevails for the purposes of IPC decision making.

9.3.6 Further, the Planning Act 2008 provides that the IPC must, in making its decision on an application, have regard to any Local Impact Report (LIR) prepared by relevant local authorities. It is anticipated that the LIRs will rely in part on PPSs, PPGs, regional and local policy to provide a context for their assessment. On this basis, regard has been given to these documents (where relevant to the technical assessment) since they are likely to inform the LIRs prepared by the relevant local authorities.

a) International

i. Inter-organisational Committee Guidelines and Principles for Social Impact Assessment (Ref. 9.3)

9.3.7 While there is no formal legislation or statutory guidance which sets out either scope or standards for socio-economic assessments there is a growing literature on appropriate standards and thresholds. Some international guidance is provided by the Inter-organisational Committee on Guidelines and Principles for Social Impact Assessment (ICGPS) (1994), with more recent academic updates by Vanclay (Ref. 9.4), Glasson (Ref. 9.5) and Chadwick (Ref. 9.6). The ICGPS defines social impacts as:

> *“the consequences to human populations of any public or private actions that alter the ways in which people live, work, play, relate to one another, organise to meet their needs, and generally cope as members of society.’’*

ii. EU Directive 85/337/EEC (the EIA Directive) (Ref. 9.7)

9.3.8 The EU Directive 85/337/EEC (CEC 1985) (as amended by 97/11/EC (Ref. 9.8)) and 2003/35/EC (Ref. 9.9)) requires a description of possible impacts on human beings. The Lisbon Strategy (European Council, 2000) remains the EU's strategy for creating growth and jobs in a sustainable manner. This identifies the main dimensions of social sustainability as: education, employment policy (to create more and better jobs), modernising social protection, and the promotion of equality to counter poverty and social exclusion. It emphasises the continuing right of citizens to live and work anywhere in the EU.

b) National Policy

9.3.9 There is no UK legislation that specifies the detailed content required for socio-economic assessments or provides appropriate standards and thresholds for impact significance. However, there are a number of guidelines of relevance to socio-economic assessment.

i. Department of the Environment (DoE) (1989) Environmental Assessment: A Guide to the Procedures, London: HMSO (Ref. 9.10)

9.3.10 Early guidance from the UK Government suggested that ''*certain aspects of a project including numbers employed and where they will come from should be considered within an environmental statement*'' (DoE, 1989).

ii. Office of the Deputy Prime Minister (ODPM) (2004) Creating, Using and Updating a Neighbourhood Baseline, London: HMSO (Ref. 9.11); and

iii. Department for Communities and Local Government (DCLG) (2006) Environmental Impact Assessment: A Guide to Good Practice and Procedures, A Consultation Paper, London: DCLG (Ref. 9.12)

9.3.11 More recent guidance on the use of official statistics in baseline assessment work is provided in ODPM (2004) and on the approach to EIA in DCLG (2006).

9.3.12 The National Policy Statements (NPS) for Energy Infrastructure set out the Government's energy policy; the need for new infrastructure; and guidance to the Infrastructure Planning Commission (IPC) in determining an application for a Development Consent Order (DCO). The NPSs include specific criteria and issues which should be covered by applicants' assessments of the effects of their scheme, and how the IPC should consider these impacts. They include specific references to socio-economic effects and health and wellbeing.

9.3.13 On 23 June 2011, the Secretary of State laid a final set of the energy NPSs before Parliament for approval. The House of Commons voted to approve the NPSs on 18 July 2011 and the NPSs were then designated on 19 July 2011.

9.3.14 There are two energy NPSs of relevance to the Hinkley Point C Project, the Overarching NPS for Energy (NPS EN-1), and the NPS for Nuclear Power Generation (NPS EN-6). NPS EN-1, when combined with NPS EN-6, provides the primary basis for decisions by the IPC on applications for nuclear power generation developments that fall within the scope of the NPSs.

iv. Overarching National Policy Statement for Energy (NPS EN-1) (July 2011) (Ref. 9.13)

9.3.15 Paragraph 4.2.2 of NPS EN1 confirms that socio-economic issues should be considered as within the scope of the Environmental Statement submitted with any relevant application stating that:

> *"To consider the potential effects, including benefits, of a proposal for a project, the IPC will find it helpful if the applicant sets out information on the likely significant social and economic effects of the development, and shows how any likely significant negative effects would be avoided or mitigated. This information could include matters such as employment, equality, community cohesion and well-being."*

9.3.16 Cumulative effects should be provided for within the ES in relation to how the effects of the development proposals would combine and interact with the effects of other development (including projects for which consent has been sought or granted, as well as those already in existence). The accumulation of, and interrelationship between, effects should be considered on the environment, economy and community as a whole, even though they may be acceptable when considered on an individual basis with mitigation measures in place (Para 4.2.5 and 4.2.6).

9.3.17 Paragraph 4.13.2 confirms that this assessment should include impacts on health and measures to avoid, reduce or mitigate these effects.

9.3.18 Part 5 of NPS EN-1 sets out policies in relation to potential impacts which are common across the range of energy NSIPs ("Generic Impacts").Section 1.2 sets out the additional generic socio-economic effects which should be assessed. This states that any effects likely to have an impact at a local or regional level should be considered (paragraph 5.12.2). This could include impacts on jobs and training, public services, tourism, the impact of the workforce on local communities and community cohesion, and cumulative effects – specifically on construction labour demand at the regional level (paragraph 5.12.3). Para 5.12.4 states that the assessment needs to identify local baseline conditions and how impacts relate to local policies.

9.3.19 The criteria for IPC consideration of these impacts confirm that assessments need to be evidence based. Para 5.12.7 states that:

> *"The IPC may conclude that limited weight is to be given to assertions of socio-economic impacts that are not supported by evidence (particularly in view of the need for energy infrastructure as set out in this NPS)."*

9.3.20 The IPC should also consider any positive contributions made by the developer (paragraph 5.12.8) and consider whether mitigation measures are necessary to mitigate any adverse socio-economic impacts of the development (5.12.9). Para 4.1.8 confirms that that the IPC should only impose planning obligations in relation to a development consent that are:

> *"…relevant to planning, necessary to make the proposed development acceptable in planning terms, directly related to the proposed development, fairly and reasonably related in scale and kind to the proposed development, and reasonable in all other respects."*

v. The National Policy Statement for Nuclear Power Generation (NPS EN-6) (July 2011) (Ref. 9.14)

9.3.21 Part 3 of NPS EN-6 sets out additional policy in relation to certain “Nuclear Impacts” for when the IPC is considering an application for a new nuclear power station. “Socio-Economic” and “Human Health and Wellbeing” are two of the seven nuclear impacts identified in paragraph 3.4.3.

9.3.22 Paragraphs 3.11.3, 3.11.4 and 3.12.7 set out what the applicant’s assessment should cover:

> *“Through the EIA, and in accordance with Section 5.12 of EN-1, the applicant should identify at local and regional levels any socio-economic impacts associated with the construction, operation and decommissioning of the proposed new nuclear power station.*
>
> *“This assessment should demonstrate that the applicant has taken account of, amongst other things, potential pressures on local and regional resources, demographic change and economic benefits.”*
>
> *“The applicant should work with the local authority and the local primary care trust (in England) or the Health Board (in Wales) to identify any potentially significant health impacts and appropriate mitigation measures. Where such measures relate to better public information on the extent of risk in relation to radiological hazard, the applicant should consult the Health Protection Agency on the appropriate standards for radiological protection.”*

vi. Appraisal of Sustainability of the Nuclear NPS (October 2010) (Ref. 9.15)

9.3.23 The Appraisal of Sustainability (AoS) for NPS EN-6 sets out what the construction of new nationally significant energy infrastructure, in accordance with the requirements of the new policy regime, is expected to mean for the environment, society and the economy.

9.3.24 The AoS (Table S.4.1) has three objectives identified in relation to the theme “*Communities – population, employment, and viability*”. These are:

- to create employment opportunities;
- to encourage the development of sustainable communities; and
- to avoid adverse impacts on property and land values and avoid planning blight.

9.3.25 The AoS (paragraphs S.11.8 to S.11.10) identifies the potential for significant positive effects on employment and the economy at the local and regional level during the construction phase and also economic benefits in the operational phase. There are possible short term negative effects on local labour supply, and local communities and demand for public services from incoming workers although it is noted that these can be mitigated. It concludes that “*Overall the revised AoS found that there are likely to be significant beneficial effects on employment and viability for communities*” (paragraph S.10.10).

9.3.26 In relation to the potentially suitable site at Hinkley Point, the Appraisal of Sustainability (AoS) of NPS EN-6 concluded that the potential likely effects and key findings recommended as guidance for the IPC to consider include:

- Positive cumulative effects associated with long-term employment and enhanced prosperity in the region;
- The site is in a cluster of two nominated sites (Oldbury being the other) in the south west region. Potential regional cumulative effects both positive and adverse may apply if both sites in the region were to be developed; and
- Further significant adverse cumulative effects if both new power stations were to be developed alongside any Severn Tidal Power scheme.

vii. Draft National Planning Policy Framework: Consultation (Ref. 9.16)

9.3.27 On 25 July 2011 DCLG published a consultation draft of the National Planning Policy Framework (NPPF). The consultation period concludes on 17 October 2011 and it is expected that the final NPPF will be adopted in 2012. The NPPF aims to streamline existing Planning Policy Statements and some Circulars into a single consolidated document that sets out the Government's key economic, social and environmental objectives and the planning policies to deliver them. These policies will provide local communities with tools to enhance their local economies, meet housing needs, plan for a low-carbon future and protect environmental and cultural landscapes. The following key points are outlined in the Consultation draft NPPF:

- a presumption in favour of sustainable development (paragraphs 13 to 18);
- supporting planning reform and decentralisation through neighbourhood planning, the Localism Bill, the provision of affordable housing and economic viability (paragraphs 25 and 28 to 30); and
- support for renewable and low-carbon energy. The NPPF envisages that applications for low-carbon energy development should be approved if the impact is or can be made acceptable (paragraphs 148 to 153).

viii. Planning Policy Statement 1: Planning for Sustainable Development (PPS1) (2005) (Ref. 9.17)

9.3.28 PPS1 sets out the Government's overarching planning policies on the delivery of sustainable development through the planning system.

9.3.29 Para 5 (The Government's Objectives for the Planning System) states that planning should facilitate and promote sustainable and inclusive patterns of urban and rural development by:

- making suitable land available for development in line with economic, social and environmental objectives to improve people's quality of life;
- contributing to sustainable economic development;
- protecting and enhancing the natural and historic environment, the quality and character of the countryside, and existing communities;
- ensuring high quality development through good and inclusive design, and the efficient use of resources; and

- ensuring that development supports existing communities and contributes to the creation of safe, sustainable, liveable and mixed communities with good access to jobs and key services for all members of the community.

9.3.30 Paragraph 23 (Sustainable Economic Development) sets out the Government's commitment to promoting a strong, stable and productive economy that aims to bring jobs and prosperity for all. In summary, planning authorities should:

- recognise that economic development can deliver environmental and social benefits;
- recognise the wider sub-regional, regional or national benefits of economic development and consider these alongside any adverse local impacts;
- be sensitive to changes in local economies and the implications for development and growth;
- promote and facilitate good quality development, which is sustainable and consistent with their plans; and
- ensure that infrastructure and services are provided to support new and existing economic development and housing.

9.3.31 Paragraph 27 (Delivering Sustainable Development) sets out the general approach to delivering sustainable development. The most relevant points to this chapter state that planning authorities should:

- provide a positive planning framework for sustainable economic growth to support efficient, competitive and innovative business, commercial and industrial sectors; and
- promote urban and rural regeneration.

ix. Planning Policy Statement 4: Planning for Sustainable Economic Growth (PPS4) (2009) (Ref. 9.18)

9.3.32 PPS 4 identifies that the Governments overarching objective is one of sustainable economic growth. In order to help achieve this overall ambition the Government sets out a series of objectives which seek to reduce the disparities between rural and urban locations, between different regions of the UK whilst regenerating failing town centres all of which will help to raise the quality of life for residents in communities across the UK.

9.3.33 Policies EC6 and EC7 set out policies for planning for the economy and tourism in rural areas. These highlight the need to protect the countryside but also to promote opportunities for sustainable economic development, tourism and leisure activities. Policy EC10 says that local authorities should take a positive approach to dealing with planning applications for economic development. Considerations which should be taken into account include whether the development limits carbon dioxide emissions and impacts on local employment.

x. Planning Policy Statement 7: Sustainable Development in Rural Areas (2004) (Ref. 9.19)

9.3.34 PPS7 sets out the Government's planning policies that apply to rural areas, including country towns and villages and the wider, largely undeveloped countryside up to the fringes of larger urban areas. It should be noted that the economic development sections of PPS7 have been replaced by PPS4.

9.3.35 PPS 7 outlines the Government's objectives for rural areas which can be summarised as follows:

- raise the quality of life and the environment in rural areas;
- promote more sustainable patterns of development;
- promote the development of English regions by improving their economic performance; and
- promote sustainable, diverse and adaptable agriculture sectors.

xi. Local Growth: Realising Everyone's Potential (CM 7961, 2010) (Ref. 9.20)

9.3.36 The Local Growth White Paper sets out the Government's approach to local growth "shifting power away from central Government to local communities, citizens and independent providers".

9.3.37 This builds on the Government's overall approach to supporting growth based on four strands:

- creating macroeconomic stability, so that interest rates stay low and businesses have the certainty they need to plan ahead;
- helping markets work more effectively, to encourage innovation and the efficient allocation of resources;
- ensuring that it is efficient and focused in its own activities, prioritising high-value spending and reducing tax and regulatory burdens; and
- ensuring that everyone in the UK has access to opportunities that enable them to fulfil their potential.

9.3.38 The Government seeks to spread growth across the UK by:

- shifting power to the right levels: abolishing Regional Development Agencies, and replacing them with new sub-national arrangements through which Local Authorities and Local Business come together through Local Enterprise Partnerships to plan for actions to support local growth;
- increasing confidence to invest: by introducing an presumption in favour of sustainable development in the planning system, simplifying the planning system, requiring local authorities to work together to plan for major infrastructure and providing financial incentives for local authorities to support growth through the New Homes Bonus and more freedom to retain other funding locally and invest in infrastructure; and

- focussed investment: through a Regional Growth Fund to support growth in areas with a string dependence on public sector employment or low private sector activity, and also direct capital investment in major infrastructure such as Crossrail, Broadband connections in rural areas, investment in low-carbon energy and climate change adaptation, including a Green Investment Bank and support manufacturing and business development, with a focus on supporting potential high growth companies and the commercialisation of technologies.

xii. HM Government (2011) 2011 Budget: A Strong and Stable Economy, Growth and Fairness (and Associated Documents), HC 836, HM Treasury (Ref. 9.21)

9.3.39 The 2011 Budget maintains and extends this focus on supporting growth. This states that the Government will:

- Introduce a powerful new presumption in favour of sustainable development, so that the default is 'yes' and pilot land auctions, starting with public sector land;
- Streamline the system for planning applications and introduce new fast-track planning for major infrastructure;
- The Government will introduce a carbon price floor for electricity generation from 1 April 2013, to drive investment in the low-carbon power sector. The Government also announces that the initial capitalisation of the Green Investment Bank will be £3 billion and that it will start operation in 2012-13;
- Fund an additional 80,000 work experience places for young people, ensuring up to 100,000 places will be available over the next two year;
- Fund up to 50,000 additional apprenticeship places over the next four years; and
- Expand the University Technical Colleges programme to establish at least 24 new colleges.

xiii. HM Treasury/BIS (2011) The Plan for Growth (Ref. 9.22)

9.3.40 The Government published a "*Plan for Growth*" (HM Treasury and BIS, 2011) alongside the Budget setting how the Government intends to support growth and re-balance the economy. This includes commitments to, among other things, ensuring investment in key sectors, including Low Carbon technologies, and significantly improving the UK skills base.

9.3.41 It was supported by a Written Statement "Planning for Growth" by the Minister of State for Decentralisation (23 March 2011) (Ref. 9.23) which confirmed that "*The Government's top priority in reforming the planning system is to promote sustainable economic growth and jobs*." The Statement says that local authorities and decision makers on other development-related consents (including heritage, environmental, energy and transport consents) should place weight on the potential economic benefits of development.

xiv. HM Government (2011) Local Government Resource Review (Ref. 9.24)

9.3.42 The Government has established a Local Government Resource Review (Written Statement by the Secretary of State for Communities and Local Government, 17 March 2011). The review will "*consider the way in which local authorities are funded, with a view to giving local authorities greater financial autonomy and* *strengthening the incentives to support growth in the private sector and regeneration of local economies*." This will include consideration as to how and whether local authorities should retain some or all of any additional business rates arising from new developments and infrastructure.

9.3.43 The first phase of the review was published in July 2011, outlining *Proposals for Business Rate Retention*. This consultation follows the commitment in the coalition Government's Programme for Government to "*provide incentives for local authorities to deliver sustainable development, including for new homes and businesses*", and also outlines how the proposals interact with wider Government initiatives to promote growth, including the existing New Homes Bonus, and considers how they will work alongside the existing architecture of the business rates system which it is not proposing to change (for example rate reliefs and the national business rate multiplier). Enabling local authorities to retain a significant proportion of the business rates generated in their area is intended to provide a strong financial incentive for them to promote local economic growth.

xv. HM Government (2010) Equality Act 2010 (Ref. 9.25)

9.3.44 The Equality Act 2010 created an "Equality Duty" on public bodies which came into force in April 2011 and covers age, disability, gender, gender reassignment, pregnancy and maternity, race, religion or belief and sexual orientation.

9.3.45 The Equality Duty applies to public bodies and is therefore not a direct requirement upon the applicant. However, assessment of "equalities" dimensions by the applicant enables public authorities in their consideration of the application, to fulfil their legal duty to consider these issues.

9.3.46 It applies in England, Scotland and in Wales. The general equality duty is set out in section 149 of the Equality Act. In summary, those subject to the general equality duty must have due regard to the need to:

- eliminate unlawful discrimination, harassment and victimisation;
- advance equality of opportunity between different groups; and
- foster good relations between different groups.

9.3.47 The Act requires equal treatment in access to employment as well as private and public services, regardless of the protected characteristics of age, disability, gender reassignment, marriage and civil partnership, race, religion or belief, sex, and sexual orientation (as defined in the Act) In the case of gender, there are special protections for pregnant women. In the case of disability, employers and service providers are under a duty to make reasonable adjustments to their workplaces to overcome barriers experienced by disabled people.

c) Regional

9.3.48 The Government's revocation of regional strategies was quashed in the High Court on 10 November 2010. However, on the same date the Government reiterated in a letter to the Chief Planning Officer its intention to revoke regional strategies through the Localism Bill. This letter was also challenged but, on 7 February 2011, the High Court held that the Government's advice to local authorities that the proposed revocation of regional strategies was to be regarded as a material consideration in their planning development control decisions should stand. The decision of the High Court was upheld by the Court of Appeal on 27 May 2011. Therefore, the regional strategies remain in place but in the case of development control decisions it is for planning decision makers to decide on the weight to attach to the strategies (see **Volume 1**, **Chapter 4** for a full summary of the position regarding the status of regional planning policy).

i. Regional Planning Guidance 10 for the South West 2001-2016 (RPG 10) (2001) (Ref. 9.26)

9.3.49 RPG10 sets out the broad development strategy for the period to 2016 and beyond. Policy SS 3 of the RPG (The Sub-Regional Strategy) states that planning of development and infrastructure investment in the Central sub-region (where HPC is located) should, amongst other things:

- raise the economic performance of the sub-region; and
- focus housing, employment, retail and social facilities in sustainable locations to reduce social exclusion and rural need.

9.3.50 Policy EC 1 advised that local authorities and other agents including Local Enterprise Partnerships (LEPs) should support the sustainable development of the regional economy by, amongst other things, positively promoting and encouraging new economic activity in the areas where it can bring the greatest economic and social benefits.

9.3.51 Policy EC 3 stated that local authorities and other agencies should aim to provide a range of employment sites, including major strategic sites, suitable for significant inward investment and large scale re-investment by existing companies.

ii. The Draft Revised Regional Spatial Strategy (RSS) for the South West Incorporating the Secretary of State's Proposed Changes 2008 – 2026 (July 2008) (Ref. 9.27)

9.3.52 The draft Revised Regional Spatial Strategy (RSS) looks forward to 2026 and sets out the Government's policies in relation to the development of land within the region.

9.3.53 Development Policy A identifies Bridgwater, Taunton and Weston-super-Mare as three of the twenty-one Strategically Significant Cities and Towns to be the focus for future growth. It sets out five aims for the Strategy:

- improving the quality of the urban environment, including new development and the public realm;
- promoting social cohesion and healthy and secure living conditions through access to good social and community facilities;
- supporting growth in the economy and skills through the availability of a range of premises and land that meet the needs of business;
- securing improvements to public transport, traffic management and use of road space to tackle congestion and poor air quality; and
- making efficient and effective use of land, including through regeneration, and planning for and delivering development and infrastructure in a comprehensive and co-ordinated way.

9.3.54 Development Policy D (Infrastructure) states that the planning and delivery of development should ensure efficient and effective use of existing infrastructure and should provide for the delivery of new or improved transport, education, health, culture, sport and recreation and green infrastructure in step with development.

9.3.55 Development Policy F (Master Planning and delivery of major development) states that major developments should be planned on a comprehensive and integrated basis to ensure that they contribute to the delivery of sustainable communities and a high quality of life. Development should provide for, amongst other things, public transport, cultural, leisure, retail, health care, education and other services and facilities commensurate with the needs of the expected population of the area and delivered in step with growth of that population; and a range of housing types and tenures.

9.3.56 The following policies within the draft RSS are of potential relevance to the socio-economic assessment of proposals at HPC:

- Policy SD1 (The Ecological Footprint) – Provides policy guidance on measures that will be taken in the region to reduce the intensive use of resources and move towards a lower carbon dependent region whilst providing more sustainable settlements;
- Policy SD4 (Sustainable Communities) – provides guidance on how development will be actively managed in order to help create and maintain sustainable communities in the region whilst also ensuring the long-term prosperity of the region;
- Policy CSS (Core Spatial Strategy) – Sets out the core spatial strategy for the region, which makes specific reference to enhancing the economic prosperity of the region, whilst ensuring this stays within the environmental limits of the region; and
- Policy SK1 (Education and Skills) – highlights the role that Local Authorities should play with other partners to help ensure the adequate provision of access for their resident population to further skills and training.

iii. South West Regional Development Agency (SWRDA) (2006) Regional Economic Strategy for South West England (2006 to 2015) (Ref. 9.28)

9.3.57 The Regional Development Agencies (RDAs) in England are due to close by March 2012. However at present they continue to operate and their research and policy objectives remain relevant for this assessment.

9.3.58 The South West Debate exercise, which fed into the Regional Economic Strategy, raised some important challenges for the region; notably the need to secure growth within environmental limits; the need to manage a growing, ageing and more diverse population, and the need for more self-sufficiency in energy, including more renewable energy.

9.3.59 The Regional Economic Strategy identifies three strategic objectives:

- successful and competitive business;
- strong and inclusive communities; and
- an effective and confident region.

9.3.60 The SWRDA has also undertaken more detailed work into specific issues of relevance to the HPC Project. The agency has identified a number of priority sectors for investment including advanced engineering and environmental technologies (including renewable energy and waste) and a budget priority (2009 to 2011) to support efforts to drive the region towards a low carbon economy.

9.3.61 The South West Low Carbon Summit (June 2009) noted the significance of the potential Hinkley Point new build for the region, including skilled employment, the need to address skills gaps through a proposed centre of excellence in Bridgwater, and the potential for HPC to "*become a source of international expertise and create a strong high value business cluster in Somerset" (SWRDA, June 2009).*

iv. The Somerset and Exmoor National Park Joint Structure Plan Review 1991-2001 (2000) (Ref. 9.29)

9.3.62 The Joint Structure Plan Review outlines, amongst other things, policies which include principles for sustainable development (Policy STR1) and development outside towns and rural centres which benefits economic activity (Policy STR6).

v. The Somerset County Plan (2010-13) (Ref. 9.30)

9.3.63 The *Somerset County Plan* (2010-13) sets out the Council's priorities and what it wants to achieve for the next three years. It presents these under the three headings of people, places and prosperity.

9.3.64 Under the '*people'* heading, the Council proposes to re-invigorate local communities and neighbourhoods to work together, reduce inequalities in health, wellbeing, access and education. Under *places*, it seeks to ensure broadband connectivity for more homes and businesses, work with partners to provide more decent and affordable homes, and reduce the size of the Council's own Carbon Footprint.

9.3.65 On *prosperity* the plan notes that Somerset has historically underperformed economically, so aims to help existing businesses grow and attract new ones. It identifies the development of HPC as a *'huge opportunity*' and that the Council will work hard to make sure it is in the best interests of Somerset.

9.3.66 It identifies the need to '*create centres of excellence in specific training areas – such as the nuclear industry*', expand energy sources to boost the economy and provide new jobs, work with partners across many business sectors to attract more tourists to Somerset, improve the infrastructure needed to support economic growth, and improve educational outcomes and learning environments in the County.

vi. The Somerset Sustainable Community Strategy: Somerset: A Landscape for the Future (Ref. 9.31)

9.3.67 The current Sustainable Community Strategy for the county; *Somerset, a Landscape for the Future (2008-2026),* was produced by the Somerset Strategic Partnership in

2008. This identified six key aims: Making a Positive Contribution; Living Sustainably; Ensuring Economic Wellbeing; Enjoying and Achieving; Staying Safe; and Being Healthy.

9.3.68 The Somerset Strategic Partnership Board suspended the formal structure of the partnership in October 2010 and its future role (if any) in the light of the changes described above is currently being reviewed.

vii. Heart of the South West Local Economic Partnership

9.3.69 A Heart of the South West Local Enterprise Partnership (LEP) has been established to cover Devon, Plymouth, Somerset and Torbay, which will replace the Regional Development Agency. This area covers the whole of the County of Somerset including West Somerset and Sedgemoor districts. The Partnership Prospectus (March 2011) identifies a number of key priorities which include:

- securing growth in key urban centres;
- providing support to strong sectors across the area such as tourism, food and drink, and land-based industries;
- encouraging investment in potential growth sectors such as marine technologies and low carbon energy generation (notably nuclear power and renewable energy) that can create and sustain new private sector jobs, rebalancing the economy away from an over-reliance on the public sector;
- create the conditions for high levels of business start-ups and increase the numbers of jobs in expanding SMEs;
- working with businesses to access international markets to grow their customer base and create additional private sector employment;
- attract inward private sector investment from high growth sectors to encourage higher paid quality jobs; and
- encouraging increased levels of indigenous investment to improve the quality and pay levels of existing jobs.

d) Local

9.3.70 The main part of the Study Area for the assessment of the effects of HPC is covered by two tier Local Government. In relation to socio-economic issues Somerset County Council is responsible for education, arts, museums and libraries and social services. The District Councils are responsible for housing, leisure, parks and recreation, and local planning and planning applications. Both tiers are involved in economic development and tourism promotion.

9.3.71 Requirements for the production of policies and targets at the local level are currently undergoing a major overhaul. The Coalition Programme for Government (May 2010) (Ref. 9.32) states that the Government will '*promote the radical devolution of power and greater financial autonomy to local government and community groups*.'

9.3.72 As part of this programme the Government has been reducing the requirement on local authorities to produce plans and strategies and also the abolition of the performance framework which required local authorities to report to central Government on a range of targets. In particular the Government has removed the requirement for local authorities to produce a Local Area Agreement and to monitor and report on associated targets.

9.3.73 The Government is also in the process of revoking statutory guidance set out in *Creating Strong, Safe and Prosperous Communities* (2008) (Ref. 9.33), including requirements to establish a "*Local Strategic Partnership*" and produce a "*Sustainable Communities Strategy*". This is set out in the document *Best Value: New Draft Statutory Guidance Consultation* (DCLG, April 2011) (Ref. 9.34) which is currently in the post consultation phase. The final guidance will be produced in 2011.

9.3.74 The approach to planning policies had already been through major reform with the Planning and Compulsory Purchase Act (2004) (Ref. 9.35) introducing Local Development Frameworks (LDFs) to replace Local Plans for district councils. However, as LDFs have a number of formal stages that they have to go through before they are adopted many local authorities still rely on their Local Plans to act as their statutory plan for the area. In these cases it is necessary to receive approval from the Secretary of State to "save" relevant policies. Neither West Somerset Council nor Sedgemoor District Council have yet adopted a Local Development Framework (LDF). Therefore references to planning policies below refer to "Saved Policies" contained in their Local Plans, and to emerging policies contained in LDFs and other documents.

9.3.75 The Localism Bill (Ref. 9.36), proposes further changes to the powers and responsibilities of local councils, neighbourhoods and communities, including planning, housing and local Government. The Government currently anticipates that this will become law in late 2011.

9.3.76 The paragraphs below set out the relevant current policy at the local level. This focuses on the two immediate districts of West Somerset and Sedgemoor, but also refers to Taunton Deane which forms part of the three district assessment area. It should be noted that some of this may fall away as part of the wider trend from central Government to streamline local policy making and reporting.

i. West Somerset Corporate Plan 2011-12 (Ref. 9.37)

9.3.77 West Somerset Council's Corporate Plan (2011/12) identifies the Council's priorities, objectives and key tasks.

9.3.78 The Council's role as "community leaders in the proposed new nuclear development at Hinkley Point" is identified as one of the Council's two corporate priorities. The Council's key objectives in relation to socio-economic issues at HPC, are set out in the table below:

Table 9.1: West Somerset Corporate Plan: Hinkley Point Objectives and Priorities

Housing
Objective 1: To ensure adequate mitigation for any negative impact on the local housing market from accommodating workers involved in the proposed construction of Hinkley Point.
Objective 2: To maximise the legacy benefit to local people of any new housing built or existing housing utilised during the proposed Hinkley construction.
Economic Development and Tourism
Objective 3: To maximise the sustainable job and skills training opportunities together with the prospects for economic development that will be created as a result of the proposed construction and operation of Hinkley Point.
Objective 4: To ensure adequate mitigation for any adverse impact that there might be on the Tourism Industry as a result of the proposed construction of Hinkley Point.
Community Engagement
Objective 7: To lead the community of West Somerset in responding to the proposed development at Hinkley Point.

9.3.79 Other relevant Council general priorities are to "provide homes for local people" (Objective 11) and "ensure the Tourism Partnership reflects and meets the needs of the whole of West Somerset. (Objective 12).

ii. West Somerset Economic Development Strategy 2009 (Ref. 9.38)

9.3.80 West Somerset Council's Economic Development Strategy (April 2009) is based around the themes of *People*, *Place* and *Business* and drivers of *Quality* and *Sustainability*. Future potential development at Hinkley is identified as one of the key challenges.

9.3.81 The key objectives in relation to each of these indicators are as follows:

People

- to stimulate an aspirational, enterprising and entrepreneurial culture within West Somerset;
- to ensure that the West Somerset workforce has the skills required by business to innovate and improve their competitiveness;
- to tackle pockets of worklessness, meeting LAA targets to reduce claimant numbers; and
- to ensure that all communities are engaged fully in economic decision making.

Place

- to create a network of sustainable rural enterprise hubs to foster business growth across the District;
- to find imaginative and sustainable solutions to transport and communication challenges, particularly in relation to Taunton/Bridgwater;
- to ensure effective, integrated and industry focused marketing of the tourism offer across Exmoor and West Somerset; and

- to ensure that the built environment of the Districts principal settlements is of a quality that will attract private sector investment.

Business

- to develop the quality tourism offer within the District, maximising its existing assets;
- to encourage the growth of small “high value” sectors, appropriate to West Somerset;
- to ensure businesses have access to the support required to enable them to innovate, grow and develop; and
- to encourage business start up and growth through provision of mentoring, support and provision of appropriate workspace.

9.3.82 West Somerset Council’s planning policies are summarised in detail in **Chapter 7** (Legislative and Planning Policy Context). Issues of relevance to the socio-economic assessment are highlighted below. Where policies relate to specific associated development sites, these are summarised in the relevant site specific Chapter.

iii. West Somerset Local Plan (2006) (Policies ‘saved’ from 17 April 2009) (Ref. 9.39)

9.3.83 The West Somerset Local Plan forms part of the development plan for West Somerset. The Local Plan was adopted in April 2006 (with relevant policies ‘saved’ from 17 April 2009).The following saved policies are considered to be potentially relevant for the socio-economic assessment and cover the following themes:

9.3.84 Policies SP1 to 5 set out the “Settlement Hierarchy” and policies relating to settlements. Minehead is identified as a Town, and Watchet and Williton as rural centres. It also identifies villages and small villages. Stogursey, in which the HPC site is located, is identified as a village. In general the plan promotes development in Minehead and the Rural centres, with development in villages, small villages and outside settlements allowed where, among other things, it supports economic and social viability.

9.3.85 Policies BD/5 and ED/1 to ED/8 relate to employment uses. They identify site allocations for employment uses, set out criteria for assessing employment related developments and conversions, and support the expansion of existing businesses and retention of existing employment uses.

9.3.86 Policies A/1 and A/2 set out criteria for diversification of uses within farms and for the protection of the “best and most versatile” agricultural land.

9.3.87 Policies T01 to TO7 address tourism. This promotes sustainable tourism within settlements, with specific policies for different levels and types of settlement, specific policies for tourism in Minehead and Watchet, and criteria for the development of camping and caravan sites and for the extension of existing holiday parks.

9.3.88 Policies SH1 to SH/5 address retail development.

9.3.89 Policies H/1 to H/6 cover housing. Policies cover housing land allocations, homes for agricultural and forestry workers, criteria for affordable housing including site thresholds, and conversion of holiday accommodation.

9.3.90 Policies R/1 and R/4 allow the provision of formal sports facilities and the improvement of playing pitches subject to certain criteria.

9.3.91 Policy PO1, Planning Obligations states that:

"The Local Planning Authority in determining planning applications for significant forms of residential, commercial or industrial development may seek to negotiate appropriate planning obligations with developers to provide or contribute to infrastructure or community facilities directly related to the proposed development and commensurate with the development proposals."

9.3.92 Given that Policy EN/5 (Nuclear Energy Developments) was not saved beyond April 2009, WSC determined that a statement outlining its position with regard to new nuclear energy development was necessary to provide clarity on the matter.

9.3.93 A position statement on major energy generation projects and their associated infrastructure was considered and approved by WSC's Full Council on 23 March 2011. The position statement is as follows:

"This Authority recognises the requirement for continued safe supply of electricity to meet the nation's varied energy needs. It will endeavour to facilitate major energy generating development proposals within its area where it can be clearly demonstrated that;

- *it makes an essential contribution to the nation's energy needs;*
- *it respects the local natural environment in which it is located;*
- *it respects the positive economic and social characteristics of communities affected especially those neighbouring it; and*
- *adequate measures are taken to mitigate the cultural, economic, environmental and social impact of any related development on the communities affected, both in the short and the longer term."*

9.3.94 The officer's report to the Full Council states that, whilst it is recognised that the position statement cannot make policy, it has been produced to facilitate WSC's role in the decision-making process in respect of specific related development proposals within West Somerset.

iv. West Somerset Supplementary Planning Document: Planning Obligations (2009) (Ref. 9.40)

9.3.95 In December 2009 West Somerset Council adopted a Supplementary Planning Document (SPD) on Planning Obligations which sets out in more detail how they will implement policy PO1 of the Local Plan. This includes more detail on affordable housing policies. It also covers Community Buildings and Education. In relation to Community Buildings it states that:-

"Where additional demand from development and local need, can be demonstrated, the District Council will use planning obligations to provide or enhance buildings used for community uses." On education it states that contributions may be sought "Where a residential development of 50+ dwellings is likely to generate additional pupil numbers and it falls in the catchment area of a school which has insufficient existing or anticipated capacity."

v. West Somerset Local Development Framework (LDF) Core Strategy (Options Paper) (January 2010) (Ref. 9.41)

9.3.96 The Core Strategy is at a preliminary stage of preparation and the Options Paper does not include any specific policies relating to socio-economic impacts. The Options Paper does however identify a number of issues relevant to this assessment, grouped under a number of broad headings:

Housing and Community

- the need for more affordable housing; and
- improved provision of sport and recreation facilities.

Settlement Hierarchy and Development Distribution

- reviewing the current settlement hierarchy (see local plan above) to see whether it should be revised to meet current circumstances; and
- testing appropriate locations for development.

Employment Business and Tourism

- promoting tourism and in particular more sustainable tourism;
- increasing the amount of, and broadening the variety of employment opportunities within the District, particularly the knowledge based, high income sector;
- continuing to encourage appropriate training and educational opportunities locally;
- the importance of the agricultural industry to the area and its contribution to sustainable food production; and
- the need to retain more young people within the community (19 to 45 age group particularly).

9.3.97 The paper also identifies the impacts of the proposed development of HPC as a key issue (paragraph 3.7), in particular, the potential impacts on housing demand and traffic. It goes on to state that:

"If these proposals proceed to implementation, the construction phase of the project will have a significant impact upon the Core Strategy area. This would have to be managed in conjunction with the implementation of the Core Strategy's proposals." (paragraph 6.8).

9.3.98 Strategic objectives are set out in Para 5.2.2. These include:

- strengthen the role and function of the District's main settlements;

- increase self-containment within the District's main settlements;
- make a step change in the provision of affordable housing to meet identified local needs;
- create an aspirational, enterprising and entrepreneurial culture within West Somerset; and
- develop the quality of the tourism offer within the District.

vi. Sedgemoor Sustainable Community Strategy 2009-2026 (Ref. 9.42)

9.3.99 The Sustainable Community Strategy for Sedgemoor (2009 to 2026) sets out a vision for Sedgemoor of "*Everybody working together to make Sedgemoor a safer, cleaner, healthier, more pleasant and vibrant district in which to live, work, learn, invest or visit*".

9.3.100 It identifies five priority needs for Sedgemoor: Climate Change; Economic Development, especially raising skills and aspirations; Reducing deprivation; Provision of decent and affordable housing; and, Preparing for an increasingly elderly population.

9.3.101 Key activities of relevance to this assessment include:

- ensuring that local communities have a say in significant development proposals (and specifically energy developments) and that local impacts of development are taken into account, positive long-term legacies secured, and a mechanism for community benefit explored;
- promoting "*Smart Growth – Smart Action*", re-structuring the economy, increasing knowledge intensive jobs and businesses, securing more inward investment and tourism expenditure, helping existing business grow and maximising benefits of this to local residents;
- improve Bridgwater including its image, revitalising the town centre and making it an engine of economic prosperity through the "*Bridgwater Challenge*";
- addressing worklessness and getting people back into work or training and promoting the use of local labour and businesses;
- working with communities in deprived wards to improve housing, educational attainment, health and quality of life and with individuals to improve their health and re-enter the labour market;
- transforming schools through Building Schools for the Future, supporting the College, including the development of a new Energy Centre, and developing a Higher Education offer;
- provide a range of affordable, decent and warm accommodation, tackling rented and private homes in poor condition, and preventing homes from getting in to disrepair;
- tackling crime and anti-social behaviour, including understanding the impacts of previous large construction projects; and
- work with investors and developers to understand local needs and deficits in social and leisure infrastructure and to find ways of making improvements that

have a sustained impact and contribute to the wider regeneration of towns and communities.

9.3.102 The Strategy also includes summaries of area based plans for Bridgwater and Burnham and Highbridge, along with the more rural areas. For Burnham and Highbridge the identified priority is to ensure that their economies continue to grow and prosper, and in particular the tourism, retail and manufacturing sectors. The key projects are to improve the town centres and, in Burnham, the seafront, provide new sites for business and training for the local workforce.

vii.Sedgemoor Economic Masterplan 2008-2026 (Ref. 9.43)

9.3.103 The Sedgemoor Economic Masterplan (2008 to 2026) sets out the Council's approach to economic development, noting that it needs to work across boundaries with neighbouring authorities.

9.3.104 The Masterplan is based around three themes: Place; Business and Investment; and People. The table below summarises the key commitments under each theme.

Table 9.2: Sedgemoor Economic Masterplan: Major Commitments

Place
1. Bridgwater will be the South West's leading exponent of a 21st Century enterprise and business hub, an exemplar town offering outstanding services and facilities, on a par with large urban centres, for knowledge based industries, set in a vibrant leisure, cultural and retail centre.
2. Burnham on Sea will be a good example of the successful regeneration of small coastal towns, with regeneration led by the private sector following catalytic public sector investment.
3. Cheddar and the Hills/Levels and Moors: as a sustainable rural community and one of the country's leading examples of a sustainable activity-led tourism product based on the natural environment.
Business and Investment
4. Sedgemoor will be one of the UKs leading centres for energy related business, employment and skills, with Hinkley, Puriton and Bridgwater College as the foundation, and other initiatives based on renewable energy and low carbon technologies.
5. A combination of enterprises based in Bridgwater and a large number of home-based businesses (through a progressive policy on home working and property adaptations in rural areas), will establish Sedgemoor as a leading centre for creative, digital and media industries, with ICT infrastructure linking smaller businesses to regional, national and international networks.
6. A regionally significant location for inward investment, with an established programme of linking local businesses and residents to business and employment opportunities from new investment and in order to grow the energy and logistics sectors.

People
7. Bridgwater College will be the leading provider of rural based further and higher education, with centres of excellence in sectors directly relevant to the Sedgemoor and Somerset economy, and drawing students from all over England.
8. Outstanding schools, using Building Schools for the Future and the newly established Education Trust as the driver, with consistently improving attainment levels, playing a central role in improving the opportunities available to young people in terms of University, further education and moving in to employment.
9. Rejuvenated neighbourhoods and communities, with areas historically affected by high levels of deprivation, established on an upward curve, moving out of the most disadvantaged neighbourhoods nationally, as more effective inter agency working including education, health, police and others provide new opportunities for those excluded from the mainstream economy.
Cross Cutting
10. Sedgemoor will be recognised as the most enterprise driven and business customer focused Council in the South West, with planning polices which support enterprise and investment, and a Senior Member and Officer Team with the capacity and experience to secure and support new investment of all types.

9.3.105 Supporting the Economic Masterplan, Sedgemoor District Council has an adopted Employment and Skills Charter, which informs the agreement of local employment, education and training measures within Section 106 Planning Obligations.

viii. Sedgemoor Local Plan 1991-2011 (2004) (Policies ‘saved’ from 27 September 2007) (Ref. 9.44)

9.3.106 The Local Plan was adopted in 2004 (with relevant policies ‘saved’ from 27 September 2007).The following saved policies are considered to be potentially relevant for the socio-economic assessment and cover the following themes:

9.3.107 The Local Plan, noting that the Structure Plan identified Bridgwater and Burnham/Highbridge as “Towns”, seeks to concentrate development in these towns, subject to a range of criteria (paragraphs 3.05 and 3.06). It also identifies rural centres and villages, the latter include Cannington, Combwich, Stockland Bristol and Fiddington which are close to the border with West Somerset and the HPC development site (paragraph 3.11).

9.3.108 **Chapter 4** of the Plan covers housing. Saved policies address housing targets (H60), criteria for residential development in the Towns and Villages (H2 and H3), identify a number of specific sites allocated for housing (paragraphs 4.27 to 4.60), exceptions policies for rural housing meeting local needs (policy H31), a presumption in favour of the provision of residential caravans and mobile homes as important in meeting the need for affordable accommodation, subject to a range of criteria, and policies relating to agricultural dwellings. **Chapter 5** of the Plan covers Employment and Economic Development. This includes a number of site specific proposals as well as generic policies relating to criteria for assessing applications for employment uses in different types of locations e.g. towns and villages (paragraphs 4.86 to 4.91).

9.3.109 Other saved policies considered to be potentially relevant include: the Protection of Recreational Space (Policy RLT1); provision of outdoor sports facilities with new housing (Policy RLT3); directing new hotel development to Bridgwater, Burnham on Sea or Axbridge or to locations adjacent to motorways or other main routes, or as a replacement for static caravans on an established site (Policy RLT15); criteria for allowing the improvement or extension of, and safeguarding of, existing holiday sites (Policies RLT18 and RLT20).

ix. Sedgemoor Local Development Framework (LDF) Core Strategy (Proposed Submission) (September 2011) (Ref. 9.45)

9.3.110 The Sedgemoor LDF Core Strategy (Proposed Submission) was consulted on from September to November 2010. Changes prior to submission proposed as a result of the consultation process were reported and endorsed by Sedgemoor District Council's Executive Committee on 9 February 2011.

9.3.111 The Core Strategy (Proposed Submission) was submitted to the Secretary of State on 3 March 2011 and an Examination in Public (EiP) was held in May 2011. Once adopted, the Core Strategy will form part of the Development Plan for Sedgemoor. EDF Energy submitted representations objecting to the Core Strategy (Proposed Submission), relating to **Chapter 4** 'Major Infrastructure Projects' (and policies MIP1, MIP2 and MIP3 contained in that chapter) and those sections relating to housing and Hinkley Point. EDF Energy also participated at the relevant EiP hearings. See **Volume 1**, **Chapter 4** for a full summary of the position regarding the status of the Core Strategy.

9.3.112 Emerging policies MIP1, MIP2 and MIP3 relate specifically to the HPC Project, as set out in the re-drafted **Chapter 4** (dated 29 July 2011).

9.3.113 Policy MIP1 (Major Infrastructure Proposals) explains that applications for major infrastructure development will be considered against the relevant national planning policy and the strategy and relevant policies of the development plan. The objective from the Council's perspective is that major infrastructure proposals should, where possible, contribute positively to the implementation of the spatial strategy and meet the underlying objectives of it.

9.3.114 Policy MIP2 (Hinkley Point C Associated and Ancillary Development) sets out the considerations that the Council will take into account in the preparation of a LIR in responding to proposals for development associated with, or ancillary or related to the HPC Project, where they are not the determining authority. Such considerations include: directing accommodation proposals to a range of sites, primarily in Bridgwater; measures to avoid, minimise and then mitigate adverse impacts on the transport network; meeting the accommodation needs of the temporary workforce in a way that does not have an unreasonable adverse effect on the housing market; providing appropriate community facilities where addition demand is generated by the project; delivery of education, employment and training opportunities for the local community; and the delivery of investment in infrastructure, buildings and green infrastructure.

9.3.115 Policy MIP3 (Hinkley Point C: Planning Obligations and Mitigation) states that the Council will seek to ensure, wherever possible, that the proposals avoid, minimise and mitigate (including, where appropriate, compensate for) impacts during the construction, operation, decommissioning, and restoration phases.

9.3.116 The Core Strategy consists of an overarching strategy, policies for major infrastructure projects, including HPC, District-wide policies on a range of key themes, and place making policies for specific locations including Bridgwater and Burnham and Highbridge.

9.3.117 Following guidance from the previous Government the spatial vision for Sedgemoor is based on the Somerset and Sedgemoor Community Strategies described above. As noted above this is likely to cease to be a statutory requirement. The Strategy is structured around the four themes of: living sustainably; ensuring economic wellbeing; enjoying and achieving; and, being healthy. In addition, Bridgwater is seen as the "focal point" for the District and driver of economic prosperity.

9.3.118 The Strategy identifies nine strategic objectives of which the following five are considered to be potentially relevant to this assessment:

- S03, Living Sustainably: To Provide Everyone with the Opportunity to Live in a Decent Home.
- S04, Living Sustainably: To Create More Sustainable Communities.
- SO6, Ensuring Economic Wellbeing: To ensure the economic wellbeing of our communities, by developing an economic blueprint to shape the restructuring of our economy and transform the workforce.
- SO7, Ensuring Economic Wellbeing: To strengthen the retail competitiveness of the town centres whilst broadening their appeal as places to shop, work, live and visit.
- SO9, Being Healthy: To improve the health and well-being of our communities by addressing inequalities and poverty, ensuring access to key services and encouraging healthy lifestyles.

9.3.119 The Strategy re-enforces Bridgwater as the "principal town", expected to accommodate 70% of additional jobs and homes, with Burnham-on-Sea and Highbridge being "*focal points for more limited growth focusing on the need to capture investment to regenerate and sustain the town centres and to promote self-containment by reducing the levels of out-commuting*." (paragraph 3.15). It also identifies seventeen "*Key Rural Settlements*" – including Cannington, Puriton, and North Petherton, and a further ten "*Other Sustainable Settlements*", including Combwich.

9.3.120 Policy S2 identifies the Council's approach to Infrastructure Delivery, based on the Infrastructure Delivery Study undertaken by the Council (see below). This includes the Council's intention to seek funding for "*Core Infrastructure*" through a Community Infrastructure Levy and for "*Onsite and Offsite Infrastructure*" through Section 106 planning agreements. The latter includes affordable housing and social infrastructure: education, sport and open space, healthcare, community and cultural facilities, local labour agreements and emergency services.

9.3.121 District-wide policies considered to be of potential relevance include Policy D5 (Housing) including proposed targets, location and mix, Policy D6 (Affordable Housing), Policy D11 (Economic Prosperity and Long Term Future), Policy E11 (Economic Prosperity) which sets a target of a minimum of 9,160 new jobs by 2026, and the promotion of skills and local labour, Policy D12 (Tourism) which supports the growth of tourism in the area subject to a range of criteria; Policy D13 which promotes retail and leisure growth in key town centres including Bridgwater and

Burnham, Policy D18, which promotes improvements to educational provision, including schools and Bridgwater College, Policy D19 which promotes the retention and enhancement of health provision, Policy D21, which seeks to "provide additional, extended or enhanced community and cultural facilities".

9.3.122 The Placemaking policies for Bridgwater (Policy P1) seek, in large part to support the implementation of the Bridgwater Vision, described above, including the transformation projects. They also identify Hamp, Newtown and Victoria, Sydenham and Eastover as housing renewal areas. The proposals provide strong support for Economic Development in Bridgwater, stating:

> *"All employment proposals in Bridgwater will be supported where they add higher value to the economy through the provision of local employment opportunities, the promotion of higher skilled jobs and/or allow for the expansion of appropriate existing businesses." Policy P2 sets out specific policies for the Town Centre.*

9.3.123 Placemaking policies for Burnham on Sea and Highbridge (Policy P3) focus on increasing self-containment, enhancing the "service" centre role of the towns, supporting development and regeneration to meet local needs, and consolidating and enhancing existing services. Outside of the two main towns, the main thrust of policies is to enhance the role of settlements as service centres for their communities, support the need of local communities and enhance the sustainability and/or increase the self-containment of settlements. Subject to criteria new housing will be allowed within settlement boundaries, but only in exceptional circumstances in "Other Sustainable Settlements".

x. Sedgemoor District Council Infrastructure Delivery Strategy (2010) (Ref. 9.46)

9.3.124 The Sedgemoor Infrastructure Delivery Strategy was published in June 2010. It sets out the likely infrastructure required to support the levels of housing development identified in Sedgemoor's emerging Core Strategy. This includes a review of current infrastructure provision and estimates of additional required provision. This suggests that the development at HPC could have impacts on local provision and that Planning Obligations and/or a packaged of Community Benefits may be required. It notes that discussions with the HPC promoter are at an early stage but that possible investments include park and rides, cycleways and footpaths, provision of sport and recreation and provision of healthcare and education. It notes (paragraph 2.5) that it is essential that "*any requirements (will need to be) set in a robust evidence base*."

xi. Hinkley Point C Project Supplementary Planning Document (Consultation Draft) (February 2011) (Ref. 9.47)

9.3.125 Sedgmoor District Council and West Somerset Council have jointly prepared draft supplementary planning guidance in relation to the HPC Project. Public consultation on the Consultation Draft version of the Hinkley Point C Project Supplementary Planning Document ("the draft HPC SPD") commenced on 1 March 2011 and concluded on 12 April 2011. EDF Energy submitted representations which object to the draft HPC SPD.

9.3.126 Following the Sedgemoor Core Strategy EiP and subsequent correspondence with the Inspector, it is clear that the SPD cannot set tests, policies or requirements for the IPC to apply to the consideration of the HPC Project. If the Councils continue with the SPD preparation, its text will need to be considered in this light and it could not carry any significant weight in the determination of the DCO application. As it may be relied upon by some stakeholders, however, the principal contents of the draft HPC SPD as it relates to the assessment of socio-economic effects are summarised below.

9.3.127 Project-wide issues and policies include:

- An expectation from the Councils that the project promoter will help support, and produce a delivery plan for, a Heart of Somerset Low Carbon Business Cluster.
- Expectations for a comprehensive scheme of economic, community/social, environmental and safety measures to mitigate and compensate for the new and increased levels of impact and harm associated with the HPC project that takes account of the needs of the communities of the two Council areas as well as the needs and impacts of the HPC workforce.
- The development and implementation of Employment and Skills Charters to support and improve local access to jobs and training.
- Support for a local business supply chain and services approach.
- Workers to be accommodated in existing settlements in proportions that reflect the local settlement hierarchy, with a higher proportion (permanent or temporary directed to Bridgwater).
- Production by the promoter of a Worker **Accommodation Strategy** based on a series of detailed principles including: sites being in line with local planning policies; proposals minimising need to travel to work and leisure; majority of accommodation should be permanent and provide a legacy; impact on local communities minimised and cohesion and regeneration enhanced; promotion of healthy lifestyles, requirement for socio-economic assessment of proposals of over 100 bedspaces, promotion of healthy lifestyles and requirement for Code of Conduct for Construction workers.
- Any on-site campus should be the minimum required for operational purposes.
- In Bridgwater accommodation should help deliver the Bridgwater Vision and temporary provision should be minimised.
- Workers use of tourism accommodation should be monitored. Criteria are set out for dealing with proposals for extended tourist accommodation or year round use of existing accommodation.
- Maximising the opportunities for the Hinkley Visitor Centre to benefit the wider tourism economy and strategic enhancements to existing attractions, such as Butlins family resort in Minehead and Brean to Burnham-on-Sea and Highbridge, to maintain their reputation and ‘pull’.
- The promoter should work with the Councils to support providers of “latent” accommodation and ensure that community relations, health and safety, emergency services and legal issues are covered.
- The promoter should contribute to the delivery of affordable housing to redress any impacts on the local housing market.
- That the promoter should protect and promote the local tourism economy.

- That a partnership approach to sports and recreation provision should be developed through which the HPC promoter should provide for the needs of its workforce, whilst ensuring facilities are available and accessible to residents. It identifies five potential locations for such provision: Bridgwater, Bridgwater Gateway, Cannington, Stogursey and Williton.

9.3.128 In relation to the on-site accommodation campus, it sets out expectations of what might be included. This includes: a robust justification for why the campus is essential including the specific types of workers; the need to avoid impacts on the residents of Shurton and Burton; the inclusion of a medical facility/clinic, and administration and security office, shops and amenity facilities, subject to them being justified in relation to the scale of the campus and impacts on the wider area; an education building, and sport facilities.

9.3.129 The SPD also contains reference to the Dillington Visions, at Appendix A of the SPD. These are a series of thematic vision statements and joint objectives for the HPC Project. These relate to the following topics:

- Economic Development – To ensure that the HPC development acts as a driver for achieving a more dynamic, entrepreneurial, inclusive and sustainable economy in Somerset and the wider region.
- Developing a Low Carbon Future – Ensure a strong business and educational reputation for low carbon and environmental technologies.
- Education, Employment and Skills – Ensure the HPC development maximises employment and skills opportunities for local people, whilst inspiring young people to achieve and seek to follow careers in the science, technology, engineering and manufacturing sectors.
- Community Well-being – associated with generating greater community cohesion and support the delivery of strategic objectives by implementing a comprehensive scheme of community well-being and safety measures that take account of the needs of the communities of West Somerset, Sedgemoor and Somerset as a whole, as well as the needs and impacts of the HPC workforce.
- Housing – ensure the Hinkley C development provides housing solutions that enable workers and their families to integrate into the community and are economically active at a local level, whilst making a positive contribution to the Councils' Housing Strategies and their wider strategic planning objectives.

xii.The Bridgwater Vision (Ref. 9.48)

9.3.130 The Bridgwater Vision (2009) sets out a "Vision" for the town which, as noted in a range of policies, is a priority location for regeneration and investment.

9.3.131 The Vision notes some of the existing projects which support the vision which includes "*the opportunity to maximise local community benefits from the potential construction of a new nuclear power station at Hinkley Point including new jobs, not only in construction, but also contributing to the development of a knowledge economy providing the catalyst for a higher skilled workforce*." Also identified are the Energy Skills Centre, the BAE systems site at Puriton, and the development of "North East Bridgwater" as a sustainable urban extension.

9.3.132 The Vision breaks the town down into thirteen character areas, linked by a green network and an access and movement strategy. It then goes on to identify a series of "catalyst" projects in the central area which can help promote change.

9.3.133 Sedgemoor District Council's planning policies are summarised in detail in **Chapter 7** (Legislative and Planning Policy Context). Issues of relevance to the socio-economic assessment are highlighted below. Where policies relate to specific associated development sites, these are summarised in the relevant site specific Chapter.

xiii. Taunton Deane Borough Council, Grow and Green, A New Economic Development Strategy for Taunton Deane, 2010 (Ref. 9.49)

9.3.134 Although not one of the two immediate host Districts for HPC, Taunton Deane Borough Council is within the three district assessment area and its economic development policies are potentially relevant.

9.3.135 Taunton Deane's Economic Development Strategy has three objectives. These are:

- to create 16,500 or nearly 30% more jobs in Taunton by 2026;
- to create better quality jobs which will close Taunton's earnings gap with the rest of the South West region; and
- to create a dynamic 'green economy' in Taunton which delivers fresh business and job opportunities.

9.3.136 The Strategy highlights the role of Somerset College and the potential links with the proposed Energy Skills Centre at Bridgwater College.

xiv. Summary

9.3.137 The policy review above demonstrates that there are a large number of policies at the national, regional and local levels relevant to the assessment of the impacts of HPC.

9.3.138 In order to assess the socio-economic impacts of the proposed development against these policies, as required by NPS EN1 (paragraph 5.12.4) the matrix set out in **Table 9.3** below, has been created which seeks to capture the key policy areas covered which need to be addressed in the assessment and can be referred to in the baseline assessment and review of impacts in the following sections.

9.3.139 The table splits the policy requirements into three categories:

- **Process and Criteria Policies**: are those which set out how the assessment should be undertaken, the weight given to different issues in the assessment, and how impacts should be addressed.
- **Assessment of Impact and Mitigation**: are those areas identified by policy makers in which the proposals at HPC might have an impact, which, if a negative impact, might require mitigation.
- **Enhancement and Legacy**: Are those areas identified, predominantly in local policy, where potential positive impacts of the HPC scheme might be delivered in a way which could be enhanced to achieve wider policy objectives.

9.3.140 The distinction between the second and third categories is important in order to identify areas in which the applicant might be expected to minimise or mitigate impacts as a requirement, and those in which longer term partnership working might provide enhanced outcomes but for which, under the 'process and criteria' rules the applicant couldn't reasonably be required to contribute.

Table 9.3: Summary/Reference to Policy

	National	Regional and Sub-Regional	Somerset	West Somerset	Sedgemoor

9.4 Methodology

a) Study Area

9.4.1 The geographical extent of the study area for this socio-economic assessment includes the full extent of the project, including the HPC development site, all associated development sites and the surrounding area as defined by each socio-economic topic.

9.4.2 The following describes the geographic areas which have been used in the baseline studies for each impact topic. The precise areas used are partly influenced by data availability issues and in some cases also reflect the boundaries of relevant service planning areas, e.g. for school or health facilities.

i. Administrative Areas

9.4.3 In terms of socio-economic baseline data, the study area is based on areas of administrative geography including National (England and Wales), Regional (South West), County (Somerset) and Local Authority/District (West Somerset, Sedgemoor and Taunton Deane).

ii. Construction Workforce Spatial Distribution Areas

9.4.4 Additionally, some analysis is conducted on a ward-based approach, based on areas derived from the Gravity Model which has been used in the **Transport Assessment**. This model includes inputs from the socio-economic assessments on the workforce profile, skills profile of the resident workforce, and accommodation location and availability. It then, based on travel times, allocates the workforce across the area.

9.4.5 There are two study areas used within this assessment derived in this way:

- *60-Minute Travel Time:* This is a collection of wards within a defined 60-minute travel distance from the HPC development site, including wards in Taunton Deane, Sedgemoor, West Somerset, Mendip, South Somerset and North Somerset. It represents the estimated extent of daily travel time to the Hinkley Point site by non-home based workers who may move into the area to work on the project.
- *Construction Daily Commuting Zone:* The Construction Daily Commuting Zone (CDCZ) is defined as the local authority districts within an approximate 90 minute commute time (c 50-55 miles) of the HPC development site. This area includes the county of Somerset (Mendip, Sedgemoor, South Somerset, Taunton Deane and West Somerset districts), the West of England area (Bath and North East Somerset, City of Bristol, North Somerset and South Gloucestershire unitary authorities), the following districts in Devon: East Devon, Exeter, Mid Devon, North Devon and Teignbridge, plus West Dorset district and Newport unitary authority in Wales. This is used primarily to define the local (home-based) labour market for construction phase. The definition of the CDCZ involves consideration of a range of factors which affect workers' willingness to commute, including time, distance and travel allowances; plus findings from other studies of the mobility of UK construction workers. The CDCZ is used primarily to define the home-based labour market for the construction phase.

9.4.6 It varies slightly from the CDCZ used in the transport gravity model, as it uses local authority rather than ward boundaries. This allows the use of more recent and wider datasets for analysis of the local labour market, and broadly corresponds with the areas used for the Sizewell studies. **Figure 9.1** outlines the Study Areas defined above. A full description of detailed inputs to the determination of the 60-minute travel distance and CDCZ is included in **Technical Note 1: Workforce Profile** (**Appendix 9A**), with specific elements covered in **Technical Note 4: Accommodation Datasets** (**Appendix 9D**) and **Technical Note 3**: **Spatial Distribution** (**Appendix 9C**) and Chapters 8, 10 and 15 of the **Transport Assessment**.

iii. Ward Clusters (Distribution of Non-home-based Workers)

9.4.7 Data to outline the baseline position in terms of local population and employment dynamics have also been collected on a 'ward cluster' basis, which outlines 12 spatial areas with anticipated proportions of non-home-based construction workers (based on the Gravity Model distribution). These areas are outlined in the following list:

- *Bridgwater ward cluster:* Bridgwater Bower, Bridgwater Eastover, Bridgwater Hamp, Bridgwater Quantock, Bridgwater Sydenham, Bridgwater Victoria, King's Isle, North Petherton, and Sandford.
- *Burnham and Highbridge ward cluster:* Berrow, Brent North, Burnham North, Burnham South, Highbridge, Huntspill and Pawlett, Knoll, Puriton, Wedmore and Mark, West Poldens, Woolavington.
- Cannington ward cluster: Cannington and Quantocks.
- *Cheddar ward cluster:* Axbridge, Axe Vale, Cheddar and Shipham.
- *Glastonbury ward cluster:* Glastonbury St Benedict's, Glastonbury St Mary's, Moor, Street North, Street South, Street West, East Poldens, Turn Hill, Wessex.

- Hinkley Point and Stogursey ward cluster: Quantock Vale.
- *Minehead ward cluster:* Alcombe East, Alcombe West, Aville Vale, Carhampton and Withycombe, Dunster, Minehead North, Minehead South, Porlock and District.
- *Somerset South ward cluster:* Curry Rivel, Islemoor, Blackdown, Monument, Neroche, North Curry, Stoke St. Gregory, Wellington East, Wellington North, Wellington Rockwell Green and West.
- *Somerset West ward cluster:* Bradford-on-Tone, Milverton and North Deane, Brompton and Ralph Haddon, Quarme.
- *Taunton ward cluster:* Bishop's Hull, Bishop's Lydeard, Comeytrowe, Norton Fitzwarren, Ruishton and Creech, Staplegrove, Taunton Blackbrook and Holway, Taunton Eastgate, Taunton Fairwater, Taunton Halcon, Taunton Killams and Mountfield, Taunton Lyngford, Taunton Manor and Wilton, Taunton Pyrland and Rowbarton, Trull, West Monkton.
- *Watchet and Williton ward cluster:* Crowcombe and Stogumber, Old Cleeve, Watchet, West Quantock, Williton.
- *Weston-super-Mare:* Banwell and Winscombe, Blagdon and Churchill, Clevedon Central, Clevedon East, Clevedon North, Clevedon South, Clevedon Yeo, Congresbury, Hutton and Locking, Kewstoke, Weston-super-Mare Central, Weston-super-Mare Clarence and Uphill, Weston-super-Mare East, Weston-super-Mare Milton and Old Worle, Weston-super-Mare North Worle, Weston-super-Mare South, Weston-super-Mare South Worle, Weston-super-Mare West.

iv. Urban Areas of High Population Density

9.4.8 Additionally, where applicable, data has been collected to reflect the major urban areas within the study area (Bridgwater, Taunton and Weston-super-Mare). The following wards are used to define these urban areas (ONS ward codes are given in brackets):

- *Bridgwater: (*40UCGN) Bridgwater Bower; (40UCGP) Bridgwater Eastover; (40UCGQ) Bridgwater Hamp; (40UCGR) Bridgwater Quantock; (40UCGS) Bridgwater Sydenham; (40UCGT) Bridgwater Victoria.
- *Taunton:* (40UEGH) Bishop’s Hull; (40UEGM) Comeytrowe; (40UEGX) Taunton Blackbrook and Holway; (40UEGY) Taunton Eastgate; (40UEGZ) Taunton Fairwater; (40UEHA) Taunton Halcon; (40UEHB) Taunton Killams and Mountfield; (40UEHC) Taunton Lyngford; (40UEHD) Taunton Manor and Wilton; (40UEHE) Taunton Pyrland and Rowbarton.
- *Weston-super-Mare: (*00HCPQ) Weston-super-Mare Central; (00HCPR) Weston-super-Mare Clarence and Uphill; (00HCPR) Weston-super-Mare East; (00HCPT) Weston-super-Mare Milton and Old Worle; (00HCPU) Weston-super-Mare North Worle; (00HCPW) Weston-super-Mare South; (00HCPX) Weston-super-Mare South Worle; (00HCPY) Weston-super-Mare West.
- *Watchet/Williton: (*40UFGM) Watchet; (40UFGP) Williton.
- *Minehead:* (40UFFX) Alcombe West; (40UFGF) Minehead North; (40UFGG) Minehead South.

- *Burnham-on-Sea/Highbridge: (*40UCGU) Burnham North; (40UCGW) Burnham South; (40UCHA) Highbridge.
- *Wellington: (*40UEHG) Wellington East; (40UEHH) Wellington North; (40UEHJ) Wellington Rockwell Green and West.
- *Cheddar:* (40UCGY) Cheddar and Shipham.

v. Other Spatial Scales

9.4.9 The following list outlines other spatial areas of study related to specific areas of socio-economic effect:

- *Local labour market for operational phase* – this is defined as the immediate districts of West Somerset, Sedgemoor and Taunton Deane. Approximately 95% of existing Hinkley Point B personnel is resident in these three districts.
- *Employment/economy/wider economy* – baseline data has been collected for the 60-minute travel distance, and CDCZ, but with a secondary focus on the more immediate districts of West Somerset, Sedgemoor and Taunton Deane.
- *Demographic/settlement characteristics – t*he main focus is primarily on West Somerset, Sedgemoor and Taunton Deane districts, which are likely to house the majority of the non-home-based workforce. There is a secondary focus on the wards in the more immediate vicinity of the site.
- *Housing market/accommodation* – primarily the three districts as above for demographic/settlement characteristics.
- *Crime/police/fire* – for police services, the main focus is on the Somerset West police district of the Avon and Somerset Constabulary. This includes the three local authority areas of Taunton Deane, West Somerset and Sedgemoor. There are four neighbourhood areas in the police district: Bridgwater, Burnham-on-Sea, Minehead and Taunton.

9.4.10 The local study areas for each of the associated development sites are based on Mid-level Super Output Areas (MSOAs) and defined individually in each chapter.

vi. The Immediate Area around Hinkley Point C

9.4.11 The definition of the Immediate Area to the development is based partly on the representation of parish and town councils on the Hinkley Point Site Stakeholder Group. Although it is not possible to collect comprehensive data at this scale, this area is included in the assessment in terms of mitigation proposals. The constitution of the Hinkley Point Site Stakeholder Group (Ref. 9.50) includes membership from the following parish and town councils:

- Bridgwater Town Council (covering Bridgwater Bower, Eastover, Hamp, Quantock, Sydenham and Victoria wards).
- Cannington, Fiddington, Nether Stowey, Otterhampton, Over Stowey, Spaxton and Stockland Parish Councils (in Cannington and Quantocks ward).
- Chilton Trinity and Wembdon Parish Councils (in Sandford ward).
- East Quantoxhead Parish Meeting (in West Quantock ward).
- Holford, Kilve, Stogursey and Stringston Parish Councils (in Quantock Vale ward).

- Pawlett Parish Council (in Huntspill and Pawlett ward).

b) Baseline Assessment

9.4.12 Baseline information has been identified through:

- Analysis of publicly-available demographic datasets including analysis of nationally recognised data and survey information obtained from the Office of National Statistics (ONS) and other Government departments including the Department of Communities and Local Government. This includes 2001 Census data and mid-year population estimates (2001-2009) (Ref. 9.51), Annual Business Inquiry data (2008) and updated ABI/BRES (2009) data (Ref. 9.52), Department of Work and Pensions Jobseekers Allowance Claimant Count data (Ref. 9.53) and the Government's Indices of Multiple Deprivation (2010) (Ref. 9.54).
- Work undertaken through various accompanying Technical Notes, listed here and included as appendices:
  - Technical Note 1: Workforce Profile (**Appendix 9A**).
  - Technical Note 2: Demographic Benchmarks (**Appendix 9B**).
  - Technical Note 3: Spatial Distribution (**Appendix 9C**).
  - Technical Note 4: Accommodation Datasets (**Appendix 9D**).
  - Technical Note 5: Leisure Audit and Estimated Demand (**Appendix 9E**).
  - Technical Note 6: Community Cohesion (**Appendix 9F**).
- Work on the transport gravity model which has been used to assess the spatial distribution of the workforce was undertaken jointly by the Socio-Economic and Transport workstreams. A full description of the model and its inputs is contained in the **Transport Assessment**.
- Consultation with appropriate Statutory Bodies as detailed.
- A study of local education facilities has been undertaken using pupil place planning documents, School Organisation Plans (Ref. 9.55) and Annual Schools Census data (2010) (Ref. 9.56).
- A study of primary healthcare facilities has been undertaken based on NHS Business Services (2010) data and data obtained from NHS Choices (2011).

9.4.13 The following table outlines the key data sources used in the production of the baseline assessment and those used elsewhere in the socio-economic assessment. No specific surveys were commissioned or undertaken for this ES assessment.

Table 9.4: Key Data Sources

NATIONAL
• Mid-year population estimates (ONS); • Estimates of internal migration flows (ONS); • Sub-national population projections (ONS); • Annual estimates of total employment and jobs density (ONS); • Annual Business Inquiry/Business Register and Employment Survey (ONS); • 2001 Census (ONS); • Annual Population Survey estimates (ONS); • Job-Seekers Allowance Claimant count unemployment data (ONS); • Working age benefit claimant data (DWP); • Annual Survey of Hours and Earnings (ONS); • Employment forecasts for the construction sector (Construction Skills Network); • Indices of Multiple Deprivation 2010 (DCLG); • GCSE exam attainment data (DCSF); • Recorded crime statistics (Home Office).
REGIONAL/COUNTY/DISTRICT
• Avon and Somerset Constabulary 12-month crime figures: • Regional Spatial Strategy for the South West (GOSW); • South West England Regional Assembly (SWRA)/ Development Agency (SWRDA), including RSS/RES/Sustainability Appraisals etc • South West Observatory, South West economy projections; • South West Public Health Observatory, health indicator set; • Fordham Research, Strategic Housing Market Assessment for Taunton and South Somerset housing market areas; • Somerset County Council, School Organisation Plan; • Somerset Primary Care Trust, strategic review of primary care infrastructure; • Somerset Strategic Partnership, local area agreement, sustainable community strategy and economic strategy; • West Somerset, Sedgemoor and Taunton Deane Districts, policy and data documentation • South West Tourism, accommodation database; accommodation occupancy surveys; • Socio-Economic Workshops and meetings of Somerset Nuclear Energy Group.

c) Consultation

9.4.14 Extensive consultation has been undertaken throughout the environmental assessment process, including formal stages as prescribed by the IPC, through a Planning Policy Agreement with the local authorities, which established a dedicated socio-economic work stream, and through other formal and informal consultation.

9.4.15 The **Consultation Report** describes the full process which EDF Energy has gone through which includes the process for Infrastructure Planning applications as set out in primary and secondary legislation, including meetings held with Sedgemoor District Council, West Somerset Council and Sedgemoor County Council throughout the EIA process to discuss the scope of the assessment. In addition, a set of initial workshops were held with local authorities and other key stakeholders to identify and confirm the likely socio-economic impacts associated with the proposed development, and to identify possible measures to mitigate these impacts.

9.4.16 The **Consultation Report** also identifies responses to all comments made by individuals, statutory bodies and other organisations, and includes a socio-economic section, cross referenced with this chapter and the appended **Technical Notes**.

9.4.17 A formal Socio-Economic Taskgroup, incorporating representatives from SDC, WSC, SCC and EDF Energy was established in October 2010. The working group has considered the methodology adopted for the estimation of employment numbers and the consequent impacts on accommodation and public services.

9.4.18 A series of **Technical Notes** were prepared as part of this consultation process and these are appended.

d) Assessment Methodology

i. Value and Sensitivity

9.4.19 The main sensitive receptors for the socio-economic assessment are the housing and labour markets, public services and communities at a number of spatial levels. It is not possible to ascribe a relative 'value' to each of these receptors as impacts could be felt at all spatial scales and are as significant to individuals and communities in a local area as they are at the regional scale.

9.4.20 There has therefore been a focus on the "sensitivity" of each receptor, and, in particular on their ability to respond to change based on recent rates of change and turnover. The socio-economic environment is a dynamic and adaptive one with constant background change and turnover, for example people moving into and out of the area and changing jobs. This is a particular feature of the construction sector.

9.4.21 The baseline assessment identifies the extent of this background change and then, where possible, the scale of likely impacts has been benchmarked against this change.

ii. Magnitude and Significance

9.4.22 The significance levels therefore combine an assessment of the overall magnitude or scale of the impact, and compare this to the ability of each receptor to respond to change. Potential impacts have been considered in terms of permanent or temporary, adverse (negative) or beneficial (positive) and cumulative.

9.4.23 Some impacts cannot be quantitatively assessed; in such cases a qualitative assessment has been used. In addition, the magnitude of the impact does not necessarily correlate with the impact significance. The key influences on the determination of impact significance include:

- the magnitude of the potential impact;
- the geographical extent of the impact;
- the duration and reversibility of the impact;
- the capacity of the relevant area to absorb the impact; and
- recent rates of change in the locality.

9.4.24 Thus, for example, a key (major or moderate) significant impact would be likely to be: of major or at least moderate magnitude, affect a wide area, be permanent or irreversible and difficult to absorb in the relevant area. The sources of impact may arise during construction and/or operational phases. Due to the nine year construction for the HPC Project the duration of many of the temporary impacts will be long term although their magnitude will vary over the project depending on the level of workforce at any one time. Most of the assessments focus on the "peak" of the construction period. This enables it to demonstrate the maximum scale of beneficial impacts and ensure mitigation measures meet the worst case for adverse impacts.

9.4.25 The table below identifies those impacts where significance can be defined with reference to the baseline and quantitative indicators. Other qualitative assessments are based on professional judgement.

9.4.26 The criteria have been reviewed and updated in response to comments on the Stage 2 Environmental Appraisal and discussions with the local authorities and their advisers. They seek, as far as possible, to identify quantitative criteria as to the level of change in relation to the current capacity of the area (for example for schools and accommodation) or in the context of current annual rates of turnover and change in population. This recognises the dynamic nature of the environment with which the HPC development will interact.

Table 9.5: Level of Significance (Magnitude and Sensitivity) of Impacts Assessed

Impact	Major	Moderate	Minor	Negligible
Economic				
Labour Market: Change in Level of Construction Employment in Regional (CDCZ) Economy	7.5% to 10% change in construction employment	5% to 7.5% change in construction employment	2.5 % change to 5% change in construction employment	Up to 2.5% change in construction employment
Change in Level of Employment in Local (3 District) Economy	1.5 to 2% change in resident based employment (3 districts)	1 to 1.5% change in residence based employment	0.5% to 1% change in resident based employment	0 to 0.5% change in resident based employment
Business and Supply Chain	To be assessed qualitatively	To be assessed qualitatively	To be assessed qualitatively	To be assessed qualitatively
Accommodation				
Overall Supply	Within 16,800 at August peak (20% of stock excluding Owner Occupied)	Within 12,600 at August peak (15% of stock excluding Owner Occupied)	Within 8,400 at August peak (10% of stock excluding Owner Occupied)	Within 4,200 units at August peak Within 14,200 off peak
Tourist Sector	Within 5,000 at August peak (beneficial at all other times)	Within 4,000 at August peak (beneficial at all other times)	Within 3,000 at August peak (beneficial at all other times)	Within 2,000 units at August peak (beneficial at all other times)

Impact	Major	Moderate	Minor	Negligible
Private Rented Sector	Up to 10,200bedspaces (20% of stock – estimated annual turnover)	Up to 5,080 bedspaces (10% of stock)	Up to 2,540 units (5% of stock)	Within 1,270bedspaces (2.5 % of stock)
Owner Occupied Sector	Within 20% of annual turnover of owner-occupied sector	Within 15% of annual turnover	Within 10% of annual turnover	Within 5% of annual turnover
Latent Sector	Up to 1,200 additional units (c.100% of projected annual housing growth in three district area	Up to 900 additional units (c.75% of projected annual housing growth in three district area	Up to 600 additional units (c.50% of projected annual housing growth in three district area	Up to 300 additional units (c.25% of projected annual housing growth in three district area
Population Dynamics				
Population	effect of new non-home-based workers represents 50%+ of annual average new residents	effect of new non-home-based workers represents 20 to up to 50% of annual average new residents	effect of new non-home-based workers represents 10 to up to20% of annual average new residents	effect of new non-home-based workers represents less than 10% of annual average new residents
Public Services				
Education	Effect of new population if additional means exceeding current capacity in ward cluster, where baseline levels were not already exceeding capacity	Effect of new population if additional takes surplus capacity to within 5% of total capacity	Effect of new population if additional takes surplus capacity to within 10% of total capacity	Effect of new population if additional means no change to within 10% of surplus capacity, or no change from baseline significance
Leisure	Provision of major new facility/ies over and above planning requirement	Basic requirement met and additional contribution made to off site provision	Sports Facilities Calculator requirement provided on site and/or through S106	No impact on demand for or supply of sports provision
Police and Emergency Services	Increase of up to 20% in crime in the policing district	Increase of up to 10% in crime in the police district	Increase of up to 5% in crime in the policing district	Increase of up to 1% in crime in policing district
Health	Net increase in demand of 5+GPs	Net Increase in demand of 3 to 5 GPs	Net Increase in demand of 1 to 3 GPs	Net increase in demand equivalent to less than 1GP
Operational Impacts				
Employment	Increase >75% in employment in higher value added sectors in 3 district area	Increase of 50-75 % in employment in higher value added sectors in 3 district area	Increase of 25-50 % in employment in higher value added sectors in 3 district area	Increase of up to 25 % in employment in higher value added sectors in 3 district area

Impact	Major	Moderate	Minor	Negligible
Wider Economic Impact	To be assessed qualitatively	To be assessed qualitatively	To be assessed qualitatively	To be assessed qualitatively
Agricultural Land Use Impacts				
Loss of land and farming activity	Agricultural land lost represents > 10% of agricultural land in Somerset	Agricultural land lost represents 5-10% of agricultural land in Somerset	Agricultural land lost represents 1-5% of agricultural land in Somerset	Agricultural land lost represents < 1% of agricultural land in Somerset
Severance of farm units	Low significance on local farm units is considered given the design features and scale of the proposed development			
Direct economic impact of loss of agricultural land where in agri-environment schemes	No impact as financial arrangements have been made with land-holders for EDF Energy to acquire land.			

iii. Cumulative Effects

9.4.27 As part of the Stage 2 Consultation it was suggested by SDC and WSC in their joint response that the labour market impacts and the consequent impacts on demand for accommodation and public services/community facilities should be considered alongside the wider labour force requirements of the proposed off-site associated developments and the HPC development site. The interactive cumulative construction employment impacts of the HPC Project (i.e. the HPC development and all the associated developments) are assessed in **Volume 2**, **Chapter 9** of this ES. In addition, an assessment of the cumulative impacts of HPC project-wide development alongside external projects (i.e. construction/development projects elsewhere in the local area and region) is set out in **Volume 11**, **Chapter 6** of this ES.

9.4.28 The assessment of the socio-economic impacts follows IPC guidance for the potential effects to be based on evidenced impacts. In relation to the accommodation campuses at the HPC development site and in Bridgwater, West Somerset Council and Sedgemoor Council have made representations on potential impacts. The assessment of potential impacts of these campuses are contained in separate Chapters of this Environmental Assessment, although they are, in the main, qualitative. In recognition of this EDF Energy is taking a precautionary approach, and extensive measures to avoid, and where necessary mitigate impacts are proposed. These are described in the relevant chapters.

iv. Assessment of Likely Significant Effects

9.4.29 The assessment of likely significant socio-economic effects within the study assessment area has been undertaken by reference to the likely changes from the baseline conditions and the effects of those changes as a result of the proposed HPC Project. The assessment has considered the following potential effects:

- *Demographic change*: Changes in the local population level and structure. For example, there is likely to be a large non-home-based and male population during the construction phase, a proportion of whom could be accompanied by families; there would be smaller numbers with a longer term presence during the operational phase.

- *Direct and indirect employment change*: As above, changes in direct site employment levels will result in changes to employment levels in the local employment structure. These will depend on both project characteristics, and associated policies, but there is likely to be a major increase in local employment/opportunities. There will also be a multiplier effect with indirect (e.g. local supplier firms) and induced (e.g. local service jobs) effects from the HPC Project. There may also be some potential loss of labour from other local employers to the HPC Project.
- *Local expenditure effects*: Expenditure by the workforce, and from HPC contracts/payments, will lead to changes in spending in the local economy and possibly in the provision of local outlets. The proposed HPC Project could also help to offset the closure of existing Hinkley Point Power Station Complex (i.e. Hinkley Point A and Hinkley Point B).
- *Wider economic effects*: There could be potential effects on key economic sectors (e.g. construction, tourism), and on the development potential and image of the area.
- *Accommodation effects*: Increased demand for accommodation in the area, including local accommodation services such as B&Bs, guest houses and caravan sites; and the local housing market. The demand for local accommodation could have implications on residential property values.
- *Impact on local social conditions and associated services*: HPC Project-related demographic changes have the potential for impacts on local social conditions and associated services. For example, during construction there could be a change in demand for local health, school and policing services, and with possible issues for the local population (e.g. impact on school places, crime in the community; traffic flows/noise).
- *Other less tangible socio-cultural change*: Changes in the level and structure of employment and demographic changes potential could have the potential to affect quality of life, community character/cohesion and distributional effects. Parts of the local community may be differently affected by the development, or there could be a shift in the character of some communities (especially those close to or on key routes to the HPC project).
- **I***mpact on agricultural land and the agricultural economy and labour market*: This chapter includes an assessment of the socio-economic impact of the potential loss of agricultural land, severance within farm units, and the related direct and indirect socio-economic impacts. This assessment has not involved the undertaking of site surveys or detailed financial implications for individual farm units. The socio-economic receptors related to agricultural land are identified as the wider sub-regional economy, and site-specific features including individual farm units, in terms of disruption to farm operations, loss of land and severance of land/access.

v. Mitigation and enhancement

9.4.30 In parallel with the assessment process EDF Energy has been working with the local authorities and other public agencies to identify and plan for activities to avoid and/or mitigate any negative impacts from the development and to enhance positive effects in the construction phase and once HPC is operational.

9.4.31 Some of these actions are regarded by EDF Energy as basic good management practice and are therefore included as a part of the "central case" against which impacts are assessed. These for example include employment and training activities to secure local recruitment and a worker code of conduct to help govern worker behaviour. If, after undertaking these activities, significant adverse impacts are still assessed as likely, further mitigation measures are identified.

9.4.32 Where there are uncertainties, and conclusions on the significance of impacts would be sensitive to changes in assumptions or outcomes, EDF Energy has adopted a precautionary approach, establishing a monitoring system to enable impacts to be managed to avoid exceeding acceptable limits or setting in place thresholds after which additional mitigation measures would be triggered. This is an important element in the adaptive approach to assessment for this major project.

9.4.33 EDF Energy has produced a number of additional documents (which are separate stand alone application documents unless otherwise stated) which include implementation strategies which set out the actions that will be undertaken. These include:

- **Economic Strategy**, including:
  - Construction Workforce Development Strategy
  - Education Strategy (Inspire)
  - Project Supply Chain Engagement Strategy
  - Public Information Centre Management Strategy
- **Accommodation Strategy** (Including **Accommodation Management Plan**).
- **Community Safety Management Plan**
  - Summary document of Outline Contingency Response Arrangements (and associated Strategic Relationship protocols)
  - Worker Code of Conduct
- **Health Impact Assessment**, including Health Action Plan

9.4.34 Where likely impacts are identified but specific strategies not required, EDF Energy has identified required mitigation measures. These mitigation measures will be controlled through the use of Requirements and set out in the draft Section 106 agreement for the site preparation works and the **Section 106 Heads of Terms,** an Appendix to the **Planning Statement**.

9.4.35 These measures are listed in relation to the relevant impacts in **Section 9.7 and 9.8** of this chapter, and a summary of the likely significant residual effects, following the proposed mitigation and enhancements is provided.

vi. Limitations, Constraints and Assumptions

9.4.36 **Table 9.6** outlines the assumed activities and timescales, for the construction phase of the proposed development.

Table 9.6: Assumed Duration and Timescales of Construction and Operational Phase of the proposed development

Activity	Assumed Timescale
Enabling and Site Preparation Works	From Q2 2011
Site Campus	Construction: April 2013 to July 2014 Operation: July 2014 to May 2020 June 2020 to March 2021
Unit 1 Construction: Unit 2 Construction: Construction of Intermediate Waste and Spent Fuel Store	Q1 2013 to Q4 2018 Q2 2013 to Q2 2020 Q3 2018 to Q4
Operational Phase	From Q1 2019 and Q2 2020 for units 1 and 2 respectively and for approximately 60 years

9.4.37 In order to assess the likely impacts of HPC a Central Case has been produced for each of the construction and operational phases. These are set out below.

vii. Construction Central Case

9.4.38 The construction programme is likely to have the most significant, and complex, impacts and therefore a very detailed set of assumptions has been produced to support this assessment.

9.4.39 **Table 9.7** shows the likely profile of the workforce required to construct HPC. A full summary of the assumptions is contained in **Technical Note 1: Workforce Profile** (**Appendix 9A**) but the key points are:

- An assumed 108 month construction period for the main power station, with a further 30 months for the Spent Fuel Store and Intermediate Waste Storage Facility.
- The workforce is broken down between different contracts and skill types – civils, mechanical and electrical (M+E), professional, managerial, administrative and other, and operational staff to reflect different characteristics and enable an assessment of likely recruitment.
- A workforce build up from July 2011 for enabling and then site preparation works, with a step up after development consent for the HPC Project. If these dates move the phasing is likely to remain the same, as will the total workforce requirement with an extended completion date.
- The inclusion of associated development construction works within the "civils curve." Individual details for each site, including operations, are dealt with in the socio-economic chapter for each site (see **Volumes 3** to **10** of this ES).
- For the on-site accommodation campus the operational workforce, which is not included in the workforce profile, will be around 60 posts with a total headcount of around 115. Most of these workers will be part time working in catering and

cleaning. It is assumed that 95% of these workers will be home based. The non-home based workers (c.5 to 7) would be negligible in the context of the overall non-home based workforce.

- The numbers give an average daily workforce for each month expressed as Full Time Equivalents (FTE) and consistent with the proposed shift patterns.
- Given the nature of the construction programme most operatives are likely to be full time; although there is likely to be a significant turnover of workforce over the construction programme reflecting the requirement specialist contractors and skill types. This means that there are likely to be at least 20,000 to 25,000 different individual posts in the main 108 month construction period, with a peak headcount of 5,600.
- These numbers have informed EDF Energy's engagement with public authorities and others and also the **Accommodation Strategy** and workforce modelling for the **Transport Assessment**.

9.4.40 The table below provides figures for each year, and the main contract breakdowns. Year 10, follows the main nine year construction period with the workforce being mainly operational with a small remaining workforce required for the construction of the Spent Fuel Store/Intermediate Level Waste Store.

Table 9.7: Predicted Workforce by Main Contract Breakdowns by Year of Construction

Year	Month	Workforce	Civils	M+E	Prof. and man. and other	Operational	Campus Operational Staff not included in main workforce profile
1	4	180	130	0	40	0	
2	16	700	530	0	170	0	
3	28	2,980	2,240	0	740	0	
4	40	4,340	2,980	250	1,060	50	120
5	52	4,840	1,970	1,580	1,170	120	120
6	64	5,600	990	3,030	1,330	250	120
7	76	4,970	520	2,900	1,130	410	120
8	88	4,020	370	2,210	850	600	120
9	100	2,140	380	630	330	800	120
10	112	1,350	340	0	110	900	

Numbers may not add due to rounding

9.4.41 The project will, in the early stages, require a predominantly civil construction workforce, which will cover the site preparation works, the construction of the power station structure and of the associated development sites. Mechanical and electrical workers will begin to build up from around Month 36, and by the time of peak construction (month 64) will be by far the largest component of the workforce. Professional, managerial and other supporting roles will be in proportion to (approximately 15-25%), and follow the phasing of, the construction workforce.

Operational staff will build up over the construction period from around the beginning of year 3 (month 35), rising to a peak of 900 by completion of the power station.

9.4.42 It is anticipated that the workforce will peak at around 5,600 in the sixth year of the project.

Likely Recruitment: Home-Based and Non-home-based Workers

9.4.43 In order to assess the impacts of this workforce in the local area it is necessary to understand where the workforce is likely to be recruited from. This allows for the identification of the extent to which workers are “additional” to the current population, and impacts on labour markets at the local and regional scale.

9.4.44 This was achieved through the identification of the extent to which the workforce is expected to be split between home-based and non-home-based workers.

- Home-based-workers (HB) are those who live within 90 minutes of the HPC site (the Construction Daily Communing Zone (CDCZ)) and will commute daily to HPC from their home.
- Non-home-based (non-home-based) workers are those who will move to the South West to work at HPC.

9.4.45 The split between home-based and non-home-based workers for each construction contract package will vary depending on the skill levels required and the timing within the project of demand. A detailed description of the skills and labour market assessment used to identify the home-based/non-home-based split is set out in **Technical Note 1**. It should be noted that the assessment uses benchmarks of developments with active local employment training programmes and therefore assumes the implementation of a **Construction Workforce Development Strategy** as identified in the Mitigation section below.

9.4.46 **Table 9.8** below shows the assumed home-based/non-home-based split over the lifetime of the project. This shows that the split at the start of the construction phase will be close to even. Over time, as more specialised skills are required, with regional and national labour pools, and the overall workforce grows, the proportion of non-home based workers rises. Then, as the scheme moves towards completion the home based proportion rises significantly as the operational workforce, ultimately all of whom will be home based workers form the majority of the workforce. It should be noted that for each year these numbers form the central point in a range of plus or minus 10%. These figures are therefore used as the “central case” but the impact assessments below test thresholds and sensitivities should they vary.

Table 9.8: Estimated Breakdown of Home-Based and Non-Home-Based Workers by Month of Construction Period

Year	Month	Home-based	Non-home-based
1	4	51%	49%
2	16	45%	55%
3	28	45%	55%
4	40	42%	58%
5	52	39%	61%
6	64	34%	66%
7	76	35%	65%
8	88	37%	63%
9	100	43%	57%
10	112	82%	18%

Workforce Demographic Breakdowns

9.4.47 The breakdown of the workforce by different demographic categories – particularly age, gender and family status – could affect the type and significance of impacts on the local area. **Technical Note 2: Demographic Benchmarks** (**Appendix 9B**) sets out the source information for the demographic assumptions set out in this section.

Age and Gender

9.4.48 **Table 9.9** below which shows the likely gender and age split at the peak of construction.

9.4.49 This shows a likely gender split that is predominantly male reflecting the current profile of the construction industry (see **Appendix 9B**), with slightly higher female recruitment for home- based workers due to the employment profiles of the types of jobs that will be recruited locally (including administrative and support staff) and EDF Energy's commitment to seek to promote construction as a career to all groups as part of the **Construction Workforce Development Strategy, Appendix C to the Economic Strategy**. The age profile is split relatively evenly between the three broad age groups.

Table 9.9: Estimated Gender and Age Breakdown of Home-Based and Non-home-based Workers at Peak Construction

	Home-Based		Non-home-based		All	
Age	Male	Female	Male	Female	Male	Female
Under 35	570	90	1,180	130	1,750	220
35-49	610	100	1,220	140	1,830	240
50+	470	70	920	110	1,390	180
All Ages	1,650	260	3,320	380	4,970	640
%age	86%	14%	90%	10%	89%	11%

Numbers may not add due to rounding

Family Type Households/Households with Dependents

9.4.50 **Table 9.10** shows the likely number of family type households/households with dependent children based on assumptions from the monitoring of Sizewell B, validated against recent data on moving groups and the composition of in-migrant households. This is again based on peak workforce. For each group this reflects a central point in a range. Thresholds and sensitivities are dealt with under relevant impacts.

Table 9.10: Estimated Non-Home Based Family Type Households and Children at Peak Construction

	TOTAL
Family Type Households	500
Non-Worker Adults	600
All Children	425
Pre-school	85
All School Age	298
Primary Age	174
Sec. Age	124
16 to 18	43

Other Demographic Breakdowns

9.4.51 There are two other demographic groups identified under the Equalities Act for which there is benchmark data available at a national and regional level. These are people with disabilities and ethnic/national groups.

9.4.52 **Technical Note 2** identifies the proportions of each of these groups in the UK and regional levels.

9.4.53 Currently 1% of the construction workforce in the South West is identified as being from a Black and Minority Ethnic Group and 1% from outside the UK. These proportions are higher for the country as a whole and on major projects can vary greatly. It is therefore not possible to set a likely benchmark for these groups for the HPC project.

9.4.54 There are a number of definitions of disability which are discussed in **Technical Note 2**. These suggest a range, depending on definition and method of reporting, from under 2% of the workforce of some major projects being disabled to up to 15% based on a wider definition and survey based method from the Labour Force Survey. A benchmark has therefore not been set in this assessment but EDF Energy will monitor recruitment and meet its legal requirements in relation to disabled workers.

Accommodation Assumptions and Spatial Distribution of the Workforce

9.4.55 The detailed background context for assumptions on the split of the HPC workforce between different types of accommodation and across the area are set out in **Technical Notes 3 and 4: Spatial Distribution and Accommodation Datasets**.

9.4.56 **Technical Note 3** uses the accommodation baseline to identify the capacity to accommodate non-home-based workers within a 60 minute travel zone of HPC, which is based on park and ride combined with a direct bus strategy for key clusters, as set out in the **Transport Assessment**.

9.4.57 **Technical Note 4** splits capacity between four broad types; tourist accommodation; private rented accommodation; owner occupied property; and latent accommodation, taking into account affordability. It also assumes the development of the three purpose built accommodation campuses as set out in the development description and individual assessments for the specific associated development sites, and that these will be filled to 97% occupancy to allow for some turnover.

Table 9.11: Accommodation Capacity Assumptions for Gravity Model at Peak Construction

Type	%	Number
Campus	39%	1,450
Tourist Accommodation	16%	600
Private Rented	20%	750
Owner Occupied	14%	500
Latent Accommodation	11%	400
TOTAL Non-home-based		**3,700**

9.4.58 The assumed split between types is shown in **Table 9.11**, above. The note also identifies the likely Home Based HPC labour force in the CDCZ using occupational data from the census. This capacity is fed into a “Gravity Model” which distributes the workforce across the 60 minute area based on this capacity and a “distance decay” function.

9.4.59 **Technical Notes 3 and 4** describe how this population would, on the basis of this model, spread spatially, across the 60 minute travel zone. This includes the spread between the main settlements in the area and between the different types of housing.

9.4.60 The outcome of this assessment for non-home-based workers is set out in **Table** 9.12 below. It should be noted that this is a “central case” to allow the assessment and, where necessary mitigation, of impacts, and the assessments below will test sensitivities and thresholds against relevant impacts.

Table 9.12: Non-home-based Workforce by Settlement Cluster and Accommodation Type, Central Case at Peak Construction

	Latent	Tourist	Private Rented	Owner Occupied	Campus	All
Bridgwater	140	70	110	110	970	1,400
Burnham and Highbridge	40	200	60	70	–	370
Cannington	30	30	20	40	–	120
Cheddar	10	40	10	10	–	70
Glastonbury	0	40	20	20	–	80
Hinkley Point/Stogursey	0	0	10	10	480	500
Minehead	20	50	30	20	–	120
Somerset South	0	10	30	20	–	60

	Latent	Tourist	Private Rented	Owner Occupied	Campus	All
Somerset West	0	10	10	0	–	20
Taunton	120	30	130	80	–	360
Watchet and Williton	40	60	30	20	–	150
Weston-super-Mare	0	70	290	100	–	460
TOTAL	**400**	**600**	**750**	**500**	**1,450**	**3,700**

9.4.61 For home based-workers, where precise ward based location is less sensitive for the purposes of socio-economic assessment (as the population is not additional to the area) the following assumptions have been identified on the basis of the assessment areas identified. The range shows the assessments based on the transport gravity model and an alternative based on experience at Sizewell. For the three districts the estimates are within 10%, with slightly greater but not significant variation for the rest of Somerset (the current administrative County) and the rest of the CDCZ.

Table 9.13: Home-Based Workforce by Broad Area at Peak Construction

	Number of Workers
3 Districts (West Somerset, Sedgemoor and Taunton)	900 to 970
Rest of Somerset	230 to 290
Rest of CDCZ	640 to 760

viii. Operational Workforce Central Case

9.4.62 The operational workforce of the completed power station, with both reactors in operation, is approximately 700 direct EDF Energy employees and up to 200 contract staff – totalling 900. The contractor support also increases significantly to over 1,000 for during each unit's refuelling outage (approximately every 15-18 months).

9.4.63 This workforce will have built up during the construction of HPC and are therefore included within the workforce profile described above.

ix. Other Assumptions

9.4.64 The assessment of effects expected to arise from the proposed development is carried out against socio-economic baseline conditions as defined by the data sources referenced above. As with any dataset they represent a set point in time and can change due to wider changes in economic conditions or demographic trends. As far as possible the assessment has aimed to reflect the dynamic nature of this environment by using future projections and identifying sensitivities to change. The assessment is also being undertaken at a time of rapidly evolving policy change at all levels of government.

9.4.65 **Table 9.6** outlines the assumed activities and, timescales, for the construction phase of the proposed development which forms the basis of the central case.

9.4.66 Given the long timescale involved, with construction expected to run from 2011 to 2019 when unit 1 is operational and 2020 when unit 2 is operational, and an operational life of 60 years for each reactor, there is the potential for variation. This is partly handled by the inclusion of ranges and consideration of alternative scenarios in several estimates. The proposed HPC Project should however, be the subject of regular monitoring and revisions may be required as new information becomes available. An adaptive assessment process is required, using a 'plan-monitor–management' approach.

9.4.67 The predictions of impacts are primarily for peak construction and full operation. The latter should be relevant for much of the operational life of the station. For the former, the shoulders and peak construction may apply to only about three years (c mid 2014-mid 2017) of a nine year programme. However, predictions for peak construction provide an important indicator of the maximum effects, and a justifiable precautionary approach.

9.5 Local Area: Socio-Economic Baseline

a) Introduction

9.5.1 This section of the ES describes the socio-economic baseline for the HPC Project and summarises key characteristics of the local area's socio-economic baseline, including demographics, economy and employment, accommodation, education, health and other community facilities.

b) Baseline Characteristics

i. Population and Population Density

9.5.2 The three immediate districts of Sedgemoor, Taunton Deane and West Somerset have a combined population of 256,200 (ONS, mid-2009 population estimates). Sedgemoor (112,100) and Taunton Deane (108,700) are of a roughly similar population size, whilst West Somerset has a much smaller population (35,400).

9.5.3 The largest settlements in the area are Weston-super-Mare (mid-2009 population 79,200), Taunton (54,200) Bridgwater (36,200) and Burnham-on-Sea/Highbridge (19,100).The smaller settlements of Minehead (population, 10,100) and Watchet/Williton (6,600) are located in West Somerset. **Figure 9.2** identifies population density by output area for the 60-minute travel distance area, highlighting the key settlements in the area.

9.5.4 Sedgemoor and West Somerset are predominantly rural districts, with relatively low population densities. Taunton Deane is also significantly rural in nature, but has a higher proportion of its population in larger urban settlements (the Taunton and Wellington urban areas).

9.5.5 **Table 9.14** summarises the total population and population density in each of the three districts; in the overall study including the 60-minute travel distance and CDCZ; and the major urban areas within the ward clusters.

Table 9.14: Population and Population Density in Districts, Wards and Urban Areas

Area	Total Population	Area Size (Ha)	Population Density
Districts			
Sedgemoor	112,100	56,436	2.0
Taunton Deane	108,700	46,236	2.4
West Somerset	35,400	72,535	0.5
Study Area			
60-Minute Travel Distance	410,329	148,024	2.5
CDCZ	2,388,400	990,698	2.4
Ward Clusters			
Bridgwater	50,380	13,651	3.7
Burnham and Highbridge	41,353	23,540	1.8
Cannington	7,142	12,315	0.6
Cheddar	11,026	7,706	1.4
Glastonbury	29,182	20,062	1.5
Hinkley Point	2,104	6,144	0.3
Minehead	17,405	19,736	0.9
Somerset South	28,264	26,532	1.1
Somerset West	10,031	32,291	0.3
Taunton	77,748	11,068	7.0
Watchet and Williton	11,026	14,035	0.8
Weston-super-Mare	124,668	16,844	7.4
Wider Scales			
Somerset	523,500	345,055	1.5
South West	5,231,200	2,383,674	2.2
England	51,809,700	13,027,872	4.0

Source: ONS, mid-year population estimates, 2010

ii. Age and Gender Profile

9.5.6 The three immediate districts have higher proportions of older people, and lower proportions of working age people, compared with the national average. This disparity is particularly striking in West Somerset district, where 29% of the population is above working age (60/64 years or over) compared with a regional average of only 19%. This is outlined in **Table 9.15** below.

9.5.7 Overall, the 60-minute area has a slightly higher than national average proportion of working-age residents, a lower proportion of children and a higher proportion of older people. In terms of the urban areas within this study area, Minehead, Watchet/Williton and Burnham-on-Sea/Highbridge have disproportionately older populations compared to other scales. The proportion of males to females is generally consistent across the 60-minute travel area and CDCZ with wider scales (approx 49:51), although there are some variations at lower spatial scales:

Table 9.15: Age Profile

Area	% Children (0-15)	% Working Age (16-59/64)	% Older People (Age 60/64+)	Gender (M:F)
Districts				
Sedgemoor	18.3%	57.5%	24.2%	49:51
Taunton Deane	18.6%	57.9%	23.5%	48:52
West Somerset	14.2%	51.6%	34.2%	48:52
Urban Areas				
Bridgwater	18.8%	65.4%	15.8%	49:51
Taunton	17.1%	63.7%	19.3%	48:52

Source: ONS, mid-year population estimates, 2009

iii. Recent Population Growth

9.5.8 The population of the three immediate districts increased by an estimated 9,850, or 4%, between mid-2001 and mid-2009. This rate of population growth is similar to the Somerset average (5.0%), but slightly below the South West average (5.8%). Within this area, population growth has been concentrated mainly in Sedgemoor (an increase of 5,001 or 4.7%) and Taunton Deane (an increase of 4,777 or 4.6%). The population of West Somerset increased by only about 100 persons, or 0.2%, between 2001 and 2009. Recent population growth in the Bridgwater area has been in the region of 3,400 people, or 7.2% since 2001.

Table 9.16: Distribution and Growth of Resident Population in Immediate Districts, 2001-2009

Area	Mid-2001	Mid-2009	% Growth
Districts			
Sedgemoor	106,000	112,100	5.8%
Taunton Deane	102,600	108,700	5.9%
West Somerset	35,100	35,400	0.9%
Ward Clusters			
Bridgwater	47,001	50,380	7.2%

Somerset	498,700	523,500	5.0%
South West	4,943,400	5,231,200	5.8%
England	49,449,700	51,809,700	4.8%

Source: ONS, mid-year population estimates

9.5.9 The latest official 2008-based sub-national population projections for local authority areas were published by ONS in May 2010 (Ref. 9.57). These provide trend-based projections for the twenty five year period from 2008 to 2033, although the focus here is on projected population change from 2008 to 2018, as this is considered to be more relevant to the likely timescale of the Hinkley Point development.

9.5.10 The latest projections for the immediate districts are summarized in **Table 9.17**. Future population growth in Sedgemoor and Taunton Deane is expected to be similar to the national average, but below projected growth in the South West region. Projected growth is higher in Sedgemoor (8.1%) than Taunton Deane (6.7%). Future population growth is expected to be much slower in West Somerset, amounting to an increase of only 3.1% between 2008 and 2018. In absolute terms, the overall population growth in the three immediate districts is expected to be 17,500 between 2008 and 2018, equivalent to a net increase of 1,750 per annum. This overall increase is expected to be distributed as follows:

- Sedgemoor – an overall increase of 9,100, or 910 per annum.
- Taunton Deane – an increase of 7,300, or 730 per annum.
- West Somerset – an increase of 1,100, or 110 per annum.

Table 9.17: Sub-National Population Projections, 2008-2018

Area	Mid-2008	2018	% Growth
Districts			
Sedgemoor	112,300	121,400	8.1%
Taunton Deane	108,600	115,900	6.7%
West Somerset	35,600	36,700	3.1%
Sub Total	*256,500*	*274,000*	*6.8%*
Wider Scale			
Somerset	524,200	558,700	6.6%
South West	5,210,400	5,647,300	8.4%
England	51,464,600	55,252,200	7.4%

Source: ONS, 2008-Based Sub-National Population Projections (published May 2010).

9.5.11 The sub-national projections indicate future changes in the age structure of the population, with a roughly static working age population and significant growth in the numbers above working age. These changes in age structure are expected to be more marked in the immediate districts than at the regional or national level. The overall population growth between 2008 and 2018 in the three districts is expected to be divided by broad age group as follows:

- *Children (aged 0-15 years*) – numbers in this age group are expected to increase by 1,200, or 2.6%, between 2008 and 2018. This is well below the projected rate of growth in the South West (5.5%) and nationally (7.2%). Numbers in this age group are expected to decline in West Somerset, but this will be offset by growth in Sedgemoor and Taunton Deane.
- *Working age population (16 to 59/64 years)* – numbers are expected to increase by only around 400 or 0.3% between 2008 and 2018. Again, this is significantly below the projected rates of growth at regional (4.0%) and national level (3.7%). Growth in Sedgemoor and Taunton Deane will again offset a projected decline in the working age population in West Somerset.

- *Above retirement age (60/64 years and over)* – growth in this age group is expected to account for the bulk of the overall projected population increase. Numbers above retirement age are forecast to increase by 15,900by 2018. This is above the forecast rates of increase in the South West (22.4%) and nationally (19.3%). Those above retirement age are expected to account for 91% of the projected population growth in the three immediate districts between 2008 and 2018. This compares with only 60% in the South West and 50% in England as a whole.

Table 9.18: Sub-National Population Projections, by Age Group 2008-2018

Area	% Growth 0-15	% Growth 15-60/65	% Growth 60/65+
Districts			
Sedgemoor	4%	2%	32%
Taunton Deane	5%	0%	28%
West Somerset	-2%	-7%	27%
Wider Scale			
Somerset	2%	-1%	32%
South West	6%	4%	22%
England	7%	4%	19%

Source: ONS, 2008-Based Sub-National Population Projections (published May 2010). Figures are trend-based projections; they show what the population will be if recent trends continue.

iv. Migration

9.5.12 The latest statistics on internal migration (Ref. 9.58) flows at local authority area level are for mid-2008 to mid-2009. The migration data for 2008/09 shows an annual net inflow of around 300 persons into Sedgemoor, 600 into Taunton Deane and 100 into West Somerset (**Table 9.19**).

9.5.13 This overall inflow of population conceals a net outward migration of young people in the 16-24 age group; in 2008/09, this amounted to a net outflow of around 300 young people from Sedgemoor, 200 from Taunton Deane and 100 from West Somerset. This is significant for the retention of a young and future working age population.

Table 9.19: Internal Migration Flows: Immediate Districts, 2008-2009

Area	Migration into District	Migration out of District	Migration Net Flow
Sedgemoor	4,700	4,400	+ 300
Taunton Deane	5,200	4,600	+ 600
West Somerset	2,000	1,900	+ 100
South Somerset	6,400	6,000	+ 400
Mendip	5,100	4,800	+ 300

Source: ONS, annual estimates of internal migration flows for local authority areas. Totals may not sum exactly due to rounding.

9.5.14 This population is relatively dynamic and mobile. Every year just under 7% of households move either within, to or from the area. The table above shows significant population flows in and out of the Districts each year.

9.5.15 National Insurance Number (NINO) registrations for foreign national adults in the three districts covered by the HPC assessments rose significantly from around 350 in total in 2002 to around 2,100 in 2007(Ref. 9.59). They have since fallen back to around 1,500 in 2009, but still above previous levels. These numbers do not track whether migrants become permanent residents or the duration of their stay. Many will be temporary seasonal workers. However, in the context of annual migration figures described above they still form a minority of migration to the south west.

v. Baseline Dynamics

9.5.16 A baseline study has been conducted to identify, on a ward-cluster basis, the turnover in population and jobs at a local scale using Census Moving Groups (2001) analysis for population turnover and by applying average job turnover for the UK (OECD, 2010) (Ref. 9.60) to the surveyed jobs (Annual Business Inquiry (ABI)/ Business Register Employment Survey (BRES, 2009) in each ward cluster. The following table outlines this estimate for the twelve ward clusters:

Table 9.20: Population and Jobs Turnover in Ward Clusters

Ward Cluster	% New Residents in 2001	Total New Residents in 2001	Jobs Turnover Estimate @ 15-20% (per year)
Bridgwater	5.5%	2,461	3,200 – 4,200
Burnham and Highbridge	7.0%	2,701	1,700 – 2,200
Cannington	8.1%	556	200 – 300
Cheddar	7.2%	725	500 – 700
Glastonbury	8.2%	2,188	1,600 -2,100
Hinkley Point and Stogursey	6.5%	134	170 – 230
Minehead	8.7%	1,408	900 – 1,300
Somerset South	7.5%	2,009	1,000 – 1,300
Somerset West	8.0%	836	400 – 500
Taunton	8.1%	5,380	6,300 – 8,400
Watchet and Williton	7.0%	757	300 – 400
Weston-super-Mare	5.5%	6,049	6,200 – 8,300

Source: 2001 Census Moving Groups; 2009 ABI/BRES

9.5.17 The population is relatively dynamic and mobile. Every year just under 7% of households move either within, to or from the 60 minute area. These flows are not uniform across housing tenures. Households in owner occupied family housing are much less likely to move (6% each year) compared to households in the Private Rented Sector (PRS) where 20% move. The high level of dynamism could be linked to the strength of tourist and agricultural economies in the area, which rely extensively on a seasonal and migratory workforce.

9.5.18 This dynamism means the local area is able to cope with outages every 15-18 months at the existing Hinkley Point B station. Outages can have a substantial non-home-based workforce of up to 1,000 workers. These are absorbed by the local accommodation market without significant difficulties.

vi. Employment

9.5.19 The latest employment estimates for the immediate districts are for the end of 2009. At that time, there were an estimated 99,700 employee jobs in the three immediate districts, although total employment including self-employed jobs was somewhat higher, at an estimated 125,000. Just over half of these jobs (around 64,000) are located in Taunton Deane district, with most of the remainder (around 45,000) in Sedgemoor. Employment is much smaller in West Somerset district, at an estimated 16,000 jobs in 2009. Employment levels in the CDCZ are estimated at 1,095,734 jobs, which represent just about one half of the South West regional total (2.16 million jobs).

9.5.20 The main concentrations of employment within the immediate districts are located in the main urban centres of Weston-super-Mare (27,800 jobs), Taunton (33,800 employee jobs) and Bridgwater (17,200 employee jobs). Smaller centres of employment are located in Burnham-on-Sea/Highbridge (6,400 jobs), Minehead (3,800) and Wellington (3,600).

Table 9.21: Employment Estimates: Immediate Districts, 2009

Area	Employee Jobs (ABI estimate)	Total Jobs (including self-employed jobs)
Districts		
Sedgemoor	37,600	45,000
Taunton Deane	51,500	64,000
West Somerset	10,500	16,000

Wider Scales		
Somerset	201,400	256,000
South West	2,166,300	2,717,000
England	21,630,000	26,246,000

Source: Annual Business Inquiry/BRES (2009, NOMIS) and annual estimates of jobs density and total jobs. ABI estimates include only employee jobs. Estimates of total jobs include employee jobs, self employed jobs, HM Forces and government-supported trainees.

9.5.21 ABI-based estimates indicate relatively strong recent employee job growth in the three immediate districts. The number of employee jobs in the immediate districts increased by an estimated 9,800 or 10.1% between 2001 and 2008. The table below shows the change in employment levels between 2001 and 2008, as changes in the sectoral classification in most recent (2009) data prevents transparent comparison of industrial sectors. This compares with increases of 6.8% in the South West region and only 4.4% in England. The rate of job growth has been particularly strong in Sedgemoor District (an increase of 13.5%) and to a lesser extent in Taunton Deane (9.5%). Much slower growth has been experienced in West Somerset (only 2.5% between 2001 and 2008). Recent employee job growth in the wider 90 minute commuting zone (7.5% between 2001 and 2008) has been slightly below the regional average (6.8%).

Table 9.22: Estimated Employee Job Growth, 2001-2008

Area	Employee Jobs, Dec 2001	Employee Jobs, Dec 2008	% Growth, 2001-2008
Districts

Source: Annual Business Inquiry (NOMIS). Figures exclude self employed jobs.

9.5.22 **Table 9.23** provides a more detailed breakdown of recent employment change in the immediate districts by broad industry sector. The figures include only employee jobs and exclude self-employed workers. Employment growth during the period 2001-2008 occurred mainly in financial, IT and other business services (net growth of

3,900 jobs) and education and health services (net growth of 4,300 jobs). Significant job growth also took place in the construction sector (1,700 jobs) and wholesale and retail distribution (1,600 jobs). Employment losses were experienced in the manufacturing sector (almost 1,900 net job losses) and mining/quarrying and electricity, gas and water supply (almost 600 net job losses in these combined sectors). Small employment losses were also recorded in the hotels/restaurants sector (200 jobs) and transport, storage and communications (200 jobs):

Table 9.23: Employment Change by Industry Sector: Immediate Districts (Sedgemoor, Taunton Deane and West Somerset) 2001-2008

Sector	2001	2008	Change
Agriculture, Forestry and Fishing; Mining and Quarrying, Utilities	4,075	3,682	-393

Education and Health	21.9%	28.6%	21.9%
Other Service Activities	4.2%	4.8%	5.9%
Tourism-related Sectors	9.8%	7.2%	25.0%

Source: Office for National Statistics, Annual Business Inquiry (NOMIS). Employment figures exclude the self-employed, government-supported trainees and HM Forces. Tourism-related sectors are defined as the following 2003 SIC categories: 55.1 to 55.4 (hotels; camping sites and other short-stay accommodation; restaurants; bars), 63.3 (travel agencies and tour operators; tourist assistance activities) and 92.5 to 92.7 (library, archives, museums and other cultural activities; sporting activities; other recreational activities)

9.5.24 The structure of employment in the immediate districts differs in a number of respects from the national average, with low representation in financial, IT and other business service activities and a greater dependence on employment in public sector services such as education and health. Compared with the national average, the immediate districts have an above average share of employment in the following broad activities:

- Agriculture, forestry and fishing, mining and quarrying, and electricity, gas and water supply – these combined sectors account for 3.4% of employee jobs in the immediate districts, compared with only 1.4% nationally;
- Wholesale and retail distribution – accounts for 19.4% of employee jobs, compared with 16.8% nationally;
- Hotels and restaurants – accounts for 8.9% of employee jobs, compared with 6.7% nationally; and,

- Public administration, defence, education, health and social services – these combined sectors, which primarily comprise public sector services, account for almost one third (31.8%) of employee jobs in the three districts, compared with 26.4% nationally.

9.5.25 Employment sectors under-represented in the local economy include transport, storage and communications (accounting for 4.0% of employee jobs, compared with 6.0% nationally), and financial, IT and other business services (which account for only 14.1% of employee jobs, compared with a national average of 22.7%). Employment levels in manufacturing, construction and other service activities are broadly similar to the national average.

9.5.26 Tourism-related sectors account for an estimated 10,800 employee jobs in the immediate districts, representing 10.1% of total employment. This compares with a national average of 8.1% (**Table 9.24** and **Table 9.25**). The significance of employment in tourism-related sectors shows wide variations across the immediate districts. Tourism-related employment is particularly important to the West Somerset economy, accounting for an estimated 25.0% of employee jobs in the district. The figures for Sedgemoor (9.8%) and Taunton Deane (7.2%) are much lower (**Table** 9.25).

9.5.27 Within this overall picture, there are detailed differences in the importance of specific sectors between the three immediate districts. Sedgemoor has much higher shares of employment in manufacturing and transport, storage and communications than the other two districts. Taunton Deane‘s employment base is particularly dependent on public sector services, including education and health, whilst the West Somerset economy is much more dependent on agriculture, forestry and fishing, electricity, gas and water supply, and hotels and catering. The proportion of employment in financial, IT and other business service activities is particularly low in West Somerset.

9.5.28 There are around 832 jobs in the three district area in the 20 highest-GVA-per-worker 4-digit SIC industrial sectors in the UK, which includes 563 jobs in ‘electric power generation, transmission’ which are likely to be attributed to the existing facilities at Hinkley Point.

9.5.29 There were around 4,500 employee jobs in the construction sector in the immediate districts at the end of 2008, plus a further 2,100 employee jobs in the related activities of architecture, engineering and technical consultancy. These employment estimates pre-date the more recent slowdown in the construction industry, although they exclude self-employed jobs. In the immediate districts and the CDCZ, around half of construction sector jobs are in the civil engineering sector. The breakdown of employment in construction and related activities (civil engineering and related technical activities) is presented in the following table.

Table 9.26: Employment in Construction and Related Activities, 2008

Sector	Construction Sector (SIC 45)	Of which: Civil Engineering (SIC 45.1)	Related Technical Services (SIC 74.2)
Districts

South West	98,835	49,627	36,473

Source: Office for National Statistics, Annual Business Inquiry (NOMIS). Employment figures exclude self employed workers.

9.5.30 Compared with the national average, the three immediate districts have a lower proportion of residents in senior managerial and professional occupations (29% compared with a national average of 30%) and in associate professional and technical occupations (14% compared with 15% nationally). However, the proportion of residents in skilled manual trades (12%) is slightly above the national average (10%). Numbers employed in personal service, sales and customer service occupations (18%) are higher than the national average (16%).

Table 9.27: Residents in Employment by Occupation, 2010

Occupational Group	Sedgemoor, West Somerset and Taunton Deane	CDCZ	National (England)
Managers/senior officials and professional	29.4%	29.9%	30.2%

vii. Labour Supply and Profile

Construction Labour Supply

9.5.31 **Technical Note 1: Workforce Profile** (**Appendix 9A**), and the central case assessment described above, splits the construction labour force into two broad groups. Those who already live in the area and will travel to work on a daily basis from their existing home – home based workers – and those who will move into the area temporarily to work on the construction project – non-home based workers.

9.5.32 The area in which home based workers is likely to be recruited is the Construction Daily Commuting Zone (CDCZ) area involves consideration of a number of factors which affect workers willingness to commute daily to the site. EDF Energy's analysis of these factors includes travel allowances for construction workers, general studies of construction workforce mobility and monitoring of previous projects.

9.5.33 The Construction Industry Joint Council (CIJC) Working Rule Agreement (Ref. 9.61) sets out national standards for pay and conditions for workers on major building and infrastructure projects in the UK. The current agreement, which took effect in June 2008, sets out rates for daily travel and fare allowances. These are currently payable on a sliding scale based on the distance travelled, up to a maximum of 75 kilometres (c.47 miles).

9.5.34 A study for the UK Department of Trade and Industry (DTI) and Engineering Construction Industry Training Board (ECITB) (IFF and University of Warwick, 2005) (Ref. 9.62) shows that a proportion of UK and South West Region construction workers are willing to travel over 50 miles to work on a daily basis. Indeed, it is estimated that 11% of South West construction workers travel more than this distance to work daily.

9.5.35 Monitoring studies of the construction of Sizewell B also show actual local recruitment extending to a 50 mile/90 minute commute (Glasson and Chadwick, 1995) (Ref. 9.63). A 90-minute commute zone (Construction Daily Commuting Zone - CDCZ) was also agreed for the assessment in the late 1980s of the previous proposal for Hinkley Point.

9.5.36 Discussions with stakeholders at the socio-economic workshops in 2009 and 2010 reinforced these conclusions with local knowledge and experience and it was agreed that the 90-minute commuting area remained a reasonable assumption.

9.5.37 It is assumed that the workers living within this CDCZ will commute daily to HPC. Workers not resident in this area will move, mainly on a temporary basis, to work on the construction programme. It is assumed that workers who move into the area are likely to live nearer to the site so a 60 minute travel distance has been adopted for these non-home-based workers for assessments of accommodation capacity and local impacts.

9.5.38 Local (Somerset) labour supplies in the construction sector are in similar proportions to national and regional supplies. It is important to distinguish between data which includes self-employment and that which does not because self-employment is very important in the construction sector due to contractors and sub-contractors not employing people directly.

Table 9.28: Employment in Construction and Related Activities, 2008

Area	Construction Sector (SIC45)	Of which: Civil Engineering (SIC45.2)	Related Technical Services (SIC74.2)
Districts

Table 9.29: Occupations Sought by Unemployed Claimants: Construction-related Occupations, July 2011

Occupations Sought (selected occupations)	Sedgemoor, Taunton Deane and West Somerset	Somerset	CDCZ
Engineering professionals: science and engineering technicians	35	85	520
Skilled mechanical and electrical trades	55	110	570
Skilled construction and building trades	165	300	1,555
Construction operatives (semi-skilled)	15	35	200
Elementary construction occupations (unskilled)	125	245	1,380
TOTAL	**405**	**770**	**4,225**

Source: Office for National Statistics, monthly claimant count data. Figures are based on the following SOC 2000 occupational categories which are regarded as relevant to the construction phase of Hinkley Point development: 21.2 – engineering professionals;31.1 – science and engineering technicians; 52.1 – metal forming, welding and related trades; 52.2 – metal machining, fitting and instrument making; 52.4 – electrical trades; 53.1 – construction trades; 53.2building trades; 81.4 – construction operatives; 91.2 – elementary construction occupations.

Age

9.5.39 The 2001 Census gives a comprehensive overview of the age and gender structure of the UK construction industry. The construction workforce is overwhelmingly male and in the 20 to 49 age range.

9.5.40 More recent data from the Annual Population Survey (2009/10) confirms that these proportions have not changed in the intervening decade. While women make up the majority of the workforce in administrative and secretarial occupations (of which there will be a number at HPC (see **Technical Note 2**) and between 10 and 20% of professional and managerial positions, the on-site operative occupations (skilled trades, elementary and operatives) are male dominated. As these dominate the sector as a whole, just fewer than 9 out of 10 workers in the construction sector are men.

9.5.41 The recent Gibson Report, reviewing productivity and skills in the UK Engineering Construction Industry (DBIS, Dec 2009)(Ref. 9.64), notes the predominantly male workforce, and the ageing of the UK engineering construction workforce – with about 65% of the current workforce over the age of 40. This covers the more skilled roles involved in designing, engineering, constructing and maintaining process plant.

Disability

9.5.42 The Labour Force Survey (now the Annual Population Survey) used the definition from the Disability Discrimination Act (Ref. 9.65) and asked whether people have a health problem or disability that limited their day to day activities or the paid work they could do. The most recent (2004) data identifies 13.7% of the construction workforce having a disability, and 16.5% in the South West. Other sources have identified lower proportions, ranging from 1.2% (ODA, 2010) (Ref. 9.66) to 15% (CIC, 2009) (Ref. 9.67).

Race, Nationality and Ethnicity

9.5.43 A report commissioned by the ODA in October 2010 for the London 2012 Olympics entitled ‘Jobs, Skills, Futures’ highlights that the construction workforce of the UK as a whole is 95% white, rising to 99% in the South West.

9.5.44 This pre-dominantly white workforce contains within it a range of nationalities. Research conducted by CSN/BRMB shows the proportion of the construction workforce that was non-migrant (i.e. UK nationals) and migrant (foreign nationals) in 2008(Ref. 9.68). This shows that the workforce was predominantly British nationals, standing at 92% of the overall workforce, rising to 99% in the south-west. Of the “migrant” workers around two-thirds are from what is described as the A8 Accession countries, the central and eastern European countries that joined the EU in 2004.

Families

9.5.45 Previous studies of the construction of Sizewell B Power Station in the 1990s, suggest that around 25% of construction staff (i.e. professional and managerial), around 4% of operatives and around 80% of operational staff, are likely to be “family type” households (i.e. with dependents/non-single households).Data from the Worker Registration Scheme (2004-2007) shows an average for the South-West of 4.2% of migrant workers having dependent children and 5.7% for the UK as a whole.

Operational Workforce at Hinkley Point B

9.5.46 Hinkley Point B has been in operation since 1976, and currently employs 538 full time staff and 17 apprentices. There are also approximately 210 contract personnel based at the power station. Approximately 70% of current Hinkley Point B employees live in Sedgemoor, and 94.5% live in the three districts of Sedgemoor, West Somerset and Taunton Deane.

Table 9.30: Residence of Employees at Hinkley B

Area	Residents in Employment
Sedgemoor	69.9%
Taunton Deane	11.2%

viii. Business and Enterprise

9.5.47 There were around 10,200 active businesses in Sedgemoor, Taunton Deane and West Somerset in 2008. This figure includes both VAT-registered and PAYE-based enterprises. Business density, at 48.2 businesses per 1,000 adult residents, is similar to the national average (48.4). Recent growth in the number of businesses in the immediate districts has been relatively slow. The number of active businesses increased by only about 140, or 1.4%, between 2004 and 2008. This compares with an increase of 5.2% in the South West region and 7.4% in England. Growth in the business stock over this period was strongest in Sedgemoor (3.2%), whilst West Somerset experienced a small reduction in the number of businesses.

9.5.48 There were 1,000 new business registrations in the immediate district during 2008. This represents an annual rate of 47.4 new registrations per 10,000 adults, which is below the national average (57.2). The relatively low rate of new business registrations in West Somerset district (32.8 per 10,000 adults) is particularly evident. The latest data on business survival rates in the immediate districts shows that the proportion of new businesses surviving for at least three years is slightly below the South West average but above the national average. This is outlined in more detail the following table.

Table 9.31: Business Stock, Density and Growth

Area	Active VAT Enterprises	Enterprises per 1,000 Adults	Growth in Enterprises 2004-2008	VAT Registrations per 10,000 Adults
Districts				
Sedgemoor	4,415	48.1	3.2%	49.6
Taunton Deane	4,280	48.4	0.8%	50.3
West Somerset	1,470	48.2	-2.0%	32.8

England	1,885,265	48.4	7.4%	57.2

Source: Office for National Statistics, business demography statistics and mid-year population estimates.

ix. Economic Activity, Unemployment and Worklessness

9.5.49 Employment rates for working age residents in the immediate districts appear to be slightly below the South West average but slightly above the national average. Estimates for the 2009 calendar year indicate that, at that time, an estimated 69.1% of working age residents (aged 16-64) in the three immediate districts were in employment. This compares with a South West average of 73.6% and English average of 70.4%. There is some apparent variation in working age employment rates between the three immediate districts, ranging from an estimated 63.5% in Sedgemoor and 69.8% in Taunton Deane to 87% in West Somerset district. However, these district-level figures are based on relatively small samples and should be treated with caution.

Table 9.32: Working Age Employment Rates (16-64), 2010

Area	Residents in Employment	Working Age Residents	Employment Rate
Districts			
Sedgemoor	44,100	69,500	63.5%
Taunton Deane	46,400	66,400	69.8%
West Somerset	16,800	19,300	87.0%
Sub Total	*107,300*	*155,200*	*69.1%*
Wider Scales			
Somerset	230,600	314,700	73.3%
CDCZ	1,116,900	1,506,900	74.1%
South West	2,400,600	3,262,200	73.6%
England	23,638,100	33,561,200	70.4%

Source: Office for National Statistics, Annual Population Survey (based on survey data for the January to December 2010 period). Figures are sample-based estimates subject to a margin of error and should be treated with caution. Working age population is defined as the population aged 16-64 years.

9.5.50 The average claimant unemployment rate for the three immediate districts was 2.4% in July 2011 (expressed as a proportion of working age residents, defined as those aged 16-64 years). This is similar to the South West average (2.5%) and lower than the national average (3.7%). Unemployment rates are currently highest in Sedgemoor (2.7%) and lowest in West Somerset (1.8%) and Taunton Deane (2.3%), although West Somerset in particular may be affected by a greater degree of seasonality in unemployment. Although average levels of unemployment in the immediate districts are below the national average, there are wide variations in unemployment rates at sub-district level. For example, Bridgwater has a higher claimant count of 4.5% of working age residents, compared to 1.2% in Cheddar. The number of unemployed claimants in the immediate districts currently amounts to 3,728 persons (including only job seekers allowance claimants). Within the wider 60-minute travel area, the average unemployment rate is similar to the regional average (2.5%). There are currently almost 5,800 unemployed claimants in this wider commuting area, and 39,400 in the CDCZ.

Table 9.33: Claimant Unemployment Rates, July 2011

Area	Unemployed Claimants	As % of Working Age Residents
Districts		
Sedgemoor	1,845	2.7%
Taunton Deane	1,533	2.3%
West Somerset	350	1.8%

Wider Scales		
Somerset	6,785	2.1%
South West	82,901	2.5%
England	1,259,484	3.7%

Source: Office for National Statistics, monthly claimant count data. Percentage rates show the proportion of working age residents who are out of work and claiming Job Seekers Allowance (claimant unemployed). Percentage rates are calculated using mid-2010 resident working age population.

9.5.51 A wider measure of unemployment is provided by the number of working age people claiming ‘out of work’ benefits, including job seekers allowance and incapacity and other related benefits. Data for Q1 2011 shows that 10.6% of working age residents (aged 16-64) in the three immediate districts were claiming out of work benefits. This is slightly below the South West average (10.1%), but above the national average (11.9%).

9.5.52 There are significant variations in the level of out-of-work benefit claimants in areas within the 60-minute travel area, for example 16.4% of working age people in Bridgwater compared to 6.2% in Cheddar, outlined in the following table.

Table 9.34: Out-of-Work Benefit Claimants, Quarter 1 2011

Area	Unemployed Claimants	As % of Working Age Residents
Districts		
Sedgemoor	7,880	11.5%
Taunton Deane	6,525	9.8%

England	4,027,950	11.9%

Source: Department for Work and Pensions, working age client group data set.

9.5.53 Amongst the immediate districts, the proportion of out of work benefit claimants is highest in Sedgemoor (11.5%). There are several areas in the immediate districts with proportions of out of work benefit claimants significantly above the national average. These wards include Bridgwater, Weston-super-Mare and Watchet/Williton.

9.5.54 Around 6.4% of unemployed claimants in the immediate districts are seeking employment in managerial, professional or technical occupations, and a further 10.1% are seeking jobs in skilled manual trades. Within the wider 60-minute Travel Distance, a higher percentage of claimants (7.9%) are seeking managerial, professional and technical employment, and the proportion seeking skilled manual jobs is similar (10.3%). There are large numbers of claimants who are looking for employment in semi-skilled operative and elementary occupations. These groups account for a similar proportion of claimants (35.7-37.6%) in the immediate districts and the wider 60-minute Travel Distance (34.8%).

Table 9.35: Occupations Sought by Unemployed Claimants, July 2011

Occupation Sought (SOC 2000 Category	Sedgemoor, Taunton Deane and West Somerset	Somerset	CDCZ
Managers and senior officials	125	270	1,750
Professional	60	220	1,335

TOTAL	**3,525**	**6,765**	**39,285**

Source: Office for National Statistics, monthly claimant count data.

9.5.55 Within the CDCZ, around 520 unemployed claimants are seeking employment as engineering professionals or science and engineering technicians. A further 2,125 claimants are seeking employment in skilled mechanical, electrical, construction and building trades, and 1,580 are looking for other construction employment (in semi-skilled or elementary occupations). This is outlined in more detail in the following table:

Table 9.36: Occupations Sought by Unemployed Claimants: More Detailed Breakdown for Selected Occupations, July 2011

Occupation Sought (SOC 2000 Category	Sedgemoor, Taunton Deane and West Somerset	Somerset	CDCZ
Engineering professionals; Science and engineering technicians	35	85	520
Skilled mechanical and electrical trades	55	110	570
Skilled construction and building trades	165	300	1,555
Construction operatives (semi-skilled)	15	35	200
Elementary construction occupations (unskilled)	125	245	1,380

Source: Office of National Statistics, monthly claimant count data. Figures are based on the following SOC 2000 occupational categories which are regarded as particularly relevant to the construction phase of the Hinkley Point development: 21.2, engineering professionals; 31.1, science and engineering technicians; 52.1, metal forming, welding and related trades; 52.2, metal machining, fitting and instrument making trades; 52.4, electrical trades; 53.1, construction trades; 53.2, building trades; 81.4, construction operatives; 91.2, elementary construction occupations.

x. Income

9.5.56 In 2010, average workplace earnings in Sedgemoor and Taunton Deane districts were lower than the national average, and regional average. In contrast, gross weekly earnings for workers in West Somerset were significantly higher. The average earnings of residents living in Sedgemoor and Taunton Deane were higher than average workplace earnings, reflecting the higher average wages of those who commute out of the districts to work.

Table 9.37: Average Gross Mean Weekly Earnings, 2010

Area	Mean Weekly Earnings, Workplace-based	Mean Weekly Earnings, Residence-based
Districts		
Sedgemoor	£447.9	£550.2
Taunton Deane	£536.2	£552.5
West Somerset	£641.1	£523.0
Wider Scale		
Somerset	£520.3	£553.0
South West	£544.2	£554.9
England	£608.6	£609.5

Source: ONS 2010 Annual Survey of Hours and Earnings

xi. Skills and Qualifications

9.5.57 The proportion of working age residents in the immediate districts with at least Level 2 qualifications (69.4%) is slightly above the national average (67.0%), but below the Somerset and regional average (70.5%; 71.0%%). There appear to be wide variations across the immediate districts, with a relatively low proportion of residents with Level 2 qualifications in Sedgemoor (61.7%) and higher proportions in Taunton Deane (76.3%) and West Somerset (73.3%).

9.5.58 The proportion of working age residents in the immediate districts with at least Level 3 qualifications appears to be similar to the national average (both around 50%). However, this proportion is again slightly below the South West regional average (53.3%). There are relatively minor differences in the proportions with Level 3 qualifications between West Somerset and Taunton Deane districts, although Sedgemoor has a lower rate.

9.5.59 The proportion of working age residents with at least Level 4 (degree level or equivalent) qualifications (30.9%) in the immediate districts is also slightly below the regional (31.5%) and national averages (31.1%).

Table 9.38: Qualifications of Working Age Residents (16-64), 2009

Area	% Qualified at Level 2+	% Qualified at Level 3+	% Qualified at Level 4+
Districts			
Sedgemoor	61.7%	46.8%	28.1%
Taunton Deane	76.3%	53.7%	34.7%
West Somerset	73.3%	53.4%	28.8%
Sub Total	69.4%	50.6%	30.9%
Wider Scales			
Somerset	70.5%	51.1%	29.8%
South West	71.0%	53.3%	31.5%
England	67.0%	50.7%	31.1%

Source: Office for National Statistics, Annual Population Survey (based on survey data for the January to December 2010 period). All figures are sample-based estimates and are subject to a margin of error. Estimates for the immediate districts are based on a relatively small sample and should therefore be treated with caution.

Note: According to the London School of Economics definition, the NVQ equivalents are NVQ 2 = five GCSEs at grades A-C, BTEC first diploma; NVQ 3 = two or more A levels, BTEC Ordinary National Diploma (OND), City and Guilds Advanced Craft; NVQ 4 = BTEC Higher National Certificate (HNC) or Higher National Diploma (HND), or City and Guilds Full Technological Certificate/Diploma /or first Degree*

9.5.60 Data on GCSE exam attainment for the 2008/09 academic year is based on the residential location of pupils rather than the location of schools. The latest results show that attainment levels for pupils living in Sedgemoor and West Somerset, and in Somerset as a whole, are below the regional and national averages. In 2009 the proportion of pupils gaining at least 5 GCSE passes at A*-C was 61.8% in Sedgemoor and 59.1% in West Somerset, compared with a South West average of 67.9% and English average of 69.8%. The figure for Somerset as a whole was relatively low, at 63.5%. Attainment levels were higher in Taunton Deane, with 67.2% of pupils gaining 5 or more A*-C passes in 2009.

Table 9.39: GCSE Exam Attainment Levels in the Immediate Districts, by Location of Pupil Residence, 2009

xii. Deprivation

9.5.61 Evidence from the national indices of deprivation 2010 highlights that average levels of deprivation across each of the immediate districts are indicated by their rank position relative to all other English local authority districts. On the overall Index of Multiple Deprivation (IMD 2010), West Somerset is ranked 90th out of the 354 local authority districts in England (where a rank of 1 indicates the most deprived district nationally and a rank of 354 the least deprived). Average levels of deprivation are lower in Sedgemoor (ranked 152nd) and Taunton Deane (ranked 181st). The proportions of income deprived and employment deprived residents are above the South West average in both Sedgemoor and West Somerset districts. An image highlighting the spatial areas of deprivation is included at **Figure 9.3**.

9.5.62 Only 6% of the lower-level super output areas (LSOAs) in Sedgemoor, Taunton Deane and West Somerset are ranked in the most deprived 20% nationally on the overall IMD 2010, and 3% are in the 10% most deprived LSOAs. However, a more detailed analysis of the individual domains and sub-domains of ID 2010, which explores different aspects of deprivation, reveals a more complicated overall pattern of deprivation:

- There are particular issues in relation to barriers to housing and services, particularly in West Somerset district. This largely reflects the geographical remoteness of certain rural communities, but it also reflects affordability issues in relation to access to housing;
- A relatively high proportion of SOAs in the immediate districts are also ranked amongst the most deprived nationally in relation to their indoor living environment, reflecting poor housing quality and lack of basic amenities; and
- Levels of income deprivation are generally low. However, levels of employment deprivation are higher.

xiii. Future Growth Prospects

9.5.63 The most recent set of employment forecasts for the region were prepared by Oxford Economics on behalf of the South West Regional Development Agency and South West Councils (previously the Regional Assembly), and were published in June 2010. These forecasts explore alternative growth scenarios for the region, providing job growth forecasts to 2030 (although the focus in this section is on the 2008-2018 period, which is considered to be more relevant to the timescale of the proposed HPC development). Three main growth scenarios are considered, including a —central growth forecast and alternative —weak growth and —strong growth scenarios. Key results for Somerset and the wider sub-region are summarized in **Table 9.40** and **Table 9.41**, for all sectors and the construction industry:

Table 9.40: Forecast Employment Growth, 2008-2018 (Oxford Economics, South West Growth Scenarios, June 2010)

Area	2008 (Baseline)	2018 (Weaker Growth)	2018 (Central Growth)	2018 (Stronger Growth)
Somerset	268,400	278,200	281,300	291,600
West of England	590,500	618,500	625,200	650,600
Exeter and Devon	474,700	495,600	500,700	520,500
South West	2,703,500	2,798,300	2,829,000	2,936,600
United Kingdom	31,602,300	32,285,500	32,742,300	34,004,200

Source: Oxford Economics, South West Growth Scenarios: Final Report, June 2010. West of England area includes Bath and North East Somerset, City of Bristol, North Somerset and South Gloucestershire.

9.5.64 The alternative scenarios suggest overall employment growth of between 9,800 and 23,200 jobs in Somerset during the 2008-2018 period, with a central growth forecast of 12,900 additional jobs. This amounts to job growth of between 3.7% and 8.6%, with a central forecast of 4.8%. This is similar to forecast job growth in the South West region as a whole (3.5% to 8.6%, with a central growth forecast of 4.6%), and higher than average forecast growth in the UK (2.2% to 7.6%, with a central forecast of 3.6%). Within the wider sub-region, comprising Somerset, Devon and the West of England, employment growth is forecast at between 58,700 and 129,100 jobs, with a central growth forecast of 73,600 additional jobs. This represents overall job growth of 4.4% and 9.7%, with a central forecast of 5.5%.

Table 9.41: Forecast Construction Sector Employment Growth, 2008-2018 (Oxford Economics, South West Growth Scenarios, June 2010)

Area	2008 (Baseline)	2018 (Weaker Growth)	2018 (Central Growth)	2018 (Stronger Growth)
Somerset	20,785	19,669	20,107	20,671
West of England	39,684	38,161	39,016	40,115
Exeter and Devon	41,499	38,846	39,712	40,827
South West	203,774	191,995	196,278	201,793
United Kingdom	2,212,663	2,128,278	2,179,892	2,240,959

Source: Oxford Economics, South West Growth Scenarios: Final Report, June 2010. West of England area includes Bath and North East Somerset, City of Bristol, North Somerset and South Gloucestershire.

9.5.65 Employment forecasts for the construction sector indicate a net decline in employment levels between 2008 and 2018 in all three scenarios for Somerset, the wider sub-region and the South West as a whole. Within Somerset, a net decline of between 100 and 1,100 construction sector jobs is forecast, with a central estimate of 700 fewer jobs. This represents a reduction of between 0.5% and 5.4%, with a central forecast reduction of 3.3%. Forecasts for the wider sub-region indicate a broadly similar reduction in employment levels of between 0.3% and 5.2%, with a central forecast of 3.1%. A slightly larger reduction in employment is expected in the

South West region as a whole, of between 1.0% and 5.8%, with a central forecast of 3.7%.

xiv. Land Use and Agricultural Economy

9.5.66 The site is generally in agricultural use (mixed pasture and arable). Land immediately adjacent to and within 100 metres of the site is also primarily in agricultural use, comprising pasture, arable land and small tracts of woodland.

9.5.67 Within the HPC Development Site are four farm units, covering 22 fields and including three derelict farm buildings. A total of 141.2 hectares of agricultural land would be required for the proposed development, of which 14% is considered 'Best and Most Valuable Land' (BMVL)' and 73% is of 'moderate' quality, as assessed in **Chapter 13** of this Volume of the ES (Soils and Land Use).

9.5.68 Agricultural land accounts for a total of 331,233ha in Somerset, and an estimated 1,738 jobs (ABI, 2008), based on an average of 1.5 self-employment jobs to every employee job in this sector across the South West.

xv. Accommodation

9.5.69 The following section examines in detail accommodation capacity. This has involved careful consideration of the potential scale of accommodation available in four sectors:

- Tourist accommodation;
- Private Rented Sector (PRS);
- Owner Occupied Sector (OOS); and,
- Latent accommodation – i.e. accommodation that is either new or not currently included in records of tourist or private rented accommodation because it has been out of use or has not sought registration.

9.5.70 The following main data sources have been used for this analysis:

- Tourist: South West Tourist Board's Accommodation Database and a survey undertaken by Arup on behalf of the local authorities.
- Private rented: Census (for ward level data), estate agents, and local authority data including the Strategic Housing Market Assessment and Housing Strategy Statistical Appendix (HSSA) returns.
- Owner occupied: Census (for ward level data), and local authority data including the Strategic Housing Market Assessment and Housing Strategy Statistical Appendix (HSSA) returns.
- Latent: Advertisements were placed in newspapers in 2009 and 2010 inviting potential accommodation providers to provide details of property that could be available for construction workers, EDF Energy's office in Bridgwater has created a database that captures these responses and further responses since the surveys were undertaken.

9.5.71 At the Stage 2 Consultation, it was assumed that non-home-based power station construction workers will move closer to the Hinkley Point site for accommodation than the 90 minutes CDCZ, and a 60 minutes zone was therefore calculated and used. It covers all of Sedgemoor, significant parts of West Somerset, Taunton Deane and North Somerset, and a small part of Mendip.

9.5.72 The 60 minute zone represents the zone within which construction workers moving into the local area to work on the Project would be expected to seek accommodation. This is smaller than the CDCZ because it is assumed that non-home-based workers will move to areas closer to the site than people who commute from home. .

General Housing Data

9.5.73 The housing stock in the districts of Sedgemoor, Taunton Deane and West Somerset is currently estimated at just over 117,000 dwellings (April 2009 estimate). The housing stock in these immediate districts increased by an estimated 11,000 dwellings between 2001 and 2009 (equivalent to an additional 1,380 dwellings per annum). This represents a 10.4% increase in the area's housing stock over this eight year period, which is significantly above the national average increase (5.6%) and also slightly higher than the average rate of housing growth in the South West region:

Table 9.42: Growth in Housing Stock in Immediate Districts, 2001-2009

Area	Dwelling Stock, April 2001	Dwelling Stock, April 2009	% Growth, 2001-2009
Districts			
Sedgemoor	45,336	50,046	10.4%
Taunton Deane	44,530	48,893	9.8%
West Somerset	16,273	18,226	12.0%
Sub-Total	*106,139*	*117,165*	*10.4%*
Wider Scales			
Somerset	216,273	237,191	9.7%
South West	2,173,221	2,367,565	8.9%
England	21,360,647	22,564,243	5.6%

Source: Department for Communities and Local Government, annual estimates of dwelling stock by tenure and condition (Neighbourhood Statistics).

9.5.74 Within the wards in the immediate vicinity of the site, there were approximately 24,000 dwellings in March 2009, of which around 16,300 are in Bridgwater. The housing stock in this immediate area has increased at a broadly similar rate in recent years as the average for the immediate districts (an additional 2,050 dwellings between 2001 and 2009, representing growth of 9.3%). Most of this local housing growth has taken place in Bridgwater and in the adjacent Sandford ward.

9.5.75 Information on the tenure of the local housing stock is available from the Taunton and South Somerset Strategic Housing Market Assessment (Fordham Research, August 2008) (Ref. 9.69). This information, derived from household surveys undertaken in each of the immediate districts results in estimates that suggest that owner occupied properties account for around 75% of the current housing stock in the immediate districts. Social rented housing accounts for an estimated 14% of the stock, and the private rented sector for the remaining 11%.

9.5.76 It is estimated that almost 12,400 households are currently in private rented housing in the immediate districts. This includes around 4,700 households in Sedgemoor, 5,500 in Taunton Deane and 2,100 in West Somerset.

Table 9.43: Estimated Tenure of Households in Immediate Districts

Area	Owner Occupied	Social Rented	Private Rented
Sedgemoor	37,500	5,900	4,700
Taunton Deane	36,200	7,900	5,500
West Somerset	12,000	2,300	2,100
TOTAL	**85,600**	**16,100**	**12,400**
Sedgemoor	77.9%	12.4%	9.7%
Taunton Deane	72.9%	16.0%	11.1%
West Somerset	73.2%	13.7%	13.1%
TOTAL	**75.1%**	**14.1%**	**10.8%**

Source: Fordham Research, Taunton and South Somerset Strategic Housing Market Assessment (August 2008), estimates based on household survey data.

Tourist Sector

9.5.77 There is a substantial local supply of tourist accommodation in the Somerset area, and in the area where non-home-based workers are expected to live. There are approximately 50,000 tourism bed spaces within the 60 minute zone, or 35,000 excluding holiday villages based on South West Tourist Board's 2009 database. This is an underestimate of the total tourist accommodation in the area because it only includes accredited or "rated" accommodation, which has undergone an independent quality assurance process, and there are many businesses that are not rated and therefore do not appear on the SWTB database.

9.5.78 Data from the SWTB indicates the following break-down by type in the 60-minute travel area:

Table 9.44: Tourist Accommodation in the 60-minute Travel Area (SWT, 2009)

	Serviced	Self-Catering	Holiday Village	Caravan/ Camping	Campus/~ Hostel	TOTAL
2009	8,657	2,818	14,632	22,264	1,448	49,819

Private Rented Sector

9.5.79 There is a substantial private rented sector (PRS) within the 60-minute travel area. The following table shows the number of private rental sector (PRS) units at the time of the 2001 Census and at the time of the 2008 update included in the Housing Needs Survey (HNS) that was undertaken as part of the local authorities' Strategic Housing Market Assessment:

Table 9.45: Private Rented Accommodation in the 60-minute Zone

District	PRS Units 2001	PRS Units 2008
Sedgemoor	3,199	4,689
Taunton Deane	3,598	5,522
West Somerset	1,347	1,870
South Somerset	335	518
North Somerset	6,457	8,069
Mendip	1,022	1,151
TOTAL	**15,958**	**21,819**

9.5.80 There are around 21,800 PRS units in the 60 minute zone. It should be noted that these are PRS units rather than bed spaces. The vast majority of units have more than one bedspace. Data used in the **Transport Assessment** identifies an average of 2.29 bedspaces per PRS unit in Sedgemoor, 2.49 in Taunton Deane, 2.30 in West Somerset, and an average of 2.26 per unit in other local authorities with wards in the 60-minute zone. This produces a total of 50,796 bedspaces across the 60 minute travel zone.

Latent Accommodation Sector

9.5.81 EDF Energy placed newspaper adverts on two separate occasions inviting potential landlords to register their property if they wished to offer accommodation to the HPC construction workforce. The initial response to these provided 750, of which over 450 were genuinely “additional” to existing supply (i.e. they had not been offered for rent before). This additional accommodation can be used without any risk of displacing existing residents.

xvi. Education

9.5.82 This section discusses primary and secondary education services. Information is included on current pupil numbers in local schools and the numbers of surplus school places. The implications of the latest school roll forecasts to 2014 in Somerset are also considered where applicable. Baseline data on these issues is provided for all LEA maintained schools within an approximate 60 minute travel time of the HPC site.

9.5.83 Brief information is also included at the end of the section on other education provision, including pre-school and nursery provision and post-16 education.

Primary Education

9.5.84 **Table 9.46** provides data on pupil numbers and school capacity for all LEA maintained primary schools within 60 minutes travel-time of the HPC Site. Pupil numbers in these schools totalled 26,781 in January 2010. Around half of these pupils are located in the primary schools in urban areas of Bridgwater, Taunton, Weston-super-Mare and Highbridge with the remainder in the more rural primary schools elsewhere in the area and in smaller settlements. There are some relatively small primary schools in the more rural parts of the area. For example, 36 schools, including Combwich, Crocombe, Spaxton, Stogumber and Stogursey each have fewer than 100 pupils. Total primary school capacity in the area is 30,884 places (based on the position as at 2011/12 entry). There were therefore around 4,103 surplus primary places in the area, representing13% of existing primary school capacity. The location of these schools is mapped in the **Figure 9.4**.

9.5.85 The proportion of surplus places varies across the defined ward clusters in the area, as follows:

Table 9.46: Local Primary School Capacity and Pupil Numbers

	Net Capacity (For 2011/12)*	Pupils on Roll (January 2010)*	Surplus Places	% Surplus Capacity
Bridgwater	3,831	3,646	185	5%
Burnham and Highbridge	2,995	2,818	177	6%
Cannington	630	597	33	5%
Cheddar	822	668	154	19%
Glastonbury	2,708	2,173	535	20%
Hinkley Point	84	63	21	25%
Minehead	1,032	662	370	36%
Somerset South	2,415	1,867	548	23%
Somerset West	644	545	99	15%
Taunton	5,551	5,179	372	7%
Watchet and Williton	627	421	206	33%
Weston-super-Mare	9,545	8,142	1,403	15%
60-Minute Travel Area	30,884	26,781	4,103	13%

**Annual Schools Census 2010; **Somerset County Council, School Organization Plan 2010-2014, published 13 July 2010.*

9.5.86 Surplus places are currently unevenly distributed across local primary schools. As a result, although some schools have significant numbers of surplus places, other local schools are operating close to or above their current capacity.

9.5.87 Forecasts of pupil numbers for the local primary schools have been obtained from the latest version of Somerset County Council's School Organization Plan Tables, published in July 2010 (SCC, School Organisation Plan 2010-2014) (Ref. 9.70). Overall, an increase in rolls for the primary schools in the Bridgwater area of 10.3% is forecast between 2009 and 2014. This represents an additional 301 primary pupils in the area over this five year period. Assuming no changes in school capacity, the effect of this increase would be to exceed the capacity in local primary schools by 2014. This represents a reduction in the proportion of surplus primary places from 8% of current capacity to 'at capacity' by 2014.

9.5.88 Based on existing levels of capacity, the following broad changes to numbers of surplus places can be expected in Burnham/Highbridge and Taunton. Note that these figures differ from those in **Table 9.46** as the Council uses slightly different clusters of schools than those shown:

- Burnham/Highbridge: Increase in the number of children on roll of 33 by 2014, with surplus capacity reducing from 7% to 4%.

- Taunton: Increase in the number of children on roll of 692 by 2014, with surplus capacity reducing from 11% to no capacity by 2014.

Secondary Education

9.5.89 There are 25 secondary-level schools within the 60-minute travel area from HPC. Of these, four are middle schools (age 9-13), based on the three-tier system used in West Somerset.

9.5.90 Total capacity in the secondary schools is currently 24,610 places (based on Somerset County Council School Organisation Plan and North Somerset Council's School Admission Documents). Pupil numbers in these schools totalled 23,134in January 2010 based on Annual Schools Census data. There are therefore 1,476 surplus secondary places in the area at this time, representing around 6% of existing capacity.

9.5.91 The Somerset County Council School Organisation Plan groups the schools into geographical areas for planning purposes, which can be broadly correlated to the ward clusters identified in the Methodology section of this chapter, as outlined in **Figure 9.1** with key areas of population being Taunton, Bridgwater and Weston-super-Mare.

9.5.92 There are four secondary schools serving Bridgwater and the surrounding rural catchment area. These schools cater for 11-16 year olds. In addition, Brymore School in Cannington is a secondary technical school for boys, specializing in rural technology, although this school has a wider than local catchment area. Current rolls and capacity for these schools is summarized in **Table 9.47**.

9.5.93 There are three secondary schools serving the urban area of Taunton, all catering for pupils aged 11-16. Two of these schools also have 6th Form provision. Current rolls and capacity for these schools is summarized in **Table 9.47**. In addition, there is a private school (Taunton International Academy) here.

9.5.94 There are four secondary schools in the urban area of Weston-super-Mare, catering for 11-16 year old pupils. These combined schools currently have 335 surplus places, equivalent to a surplus capacity of around 7%. **Figure 9.5** maps the location of secondary schools.

9.5.95 The following table outlines the capacity, number on roll and surplus capacity of these schools.

Table 9.47: Local Secondary School Capacity and Pupil Numbers

School	Net Capacity (January 2011)*	Pupils on Roll (January 2010)*	Surplus Places	% Surplus Capacity
Robert Blake Science College	700	648	52	7%
Chilton Trinity Technology College	1000	944	56	6%
Haygrove School	1070	1107	-37	-3%
East Bridgwater Community School	870	804	66	8%
The King Alfred School	1380	1368	12	1%

School	Net Capacity (January 2011)*	Pupils on Roll (January 2010)*	Surplus Places	% Surplus Capacity
Hugh Sexey Middle School	600	661	-61	-10%
Brymore School	316	162	154	49%
The Kings of Wessex School	1246	1191	55	4%
Fairlands Middle School	508	505	3	1%
Crispin School	1090	1098	-8	-1%
Minehead Middle School	648	609	39	6%
West Somerset Community College	1554	1301	253	16%
Court Fields Community School	860	822	38	4%
Kingsmead Community School	725	780	-55	-8%
The Castle School	1150	1201	-51	-4%
Heathffield Community School	1159	1199	-40	-3%
Bishop Fox's School	915	823	92	10%
The Taunton Academy	1050	1020	30	3%
Danesfield Community Middle School	464	396	68	15%
Worle Community School	1500	1350	150	10%
Broadoak Mathematics and Computing College	900	897	3	0%
Clevedon School	1200	1016	184	15%
Hans Price Academy	1200	761	439	37%
Churchill Community Foundation School and Sixth Form Centre	1305	1277	28	2%
Priory Community School	1200	1194	6	1%

* *Taunton Academy opened in Jan 2010 as an amalgamation of Ladymead Community School and St Augustine of Canterbury School. The numbers represented are pupils registered at these schools that it is assumed would transfer to the Academy.*

* *Hans Price Academy opened in 2009, as a conversion from the previous Wyvern Community School. The numbers represented are pupils registered at this school that it is assumed transferred to the Academy.*

Forecast Pupil Rolls

9.5.96 Forecasts of pupil numbers for the local secondary schools are taken from the latest version of Somerset County Council's School Organization Plan for 2010-2014. Overall, the latest forecasts indicate a decline in secondary pupil numbers in the area. Local secondary school rolls are expected to decline between 2009 and 2014. This represents a reduction of pupil numbers over this five year period. Assuming no changes in school capacity, the effect of this decline will be to increase the number of surplus places locally by 2014, although this will not be uniform across the area. There would be an increase in surplus capacity from 5% (174 places) to 8%

(306 places) in schools in Bridgwater, although schools in Taunton would be operating at capacity.

Future Development

9.5.97 In 2007, Somerset County Council secured £450 million in funding for the Somerset Building Schools for the Future (BSF) programme. The BSF programme in Somerset was planned to start in Bridgwater with the rebuilding of all four of the town's secondary schools plus two special schools. The original plans envisaged the following new secondary provision in Bridgwater (SCC, Building Schools for the Future: Outline Business Case, April 2008) (Ref. 9.71):

- 1,050 place 11-16 Chilton Trinity Technology College, to be rebuilt on its current site (current capacity is 1,000 places);
- 900 place 11-16 East Bridgwater Community College, to be rebuilt on its current site (current capacity is 870 places; the plans incorporate the potential to increase the school's capacity to 1,050 places in the future if required);
- 1,050 place 11-16 Haygrove School, to be rebuilt on a new greenfield site at Queenswood Farm (current capacity is 1,070; the plans incorporate the potential to increase the school's capacity to 1,200 in the future if required); and
- 900 place 11-16 Robert Blake Science College, to be rebuilt on its current site (current capacity is 700 places; the planned additional new capacity allows for a projected increase in roll numbers due to significant residential development close to the school).

9.5.98 Completion of the rebuilding projects was scheduled for autumn 2012. The plans also included co-location of specialist provision at Haygrove School (50 places) and Robert Blake Science College (60 places). Significant changes to the original proposals have occurred following the government's announcement in July 2010 of the withdrawal of funding for all future BSF construction projects. In Bridgwater, the rebuilding of Chilton Trinity and Robert Blake is to proceed as planned (with completion by November 2012), but the BSF funding for the rebuilding of East Bridgwater and Haygrove Schools has been withdrawn. Rebuilding of Chilton Trinity and Robert Blake secondary schools will result in an additional 250 secondary places in Bridgwater from late 2012 onwards.

Pre-School Provision

9.5.99 Data on existing local childcare provision for 0-5 year olds has been obtained from the Somerset Family Information Service (FIS). A total of 13 day nurseries or pre-school playgroups are listed in Bridgwater and a further 10 groups are listed in the surrounding rural area. The total number of registered childcare places for 0-5 year olds currently listed by the Somerset FIS is as follows (excluding places with individual childminders):

- *Urban Bridgwater area*: 455 registered places, excluding nursery classes at Hamp and Sedgemoor Manor Infants Schools.
- *Rural Bridgwater area*: 150 registered places, mainly in Cannington (65) and North Petherton (65).

- *West Somerset area*: 100 registered places, excluding nursery classes at Old Cleeve First School. These places are located mainly in Watchet (50) and Williton (30).
- *Other local*: 50 registered places.

9.5.100 Somerset County Council's *Childcare Sufficiency Assessment*, published in March 2011 (Ref. 9.72) highlights that:

- As a whole the county has sufficient childcare and EYE places for children aged 3-4, with some local gaps in primarily rural areas.
- There are insufficient childcare places for children aged 0-2, based on average national demand, but sufficient EYE places for 2-year olds.
- Despite the new and extended provisions created through Sure Start capital funding, further childcare provisions are required in the near future. District councils have identified sites for up to 36,892 new houses across Somerset up to 2026. It is possible that not all of these houses will be built, but the allocation does indicate that a substantial growth in population is anticipated over this period. The current levels of childcare provision are not sufficient to meet this expanded need, so new childcare provisions will be required as new housing, and the corresponding population rises develop.

The following table highlights the current provision and demand for places for different kinds of childcare in Sedgemoor, Taunton Deane and West Somerset based on national average indicators of the proportion of children in each type of childcare, applied to the number of children, by age group, in each district.

Table 9.48: Local Preschool Provision and Pupil Numbers

	Sedgemoor	Taunton Deane	West Somerset
Childminder (age 0-4)	Sufficient	Sufficient	Insufficient* (-5)
Pre-School (age 0-2)	Insufficient (-329)	Insufficient (-264)	Insufficient (-40)
Pre-School (age 3-4)	Sufficient	Insufficient (-34)	Sufficient
Early Education Entitlement (EEE)	Sufficient	Sufficient	Sufficient
Out of School	Insufficient (-333)	Insufficient (-333)	Broadly Sufficient (-4)

**Exacerbated by rural nature*

9.5.101 In Sedgemoor, there are sub-district shortages of places, particularly in urban areas of Bridgwater, Highbridge (pre-school and EEE) and rural areas of Spaxton and Nether Stowey, and Wedmore and Mark (childminder).

9.5.102 In Taunton Deane, there are sub-district shortages of places, particularly in the most sparsely populated areas south of Taunton and south of Wiveliscombe/east of Wellington in terms of childminder provision, with only marginal sufficiency in Taunton. There are sufficient 3-4 group childcare places in most areas, with the exceptions of Bishop's Lydeard (also insufficient in EEE provision) and some rural villages, though there are sufficient places in the wider area.

9.5.103 There are shortages of childminder places in very large rural areas of West Somerset, though these areas were very sparsely populated with the exception of

Dulverton. There are insufficient 0-2 group childcare places, based on average national demand, in every part of West Somerset, except Watchet. There are sufficient 3-4 group childcare places in most areas, with the exceptions of Porlock and some rural villages, though overall there is an insufficiency. Here are shortages of Early Years Entitlement places in the west of the District (Kilve, Stringston, Stogursey) but sufficient places nearby, including provisions in Sedgemoor. There are shortages of before school care places in rural parts of West Somerset. All urban areas had sufficient before and after school places.

Post-16 Provision

9.5.104 Post-16 education and training in Sedgemoor is mainly provided by Bridgwater College. The College has two campuses, in central Bridgwater and Cannington. There are currently around 3,000 students aged 16-18 years, including over 800 following AS/A level studies. There are also around 600 students following higher education courses.

9.5.105 In West Somerset the main provider is West Somerset Community College, which, in addition to the provision for secondary school aged children described above also provides a range of post 16 provision with a strong focus on vocational and technical education.

9.5.106 In addition, post-16 education is also provided at Richard Huish College and Somerset College of Arts and Technology, both in Taunton, and Weston College in Weston-super-Mare.

xvii. Primary Healthcare

9.5.107 See also separate **Health Impact Assessment** prepared by RPS (2011) for the HPC Environmental Statement.

Health Indicators

9.5.108 On many health indicators Somerset, and Sedgemoor and West Somerset, perform very well. The Indices of Deprivation (2010), Health, Deprivation and Disability Domain provide a measure of illness and disability, mental health problems and hospital admissions. Somerset County performs better on overall health indicators than the England average. Life expectancy for both men and women exceeds the England average by 1-2 years; levels of physical activity are high (Somerset); early deaths due to cancer, heart disease and strokes are lower than the England average and have fallen over the last 10 years. On the other hand, the rate of road injury and death is high compared to England averages; around 340 people are killed or seriously injured on the roads in Somerset each year. The proportion of women who smoke during pregnancy is higher than for both the region and England. The Socio-Economic Workshop also noted that the high level of incapacity benefits/issues needs to be recognised and responded to in relation to skills development /employment opportunities; this is currently a barrier in developing the skills base of the area. There are also particular problem pockets across the county, mainly in towns but also in rural West Somerset. The Somerset Local Area Agreement (LAA) prioritises: healthy life expectancy, teenage pregnancy, early deaths from circulatory disease, childhood obesity, drug and alcohol abuse, road injuries and Child and Adolescent Mental Health Services.

Local Healthcare Facilities

9.5.109 There are currently 62 GP practices based within 60 minutes travel time of the Hinkley Point site. The closest practices to the site, serving the immediate area, are the Cannington Health Centre (which includes branch surgeries in Combwich, Spaxton and Stogursey) and the Quantock Medical Centre in Nether Stowey. There are six GP practices in Bridgwater, plus an additional practice in North Petherton, to the immediate south of Bridgwater. A single practice (West Somerset Healthcare) serves the area to the west of the site, with surgeries located in both Watchet and Williton. There is also a small practice located near Washford in West Somerset (Brendon Hills Surgery). **Figure 9.6** maps the location of these GP surgeries.

9.5.110 There are currently around 457,343 patients on the lists of those practices within a 60-minute travel distance of the site. These local practices have a total of 393 whole-time equivalent general practitioners (excluding registrars). The local practices vary widely in size, from only 600 to 14,000 registered patients. Average list sizes per GP in the study area and major urban areas are shown in **Table 9.49**. Across all the local practices, there is an average of 1,164 patients per whole-time equivalent GP (excluding registrars). This is below the average for all Somerset GP practices (1,725). The average list size is higher for the Bridgwater practices (1,239 per whole-time equivalent GP) than for the more rural practices. By national standards these are relatively low numbers suggesting reasonable GP capacity in the area.

Table 9.49: List Sizes and Practitioner Numbers in Local GP Practices

Practice	List Size	GPs	Patients per GP
Urban Areas			
Bridgwater	49,570	40	1,239
Taunton	75,976	65	1,169
Weston-super-Mare	92,486	73	1,267
Watchet/Williton	10,044	8	1,256
Minehead	13,898	14	993
Burnham-on-Sea/Highbridge	28,919	21	1,377
Wellington	19,514	19	1,027
Cheddar	7,438	6	1,240
Study Area			
60-minute Travel Distance	457,343	393	1,164

Source: NHS Business Services, 2011

9.5.111 These overall averages conceal some significant variations between individual local practices. List sizes per whole-time equivalent GP in individual practices range from only 800 to almost 4,700. List sizes are above the Somerset average of 1,725 per GP in four of the practices.

9.5.112 A development framework was approved by NHS Somerset in September 2008, following the review of primary care infrastructure. The framework covers the period to 2015 and includes recommendations to replace or extend some existing surgery premises in the area. This includes the replacement of Brent House Surgery in Bridgwater (by 2011) and North Petherton Surgery (by 2012/13). The framework also includes the provision of capital grants to enable the extension of existing premises at Redgate Medical Centre and Taunton Road Medical Centre, both in Bridgwater. Proposals for a new surgery in south Bridgwater were not supported as part of NHS Somerset's current development framework, as existing primary care capacity in Bridgwater was considered to be sufficient.

9.5.113 The nearest accident and emergency facilities are located at Musgrove Park Hospital in Taunton. The hospital is located about 18 miles by road from the Hinkley Point site, with an estimated journey time of just over 40 minutes.

9.5.114 There are two community hospitals within a 30 minute drive of the Hinkley Point site, located in Bridgwater and Williton, with another slightly further away in Minehead. These hospitals are operated by NHS Somerset. The services currently provided by these hospitals are summarized below.

- Bridgwater Hospital – the hospital has 50 beds for consultant and GP patients, plus a maternity unit with 8 beds. Services provided include outpatients, the rehabilitation unit, X-ray, physiotherapy and occupational therapy. There is a Minor Injuries Unit which operates from 7.00 to 23.00, seven days a week.
- Williton and District Hospital – the hospital has 45 inpatient beds. Services include the rehabilitation unit, palliative care, physiotherapy and occupational therapy.

9.5.115 Elsewhere in the 60-minute Travel Distance are:

- Musgrove Park Hospital (Taunton) – this is the largest general hospital in Somerset, and includes 700+ beds, 15 operating theatres, an intensive care and high dependency unit, a medical admissions unit, a fully equipped Diagnostic Imaging Department and a specialised Children's Department including a Paediatric High Dependency Bay. Musgrove Park also provides Neonatal Intensive Care for all of Somerset and has an Accident and Emergency facility.
- Burnham-on-Sea War Memorial Hospital (Burnham-on-Sea) – this hospital has 22 beds where patients can be admitted under the care of local GPs. A rehabilitation team of doctors, nurses, physiotherapists and occupational therapists support patients during their hospital stay. Patients often return to Burnham Hospital following treatment at Musgrove Park Hospital or Weston General Hospital so they can be close to their home and families. The Minor Injuries Unit operates a Nurse Led Treatment Centre seven days a week 10.00 - 18.00 hrs, April to October and 11.00 - 15.00 hrs, November to March.
- Weston General Hospital (Weston-super-Mare–run by the Weston Area NHS Trust) – Among the key services is the 24-hourEmergency Department (Urgent Care Centre) and Intensive Care Unit for patients with serious injury or illness.

9.5.116 Other primary care facilities within 60-minutes travel distance of HPC include 63 dentists, 76 pharmacies and 39 opticians. **Table 9.50** and **Figure 9.7** outline the spatial location of these facilities:

Table 9.50: Pharmacies, Dentists and Opticians

xviii. Sport and Leisure Facilities

9.5.117 **Technical Note 5: Leisure Audit and Estimated Demand** (**Appendix 9E**) sets out the existing provision of sports facilities in Sedgemoor, West Somerset and Taunton Deane districts. The approach taken to the assessment of the existing provision of sports facilities is based on two sources of information:

- A survey undertaken by ARUP in 2010 which highlights the location and type of a range of sports and leisure facilities in West Somerset and Sedgemoor.
- Sport England's Active Places database, which includes a list of facilities by type and size/capacity for all areas.

9.5.118 In terms of wider sports needs, most areas have existing provision that is adequate, the exception to this being the lack of a publicly accessible indoor swimming pool in a number of areas, including Minehead and Bridgwater. Minehead has an outdoor pool at Hoburne Blue Anchor Holiday Park and an indoor leisure pool at Butlins, although these may not be accessible for HPC workers. The proposed refurbishment of Chilton Trinity School in Bridgwater includes the provision of a new swimming pool. Elsewhere in the 60-minute Travel Distance Area, there is an indoor swimming pool in Burnham-on-Sea and public pools in Taunton, Weston-super-Mare, Glastonbury, Cheddar and Wellington.

9.5.119 Somerset County Council operates a network of Leisure Centres across the County. These are all school-based and operate on a dual-use model, combining school and community access.

9.5.120 Specifically in terms of Bridgwater, SCC operated Leisure Centres include the Chilton Trinity Sports and Leisure Centre and the East Bridgwater Sports Centre. Details of the facilities at the centres in Bridgwater are shown below:

- Chilton Trinity Sports and Leisure Centre – the centre is based at Chilton Trinity Technology College and was constructed in the late 1980's. The centre is open seven days a week and offers the following range of facilities:
  - Squash court;
  - Two fitness studios;
  - Floodlit artificial turf pitch;
  - Children's indoor activity play area;
  - Four court sports hall; and
  - Public bar area and party room.
- East Bridgwater Sports Centre – this centre is based at East Bridgwater Community School and was constructed in the 1970s. The centre is open seven days a week and provides the following facilities:
  - Four badminton courts;
  - Four squash courts;
  - Outdoor football pitches;
  - Floodlit court; and
  - Public bar.

9.5.121 Under the BSF programme in Somerset, it is currently envisaged that both Chilton Trinity and East Bridgwater secondary schools will be rebuilt on their existing sites by 2012. The current plans also include the rebuilding of both leisure centres, with dual school-community use of facilities retained. The proposals include provision of a new dual-use swimming pool as part of the rebuilding of Chilton Trinity.

9.5.122 Provision of indoor sport facilities is relatively limited in West Somerset. There is only one sports hall in the district, no public swimming pool, no indoor tennis courts and relatively limited per capita provision of health and fitness facilities. The exception is facilities for indoor bowls, where per capita provision is above that in Taunton Deane. Provision of indoor facilities in Sedgemoor includes nine sports halls and one public swimming pool. There is currently no provision for indoor tennis.

9.5.123 Per capita levels of provision for outdoor sport in Sedgemoor appear to be relatively favourable for outdoor bowls and grass playing pitches (for football, cricket and rugby). However, provision is less extensive in relation to synthetic turf pitches and multi- use games areas.

xix. Other Community Facilities

9.5.124 Within 60-minutes Travel Distance of Hinkley Point, there are28 libraries operated by Somerset County Council, North Somerset Council in urban areas including Bridgwater (1), Weston-super-Mare (3), and Taunton (4).

9.5.125 Closer to the Site, there are also libraries in Bishops Lydeard, Nether Stowey, North Petherton, Watchet and Williton. There are also mobile library services based in Bridgwater and Minehead which serve the more rural settlements in these areas.

9.5.126 **Table 9.51** and **Figure 9.8** highlight the spatial distribution of libraries and community centres within the 60-minute Travel Distance Area:

Table 9.51: Other Community Facilities

	Community Facilities	
	Libraries	Community Centres
Bridgwater	1	6
Taunton	4	6
Weston-super-Mare	3	8

xx. Crime and Community Safety

9.5.127 Somerset experiences relatively low levels of crime and disorder compared to the national average. Levels of crime and fear of crime are highest in the larger centres within the county and typically coincide with areas of relative deprivation. Improving economic opportunities in these deprived communities will continue to contribute to addressing the incidence and fear of crime (Somerset Strategic Partnership, 2007) (Ref. 9.73).

9.5.128 Home Office statistics on numbers of recorded offences in the immediate districts are presented for Local Authority and wider scales, based on the number of recorded offences during the 12 month period to December 2010.

9.5.129 There were 14,353 recorded offences in the immediate districts during the 12 months to December 2010. Adjusting for the districts' resident population, this represents an annual crime rate of 56.0 offences per 1,000 population. This is below the South West average of 57.9 offences. Recorded crime rates are particularly low in West Somerset district (44.4 offences per 1,000 population), but are higher in Sedgemoor (56.8) and Taunton Deane (59.0).

9.5.130 Data is available on a neighbourhood-level for smaller areas which identifies the total recorded offences per month. This data has been equivalised over 12 months to give estimates of comparative crime rates for urban areas in the 60-minute travel distance. This illustrates the higher crime rates in urban areas.

Table 9.52: Recorded Offences 12 Months to December 2010

	Recorded Offences (annual, monthly Dec 2010 for urban areas)	Mid-2009 Population	Offences per 1,000 Population
District			
Sedgemoor	6,363	112,100	56.8
Taunton Deane	6,420	108,700	59.0
West Somerset	1,570	35,400	44.4
Sub-Total	*14,353*	*256,200*	*56.0*
Urban Areas			
Bridgwater	587	36,200	194.6
Taunton	642	54,200	142.1
Weston-super-Mare	872	79,200	132.1

Source: Home Office, Crime in England and Wales: Quarterly Update to December 2010, published February 2011; and National Policing Improvement Agency, Local Crime Mapping. Crime rates per 1,000 population are calculated using mid-2009 population estimates (published by the Office for National Statistics on 24 June 2010). Number of recorded offences is for the 12 month period to 30 December 2010.

9.5.131 Data on the number of anti-social behaviour incidents recorded by the police is shown in the following table. This data relates to the 12 month period to June 2010. There were around 13,500 incidents of anti-social behaviour recorded during this period in the three immediate districts. This represents a total of 52.7 incidents per 1,000 population, compared with the regional average of 53.9. Numbers of incidents per 1,000 population are again relatively low in West Somerset (42.1) and somewhat higher in Sedgemoor (52.1) and Taunton Deane (56.7). As with recorded crime, there is a relatively high level of anti-social behaviour in Bridgwater (85.0 incidents per 1,000 population) and much lower levels in the rural wards closer to the site (20.2).

Table 9.53: Anti-Social Behaviour: Immediate Districts, 2009/10

	Recorded ASB Incidents	Mid-2009 Population	Incidents per 1,000 Population
Districts			
Sedgemoor	5,835	112,100	52.1

England	-	51,809,700	-

Source: National Policing Improvement Agency, Local Crime Mapping. Incidents per 1,000 population are calculated using mid-2009 population estimates (published by the Office for National Statistics on 24 June 2010). Number of ASB incidents is for the 12 month period to 30 June 2010.

9.6 Assessment of Construction Phase Impacts

9.6.1 The socio-economic construction impacts of the scheme in the main result from the workforce required to build HPC and the demand from EDF Energy for goods and services to support the development.

9.6.2 Section 9.4 (above) summarises the "central case" in relation to:

- likely workforce profile and timing;
- where workers are likely to be recruited from (home-based and non-home-based recruitment);
- the demographic make-up of the workforce;
- where workers are likely to live, based on accommodation capacity assumptions and EDF Energy's **Accommodation Strategy**, and the "Gravity Model" produced for the **Transport Assessment**; and
- the demographic make-up of the workforce.

9.6.3 This section then assesses the impacts of the proposals against the policy, baseline and significance criteria described above in relation to the following topics:

- Labour market and local economy.
- Accommodation Impacts.
- Population and demographics.
- Public services including:
  - Education.
  - Health.
  - Emergency Services.
  - Leisure and Recreation.

  - Other Services.
- Community Cohesion.
- Specific Locational Impacts.

9.6.4 The spatial spread of impacts and equalities issues are considered as cross cutting themes where relevant.

a) Economic Impacts

9.6.5 The construction of HPC could have a range of economic impacts. In this section the areas of impact will focus on four levels identified in the baseline assessment, the CDCZ (90 minute) area in which the home-based workforce will live, the 60 minute non-home-based workforce accommodation area, the county of Somerset and the three immediate district area (Sedgemoor, West Somerset and Taunton Deane).

9.6.6 The main areas covered are:

- Labour Market:
  - impact on demand for labour; and
  - impact on wider labour supply;
- Impact on Supply Chain and Procurement:
  - The direct demand for goods and services arising from the HPC development;
  - expenditure of workforce (non-home-based);
  - expenditure of workforce (HB); and
  - multipliers and wider effects.
- Impact on Sectors:
  - tourism; and
  - other sectors, including agriculture.

b) Labour Market Impacts

i. Total Workforce

9.6.7 Assumptions about the labour force requirements for the construction of HPC are set out in **Technical Note 1** and in the paragraphs describing the scheme above.

9.6.8 This shows a slow build up over the first 18 months before a step change, with an increase of around 2,000 workers over a year, as the main contracts begin. There is a further increase of 1,500 between years 3 and 4, after which the workforce stays at above 4,000 until year 8, with a peak of 5,600 in year 6.

9.6.9 This “gross” peak employment total of 5,600 equates to less than 1% of jobs in the CDCZ, approximately 3% of jobs in Somerset and the 60 minute area, and approximately 5% of jobs in the three district area.

9.6.10 The build-up of the workforce equates to approximately 1,000 jobs per year for the first six years of the project. This equates to under 1% of total jobs at all levels and is lower than the annual jobs growth in each area from 2001 to 2008.

9.6.11 In relation specifically to construction employees, detailed data is contained in **Technical Note 1: Workforce Profile (Appendix A)** on current and projected construction employment in the CDCZ and Somerset. The 5,600 peak jobs figure equates to around 11% of total construction jobs in the CDCZ and is therefore assessed as an impact of **moderate beneficial** significance at the CDCZ level.

ii. Recruitment by Area

9.6.12 Because of the relatively high levels of labour demand, particularly compared to the immediate three District area, it is projected that a substantial proportion of the workforce will be recruited from outside the CDCZ. This will vary by skill type and timing within the project as described in **Technical Note 1** and set out above.

9.6.13 **Table 9.54** below, shows, for illustrative purposes the likely “central range” estimates of how the workforce could break down, in terms of residence location, over the impact areas in each year. The home based numbers are based on the central point of the assessment in **Technical Note 1**, which vary slightly, but not significantly, from those in the gravity model used in the **Transport Assessment**. The non-home based split is based on the gravity model assumptions. The three district peak home based total represents approximately 1% of total residence based employment in the 3 Districts. This impact is assessed as of **moderate beneficial** significance at the three district level.

Table 9.54: Central Range of Workforce

Year	Home-based Total	Of which			Non home-based Total	Of which		
		3 Districts	Rest of Somerset	Rest of CDCZ		3 Districts	Rest of Somerset	Rest of 60-minute Zone
1	90	50	10	30	90	70	10	10
2	320	160	50	110	380	300	30	60
3	1,350	690	210	460	1,630	1,280	110	240
4	1,900	1,170	220	500	2,520	1,980	170	380
5	1,840	1,055	235	550	2,970	2,330	190	440
6	1,900	970	290	640	3,700	2,900	240	550
7	1,680	860	260	570	3,130	2,460	210	470
8	1,280	650	200	430	2,080	1,630	140	310
9	830	420	130	280	1,080	850	70	160

Source: HDS/IAU Analysis of Construction Workforce Profile

iii. Impacts on the Labour Market

9.6.14 The labour market is dynamic: people move in and out of the labour market and move between jobs regularly. As demand for workers increases, jobs are filled by people currently in employment moving jobs, people who are registered as unemployed, and people who do not form part of the labour market because they are classed as economically inactive.

9.6.15 **Table 9.55**, below, shows claimant unemployment in construction related professions in the relevant impact areas in July 2011. It should be noted that there will also be significant demand for non-construction skills such as administration, security and transport operatives.

Table 9.55: Claimant Unemployment, July 2011

Occupation sought (selected occupations)	Sedgemoor, Taunton Deane and West Somerset	Somerset	90 Minutes CDCZ
Engineering professionals; Science and engineering technicians	35	85	520
Skilled mechanical and electrical trades	55	110	570
Skilled construction and building trades	165	300	1,555
Construction operatives (semi-skilled)	15	35	200
Elementary construction occupations (unskilled)	125	245	1,380
TOTAL	**395**	**775**	**4,225**

Source: Office for National Statistics, monthly claimant count data. Figures are based on the following SOC 2000 occupational categories which are regarded as relevant to the construction phase of Hinkley Point development: 21.2 – engineering professionals; 31.1 – science and engineering technicians; 52.1 – metal forming, welding and related trades; 52.2 – metal machining, fitting and instrument making; 52.4 – electrical trades; 53.1 – construction trades; 53.2 – building trades; 81.4 – construction operatives; 91.2 – elementary construction occupations.

9.6.16 The number of people who are economically inactive but who want to work is significantly greater than the numbers who are registered as unemployment benefit claimants (JSA Claimants). The Government's preferred definition of unemployment – the ILO measure – shows higher numbers of people unemployed than either the JSA measure or the economically inactive who want to work, as the following table shows:

Table 9.56: ILO Unemployment, JSA Unemployment and Economically Inactive who Want to Work

	JSA Claimants (July 2011)	ILO unemployed (Jan 2010-Dec 2010)	Economic inactive, but want to work (Jan 2010-Dec 2010)
Sedgemoor	1,845	6,000	3,800
Taunton Deane	1,533	4,200	4,500*
West Somerset	350	N/A – disclosive sample	N/A – disclosive sample**
Somerset	6,785	20,200	13,600

Source: ONS – Annual Population Survey (2010); DWP – JSA Claimant Count (July 2011)
* *Confidence Error*
** *Previous year = 1,800*

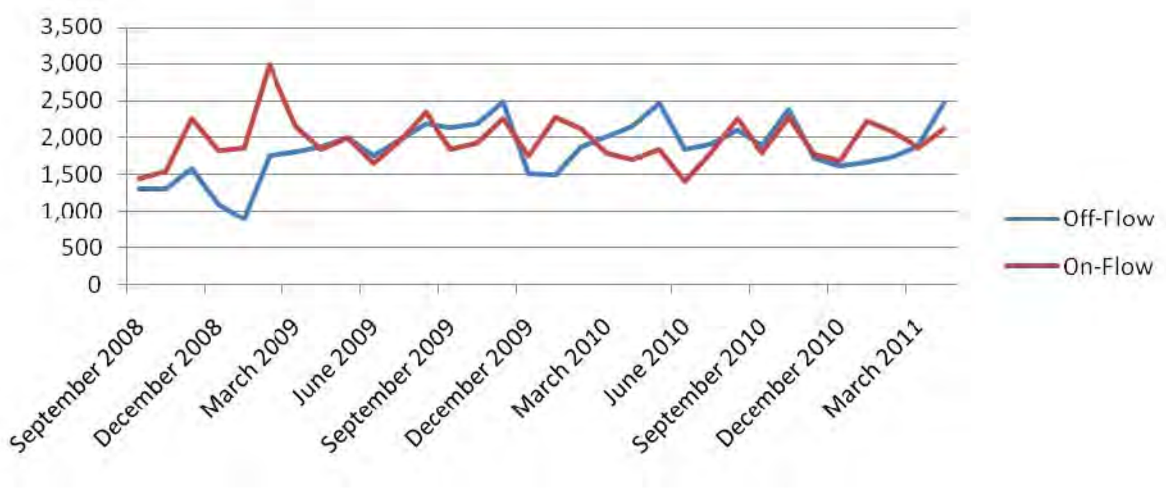
9.6.17 These numbers are volatile and there are significant annual changes in the level of economic inactivity, which is significantly more sensitive to changes in economic output than unemployment. It can therefore be seen that the number of people who are active in the labour market is not fixed – it expands and contracts according to economic environment, so when there are more jobs available, it can be expected that more people will be economically active.

9.6.18 Increases in demand for labour, for example. During the HPC construction phase, are likely to cause an expansion in the labour supply, in part by reducing economic inactivity.

9.6.19 In addition to people moving in and out of the active labour market, there are also significant moves into and out of claimant unemployment.

9.6.20 **Plate 9.1** shows the flows of people on and off Jobseekers' Allowance in Somerset. Since spring 2009 both have stabilised around 2,000 movements in each direction every month.

Plate 9.1: Claimant Unemployment Flows, September 2008 to March 2011



Source: NOMIS

9.6.21 In addition to a large number of people moving in and out of work, there are also regular changes of jobs. There is no single data source for average job tenure, but a number of UK studies have been conducted based on the Labour Force Survey, and the OECD produces an annual dataset. The following table summarises their broad statistics on job tenure.

Table 9.57: Job Tenure

Tenure	Less than one year	1-5 years	5-10 years	10+ years
Percentage	15-20%	30-35%	15-20%	30%

Source: OECD (2010)

9.6.22 The ONS estimates that there are just over 250,000 jobs in Somerset. The application of the OECD data described above would suggest that between 37,500 and 50,000 people in Somerset change jobs every year. The data also show that around half of all workers have job tenure of less than five years, therefore within the

NOT PROTECTIVELY MARKED

construction phase of HPC, most workers would change job twice. By extension, most employers would expect to fill each of their posts twice.

9.6.23 Job tenure is particularly short in construction. A survey for Construction Skills found that in the South West, job tenure was as follows:

Table 9.58: Total Length of Time Expected to Work at a Construction Site in the South West

	2007	2004
< 1 Month	11%	13%
1-3 Months	20%	17%
> 3-6 Months	16%	17%
> 6 Months – 1 year	17%	18%
> 1 Year	20%	9%
Don't Know	17%	25%

Source: Construction Skills (2010) All respondents (2007: 3,877; 2004: 8,436)

9.6.24 Only around two in five workers in the South West (37%) expected to be on site for more than six months and one in five (20%) expected their work on site to last over a year. Looking at variation by occupation, the report states that it tended to be trades whose work is undertaken at specific times in a project who expect the shortest duration on site: Electricians (62%), dry-liners (57%) and roofers (56%) were most likely to expect to be employed at the site for six months or less.

9.6.25 Tenures in key existing sectors in the Somerset economy in particular– tourism and agriculture – are also likely to be very low, because the nature of the work is seasonal.

9.6.26 There are around 47,996 construction sector jobs in the CDCZ, and 9,366 in Somerset. **Table 9.59**, below, shows the proportion of total jobs in the construction sector in Somerset and the CDCZ that the total construction workforce at HPC represents in each year of the project (comparable data is not available for the three districts). Given the relatively high proportions that would be required the assumptions in the central case in relation to the home-based workforce (1,900 of the 5,600 at peak) are significantly lower representing 20% of the Somerset construction workforce and 4% of the CDCZ.

Table 9.59: Construction Jobs

Year	% of Construction Jobs in Somerset	% of Construction Jobs in the CDCZ
1	4%	1%
2	18%	3%
3	34%	7%
4	48%	9%
5	54%	11%
6	60%	12%
7	49%	10%
8	36%	7%
9	17%	3%

9.6.27 There is the potential as part of this process that employees will be recruited from other local employers, thus causing recruitment problems. Experience at Sizewell B was that around 20% of locally recruited employees had previously been unemployed or economically inactive and around 30% (600 of 2,200) recruited in the peak recruitment year had come from other local employers. But a survey of 160 local companies found that less than 10% of the companies thought the power station project made it more difficult to retain or recruit (replacement) staff (Glasson and Chadwick, 1995 (Ref. 9.74)).

9.6.28 If similar proportions were to occur at the peak of the HPC construction programme, this would be around 380 formerly unemployed or previously inactive workers and around 570 workers from existing firms. This would equate to around 96% of unemployed construction workers in the three district area, 49% in Somerset and 9% of the CDCZ. This is assessed as an impact of **moderate beneficial** significance at all spatial levels. In terms of potential “displacement” the 570 workers would account for 6% of the construction workforce in Somerset and 1% in the CDCZ, which would in the context of the overall “churn” within the construction and overall labour market in the area.

iv. Impact on Supply Chain and Procurement

9.6.29 The development of a two UK EPR reactor units at Hinkley Point C will create supply chain opportunities, particularly as it is intended to form the start of a new fleet of nuclear power stations in the UK.

9.6.30 The supply chain will operate on a number of levels:

- There will be around 160 ‘*Tier 1*’ contractors appointed for the construction of the project – national and international companies working independently or through joint ventures who will be responsible for delivering one or more packages of works. A substantial proportion of construction expenditure will be on equipment and materials through this group. There will be a large number of ‘*Tier 2*’ sub-contractors and suppliers working for these contractors – ranging from providing materials, equipment, very specialist skills, through to more general trades.
- EDF Energy and its supply chain will also procure a large range of other (non-construction) services including, for example, professional and design services, facilities management (for campuses and park and rides), transport services, security, events and catering.

9.6.31 The technology suppliers/engineers and equipment and materials contracts will be at the national and international level and will contribute to national policy ambitions to develop the UK’s low carbon manufacturing capacity.

9.6.32 There are however, a number of local and regional firms that may benefit from these contracting opportunities. Over three quarters of the companies registered on the South West Supply Chain portal managed by the Somerset Chamber of Commerce are Somerset based (over 700 firms).

9.6.33 Construction contracts and sub-contracts, and particularly non-construction packages will have a much stronger local and regional element, with a substantial proportion of construction value retained in the local economy through wages to home-based workers and expenditure by non-home-based workers.

9.6.34 Early contracts let by EDF Energy have had a high local component. As of August 2011, contracts worth over £25.8m have been let by EDF Energy to local and regional businesses. The Site Preparation Works contract has been let to Kier/Bam Joint Venture and, in value terms, over 83% of their sub-contracts have been placed with Somerset businesses and organisations with a further 13% going to regional businesses.

9.6.35 Recent information on local contract expenditure for the main civils contractor at Flamanville 3 shows about 2% local expenditure out of Euro 400m total (2007-mid-2009), within 50km of the site, mainly in Cherbourg. At Sizewell B the figure of contracts with local firms in the larger area of Suffolk and Norfolk was a little higher at about 4% (i.e: c £80m out of total contract value of about £2bn).

9.6.36 The total value of the HPC project is estimated at £10bn. This would equate to a total “local” retention of between £100m and £400m over the construction period of the contract, equivalent to up to £45m per year. **This is a moderate beneficial impact** at the CDCZ level**.**

v. Multiplier and Other Local Economic Benefits

9.6.37 In addition to this local supply chain retention, is the “multiplier” income from expenditure by HPC employees in the area. This would include the additional incomes from home-based employees, and the retained expenditure from non-home based employees – i.e. local expenditure on accommodation, goods and services as opposed to that which is saved or remitted to families at home.

9.6.38 The estimated net additional outcome at Sizewell for additional workforce expenditure in the locality (i.e. setting aside some of the expenditure by local recruits which would have been undertaken even if the project had not gone ahead) was around £80 million. Up rating this taking into account the construction costs for HPC would give a total of £400 million.

9.6.39 Annual wages averaged for the whole of the construction period are estimated at £85 million per year, split between £32 million for HB workers and £53 million for non-home-based workers. This is based on the following assumptions of median wages in 2010:

- Site services – all sectors in Somerset
- Civils and M&E operatives – Construction of other civil engineering projects
- Staff and management – Civil engineering
- Associated development – Construction

9.6.40 This produces a total for wages over the construction process of just under £800 million. The amount of this that is captured locally will vary by whether they are home based or not, where non-home-based workers choose to live, and whether they bring their families.

9.6.41 A more detailed analysis would disaggregate the construction workforce expenditure into various expenditure groups. For example, non-home-based employees with families will spend more locally than un-accompanied non-home-based employees. Previous studies for Hinkley Point suggest a multiplier range of 1.3 to 1.5 for those with families, compared with 1.05 to 1.11 for unaccompanied workers, although the latter will still be of most significance in expenditure terms by virtue of the larger workforce numbers involved (Glasson, van Der Wee and Barrett, 1988).

9.6.42 Such an analysis can be used to estimate the wider indirect employment effects generated by the various types of local expenditure. Again the previous studies suggest indirect employment effects in the CDCZ, for example in retailing, plus local suppliers to the main contractors, of up to 50% of the main project employment. For capital projects the Department of Business Innovation and Skills (Ref. 9.75) estimates an average multiplier of 1.4 at the regional level and 1.33 at the sub-regional level.[1] This would mean that for every ten directly employed jobs at the regional level, a further four would be supported in other businesses, three of which would be at the sub-regional level.

9.6.43 This would suggest an additional employment impact of 2,240 for the CDCZ (taken here as the regional level) of which 1,850 would be in the local (taken here as the 60 minute zone) level. It is not appropriate to project multipliers at the very local (district level) as such assessments are very sensitive to small changes in assumptions. These jobs would be mainly outside of the construction sector and therefore not affect the conclusions drawn above, or in the cumulative assessment about construction recruitment. This impact would constitute a **moderate beneficial significance** at the 60 minute zone and CDCZ levels**.**

vi. Impact on Tourism, the Rural Economy and Logistics

9.6.44 In addition to the impact of HPC on other local employers, which is dealt with above, three other issues have been raised in scoping and consultation about impacts on important sectors in the local and sub-regional economy. The main sectors identified have been tourism and agriculture. The potential for HPC to cause traffic congestion in the area has been identified by the local authorities as a possible issue for tourism, agriculture and logistics.

vii. Tourism

9.6.45 In relation to tourism three specific potential effects have been identified:

- Effects on accommodation supply;
- Effects on the 'image' of the area;
- Effect of the Public Information Centre in attracting new visitors; and

9.6.46 Tourist accommodation supply is primarily dealt with in the accommodation section (below). This identifies capacity at peak (August) season and in the off season period (February). Vacancy ranges from around 6,500 places in August in the 60 minute zone, and around 24,500 places in February. On the basis of average worker accommodation allowances and the number of workers likely to be living in tourist accommodation over the lifetime of the construction period, using the central case there would be £15,000,000 expenditure in local tourism accommodation. This is assessed as an impact of **negligible** significance at the 60 Minute Zone level.

---

[1] *BIS Occasional Paper No. 1, Research to improve the assessment of additionality, October 2009*

9.6.47 Some concern has been expressed in the consultation process around the potential displacement of tourists who have higher average daily expenditure than workers, and impacts on return visits. In effect however, this will be a commercial decision for accommodation providers, who decide whether to let accommodation to workers – within any planning or other regulatory restrictions with which they must comply. The central case assessment suggests capacity in tourism accommodation even in peak season, and where this is the case expenditure would be additional. Even if there were to be a small level of displacement in the summer in some locations, this would be balanced by the benefits to providers outside of the peak season. This is assessed as an impact of **negligible** significance at all spatial scales.

9.6.48 In relation to the image of the area it has been suggested that there may be an 'image' impact on tourism on the area of the development of a New Nuclear Power Station. Yet there has been a nuclear power station at Hinkley Point since 1965, so this effect, if there was one, would to some extent already be part of the baseline.

9.6.49 Other studies (e.g. Travers Morgan, 1988, on Wylfa) (Ref. 9.76) have found no evidence that such developments deter tourists. A more recent study (Cogent et al, 2008) (Ref. 9.77) similarly found only very limited economic impact on tourism for the, partly analogous, energy developments of wind farms—and most of the concern was related to the early planning period for such developments. In the absence of any evidence to the contrary this impact has a **negligible** significance at all spatial levels.

9.6.50 A new Public Information Centre is proposed as part of HPC development. It is the intention of EDF Energy that this would be open to the public with a mix of local, tourist and educational visitors. The detailed content of the centre is still under development but it will include a reception, cafe and auditorium, high quality modern exhibition galleries. It is anticipated that the centre will open in 2014 and allow visitors to view the progress of the development.

9.6.51 The current intention is for the Centre to be open seven days a week from 10am to 4pm, although Sunday hours may be slightly shorter. As such it is expected to be a popular visitor destination for tourists and local residents alike. EDF Energy intends to have an initial cap of around 250,000 annual visits per year, with capacity for up to 1,000 a day in August peak. If it attracted 250,000 annual visitors it would be the equal most popular visitor attraction in Somerset County Council area alongside the West Somerset Railway (250,000), with nearly twice the total visitors of the next two largest Glastonbury Abbey (125,000) and the Fleet Air Arm (113,000). This impact would be of **major beneficial significance** at the local and county level**.**

c) Impact on Agricultural Land and Farming Activity

Farm Land and Activity

9.6.52 The proposed development would lead to the loss of farming activity, arable land and pasture both temporarily and permanently within site boundary.

9.6.53 Some land take impact will be short term/medium term during the construction period, with land required on a temporary basis to accommodate the construction activities and then restored post-construction. Of the total 171.4 hectares site area, approximately 66.6 hectares of land will be permanently lost. Following the construction phase, 104.8 hectares of land will be restored (as part of the Landscape

Restoration Plan) to arable agricultural land, grassland, woodland and scrub, hedgerow and wetland habitats.

9.6.54 Overall, the area of agricultural land affected within the site (141.2ha) represents approximately 0.04% of the total 331,233ha of agricultural land (Grades 1-5) across Somerset as a whole. As a proportion of the total employment in the agricultural sector in Somerset in 2009, this would equate to an average loss of 0.7 jobs in this sector.

9.6.55 Given the very low proportion of jobs that would be lost, the magnitude of the impacts would be very low (insignificant in terms of the sub-regional economy) and the sub-regional economy as a receptor would have very low sensitivity to the proposed changes, resulting in an impact of **negligible** significance in terms of the sub-regional economy.

Severance/Disruption

9.6.56 No severance is experienced through the construction and operational phases of the Hinkley Point C Development Site due to the natural boundary features and the scale of the area involved. Agricultural access to the surrounding land remains unaffected by EDF Energy's proposals as there remain sufficient linkages between adjoining fields to allow for the continuation of agricultural practices in adjacent farm units, therefore no impact is identified.

Direct Economic Impact

9.6.57 The HPC Project would affect land currently under agri-environment schemes (comprising Entry Level Environmental Stewardship and Countryside Stewardship Agreements). Schemes within the site will cease prior to commencement of the earthworks associated with the construction of Hinkley Point C.

9.6.58 According to Natural England, the total number of agreements and the total area of land in Countryside Stewardship Schemes or entry level Environmental Stewardship Schemes in Somerset (as July 2011) is as follows:

- Total Entry Level Environmental Stewardship Schemes – 1,128 agreements, amounting to 88,406.8 hectares of land.
- Total Countryside Stewardship Scheme – 211 agreements, amounting to 6,113.2 hectares of land.

9.6.59 The amount of land under Entry Level Environmental Stewardship Agreements within the site is therefore approximately 0.09% of the land under such agreements in the whole of Somerset, representing a very low magnitude impact and low sensitivity of the receptor to change as a result of the proposed development. This results in an impact of **negligible** significance in terms of the wider economy.

9.6.60 The loss of the derelict farm buildings on the site has no socio-economic impact due to the structural condition of these structures making them unsuitable for agricultural use.

9.6.61 Land owners will be compensated for any loss of land prior to the start of construction of the proposed development; therefore no impact is identified on individual farm units.

d) Impacts of Transport on Business

9.6.62 The **Transport Assessment** assesses the peak traffic generation for HPC and associated developments on a weekday and identifies that there are no significant delays caused as a result of HPC across the modelled network (which broadly covers an area between junctions 23 and 24 and Cannington), during the peak construction phase of HPC (2016). By 2021, the assessment indicates that there is an improvement to the overall transport network in Bridgwater as a result of the proposed highway improvement measures delivered through the HPC project. The assessment also states that there is very little seasonal variation and that there will be less traffic on Saturdays. Therefore, it can be concluded that there will be no significant additional delays to tourist traffic on routes through Bridgwater arising as a result of the HPC project, and negligible impacts on the delivery of goods or on the agricultural sector. This is assessed as an impact of **negligible** significance at all spatial levels.

e) Financial Benefits (Business Rate Retention)

9.6.63 On 18th July 2011 the Secretary of State made a statement to the House of Commons, drawing attention to the publication of the Government's proposals to enable local retention of business rates, and Tax Increment Financing (Ref. 9.78).

9.6.64 The consultation seeks views on the Government’s proposals to change the way local government is funded by introducing retention of business rates. It also seeks views on options for enabling authorities to carry out Tax Increment Financing within the business rates retention system.

9.6.65 The consultation sets out the Government’s proposed core components for a business rates retention system. In addition, the consultation sets out the proposals for TIF to operate within the business rates retention system as a way of funding infrastructure investment to unlock economic growth. The consultation also outlines how the proposals interact with wider Government initiatives to promote growth, including the existing New Homes Bonus, and considers how they will work alongside the existing architecture of the business rates system which will not be changed – for example rate reliefs and the national business rate multiplier.

9.6.66 While this policy is still in development, and is relatively uncertain, if implemented there could be a potential positive effect at the local scale in relation to the HPC Project.

9.6.67 The Government’s proposals include:

- Setting a baseline business rate in 2013/14 for each local authority;
- Setting a baseline level which local authorities will retain, and a baseline contribution to the national pot (a tariff);
- Identifying an incentive as to what percentage of any business rate increase from the baseline local authorities retain; and
- Introduce a levy for claiming back any “disproportionate” benefit (i.e. an overage component).

9.6.68 For West Somerset Council, there could therefore be a significant benefit generated from retention of business rates as a result of HPC, noting that there are uncertainties over, for example, how gains will be shared with upper-tier authorities, and what proportion could be retained ("windfall"). Without further information it is not possible to assess the magnitude of this impact.

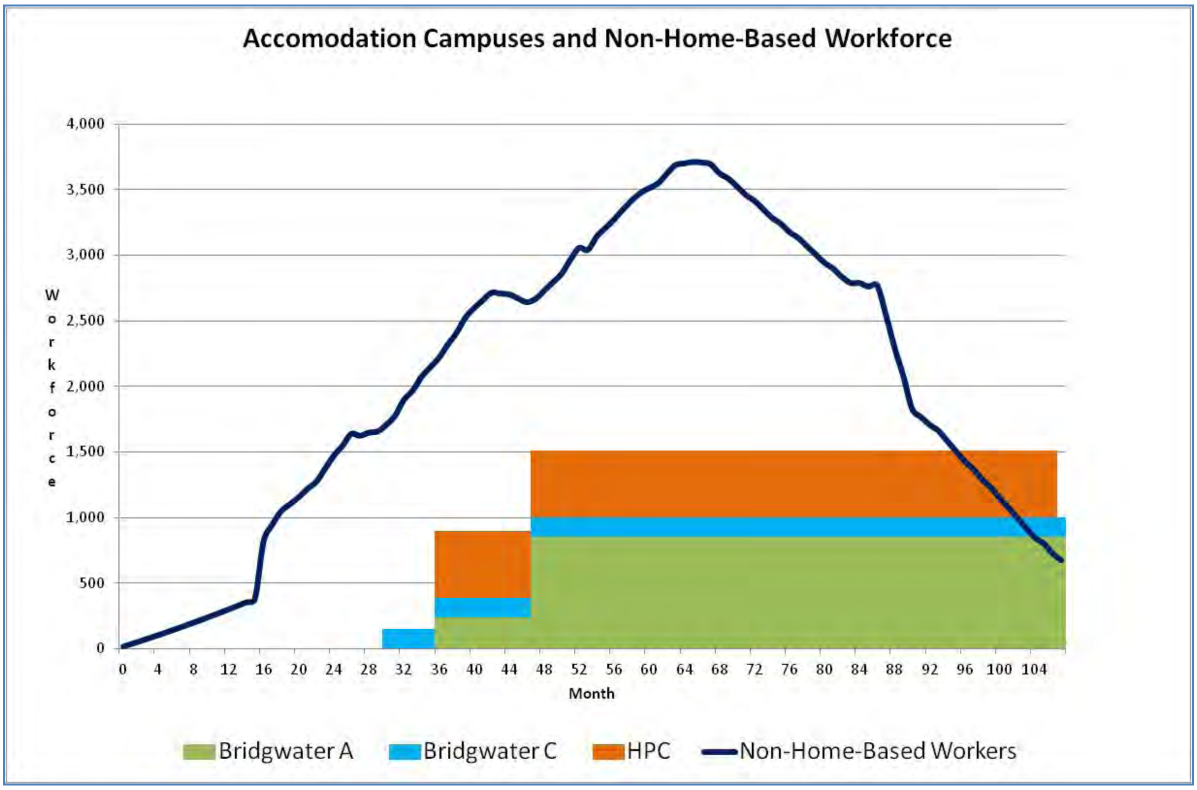
i. Accommodation Impacts

9.6.69 The central scenario for the construction phase identifies the non-home based workforce that will be required to build HPC, and that they will live within a 60 minute travel time of the HPC site. However, there are significant uncertainties related to the locations where workers will choose to live, how many non-home-based workers will be required, and which sectors of the housing market they will choose to live in. The precise location that workers choose will be dependent on a number of factors, including their duration of stay; the price and type of accommodation; access to their permanent homes, Park and Rides and the site (via direct buses); and access to amenities such as sport and leisure, and, in the case of families, schools.

9.6.70 As identified in the baseline, there are an estimated 4,200 vacant bedspaces at peak. However, some assumptions have been made relating to the likelihood/ability for non-home-based construction workers to take up accommodation in different sectors, for example affordability of tourist accommodation, where a 60% discount has been applied to take account of limited affordability of much tourist accommodation.

9.6.71 As part of the "built-in" mitigation for the scheme a campus-based accommodation strategy will underpin the development. **Plate 9.2** below shows how the construction of the campuses will be phased to reflect the numbers of workers requiring accommodation in the local area based on the central case workforce profile. It can be seen that the gap between the availability of campus accommodation and the total amount of accommodation required is at peak, in balance with the 4,200 bedspaces which EDF Energy assesses to be the minimum spare capacity available in the local area at August peak season. At the peak of construction they will provide accommodation for around 40% of the non-local workforce. The central case assumption therefore is that there is an impact of **negligible** significance on accommodation at the 60 minute drive time spatial level.

Plate 9.2: Construction Campus Phasing



9.6.72 Use of existing accommodation will be required prior to the completion of any purpose built campus accommodation provided by EDF Energy.

9.6.73 Overall, and noting that a degree of uncertainty is inherent in estimating the accommodation demand that will be generated by the project, it has been concluded that a total campus provision of around 1,500 will be provided, based on the following assumptions which are outlined in more detail in the **Accommodation Strategy**:

Table 9.60: Accommodation Analysis at Peak Construction

Accommodation at Peak Construction	
Peak workforce	5,600
Local recruitment at peak	34%
Non home based workforce requiring accommodation at peak	Approx. 3,700
Minimum spare accommodation capacity locally within 60 minutes	Approx.4,200
Additional accommodation to be provided by EDF Energy at peak	Approx.1,500

9.6.74 As well as the avoidance of impacts on the local accommodation market the campus accommodation is regarded by EDF Energy as essential because of availability for short stays, the ability to provide high quality and well managed amenities on the site, and the ability to manage workers' effects on the wider area. The on-site campus has additional advantages in that:

- Workers can either walk directly to site or take a very short bus journey within the site compound. This would materially reduce the trips of workers through Cannington and other local villages on the local road network.

- Having personnel close to site would ensure a rapid and effective response to any on-site issues or incidents.
- Minimising travel times between the accommodation campus and the construction area site helps to increase the productivity and efficiency of the workforce through minimising the effective length of their working day.
- It would be particularly beneficial for those working night shifts or irregular unsocial hours, including some supervisory and maintenance staff.

9.6.75 At the peak of construction around 3,700 (34%) of the 5,600 workforce will require accommodation locally (within the 60-minute travel distance) based on the 'central case'. It should be noted that, for several years either side of peak construction, accommodation demand generated by the project is expected to be less than this, but still substantial. It should be noted that these are "snapshot in time" figures (many employees will stay for only a limited period).

9.6.76 The scale of the HPC construction workforce, and especially the number of non-home based workers who will seek accommodation in the local area, needs to be seen in the context of wider local demographics. The non-home-based workforce will be relatively small in number when seen in the context of the existing population of Somerset (523,000) of the nearest districts of West Somerset, Sedgemoor and Taunton Deane (just under 260,000), and neighbouring North Somerset (212,200).

9.6.77 In order to assess impacts more specifically each component of the housing market has been considered separately. This includes owner occupied housing, the private rented sector, tourist accommodation, and latent accommodation.

Owner-Occupied Sector

9.6.78 Under the central scenario, it is anticipated that by the time of peak construction, around 500 workers will have moved to owner occupied properties. Some of these will eventually form part of the operational workforce, others will be long-term construction workers.

9.6.79 If spread over the first four years of the construction programme – given that those buying property are likely to arrive earlier in the construction programme and stay longer, the resulting 100+ units required per annum to accommodate the demand from non-home-based workers seeking owner-occupied units would account for less than 3% of all sales in 2009, which was a low year for sales. A comparison with the higher level of sales in 2006 reduces the figure to only 1.5%. These are very small impacts in the context of the regular churn of the owner–occupied housing market. In the context of the baseline of the total owner occupied housing stock within the three districts, an additional 500 units would only equate to 0.5% of the baseline stock.

9.6.80 As such, this impact is considered as being of **negligible** significance at all spatial scales.

Private Rented Sector

9.6.81 Based on the central scenario, around 750 non-home-based workers are expected to live in private rented accommodation at peak construction.

9.6.82 There is a substantial private rented sector accommodation (PRS) within the 60 minute zone, based on the 2001 Census, and at the time of the 2008 update included in the Housing Needs Survey (HNS) that was undertaken as part of the local authorities' Strategic Housing Market Assessment.

9.6.83 In total it can be seen that there are around 21,800 PRS units in the 60 minute zone equating to around 50,796 bedspaces.

9.6.84 The overall vacancy rate for dwellings in West Somerset, Sedgemoor and Taunton Deane were set out in the Strategic Housing Market Assessment (SHMA) at 3.5%, 4.2% and 3.3% respectively. However, there is significant difference in vacancy between tenures. The latest results from the 2008 English Housing Survey show national average vacancy rates by tenure of housing (where the tenure assigned to vacant properties relates to the previous occupancy), as follows:

- owner occupied: 2.7% of properties vacant;
- social rented: 4.6% of properties vacant; and
- private rented: 13.3% of properties vacant.

9.6.85 It is also important to note the degree of annual turnover (or 'churn') in the property market. The greater the degree, the more dynamic is the market. There is no comprehensive data on levels of turnover within the local housing stock; however evidence from the SHMA and the Census indicates the following annual turnover (churn) rates:

- West Somerset: 13%.
- Sedgemoor: 20%.
- Taunton Deane: 24%.

9.6.86 An indication of the likely degree of turnover can also be obtained from national survey-based evidence. The English Housing Survey provides data on the proportion of households living in their current home for less than a year (EHS Annual Household Report 2008/09). This provides an indication of typical annual turnover in the housing stock, and illustrates for example the very high churn in the private rented market. The latest results for 2008 are as follows:

- owner occupied: 4% of households have moved within the last 12 months;
- social rented: 8% of households have moved within the last 12 months; and
- private rented: 36% of households have moved within the last 12 months.

9.6.87 In order to understand the spare capacity in the private rented sector, this assessment has sought to break capacity down into two components. First, to operate effectively housing markets need a small level of capacity to allow for people in the process of moving, or the process of letting homes: this is called "frictional" capacity. Any capacity on top of that can be described as additional or spare capacity and it is this capacity that has been assumed would be available to HPC workers. There is no single data source which provides this capacity at the local level so a combination of national and local datasets has been used to identify some parameters.

9.6.88 Using the English Housing Survey data some parameters can be established. The annual churn rate of 36% equates to 3% of all properties turning over in each month. This would be the absolute minimum vacancy required for the market to turnover. However, using the same dataset, the vacancy rate at a given point in time is 13%, which suggests a maximum spare capacity of up to 10%.

9.6.89 Using more local data (HSSA, 2009), annual turnover is highest in Taunton Deane at 24%, which means 2% of all stock turns over each month. This sets the minimum benchmark for spare capacity required for the market to function. The local vacancy rate in the PRS is not known, however if it is similar to the national rate this suggests capacity up to a maximum of 11%.

9.6.90 Given the high levels of churn in the market, it is possible that genuinely spare capacity could be used, but that this could appear to be displacing existing tenants, either because it is concentrated in one location or in one part of the market, e.g. for the cheapest accommodation. However, the assessment suggests that the scale of demand from non-home-based workers will be low enough to prevent this happening. As such, this impact is considered as being of **negligible** significance at all spatial scales**.**

Tourist Sector

9.6.91 It is estimated in the central scenario that at peak around 600 non-home-based workers will live in tourist accommodation in the 60-minute area, in serviced, self-catered and caravan/camping sectors.

9.6.92 Moreover Somerset has a substantial tourist accommodation industry, where each year some 2.4million visitors spend almost 10million nights (Ref. 9.79). Relative to that, demand for accommodation from the HPC workforce will be small.

9.6.93 There are approximately 50,000 tourist bed spaces within the 60 minute zone, or 35,000 excluding holiday villages, based on 2009 South West Tourism data. This is an underestimate of the total tourist accommodation in the area because it only includes accredited or “rated” accommodation and there are many businesses that are not rated and therefore do not appear on the SWT database.

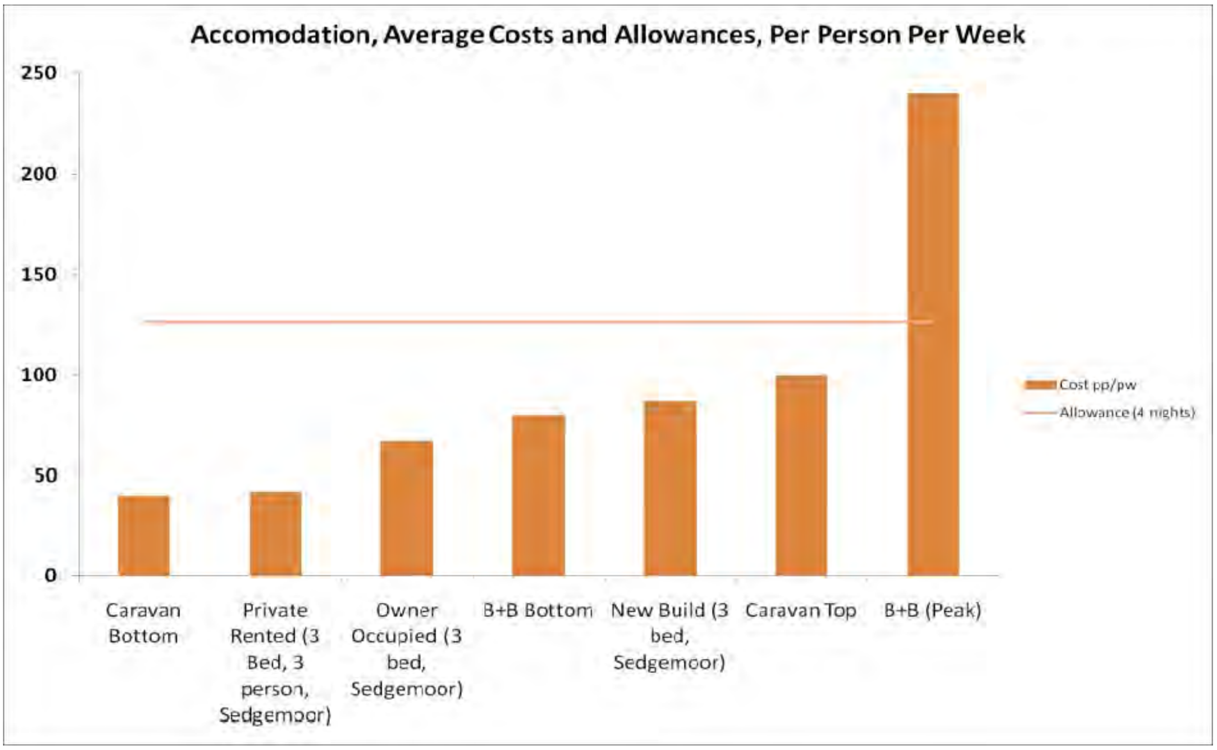
9.6.94 There are also significant fluctuations in the occupancy/vacancy levels of tourist accommodation based on seasonality. In assessing the potential availability of tourist accommodation for EDF Energy’s workforce, a conservative estimate has been made, based on the peak levels of tourist demand in August. Average occupancy levels for this accommodation outside of peak holiday periods are typically much lower – there are 24,500 vacant bedspaces in March and 6,500 in August.

9.6.95 There is therefore a large pool of tourist accommodation that could potentially be utilised by the construction workforce in off-peak periods. Use of some of this accommodation during off-peak periods would clearly offer economic benefits to tourist accommodation providers and other related local businesses.

9.6.96 However, it is recognised that not all of this accommodation is suitable for workers. Some rooms will be double or family rooms which workers are unlikely to want to share. There are also planning restrictions on the use of camping and caravan sites. These include restrictions on the use of sites during winter months, limits on the length of time a person can occupy a site and restrictions on non-tourist use. This will reduce the available supply to HPC workers below the figure above (and also limit demand to those who want only short-stay accommodation).

9.6.97 In addition, some accommodation will not be affordable to workers. The average costs per week of different forms of accommodation have been compared against a union-agreed accommodation allowance paid to construction workers. This shows that a significant proportion of serviced tourist accommodation will not be affordable to HPC construction workers, highlighted in the following chart:

Plate 9.3: Accommodation, Average Costs and Allowances Per Person Per Week



9.6.98 However, caravans and the bottom end of the bed and breakfast market will be accessible in price terms. To account for the fact that not all serviced accommodation will be suitable or affordable; a 60% discount has been applied to availability. That leaves an estimate of in the region of 2,070 spare bedspaces in August:

Table 9.61: August Vacancy

Type	August Vacant and Affordable
Serviced	840
Self-catering	172
Caravan/Camping	1,058
TOTAL	**2,070**

9.6.99 In practice, the risk of adverse effects on the tourism sector will also be further reduced by the seasonal pricing operating within tourist markets. Providers tend to put their prices up quite significantly over the peak holiday periods, such that it would not be affordable for the vast majority of HPC workers. This is likely to act to significantly reduce the take up by the HPC construction workforce of tourist accommodation during peak periods – for example the average price of a hotel or bed and breakfast accommodation in Somerset in August is substantially above the normal union-agreed accommodation allowance for the majority of the construction workforce. Therefore, the normal operation of market mechanisms would be likely to encourage the use of tourist accommodation mainly during the cheaper non-peak periods when there is significant spare capacity and when the tourism industry stands to benefit from the additional demand generated by the construction workforce.

9.6.100 There will also be a beneficial economic impact resulting from the spend by non-home-based construction workers on nights in tourist accommodation, off-peak and year-round, as identified above. Overall impacts on the tourist accommodation sector are anticipated to be of **negligible** significance at the 60 minute level.

Latent Sector

9.6.101 In addition to the above, it is expected that a proportion of non-home-based workers will live in accommodation that is considered ‘latent’ (i.e. not identified as being currently or previously rented, or within the tourist sector).

9.6.102 The central scenario estimates that around 400 non-home-based workers would live in latent accommodation at peak construction.

9.6.103 There is evidence from the responses to EDF Energy’s consultations and accommodation surveys of a high level of interest from local providers to offer accommodation to the construction workforce.

9.6.104 EDF Energy placed newspaper adverts on two separate occasions inviting potential landlords to register their property if they wished to offer accommodation to the HPC construction workforce. The initial response to these provided 750, of which over 450 were genuinely “additional” to existing supply, i.e. they had not been offered for rent before. This additional accommodation can be used without any risk of displacing existing residents. As at September 2011 the EDF Energy Accommodation database had increased further to 1,500 properties.

9.6.105 It is likely that the amount of latent accommodation of this kind will increase over time as the construction phase starts and more people realise that they can take advantage of the commercial opportunities which arise from it. Once people are aware of construction workers arriving in the area, and see others they know renting out rooms, it is likely that more people will come forward with offers of rooms to rent. EDF Energy has recently contacted those who expressed an interest in providing accommodation to check their availability and from a limited sample it appears that most of the rooms remain available to rent.

9.6.106 Given the economic impact of bringing forward rooms for rent, the impact on latent accommodation is estimated as being temporary and of **minor beneficial** significance at the 60 minute travel area level.

Summary

9.6.107 Overall, there is clear evidence that some local accommodation sources have significant spare capacity at certain times of the year (notably tourist accommodation during off-peak periods).

9.6.108 Based on the above analysis it is estimated that, during the peak tourist period, and looking across all sources of accommodation, the minimum capacity that HPC construction workers would be able to use without creating any risk of significant disruption to accommodation markets is 4,200 spaces. As explained above, this figure is based on very conservative assessments of spare capacity, in particular in relation to tourist accommodation where there is much more spare capacity outside the peak tourist season. For most of the year, there will be much more accommodation available without any risk of significant disruption to accommodation markets.

9.6.109 As a result of this analysis, EDF Energy has concluded that it is reasonable to assume that at least 4,200 bed spaces will be available locally to support the accommodation of the HPC construction workforce without displacing local people or tourists. Use of local accommodation up to this level will offer net positive benefits to the local area and economy, with a low risk of any material negative impacts. For the reasons set out above this is a very conservative estimate and there is potential to use much more tourist accommodation, in particular outside of the peak holiday periods.

9.6.110 Additionally, the demand created by the project should help to stimulate improvements in the existing housing and tourist stock, thus generating legacy benefits.

Sensitivity and Thresholds

9.6.111 The previous section highlights that there are defined negligible impacts within the owner-occupied sector, given the relative size of existing supply, levels of churn/migration, compared to the estimated non-home-based worker demand for this kind of accommodation.

9.6.112 However, there is a level of uncertainty related to other sectors, most notably the tourist and private rented sectors. The following tables identify variations on the central scenario of workers anticipated in each sector, and in specific locations based on the gravity model central assumptions.

9.6.113 Increased numbers could occur if there were more workers overall, a higher proportion of non-home based workers or if they were to occupy different locations. The tables show each of the "ward clusters" and compare their available accommodation capacity (at peak August season for tourism accommodation) to the likely number of workers using the central scenario, 600 workers at peak for the tourist sector and 750 for private rented accommodation. It then shows capacity where there are higher numbers of construction workers using the same distribution.

9.6.114 Those areas highlighted in red are where the number of workers could exceed capacity.

Tourist Sector

9.6.115 **Table 9.62** demonstrates that HPC would be likely to have a **negligible** impact on the supply of bedspaces in all areas except for Cannington and Bridgwater, and an overall **negligible** impact for all scenarios. It could have a moderate adverse impact in Cannington before mitigation for higher scenarios.

9.6.116 Cannington is sensitive to the central case scenario and Bridgwater would be sensitive to a two-thirds increase in the number of workers demanding tourist accommodation at peak construction in the August peak. At other times of the year there would not be a problem. Even if there were higher demand in those two clusters it is unlikely to have wider economic impacts as tourists seeking accommodation in the area should be able to find alternatives in other clusters in the local area.

Table 9.62: Tourist Sector: Sensitivity Analysis

Forecast Available Capacity Levels – August			Non-home-based Construction Workers Sensitivity Scenarios						
			596	750	1,000	1,250	1,500	1,750	2,000
Ward Cluster/Available Bedspaces	Bridgwater	100	70	80	110	140	170	200	220
	Burnham and Highbridge	590	200	250	340	420	500	590	670
	Cannington	20	30	40	50	60	70	80	90
	Cheddar	230	40	50	70	80	100	120	130
	Glastonbury	90	40	50	70	80	100	120	130
	Hinkley Point	10	0	0	0	0	10	10	10
	Minehead	230	50	60	80	100	120	140	170
	Somerset South	80	10	10	10	20	20	20	30
	Somerset West	80	10	10	10	10	10	20	20
	Taunton	170	30	30	50	60	70	80	90
	Watchet and Williton	120	60	70	100	120	150	170	200
	Weston-super-Mare	360	70	90	110	140	170	200	230
	60-minute Area	2,050	600	750	1,000	1,250	1,500	1,750	2,000

Private Rented Sector

9.6.117 **Table 9.63**, below, demonstrates that HPC would be likely to have a **negligible** impact on the supply of private rented accommodation in all areas in the central scenario. The Bridgwater, Cannington and Williton and Watchet clusters could be sensitive to a one-third increase in demand. In general the potential impacts on the private rented sector would be more sensitive to increased demand than those on tourism – as highlighted in red where the number of workers could exceed capacity.

Table 9.63: Private Rented Sector Sensitivity Analysis

Ward Cluster/Available Bedspaces		Non-home-based Construction Workers Sensitivity Scenarios					
		750	1,000	1,250	1,500	1,750	2,000
Bridgwater	130	110	150	180	220	260	290
Burnham and Highbridge	90	60	80	110	130	150	170
Cannington	20	20	30	40	50	60	60
Cheddar	20	10	10	20	20	30	30
Glastonbury	60	20	30	40	40	50	60
Hinkley Point	10	10	10	10	20	20	20
Minehead	60	30	40	50	60	70	80
Somerset South	80	30	40	50	60	70	80
Somerset West	40	10	10	10	10	20	20
Taunton	240	130	180	220	270	310	360
Watchet and Williton	30	30	40	40	50	60	70
Weston-super-Mare	780	290	380	480	570	670	760
60-minute Area	1,570	750	1,000	1,250	1,500	1,750	2,000

9.6.118 Whilst the ward clusters provide a useful way of understanding the balance of supply and demand at a more local level, it must be remembered that the tables provide a static snapshot of the position at the current time. In reality the market is dynamic and existing residents already move both within and between districts and out of the area altogether. Analysis of the 2001 Census shows that only 37% of household moves in Sedgemoor and West Somerset were within the same ward so, as with tourism, there is some degree of movement between clusters from other sources of demand.

ii. Population and Population Dynamics/Structure

9.6.119 The population structure of the 60-minute travel area is likely to experience a level of change associated with the presence of a non-home-based construction workforce. Based on the central case, as described above, there would be an overall increase of approximately 3,700 non-home-based workers within the 60-minute area, distributed across the area. This distribution has been assessed against average annual population turnover (new residents taken from Census 2001 Moving Groups data) to identify the proportion of non-home-based workers compared with ‘usual’ turnover:

Table 9.64: Non Home Based Workers as Proportion of Annual New Residents

Ward Cluster	Total New Residents in 2001	% New Residents in 2001	Non-home-based construction workers at peak	Non-home-based workers as % of Average Annual New Residents
Bridgwater	2,461	5.5%	1,392	57%
Burnham and Highbridge	2,701	7.0%	378	14%
Cannington	556	8.1%	120	22%
Cheddar	725	7.2%	109	10%
Glastonbury	2,188	8.2%	81	4%
Hinkley Point and Stogursey	134	6.5%	496	370%
Minehead	1,408	8.7%	119	8%
Somerset South	2,009	7.5%	55	3%
Somerset West	836	8.0%	19	2%
Taunton	5,380	8.1%	362	7%
Watchet and Williton	757	7.0%	150	20%
Weston-super-Mare	6,049	5.5%	454	8%

9.6.120 As the table demonstrates the area which would have the largest proportionate population impact would be the Hinkley Point and Stogursey area adjacent to the site – principally because of the on-site campus. Bridgwater, being the nearest main town and location of the two other purpose built campuses would be likely also see a population increase at peak of over 50% the annual average increase. These would both be temporary **major impacts** at the local level. Cannington and Williton could also see **moderate temporary** impacts in terms of population growth. Impacts are likely to be **minor** or **negligible** for all other clusters.

Sensitivities and Thresholds

9.6.121 As highlighted in **Table 9.65** there is a baseline level of population 'turnover' within each ward cluster each year, against which the significance of the increase in non-home-based workers is assessed, outlined in the following table. This is set against sensitivity levels whereby the non-home-based workforce is increased by up to 50% on the central case, identifying a similar significance level to the central case, although 'moderate' significance in Burnham and Highbridge at 40% increase.

Table 9.65: Non Home Based Workers as Proportion of Annual New Residents: Sensitivity Test

Non-home-based construction workers			non-home-based workers as % of Average Annual New Residents					
			Central Case	10%	20%	30%	40%	50%
	Bridgwater	1,392	57%	62%	68%	74%	79%	85%
	Burnham and Highbridge	378	14%	15%	17%	18%	20%	21%
	Cannington	120	22%	24%	26%	28%	30%	32%
	Cheddar	109	10%	11%	12%	13%	14%	15%
	Glastonbury	81	4%	4%	4%	5%	5%	6%
	Hinkley Point	496	370%	407%	444%	481%	519%	556%
	Minehead	119	8%	9%	10%	11%	12%	13%
	Somerset South	55	3%	3%	3%	4%	4%	4%
	Somerset West	19	2%	3%	3%	3%	3%	3%
	Taunton	362	7%	7%	8%	9%	9%	10%
	Watchet and Williton	150	20%	22%	24%	26%	28%	30%
	Weston-super-Mare	454	8%	8%	9%	10%	11%	11%
	60-minute Area	3,700	15%	16%	18%	19%	21%	22%

9.6.122 It is not possible to identify the extent to which a population impact is "beneficial" or adverse" without considering the specific impacts which that population might have. This is dealt with further below. The area immediately around Hinkley Point is unlikely to see the higher proportions of workforce as there will be limited availability of accommodation outside the campuses.

iii. Public Services

9.6.123 The introduction of a new non-homed-based workforce into the 60 minute travel zone could have impacts on demand for public services, and the ability of service providers to respond. Demand will vary between different types of service depending on how the demographic profile of the workforce (particularly age and gender), and in some cases the location of workers.

9.6.124 Current services in the area which might have some relevance to the HPC workforce can be split between the following key service providers and topic areas. The proportions of public expenditure relate to service provision and therefore exclude benefit payments. This does not include the Unitary Authority of North Somerset which is also likely to house some non-home based workers and provides, for its area, all of the services provided by the Districts and the County.

9.6.125 Somerset County Council (SCC) (responsible for around 40% of public expenditure):

- Education and Social Services (between them accounting for around 80% of SCC expenditure).
- Regulatory and Environmental Services (County/District).
- Economic Development and Tourism (County/District).

- Libraries.

9.6.126 District Councils – mainly West Somerset and Sedgemoor (around 5% of public expenditure):

- Housing.
- Leisure.
- Economic Development and Tourism (District/County)).
- Regulatory and Environmental Services (District/County).

9.6.127 Emergency Services (around 10% of public expenditure):

- Policing.
- Fire.

9.6.128 Health (around 45% of public expenditure):

- Primary Care Trust – Commissioning services.
- Ambulance Service Trust (Providing Services).
- Other Health Trusts (Providing Services).

9.6.129 With the exception of health services all other services are funded by a combination of Council Tax, Central Government grants and fees. Health services are funded by a complex grant formula from Central Government.

9.6.130 Where workers are living in accommodation where they pay Council Tax, this should in effect self “mitigate” the impacts of their demand, and similarly where there are fees and charges for services (e.g. leisure). In theory central Government grant formulae should also respond to changing population, however they are generally based on population estimates which don’t take into account short term migrant workers and funding can be slow to adjust.

9.6.131 It should be noted more broadly that migrant construction workers generally make a net contribution to the national exchequer on the basis that they are in work and generally of age groups (younger) and in household types (with few dependents) that make less demand on public services, for example on social services, education and acute healthcare.

9.6.132 The assessment of the key service areas below therefore identifies a “gross” impact, based on the workforce model and spatial spread, and then a net impact on the basis of “automatic mitigation” by services provider and management proposals by EDF Energy for certain services. It is against the latter assessment that significance criteria are attached and any mitigation measures required. The assessment also identifies uncertainties, giving consideration to sensitivities and thresholds should the central case be exceeded.

9.6.133 This section covers all of the services listed above with the exception of housing services – which is covered in the accommodation section) and Tourism and Economic Development (which is covered in the economic impacts section).

f) County Council Services

i. Education – Gross Impacts

9.6.134 Demand for education provision would come from the children of non-home-based workers in the family type households identified above. The table below shows the possible spread of those family households, at peak, based on the owner occupied component of the gravity model. Experience from Sizewell suggests that family based workers are likely to arrive earlier and stay longer, so it is likely that these families will build up over the five years prior to the peak. Evidence also suggests that these families are likely to be more widely spread than single person non-home-based households.

Table 9.66: Spatial Spread of Family-type Households with Children in Non-home-based workforce

	Family Type Households	Pre-school	Primary	Secondary
Bridgwater	108	18	37	27
Burnham and Highbridge	74	13	26	18
Cannington	37	6	13	9
Cheddar	12	2	4	3
Glastonbury	6	3	6	5
Hinkley Point	6	1	2	2
Minehead	17	3	6	4
Somerset South	19	3	6	5
Somerset West	4	1	2	1
Taunton	83	14	29	21
Watchet and Williton	24	4	8	6
Weston-super-Mare	98	17	34	24
60-Minute Travel Distance	500	85	174	124

ii. Pre-School

9.6.135 Based on estimates of children of pre-school age taking residence within the area as a result of a non-home-based worker population in the area there are likely to be around 37 pre-school aged children in Sedgemoor, 17 in Taunton Deane, nine in West Somerset, 17 in North Somerset and 5 in Mendip. As such, against the assessed levels of sufficiency and existing provision, the impact at district-level is considered to be **negligible**.

iii. Education – Net Impacts

9.6.136 The way education demand interacts with current and projected education capacity depends whether the children are net additional to current demand. It is likely that if they live in owner occupied family accommodation they will be included in current and future projections as they are part of the overall housing market "churn". If families live in private rented accommodation they may contribute to net additional demand for school places. In either case the "revenue" cost of providing for additional pupils is formula based and these households will also be paying Council tax. Therefore the only impact would be if additional "physical capacity" was required to meet demand, or if high levels of turnover or mobility put increasing pressure on school resources.

9.6.137 The following tables outline the current capacity in local ward clusters and across the 60-minute travel area, and identify the possible impact at each locality of the forecast child population if they were all net additional.

Table 9.67: Primary Education Capacity Change as a Result of Forecast Population Increase (Primary School Places)

	Current Capacity	Current Surplus Places	Current Surplus Capacity	Possible HPC Children	Surplus Capacity If All Net Additional
Bridgwater	3,831	185	5%	37	4%
Burnham and Highbridge	2,995	177	6%	26	5%
Cannington	630	33	5%	13	3%
Cheddar	822	154	19%	4	18%
Glastonbury	2,708	535	20%	6	20%
Hinkley Point	84	21	25%	2	22%
Minehead	1,032	370	36%	6	35%
Somerset South	2,415	548	23%	6	22%
Somerset West	644	99	15%	2	15%
Taunton	5,551	372	7%	29	6%
Watchet and Williton	627	206	33%	8	32%
Weston-super-Mare	9,545	1,403	15%	34	14%
60-Minute Travel Distance	30,884	4,103	13%	174	13%

Table 9.68: Secondary Education Capacity Change as a Result of Forecast Population Increase (Secondary School Places)

	Current Capacity	Current Surplus Places	Current Surplus Capacity	Possible HPC Children	Surplus Capacity If All Net Additional
Bridgwater and Cannington	3,802	264	7.5%	36	6.0%
Burnham and Highbridge	1,980	-49	-2.4%	18	-3.4%
Cheddar	1,754	58	3.4%	3	3.1%
Glastonbury	1,090	-8	-0.7%	5	-1.2%
Minehead	2,202	292	15.3%	4	13.1%
Somerset South	860	38	4.6%	5	3.9%
Somerset West	725	-55	-7.1%	1	-7.7%
Taunton	4,274	31	0.7%	21	0.2%
Watchet and Williton	464	68	17.2%	6	13.4%
Weston-super-Mare	7,305	810	12.5%	24	10.8%
60-Minute Travel Distance	24,456	1449	6.3%	124	5.4%

9.6.138 On this basis, and assuming the central case scenario, the non-home based workforce could have a **negligible** impact at the 60 minute level, with a possible minor adverse impact in specific locations, including Bridgwater and possibly Cannington and Taunton.

9.6.139 It should be noted that as a result of increasing birth rates school rolls in Bridgwater and Taunton and some other areas at primary school level are anticipated to rise and capacity fall in future years. This is a background trend and will require new school places regardless of HPC but will need to be considered in monitoring and planning any mitigation measures.

iv. Childcare and Education – Sensitivity and Thresholds

9.6.140 There are two variations to the assumptions that have the potential to change the assessment of the impacts. These would be:

- More workers with dependent families
- Concentrations of workers in different locations from those suggested by the gravity model

9.6.141 The table below therefore tests the possible impacts on education services. Those scenarios highlighted in yellow are where capacity could move within 5% of total places and therefore result in an increased impact at the local level. The impact sensitivities take into account the existing baseline levels of surplus capacity, relative to the effect of the proposed development, since some areas are already close to capacity currently.

9.6.142 The following table highlights the sensitivity of the impact of the non-home-based construction workers' families on primary education capacity across the 60-minute travel area. It uses as threshold standard school planning measures, with a major impact being where a school was taken over capacity, a moderate impact where a school came within 5% of its capacity, and a minor impact within 10% of its capacity.

9.6.143 The table shows that Bridgwater schools are already within the 5% threshold, but that Burnham and Highbridge and, particularly, Cannington could be taken within the 5% threshold with a small uplift in numbers.

Table 9.69: Primary Education Capacity Sensitivity

	Baseline	Central Case	25%	50%	75%
Bridgwater	4.8%	3.9%	3.6%	3.4%	3.1%
Burnham and Highbridge	5.9%	5.1%	4.8%	4.6%	4.4%
Cannington	5.2%	3.2%	2.7%	2.2%	1.7%
Cheddar	18.7%	18.2%	18.0%	17.7%	17.4%
Glastonbury	19.8%	19.5%	19.5%	19.4%	19.3%
Hinkley Point	25.0%	22.5%	21.9%	21.3%	20.6%
Minehead	35.9%	35.3%	35.1%	35.0%	34.9%
Somerset South	22.7%	22.4%	22.4%	22.3%	22.2%
Somerset West	15.4%	15.1%	15.1%	15.0%	15.0%

	Baseline	Central Case	25%	50%	75%
Taunton	6.7%	6.2%	6.1%	5.9%	5.8%
Watchet and Williton	32.9%	31.5%	31.2%	30.9%	30.5%
Weston-super-Mare	14.7%	14.3%	14.3%	14.2%	14.1%
60-Minute Travel Distance	13.3%	12.7%	12.6%	12.4%	12.3%

9.6.144 The following table highlights the sensitivity of the impact of the non-home-based construction workers' families on secondary education capacity across the Schools Planning Areas within the 60-minute travel area, highlighting that the change in capacity is largely negligible in local areas, although may be specific to individual schools, and several of the areas are operating close to or at capacity at present.

Table 9.70: Secondary Education Capacity Sensitivity

	Baseline	Central Case	25%	50%	75%
Bridgwater and Cannington	**7.5%**	6.0%	5.8%	5.5%	5.3%
Burnham and Highbridge	**-2.4%**	-3.4%	-3.6%	-3.8%	-4.1%
Cheddar	**3.4%**	3.1%	3.0%	3.0%	2.9%
Glastonbury	**-0.7%**	-1.2%	-1.3%	-1.4%	-1.5%
Hinkley Point	**N/A**	N/A	N/A	N/A	N/A
Minehead	**15.3%**	13.1%	13.0%	13.0%	12.9%
Somerset South	**4.6%**	3.9%	3.7%	3.6%	3.5%
Somerset West	**-7.1%**	-7.7%	-7.8%	-7.8%	-7.8%
Taunton	**0.7%**	0.2%	0.1%	0.0%	-0.1%
Watchet and Williton	**17.2%**	13.4%	13.1%	12.7%	12.4%
Weston-super-Mare	**12.5%**	10.8%	10.7%	10.6%	10.6%
60-Minute Travel Distance	**6.3%**	5.4%	5.3%	5.2%	5.0%

v. Social Services

9.6.145 Around 20% of Somerset County Council's Social Services expenditure is on children and families on which an additional "family" population may impact. The majority of the remaining expenditure is on older people and therefore unlikely to be impacted on by the HPC workforce. Possible "indirect" impacts are dealt with below under "Community Cohesion".

vi. Gross Impacts

9.6.146 The 380 children living in households with non-home-based workers represent approximately 0.2% of the total number of children in Somerset and North Somerset. As these are authority wide services specific local capacity issues are not relevant.

vii.Net Impacts

9.6.147 It is anticipated that all family households will live in accommodation through which they will pay Council Tax. As noted above, those living in owner occupied accommodation are unlikely to be additional to the current population. Net additional impact on social services is therefore regarded as ***negligible*** at all levels.

viii. Sensitivity and Thresholds

9.6.148 As it is assumed that all family households will live in accommodation where they pay Council Tax which should mitigate any impacts, an increase in such households would be likely to have a negligible impact on services at all levels.

ix. Other County Council Services Impacts

9.6.149 Due to the demographic profile of the non-home based workforce – mainly single, male and of working age – their likely shift patterns, and the temporary nature of much of the workforce – impacts on other County Council run services for example libraries, arts and other cultural services are assumed to be negligible.

District Council Services

x. Leisure – Gross Impacts

9.6.150 The non-home based workforce is likely to create some additional demand for leisure provision. In order to assess the scale of this the age and gender profile of the non-home-based workforce has been entered to Sport England's Sports Facilities calculator (SFC), both for the peak and the average workforce, to identify the likely demand for provision.

9.6.151 The sports facilities calculator relates to the need for new facilities for new permanent residential communities. The following table shows the additional demand at the peak and the average across the whole construction period. The non-home-based workforce is only temporary and therefore an adjustment has been made to take account of this. **Technical Note 5** (**Appendix 9E**), breaks this assessment down to the main accommodation clusters, which given the likely very small overall demand, confirms negligible requirements at all levels.

Table 9.71: Sports Facilities Calculator

		Average Non-home-based Workforce over Construction Period	Peak Non-home-based Construction Workforce	Permanent Equivalent (Average)
Pools	Area	17.24	35.92	11.21
	Lanes	0.32	0.68	0.21
	Pools	0.08	0.17	0.05
Halls	Courts	0.62	1.29	0.40
	Halls	0.15	0.32	0.10
Indoor Bowls	Rinks	0.09	0.18	
	Centres	0.01	0.03	
Synthetic Pitches	Pitches	0.09	0.19	

9.6.152 **Table 9.71** highlights the overall requirements for sports facilities across the 60-minute travel area arising from the non-home-based workforce in terms of facilities and proportions of facilities.

9.6.153 In addition to the SFC, Sport England has produced typologies of demand for a wider range of sports, based on key demographics such as age, gender and employment. For the demographic of non-home-based workers, football and going to the gym are by far the activities most in demand, along with cycling which is undertaken by a much smaller proportion. There is very limited demand for swimming, and racquet sports.

9.6.154 Demand for sports facilities is therefore very modest and is likely to be able to be met from existing provision. The exception to this is where there is already a significant deficiency in sports provision, for example swimming pools in Minehead and Bridgwater, although as noted above the increased demand would in any case be small.

xi. Leisure – Net Impacts

9.6.155 Those workers living in private rented and owner occupied accommodation will contribute to the revenue costs of service provision through Council Tax. In addition most Council leisure services are subject to fees and charges and users will therefore be making a net contribution to that provision. For those workers living in campus accommodation EDF Energy will be providing on site sports provision. This will include one full size grass football pitch and two all weather 5-a-side pitches in the Bridgwater-A campus, one all-weather 5-a-side pitch at the Bridgwater-C campus, and two all weather 5-a-side pitches at the on-site accommodation campus. This will meet the main likely preferences of the construction workforce. The impact on leisure provision is therefore likely to be **negligible** at all levels.

xii. Leisure – Sensitivity and Thresholds

9.6.156 The non-home-based workforce would need to more than double to generate a net impact on provision greater than that already being provided through the campus facilities. Impacts on other sports provision are likely to remain negligible in any plausible scenario.

xiii. Regulatory and Environmental Services – Gross Impacts

9.6.157 The District Councils provide a range of regulatory and environmental services. These include:

- Waste Collection.
- Street Cleaning.
- Food Safety, Health and Safety, Pest Control and Public Health.
- Crime Reduction and Community Safety.

9.6.158 It is likely that a net temporary increase in population would require a proportionate increase in the delivery of these types of services although there is no detailed method for identifying impacts on specific services.

xiv. Regulatory and Environmental Services – Net Impacts

9.6.159 Those workers living in private rented and owner occupied accommodation will already be paying for these services through Council Tax. In addition, all accommodation providers (including the campus and tourist accommodation providers who may pay business rates) will be required to pay for waste collection.

9.6.160 There may be a small increase in demand for services, other than waste collection – which the facilities manager or EDF Energy will be required to pay for -, as a result of workers living in campuses and temporary accommodation. The central case assumption is that around 2,500 of the 3,700 peak workforce will live in these types of accommodation. This represents less than 1% of the total current population of the three immediate districts and is therefore a negligible impact at the local level.

9.6.161 However due to the location of the campuses and therefore a concentration of these workers in two specific locations, Bridgwater and Stogursey, the local significance is likely to be greater in these locations. In Bridgwater the increase would be just over 2%, and at the site 23%, although in the latter case this would be a self-contained campus.

Table 9.72: Non Home Based Workers in Non-Council Tax Accommodation

	Non-home-based Construction Workers in Non Council Tax Accommodation	Total Population	%
Bridgwater	1,180	50,380	2%
Burnham and Highbridge	100	39,009	0%
Cannington	60	7,142	1%
Cheddar	50	26,219	0%
Glastonbury	40	19,081	0%
Hinkley Point	480	2,104	23%
Minehead	70	14,140	0%
Somerset South	10	20,802	0%
Somerset West	10	4,814	0%
Taunton	150	77,748	0%
Watchet and Williton	100	11,026	1%
Weston-super-Mare	200	83,608	0%
TOTAL	**2,450**	**375,684**	**1%**

xv.Regulatory and Environmental Services – Sensitivity and Thresholds

9.6.162 This impact is potentially sensitive to a higher non-home-based workforce, a higher proportion of people living in tourist, or latent accommodation, and/or fewer in campuses. Any increase in non-home-based workers in these accommodation types would be likely to be more thinly spread as the main concentrations of population are caused by campus accommodation. The proposed monitoring system would identify the non-home-based workforce by location and type of housing and could therefore be used to manage and mitigate any additional impacts.

xvi. Crime, Anti-Social Behaviour and Policing

Gross Impacts

9.6.163 An increase in population arising from the non-home based workforce could have impacts on crime and anti-social behaviour, and consequent impacts on the requirement for policing services.

9.6.164 Likely impacts on crime are difficult to estimate as they will depend on both the behaviour of workers and the behaviour of current residents.

9.6.165 Using the construction of Hinkley Point A and B stations as a guide, there are indications that some increases above the norm in behavioural offences, such as drunkenness, minor public disorder, and car theft could occur. Increases in traffic could increase road accidents.

9.6.166 More recent experience from the construction of Sizewell B in the 1990s suggests some increases above the norm in petty crime and behavioural offences, such as drunkenness, minor public disorder and traffic incidents and offences, although the introduction of appropriate mitigation measures meant that rates fell even with major increases in the construction workforce.

9.6.167 EDF Energy has been working with Avon and Somerset Constabulary to anticipate the potential scale of impacts based on current incident rates in the area – on the assumption that a small proportion of non-home based workers and their families, like the current population – could be both perpetrators and victims of crime.

9.6.168 As noted in the baseline assessment, Somerset West Police District of the Avon and Somerset Constabulary covers the districts of West Somerset, Sedgemoor and Taunton Deane. Rates of crime and disorder vary between different parts of the District with very low rates in the more rural areas and higher rates (although at or slightly below the national average) in urban areas.

9.6.169 Avon and Somerset Constabulary's STORM and crime data identifies an average of 191 total incidents including 47 crimes per 1,000 head of population each year. It should be noted that around a third of the crime numbers relate to domestic violence which is likely to be lower for the HPC non-home based workforce given the low proportions of non-home-based workers with families, although some other rates could be higher e.g. "Nighttime economy crime". Application of these rates to the 4,725 HPC associated residents – 3,700 non-home-based workers and 1,025 family members at peak – would equate to around 902 incidents of which around 222 could be crimes. This would equate to 1.8% of current incidents and crimes. For the average annual workforce of 1,750, with a possible 375 family members, this would equate to around 400 incidents, and 98 crimes. This would equate to 0.7% of current incidents and crimes.

Net Impacts

9.6.170 Current police services are paid for through Police Grant, which is formula-based funding based on a range of demographic, social, economic and crime indicators, and through Council Tax. Those non-home-based workers living in owner occupied accommodation and private rented accommodation, which is likely to include up to 1,250 of the workforce and all households with families and dependents, will therefore have their services funded through normal mechanisms like any other local resident.

9.6.171 This would leave a potential net impact of around 470 incidents and 115 crimes at peak, equating to 0.9% of current incidents and crimes at peak. This is regarded as a **negligible** impact at the West Somerset Police District level.

9.6.172 There is the potential for crime and disorder to be concentrated in locations where there will be a significant concentration of non-home-based workforce. The table below shows indicative incidents and crimes at peak if one applies the incident and crime rates to the location of workers in "non-Council tax accommodation" in key town centre areas in the Somerset West Police area. This shows the potential, before mitigation, of greater potential impacts in Bridgwater and, to a lesser extent, Burnham town centres.

9.6.173 The same approach has not been applied to the area around the on-site campus as it is not appropriate to ascribe potential crime and disorder impacts to the immediate area given the relatively limited facilities, particularly the large scale town centre "night-time" uses where a high proportion of crime takes place. The location of any incidents arising from these workers is difficult to predict but picked up in the gross impacts described above.

9.6.174 Therefore in Bridgwater and Burnham before mitigation, there could be a **minor adverse** impact at peak. The impact would be **negligible** in all other areas.

Table 9.73: Workers in Non-Council tax Accommodation and Indicative Incidents

	Non Council Tax Accommodation	Incidents (2010)	Crimes (2010)	Indicative Incidents as % of Current Total) (Peak Workforce and W Somerset Rates)	Indicative Crimes as % of Current Total (Peak Workforce and W Somerset Rates)
Bridgwater (Town Centre and **Campus LSOAs)**	1,180	4,263	1,317	5%	4%
Burnham (Town Centre)	100	994	224	2%	2%
Minehead (Town Centre)	70	1,169	298	1%	1%
Taunton (Town Centre)	150	4,462	1,521	1%	0%

Sensitivity and Thresholds

9.6.175 This impact is potentially sensitive to a higher non-home based workforce, a higher proportion of people living in tourist, or latent accommodation, and/or fewer in campuses. Any increase in non-home-based workers in these accommodation types would be likely to be more thinly spread as the main concentrations of population are caused by campus accommodation.

9.6.176 The proposed monitoring system would identify the non-home-based workforce by location and type of housing and could therefore be used to manage and mitigate any additional impacts.

xvii. Fire Service

Gross Impacts

9.6.177 The development of HPC could potentially have impacts on the Devon and Somerset Fire and Rescue Service in two ways, firstly through potential incidents on the site during the construction process, and secondly through in any increase in services required arising from the temporary increase in population caused by the construction workforce. It is not possible to quantify these impacts as they will be based on responses to specific incidents.

Net Impacts

9.6.178 In relation to on-site incidents EDF Energy will have internal operating procedures in place to ensure that contractors operate in a safe way, and will provide equipment , resources and training so that it can provide first response to any fire incidents.

9.6.179 In relation to any increase in services required as a result of non-home based workers, those workers in owner occupied and private rented accommodation will be contributing to the cost of fire services. For workers living in Campus accommodation, EDF Energy will operate in line with statutory fire safety requirements.

9.6.180 Any additional impacts on services (apart from any possible large scale incidents which are dealt with in the mitigation section below) are likely to be small and relate either to residents in latent and tourist accommodation and the Fire and Rescue Service role in dealing with road traffic accidents. These are likely to be of **minor adverse** significance at the local level before mitigation and **negligible** at the County level.

Sensitivity and Thresholds

9.6.181 This impact is potentially sensitive to a higher non-home based workforce, a higher proportion of people living in tourist, or latent accommodation, and/or fewer in campuses. Any increase in non-home-based workers in these accommodation types would be likely to be more thinly spread as the main concentrations of population are caused by campus accommodation.

9.6.182 The proposed monitoring system would identify the non-home-based workforce by location and type of housing and could therefore be used to manage and mitigate any additional impacts.

xviii. Health and Ambulance Service

Gross Impacts

9.6.183 The site workforce and the non-home based workforce in the 60-minute travel area could have impacts on health and ambulance service provision in the area. This could include impacts on:

- GP services.
- Hospital services (acute and chronic care).
- Ambulance Services.
- Community Services, including:
  - Dental services.
  - Out of hours services.
  - Prescribing costs.
  - Mental health.

9.6.184 These services are mainly Primary Care Trust commissioned services together with some South Western Ambulance Service NHS Foundation Trust services.

Net Impacts

9.6.185 Increased demand for local health provision will arise from non-home based workers where:

- they, or their families, register for services with a local GP, and/or are referred by the GP for other specialist services;
- they require ambulance services; and
- the funding formulae through which health services are funded does not take into account growth in temporary or other population, or takes time to respond to changes in population.

9.6.186 EDF Energy has contracted with an external provider (Dura Diamond), to provide occupational healthcare services for both the HB and non-home-based workforce, with a clinic on site. As part of this they will also provide a comprehensive primary care service for non-home-based workers. It is assumed that the non-home-based workforce will not need to register with a local GP and that therefore the funding for any services they require (e.g. prescriptions and other services) will be met from their home PCT.

9.6.187 The principal net impact on health services will be in:

- cases where Dura Diamond have to refer workers to mainstream health services;
- where any incidents on site require ambulance call out or where non-home based workers require ambulance call out; and
- the families and dependents of non-home based workers who register for local GP (and other services) for the period that funding formulae need to “catch up” with any population growth.

9.6.188 As described above this latter group are not technically necessarily “additional” to the current population as there is in any case a significant annual population churn and if they weren’t living in a property it is likely another family group would.

9.6.189 The **Health Impact Assessment** sets out an assessment of these two types of impact based on assumed rates of use of health services.

9.6.190 For non-home-based workers these are based on the use of similar health services for the development of the Olympic Park, which involved a 4.1% take up of on-site health services, with 5.9 per cent of these referred to NHS providers. For HPC this would result in around five referrals per year to NHS services. This is a negligible impact at all levels.

9.6.191 For non-home-based workers families, there would be around 1,025 family members of which around 425 would be children at peak. Depending on the extent to which these residents are additional they could make additional demands on local health provision. However, demand on this scale would require the equivalent of half a GP, spread over a wide area with significant current capacity at peak, and around a quarter of a GP on average over the period. For other services delivered at a PCT level this population would account for less than 0.5% of the current Somerset PCT population. It would therefore be likely to have a **negligible** impact on demand for health care provision at all spatial scales.

9.6.192 For Ambulance Service provision, an assessment has been undertaken using current ratios of ambulances to population: one ambulance to every 8,290 people. As virtually all HB workers will live in the Avon and Somerset Ambulance Services area they can be discounted from having any net impacts. This leaves, at peak, 3,700 non-home-based workers, with an annual average of 1,900, both significantly below a level where new ambulance provision would be required. This would be a **negligible** impact at all spatial scales.

9.6.193 For the on-site construction workforce, the assessment has been based on the call out rate for the Olympic Park development in London which had a similar construction peak (c.5,000). This had a call out rate of 0.09 per worker per year. For HPC this would equate to around 45 call outs in the peak year and around 23 on average per year. This could have a **minor adverse** impact on ambulance services at the local level before mitigation, and a **negligible** impact at all other spatial scales.

Sensitivity and Thresholds

9.6.194 This impact is potentially sensitive to a higher overall workforce, a higher non-home based workforce, the types of accommodation in which the workforce reside and higher call out rates.

9.6.195 Given the relatively small impacts it is unlikely that any increase in these areas would change the significance of impacts outlined above, however the proposed monitoring system would identify the non-home-based workforce by location and type of housing and also cover call out rates for the ambulance service and could therefore be used to manage and mitigate any additional impacts.

xix. Community Cohesion

9.6.196 **Technical Note 6: Community Cohesion** (**Appendix 9F**) identifies and reviews current and recent community cohesion issues in the South West, which already has a substantial migrant workforce and has been the subject of a number of research papers. It should be noted that this body of research relates to workers born overseas and overseas nationals who will only make up a proportion of the non-home based workforce. However a number of the areas identified in the note would be generic amongst long-term migrant workers whether national or international and are therefore considered here.

9.6.197 The evidence review described in **Technical Note 6** is mainly qualitative, identifying a broad range of issues which have been raised by a (international) migrant workforce. It is therefore not possible to make a quantitative assessment of what the impacts of the HPC workforce might be. However, based on evidence from studies and experience elsewhere, it is possible to identify the types of impacts which could arise and plan to avoid any negative effects. Some of these issues are relevant to a non-home based workforce regardless of nationality, whilst others, in relation to language issues for example, could arise from the specific needs of foreign nationals.

9.6.198 The need for information is a key issue for non-home-based construction workers regardless of nationality, and can be addressed through the provision of 'welcome packs' and via a system of on-going and consistently updated information and guidance for workers, access to which can be gauged by monitoring the use of services. A key example is access to housing information, including the need to signpost access to housing for workers and to manage impacts particularly relating to houses in multiple occupation. A potential adverse effect that could arise is maintaining equal access to employment opportunities through positive community outreach projects and through supporting employment training.

9.6.199 It is critical to ensure equality of access to services – that non-home-based workers have equal access to necessary public services, whilst at the same time ensuring that existing residents have equal access to provision. Concerns have been raised through consultation about the integration of a predominantly male non-home-based worker population with existing residents, with potential adverse effects relating to community tension, the behaviour of workers in the local area, crime and anti-social behaviour. Overall, local tensions can be mitigated through other actions described above (maintaining equality of access to services and employment), and ensuring that the police and other services have the resources to deal with any specific problems should they arise.

9.6.200 Comparative data from the monitoring of the construction of Sizewell B noted that 'Representatives of the local police on the Sizewell B local consultative committee consistently expressed the view that, overall, the construction workforce had been relatively trouble–free, with fewer serious incidents than had been anticipated (Glasson and Chadwick, 1995).It should also be noted that developer drink and drugs policies/testing are now much more rigorous than for earlier developments.

xx. Localised Impacts (Bridgwater and Stogursey/Hinkley Point)

9.6.201 As noted above there are two areas where the concentration of the non-home based workforce could have a significant impact on the local area. These are Bridgwater and the area immediately around the HPC site.

9.6.202 In Bridgwater the identified local impacts will be likely to include:

- two worker campuses at Bridgwater A and Bridgwater C, and Park and Ride sites at Junctions 23 and 24 of the M5;
- the largest concentration of Non-Home Based workers in private rented accommodation, and probably the largest number of families;
- potential impacts on community cohesion, crime, anti-social behaviour and policing;
- employment and educational opportunities for local residents;
- expenditure from the workforce in local businesses and supply chain opportunities; and
- investment in leisure provision through the Site Preparation Section 106 agreement.

9.6.203 EDF Energy's proposed mitigation and enhancement measures through the Site Preparation Works Section 106 agreement and the Section 106 agreement associated with the current application will need to directly address these issues.

9.6.204 In Stogursey Parish, immediately adjacent to Hinkley Point, the main direct socio-economic impact will be the on-site campus.

9.6.205 The campus has been located in an area as far north as possible, away from Shurton. EDF Energy recognises the concerns of some in the local community regarding an on-site campus and has proposed a number of mitigation methods to address them. A planted landscape bund (area of raised ground) is proposed to screen the on-site accommodation campus at the time of construction, providing visual mitigation and some noise attenuation both for Doggetts and for the residents of Shurton. The lighting design, together with the landscaping strategy, has been designed to minimise light spill to the residential properties to the south.

9.6.206 The accommodation campus layout has been designed to reduce potential noise, light and visual impacts on the local community. The quieter, residential buildings have been positioned along the southern boundary of the site and the recreational facilities have been positioned to the north of the campus development, at the furthest point from Shurton village. There is no direct pedestrian access or road to the village of Shurton and access will only be obtained from Wick Moor Drove, the main access point. This will ensure that the development includes effective measures that prevent unofficial shortcuts from the site to Shurton and Stogursey.

9.6.207 It is not possible to quantitatively assess the extent to which workers living on the on-site campus will seek to use facilities in the nearby villages. However the design and operation of the campuses has taken into account the lessons from previous experience of Sizewell B with facilities on site and direct bus services to the larger settlements to limit impacts on the immediate area.

9.7 Assessment of Operational Phase Impacts

a) Employment

9.7.1 The predictions for the operational station takes the workforce at full operation of both reactors (in year 10 after the start of construction), and relates primarily to the more immediate districts. As noted previously the vast majority of the current HPB workforce lives within the three district area so that area has been used as local for this part of the assessment. Non-local are any residents from outside this area.

Operational Workforce

9.7.2 The operational workforce of the completed power station, with both reactors in operation, is approximately 700 direct EDF Energy employees and up to 200 contract staff – totalling 900. The contractor support also increases significantly to over 1,000 for during each unit's refuelling outage (every 15-18 months).

9.7.3 Estimates draw on previous studies of operational stations, including Hinkley Point A and B, and Sizewell B. These show that, on average, around 50% of the new workforce comes from within 10 miles of the new development. As for construction stage employment, they also show considerable variations between skill groups. Information from previous studies suggests a low local recruitment ratio, usually from 5% to 15%, for the managerial and technical category, but much higher ratios for administrative and clerical (55 to 85%) and the largest category, industrial staff (50 to 70%). For example, the combined pattern of recruitment at the Hinkley Point A and B stations showed only 5% local recruitment of managerial and technical staff, but around 60% for both administrative and clerical staff, and industrial staff (rising to 80% for the unskilled industrial staff).

9.7.4 The table below shows the recruitment assumptions for the directly employed EDF Energy operational workforce. It is assumed that contract workers (with the exception of outage workers) will follow a similar pattern. The predictions in this table suggest relatively high local recruitment figures, taking into account:

- The likelihood of some transfers from Hinkley Point B (and possibly from the decommissioning activities at Hinkley Point A); and
- Aspirations from EDF Energy and the local authorities to strongly encourage local recruitment through a number of channels.

Table 9.74: Operational Workforce: Local Recruitment

Employee Category	Total	Local			Non-Local		
		Proportion	Central Estimate	Range	Proportion	Central Estimate	Range
Managerial and Technical	180	15%	30	15-35	85%	150	145-165
Administrative and Clerical	60	70%	40	35-50	30%	20	10-25
Industrial	460	65%	300	260-340	35%	160	120-200
	700		**370**	**310-425**		**330**	**275-390**

Local= the immediate Districts of Sedgemoor, West Somerset and Taunton Deane. The numbers of employers are taken from EDF Energy's emerging operational workforce plans and then split into *broad occupational categories. The splits between local and wider recruitment are based on studies of operational stations.*

Local Recruitment

9.7.5 In summary, it is estimated that approximately 53%, or 370 of full operational employment, could be recruited locally. This is the midpoint of a range of 310 to 425 operational employees estimated to be recruited locally. The number of employees therefore likely to migrate into the three-district area from outside the local area is estimated at 275 to 390.

9.7.6 In addition, it is estimated that there will be up to 200 contract workers working on the HPC operational station at any one time; these are more likely to be from outside the local area, and many may be non home-based.

9.7.7 This workforce is included in the overall 'Workforce Profile' described in Appendix 1, and begins to build up from month 35 of the project. The precise levels of local recruitment at any one point are likely to vary depending on a variety of factors including the operational requirements at HPB at the time and EDF Energy's overall workforce management strategy in relation to its nuclear fleet including Sizewell. There is likely to be some fluidity between the different station workforces.

9.7.8 This would be a **moderate beneficial** impact at the three district level.

Higher Value Added Jobs

9.7.9 The proposed development, when operational, would cause an increase of 109% in jobs within the top 20 GVA-per-worker industrial sectors in the UK in the three district area, representing a **major beneficial** impact in terms of the policy aspirations of the local authorities and the sub-regional economy.

Outages Hinkley Point C

9.7.10 During the operational phase of the HPC project, there will be a number of planned outages, which will require a short-term, temporary additional workforce at the HPC site at regular intervals.

9.7.11 The outages will occur every 15 to18 months, and on average last 12 to18 days (up to a maximum of around 30 days). Every 10 years there will be an outage that lasts up to 40 days.

9.7.12 The first outage will occur 15 to-18 months after unit 1 of the HPC project has become operational, approximately at the same time unit 2 commences operation. When both units are operational, the outages for each will happen in sequence (i.e. unit 1 outage, followed by unit 2 outage).

9.7.13 A short-term, temporary workforce of 1,000 will be required in addition to the 900 (700 permanent and 200 contract staff) per outage. The largest outage at Hinkley Point B required 1,600 workers.

9.7.14 It is estimated that the majority of the annual temporary outage workforce will be recruited from outside the local area (around 80%), and that there will be much continuity of employment between the current and future outage teams – thereby minimising any additional new employment, but increasing the frequency for current employees.

9.7.15 It is therefore anticipated that around 800 outage workers would be non-local and therefore would require accommodation in the area. There is likely to be an impact on local accommodation, including tourist accommodation. A small proportion, estimated at fewer than 10%, tend to take up spare rooms in houses (latent accommodation) based on previous experience, and this is usually facilitated by people advertising in local shops, at the power station itself, and in newspapers.

9.7.16 Planned outages will be timed to avoid peak (August) seasons, in order to limit the level of significance of the impact on local accommodation provision. The 800 outage workers requiring bedspaces would be comfortably accommodated by the baseline demand in off-peak seasons, and the impact on accommodation is therefore likely to be negligible. If outages were to occur in peak season, given the identified 4,200 capacity in accommodation this should remain a negligible impact. The short-term increase in the local population and workforce is likely to have a **minor beneficial** economic impact through worker expenditure on local goods and services, the potential for employment and skills/training, and an overall temporary increase in local GDP. It is expected that suppliers will manage the needs of the staff brought in during outages in terms of accommodation and services, while EDF Energy will agree work patterns and on-site training.

b) Accommodation

9.7.17 It is estimated that by the time of peak construction, around 450 workers will have moved to the area with their families, and some of these will form part of the operational workforce, while others will be long-term contract workers.

9.7.18 An element of the operational workforce will be comprised of some of the 450 workers that are expected to have moved to the area at peak construction with their families, most likely into owner-occupied accommodation.

9.7.19 Information from Hinkley Point B shows that 94% of the operational workforce lives within the three immediate districts, with 70% living in Sedgemoor. It is EDF Energy existing nuclear policy that all operational permanent staff should live within 25 miles of the station, and it is envisaged that all but a very small minority will live in the three immediate districts. It is similarly envisaged that the non-local outage workforce will also be accommodated in the same area for the duration of their activities. As noted, of the 700 permanent operational staff, around 370 are likely to be recruited locally, with the remaining 330 likely to be drawn from the rest of the South West region, and some from further afield.

9.7.20 In terms of accommodation sectors, studies at a number of power stations show that permanent employees in the electrical supply industry have higher rates of owner occupation than the national average. Ownership rates are particularly high for staff employees. In the absence of any public sector provision, it is anticipated that most of those not buying will rent in the private sector. As such, the approximate tenure mix at full operation is estimated to be around 80% owner occupation, and around 20% private rented.

9.7.21 The anticipated demand in total for owner occupation and private rented accommodation is relatively low in comparison with the construction stage, and as the demand is likely to be spread over a number of years, coinciding with the rundown of construction (and the release of some accommodation previously used by construction stage workers), it is not expected that there will be any adverse effects in meeting the accommodation demands associated with the operational phase.

9.7.22 **Table 9.75** provides an estimate of the geographical distribution of operational staff accommodation, based on the premise that the pattern will be similar to that for the current operational Hinkley Point B.

9.7.23 It is envisaged that the temporary outages would be handled in similar ways to the current arrangements for the Hinkley Point B station, primarily via the use of serviced and rented accommodation. There would therefore be a **negligible** impact on local accommodation demand.

Table 9.75: Estimated Geographical Distribution of the Non Home-based Operational Workforce, by Accommodation Type – at Full Operation

District	Owner Occupied		All Rented		Total	
	#	%	#	%	#	%
Sedgemoor	190	70	40	62	230	68
West Somerset	40	15	20	31	60	18
Taunton Deane	25	10	5	7	30	9
Outside AIA	15	5			15	5
TOTAL AIA	**270**	**100**	**65**	**100**	**335**	**100**

Note: AIA (Accommodation Impact Area) = the three districts of West Somerset, Sedgemoor and Taunton Deane

c) Public Services

9.7.24 As noted above the operational workforce will have become established over the time of the construction period and become part of the permanent population of the area. Any impacts on education and public services will therefore have already been mitigated during the construction programme. As occupants of private rented or owner occupied accommodation the workforce will be Council tax and taxpayers and entitled to public services in common with other residents.

i. Perceptions

9.7.25 It is anticipated that community perceptions during the operational phase of the HPC project will differ little from those of the existing Hinkley Point B power station, with the new station being a provider of well paid, high technology and permanent employment, and contributing well to community activities.

d) Wider Economic Effects

i. Labour Market

9.7.26 It is anticipated that power station operational employment will be attractive to the local workforce as a result of the traditionally high level of wages in these industries. Local authorities and agencies will be keen to develop the external image of Somerset as an advanced economy, diversify the economic base, address some pockets of deprivation, improve the local long term skills base (especially in engineering and construction) and attract more workers (especially younger workers) to remain in employment within the immediate districts.

9.7.27 The operational project should provide a long term continuation of a substantial quota of skilled and secure jobs for local people with a major high-technology employer, partly offsetting the closure and decommissioning of Hinkley Point A and the eventual closure of Hinkley Point B. The significance of the project as a high tech/innovative activity, raising the local high tech business image, was seen as positive by participants in the Socio-Economic Topic Workshops.

ii. Local Indirect Employment

9.7.28 At full operation, the indirect employment effects and the increase in the level of income in the local economy will be of a more permanent nature. Estimates for the current Hinkley Point B station of the annual addition to local income from c.700 power station workers' and contract staff earnings and local contracts are of the order of £30 million (the average earnings of power station employees (both construction and operational) are substantially above the average for the area and will give a major boost to local average earnings, and to local services).

9.7.29 Figures for the new station are likely to be at least this, and may be of the order of £40million per annum (at 2010 prices). Previous studies suggest the additional local indirect employment of about 60% of direct employment, which would be of the order of 360 jobs for the proposed operational HPC station.

9.7.30 There will also be an extra 1,000 contract partner workforce during planned outages (approximately every 15-18 months for each reactor for 12-18 days, up to a maximum of one month). The outages will occur outside of summer months where possible, and will happen in sequence. Every 10 years there will be an outage of up to 40 days. The 1,000 additional workforce will be likely to have multiplier expenditure and employment impacts, proportionately more akin to those for un-accompanied non home-based construction workers. The local economic impact of outages may be of the order of £25million.

iii. Business Development and Supply Chain

9.7.31 It is also envisaged that the project will provide many opportunities for business growth, both directly associated with project contracts (construction and operational), and also indirectly (e.g. in encouraging new serviced and non-serviced accommodation provision).

9.7.32 In terms of potential impacts on other local industries, especially tourism, similar points can be made as for the construction stage, but on a smaller basis. Overall the development is likely to contribute to longer term economic stability in the area. It should also provide opportunities for the development of local firms with both nuclear construction and operational phase supply chain links, which will help to raise the skill level and presence of high-technology activity in the area.

9.7.33 Overall this should lead to economic diversification away from declining sectors, offering high quality employment and opportunities for local businesses in the first new nuclear project in the UK, through an intensive construction period of some nine years and a prospective operating lifetime of 60 years.

9.8 Mitigation and Enhancement

9.8.1 For the purpose of this assessment, mitigation measures have been proposed where there is an adverse impact of greater than minor significance and the impact magnitude, spatial scope and temporal nature make it appropriate to do so.

9.8.2 Socio-economic impacts are potentially sensitive to an increased overall workforce, a higher non-home based workforce, the mix of types of accommodation in which the workforce reside and higher use of services.

9.8.3 Across the socio-economic areas, EDF Energy has adopted a best practice precautionary approach to ensure that all evidenced impacts can be addressed, and that a monitoring system is in place to address the sensitivities and thresholds described in the impact assessments. These are listed and cross referenced below along with their key points. Where possible enhancements have been identified which can bring additional benefits to the area.

9.8.4 Through the managed signposting of workers, the HPC Accommodation Office will seek to reduce pressure in specific locations or on specific public services. Information will be held on such things as such as public transport, local amenities and school capacity. This will allow a worker to select accommodation which suits his/ her needs whilst minimising impact on public services and pressure on the road network.

9.8.5 Relevant mitigation and enhancement measures are listed and cross referenced below.

a) Economy and Skills

9.8.6 EDF Energy proposes to mitigate impacts and enhance benefits in relation to economy and skills through four main strands: The **Construction Workforce Development Strategy** (CWDS), the **Education (Inspire) Strategy**, the **Project Supply Chain Engagement Strategy**, and Tourism and Area Promotion. These are summarised in the **Economic Strategy** submitted with the planning application and the former three are appended to that document.

i. Construction Workforce Development Strategy

9.8.7 EDF Energy is committed through its **Construction Workforce Development Strategy** to maximising benefits to West Somerset, Sedgemoor and Somerset. The strategy was produced in consultation with partners and reflects jointly held priorities for action.

9.8.8 The CWDS comprises six key projects through which EDF Energy and partners will work to achieve this objective. They are:

- **Employment Brokerage**: The Brokerage will be a service delivered on behalf of EDF Energy and in collaboration with external partners. Its role is to place people into sustainable employment created by the building of Hinkley Point C and the construction of its associated developments. EDF Energy will also seek to extend the model in the future to include the employment of operational staff, recruited from the Somerset area. The remit of the Brokerage is to focus on:

- Providing employment opportunities for residents of Sedgemoor, West Somerset and the wider county of Somerset;
- Helping to tackle unemployment through the pre-training of suitable and assessed candidates at the proposed Construction Skills Centre in Sedgemoor in occupations that are in demand by EDF Energy's contractors;
- Working with contractors to provide apprentice opportunities for people;
- Widening employment and skills opportunities for Women, Disabled people, Black and Minority Ethnic People (BAME) and all under-represented groups in the construction and engineering sectors;
- Maximising leverage and support from funding agencies, sector skills councils, trusts, support organisations and businesses to ensure opportunity is available to a broad spectrum Somerset people and not only those who are in long term unemployment.

- **Employment Outreach:** This project will provide opportunities for "work ready" people, to become "job ready" and capable of entering sustainable employment at HPC, or elsewhere in the supply chain or wider economy. The role of Employment Outreach is to motivate and encourage people within the community to participate in the workforce. Through the Section 106 planning agreement for Site Preparation Works EDF Energy are supporting local councils through the provision of dedicated community outreach resource. Whilst the councils are responsible for the strategic use and deployment of their own dedicated staff there is future opportunity for EDF Energy to partner with them in outreach activities;
- **Construction Skills Centre**: EDF Energy has been working in partnership with Bridgwater College to enable local, demand led training to be delivered at a Construction Skills Centre in Cannington. The centre will be able offer courses ranging from basic health and safety and card schemes through to advanced training in specific skills. This will include a dedicated Civil Engineering site designed to accommodate state of the art training in all types of plant being used at HPC, OSAT NVQs, Building Services/Utilities, Formwork, Steel Fixing, Steel Erecting, New Roads and Street Works. The skills centre will host the Constructionarium, a hands-on construction experience for students following civil engineering and built environment courses. It allows the students to learn practically from industry - their future employers. It is designed to be part of a 21st Century engineering education which links academic theory with contractors and consultants from the construction industry. It will be established in partnership with education providers and based at the Construction Skills Centre;
- **Hinkley Skills Ready Project**: This will enable residents of West Somerset to get the skills they need to work at HPC. The project involves an element of physical remodelling of existing buildings at the school and the construction of a small extension. Collectively these modifications will enable the school to offer additional vocational subjects and qualifications, which are aligned to skills and employment needs at Hinkley Point C and the wider economy in West Somerset.
- **Apprenticeships**: EDF Energy has the aspiration to achieve the national benchmark for construction apprenticeships. EDF Energy will produce a specific Apprenticeship Strategy and work with its supply chain and other agencies to maximise apprenticeships for local residents.

- **The Enterprise Centre Project**: EDF Energy is working with West Somerset Community College and West Somerset Council on a feasibility study for an enterprise centre project, to support Somerset residents and businesses in providing services to the incoming workforce and prepare for other new markets (e.g. visitors and tourists) that may arise as a result of the HPC development.

9.8.9 An Employment and Skills Operations Group (ESOG) will meet monthly and include senior members of staff from each of the core stakeholders and partner organisations. EDF Energy's Construction Workforce Team will host meetings and provide the Secretariat. Key Performance Indicators have been produced and will be regularly monitored, so that the effectiveness of projects can be assessed and reviewed over the lifetime of the development. Quarterly performance data and analysis will also be used in a series of quarterly updates with stakeholders through the ESOG.

Education Strategy

9.8.10 EDF Energy is committed through its Education Strategy to working with schools, other education providers and young people in Somerset to engage and inspire young people in Somerset to follow a pathway in Science, Technology, Engineering and Mathematics (STEM), with the primary aim of raising aspiration and attracting school leavers into a career in Construction or Engineering.

9.8.11 The Inspire Strategy will include different themes for different age groups. These are:

- 6 to 11 year olds: Proposition: Inspire and Engage, the aim is to support activity that will help capture interest and inspire children to carry that interest into the next phase of their school life.
- 11 to 14 year olds: Proposition: Build STEM Skills and Influence Choices; Research in Somerset has identified a gap in informing the decision making process and advising on careers. The offer at this level is based on a series on interventions that will provide guidance and understanding of the opportunities available so they can make informed decisions.
- 14-19 year olds: Proposition: Career pathways/Job ready; Offering experiences and guidance regarding opportunities available in the construction and engineering industry will be the focus of the offer for this group. The next generation of construction workers, technicians and engineers will require a programme of career and Job Ready interventions in order to maximise the opportunities arising from HPC. This is an important cohort to focus on as current students in this age group will be entering the employment market at the time of peak build on HPC.

9.8.12 The strategy will include engagement with all primary schools in Sedgemoor and West Somerset, secondary and further education institutions throughput Somerset, and Higher education institutions in the wider 90 minute travel zone (CDCZ) from HPC.

9.8.13 Activities for younger groups will include the production of information packs, curriculum and teacher support, site visits, classroom support, careers events, an online environmental education tool (“the Somerset Pod”), specific training and support, expert visits to schools, and virtual work experience.

9.8.14 Activities for older groups will be linked with, and enhanced by, EDF Energy’s wider investments in the Construction Skills Centre and Constructionarium at Bridgwater College and the Hinkley Ready and Enterprise projects with West Somerset Community College.

Project Supply Chain Engagement Strategy

9.8.15 EDF Energy will use its role at the top of the supply chain for the project to seek to enable local participation. Its intention is to help UK and local companies to become part of the global supply chain for its new nuclear reactors. EDF Energy sees considerable advantages in being able to develop relationships with suppliers who will go on to play a part in supplying a number of its new build projects, including at Hinkley Point and Sizewell. This means that for local suppliers who get involved in the Hinkley Point project, there will be opportunities to leverage their involvement into other new build projects.

9.8.16 EDF Energy is working with the local authorities, local businesses and others to develop an understanding of the capabilities of the local area, and to produce a database of local firms who might be interested in playing a part in the supply chain. Due to the scale and specialist nature of the new build project, it is likely that most of these firms will be at a relatively low tier in the supply chain. EDF Energy’s efforts must therefore focus on enabling them to make links with upper-tier contractors, and encouraging those contractors to make use of local suppliers where possible.

9.8.17 Somerset Chamber of Commerce has been contracted as an independent broker to facilitate the involvement of local businesses in EDF Energy’s supply chain. The Chamber will act as the primary point of contact and information for both EDF Energy and local businesses through an online supplier portal and will have the primary focus to promote the health and development of the Somerset economy.

9.8.18 Local companies have been invited to register their interests, business details, capacity and capabilities on the online supplier portal and to update them as they change. The Chamber will then support those that are not yet ready to meet the basic requirements and those that are ready will be invited to local events organised by the Chamber which seek support local involvement in the supply chain and to match businesses with new opportunities.

9.8.19 While EDF Energy cannot prescribe the proportion of local suppliers who will be contracted by the Hinkley Project, the contracts will include a strong encouragement to the contractor and subcontractors to maximise the use of Somerset businesses.

9.8.20 In addition to the nuclear supply chain, the Hinkley Project will also generate more generic contracts and opportunities that will be made available to local businesses. These include contracts and arrangements for transport, hotel accommodation, office supplies, recruitment, work wear and catering. EDF Energy’s commitment to mitigate the effect of the HPC’s construction activities on nearby residents will also create a range of local supplier opportunities in double glazing, sound deadening loft insulation, window cleaning, window blind installation, and tree planting.

Tourism and Area Promotion

9.8.21 EDF Energy is committed to working in partnership with the local tourism industry and public bodies to promote tourism in Somerset. This includes supporting the development of a Tourism Strategy and Marketing Plan and marketing and promotional initiatives as well as utilising the benefits of the on-site Public Information Centre to enhance Somerset's tourism offer.

Agriculture

9.8.22 On completion of the construction phase, the land outside of the permanent development site would be restored as proposed in the Landscape Restoration Plan. This would involve the restoration of land to agricultural use and ecological habitat creation. As the scheme design incorporates elements that result in negligible socio-economic effects in terms of direct economic impact and severance/disruption impacts, the potential impacts do not require mitigation.

Summary and Residual Impacts after Mitigation

9.8.23 The impacts identified in relation to the labour market, local economy and skills were all beneficial. The actions outlined above have the potential to significantly enhance those impacts and create a ***long term major beneficial impact for the economy of the three districts and Somerset*** by improving the skills base and competitiveness of the economy and helping residents and businesses become part of a larger UK labour force supply chain for infrastructure development.

b) Accommodation

9.8.24 Although the central scenario assumes a negligible effect on the accommodation market, there are significant uncertainties related to the locations where workers will choose to live, how many non-home-based workers will be required and which sectors of the housing market they will choose to live in.

9.8.25 As such, mitigation has been proposed and targets pre-mitigation of adverse minor impacts to avoid them becoming moderate impacts. This is set out in the **Accommodation Strategy** submitted with the application and summarised below.

i. Housing Fund

9.8.26 EDF Energy is proposing additional support for housing in the local area by establishing a Housing Fund, informed by a clear understanding of local housing issues. The Housing Fund is to provide £5 million of financial support to a range of initiatives which deliver additional capacity within the housing market area which relates (by travel to work area) with the development site.

9.8.27 A priority is to target the low cost housing sector locally where the housing impacts could have the most significant affect.

9.8.28 A particular focus is the private rented sector with the Fund capable of both increasing supply and investing in a range of initiatives which provide greater housing choice and opportunities which would either not otherwise exist or be unduly constrained by existing funding.

9.8.29 The following initiatives and contributions are planned as part of the Housing Fund, which have been developed in conjunction with the local authorities stimulating new supply in the private rented stock:

- bringing empty homes back to beneficial use;
- supporting a rent deposit/guarantee scheme;
- providing equity loans to social rented sector residents;
- providing equity loans to residents in the owner occupied or private rented sector;
- tackling incidence of under occupation in the existing affordable stock;
- providing equity investment into new-build development schemes; and
- funding to act as ‘grant replacement’ for new-build development schemes.

9.8.30 A basket of these initiatives can be assumed to have an average cost of £5,000 to support an additional unit of accommodation or housing opportunity. Therefore the fund, if used effectively, could provide for 1,000 additional units or housing opportunities. Further support could be triggered if monitoring suggests that, at peak, or in specific locations, the project has exceeded the accommodation capacity by more than this amount.

ii. Monitoring and Management Strategy

9.8.31 Monitoring of accommodation take up will be addressed through the pre-induction questionnaire and induction process, which will confirm worker accommodation choice at arrival on site. In due course it is proposed that, through the operation of the accommodation website, information on bookings will be collected from listed providers.

9.8.32 Information will be collected by the workforce monitoring manager throughout the construction period. Pertinent to the Accommodation Office will be the collection of data on accommodation choices by; post code, accommodation type and duration of stay.

9.8.33 By monitoring accommodation patterns and through on-going stakeholder consultation, potential impacts arising from accommodating workers will be identified. A powerful tool available to EDF Energy will be to sign-post workers away from geographical areas or accommodation sectors where any issues have been identified, and adopting a pricing regime for the campuses that is attractive to the workforce. Additionally, EDF Energy is proposing a flexible bus strategy which will allow routes to be varied. This could be used to make areas that have spare accommodation more attractive to workers. This would then reduce pressure on areas that have attracted large numbers of workers and where there may be pressure on accommodation capacity.

9.8.34 Through the managed signposting of workers, the Accommodation Office can seek to reduce pressure in specific locations or on specific public services. Information will be held on such things as public transport, local amenities and school capacity. This will allow a worker to select accommodation which suits his/ her needs whilst minimising impact on public services and pressure on the road network.

9.8.35 There is potential for workers to make use of accommodation that would otherwise be let to tourists, so potentially causing pressure on availability, tourist frustration and the possibility of tourists staying away from the area.

9.8.36 While it is anticipated that the tourist market would largely be self-regulating, with summer time prices exceeding HPC workers' budgets, EDF Energy will be able to sign-post workers away from areas or types of accommodation under pressure by way of mitigation. Through a look-ahead with the construction team, spikes in worker demand can be mitigated through a proactive approach to identifying suitable accommodation with particular regard to holiday periods.

iii. Quality of Accommodation

9.8.37 Many providers of latent accommodation will be new to letting and may be unaware of the rules and regulations that apply. In addition, increasing demand may lead to providers entering the market with accommodation of an unacceptably low standard.

9.8.38 The Provider Information Pack will be issued to potential providers and serve to raise understanding of applicable regulations and sources of further information as well as confirming EDF Energy's expectations. It will also make expectations on quality clear, together with actions to be taken when minimum levels are not met.

9.8.39 The carrying out of home safety visits to a random sample of properties by the Fire Service and an awareness by accommodation providers that their information is being shared with public service providers will reduce risk of properties of an unacceptable standard being registered with EDF Energy.

iv. Summary

9.8.40 Impacts on accommodation were identified as **negligible** at all spatial levels. The mitigation proposals are intended to ensure that they remain negligible across the area and in specific locations through a monitor and manage approach. The investment of the Housing Fund in the local area could make 1,000 housing opportunities available in the 60 minute area which would have a long term use. This would have a **minor beneficial** impact at the 60 minute area level.

c) Population and Population Dynamics

9.8.41 As noted above the HPC workforce is likely to have a major impact on population and population dynamics in two areas: Bridgwater and the area immediately around Hinkley. This will partly be addressed through the mitigation measures on the economy and skills, accommodation and public services described elsewhere in this section but EDF Energy also proposes a number of actions to avoid/limit any negative impacts and to mitigate impacts locally. This is set out in the **Community Safety Management Plan** submitted with the application, which includes the Worker Code of Conduct as an appendix.

i. Worker Code of Conduct

9.8.42 A Code of Conduct (the Code), attached as an Appendix to the **Community Safety Management Plan,** has been written to set expectations of how workers use accommodation and the way they interact with the local community, and will:

- communicate the behaviour expected of workers and outline the means by which the Code will be communicated to all site preparation workers;
- outline the role of employers;
- outline the monitoring mechanism for the Code during the site preparation works; and
- inform the community of the standard of behaviour they should expect from workers and their employers.

9.8.43 The Code will be explained to workers at induction and in the course of the project through awareness campaigns. Each worker will be required to sign a copy of the document at induction. The Community Liaison Officer (see below) will monitor comments and complaints and will take necessary action, giving feedback to the person making initial contact. Whilst the absence of a contractual relationship means EDF Energy are not able to discipline workers directly, regular performance reviews with contractors will provide a means of ensuring good worker behaviour.

ii. Community Liaison Officer

9.8.44 The Community Liaison Officer will provide a point of contact between the community and the project, receiving comments, establishing a network of key stakeholders, and holding regular meetings. He or she will work to minimise negative impacts and community tension and will build on positive opportunities for community cohesion, and pro-actively monitor worker activity so as to minimise concerns. The terms of reference of the Community Liaison Officer are set out within the **Community Safety Management Plan.**

iii. Campus Management

9.8.45 EDF Energy will ensure the active management of its accommodation campuses, on site and in Bridgwater. This will include expected standards of behaviour from workers, hours of operation, security issues, liaison with public services and complaints procedures for local residents.

iv. Main Site Neighbourhood Support Scheme

9.8.46 A Main Site Neighbourhood Support Scheme has been established which recognises that hamlets in the immediate vicinity of HPC (Shurton, Burton, Knighton, Wick and parts of Stolford) will be affected by a unique combination of issues throughout the duration of the construction period. The Scheme contains elements to mitigate potential effects of noise, dust, and property value impacts that may arise. This includes a property price support scheme to assist residents who wish to move away and a noise insulation scheme that offers properties double glazing and ventilation. EDF Energy will provide window cleaning when monitoring equipment has indicated that agreed dust levels have been exceeded.

9.8.47 For property price support, properties would have to have been marketed at a realistic value for at least six months from the date of launch. Properties within the boundary can participate at any time from the date of trigger. The Scheme will run for five years from date of launch at which time the scheme will be reviewed.

v. Community Impact Fund

9.8.48 EDF Energy is also proposing a broader fund which can be used to address priorities identified by the communities most affected by the HPC project. This is in recognition of the fact that there are likely to be qualitative adverse impacts on the lives of people in the areas most affected by the development which can't be mitigated by conventional approaches.

d) Public Services

i. Education

9.8.49 The central assessment is that impacts on physical provision are negligible, although there are significant uncertainties around the likely location of the workforce, and available school capacity which could create more significant impacts in localised areas.

9.8.50 EDF Energy is therefore proposing in the draft Obligations, appended to the **Planning Statement**, to make an initial payment to Somerset County Council in advance of the main workforce build up which can be used to expand provision in locations with limited capacity. EDF Energy will also establish a monitoring system which will identify the locations of family households and, with Somerset County Council, identify impacts on education capacity. Where children of EDF Energy workers do lead to the exceeding of local school capacity in excess of the places funded in advance financial contributions will be made to address this. EDF Energy also proposes to contribute to funding a support teacher or member of staff who can co-ordinate any additional activities required to integrate children into the local school system. This will ensure that residual impacts are **negligible** at all spatial levels. Investment in new school places will continue to be available after the construction period and would be a **minor beneficial** impact at the local level.

ii. Social Services

9.8.51 Impacts on social services are identified as **negligible** at all spatial levels. EDF Energy is committed to seeking to link its other implementation strategies with priority social services target groups, for example so that outreach programmes target children Not in Education, Employment and Training (NEETs) and other vulnerable groups. The Community Liaison Officer identified in the **Community Safety Management Plan (CSMP)** will also liaise with those working with vulnerable groups to address any issues.

iii. Leisure

9.8.52 The impact on leisure service provision is likely to be negligible. However, in recognition that investment in facilities would be likely to make a positive contribution to integration and the experience of the workforce and local community EDF Energy has committed to significant investment in local leisure provision in West Somerset and Sedgemoor Districts as set out in the S106 for Site Preparation, and summarised in the **Section 106 Heads of terms which are appended to the Planning Statement**. These are significantly in excess of what would be required to mitigate any impacts of the workforce (**see Technical Note 5, Appendix E**) and site specific issues on associated development sites (see **Chapter 7** of **Volumes 3** and **4** of this ES) This will have residual impacts on leisure services which will be permanent **moderate beneficial** at the local level.

iv. Regulatory and Environmental Services

9.8.53 mpacts on regulatory and environmental services are identified as negligible at the district level, with the potential to be minor negative at the local (settlement) level. The proposed approach to mitigating housing impacts described above in paragraphs 9.9.35 to 9.9.37 will mitigate the impact on the main regulatory service functions. The residual impacts will therefore be **negligible** at the district and local levels.

v. Emergency Services

9.8.54 EDF Energy has been working with service providers (The District and County Councils, Avon and Somerset Constabulary, Devon and Somerset Fire and Rescue Services, South Western Ambulance Service Trust and NHS Somerset to address any potential community safety impacts arising from the project.

9.8.55 A **Community Safety Management Plan** has been produced which sets out the overarching approach to ensure that community safety and emergency services issues are comprehensively addressed, any identified impacts mitigated and monitoring arrangements are in place to deal with any sensitivities or variances from the central assessment.

9.8.56 EDF Energy has also produced draft Strategic Relationship Protocols (SRPs) with the emergency services setting out how the parties will work together and the roles and responsibilities of each. Where appropriate they confirm remuneration for services to avoid and/or manage impacts and financial and other contributions from EDF Energy towards this.

9.8.57 Likely impacts on crime and policing are identified as negligible at the level of the Police District, but there is a risk they could be minor negative in locations with a concentration of non-home based workers, particularly Bridgwater.

9.8.58 The SRP with the Police includes:

- funding of a Community Safety Beat Team to police the communities surrounding the construction sites;
- funding of intelligence officers to research and plan for potential impacts arising as a consequence of HPC;
- contribution to policing costs, including intelligence and incident planning, as well as costs associated with the increased non-home-based workforce; and
- a formula based approach has been developed for assessing future payments based on the level of non-home based workforce (excluding those paying Council tax).

9.8.59 As a result impacts on policing and community safety are likely to be **negligible** at all levels.

vi. Fire Service

9.8.60 Impacts on the Fire Service are likely to be negligible at the Devon and Somerset Fire Service level but there is a risk they could be minor adverse at the local level subject to the types of incidents.. As noted these risks have been minimised by the service which EDF Energy will purchase from DuraDiamond.

9.8.61 The SRP with the Fire Service therefore includes:

- contributions to incident planning and training prior to the substantial build up of the HPC workforce; and
- the employment of a Community Safety officer to raise awareness of fire safety issues in the local community and carry out home safety visits of private rented property.

9.8.62 As a result impacts on the fire service are likely to be **negligible** at all levels.

vii. Health and Ambulance Services

9.8.63 Due to EDF Energy's own internal mitigation the likely impacts on health provision are identified as negligible at all levels. The impact on the ambulance service is identified as negligible at the South Western Ambulance Service level with the risk of a minor negative impact at the local level.

9.8.64 Through discussion with the Primary Care Trust and Ambulance Service EDF Energy has proposed the following approach, details of which are set out in the Health Action Plan and draft Obligations.

9.8.65 For main health provision EDF Energy will provide contributions for referrals of workers from EDF Energy's contracted provider to NHS services – where these are not funded by their home PCT/Commissioning Body, and for families of non-home based workers, subject to monitoring demonstrating that they are net additional to the population for which the PCT is already funded and only for the time that such funding takes to adjust.

9.8.66 The SRP with the Ambulance Service includes:

- payment for emergency calls to site; and
- contribution to the cost of operational planning to address the specific demands of the HPC project.

9.8.67 As a result impacts on health and ambulance services are likely to be **negligible** at all levels.

9.8.68 In addition EDF Energy is also committed to provide £60,000 for a Fit to Work project. This will be a **minor beneficial** impact at the local level.

e) Operational Phase Mitigation and Enhancement

i. Operational Workforce

9.8.69 EDF Energy will work with partners at the appropriate time to plan for the recruitment and training of the operational workforce at HPC. This is likely to utilise many of the same routes as the construction workforce development strategy, and is also likely to offer apprenticeships and develop close relationships with Further and Higher Education institutions.

ii. Summary

9.8.70 The operational phase is identified as having long term **major** and **moderate beneficial** impacts at the three district level respectively. This assessment remains unchanged as a result of enhancements.

Table 9.76: Summary of Impacts with Mitigation and Enhancement Measures

	Duration	Temporary/ Permanent	Significance	Uncertainty/ Sensitivity	Mitigation and Enhancement	Residual Impact
Construction Employment (CDCZ)	Long term	Temporary	Moderate beneficial	None	Enhancement	Major Beneficial
Construction Labour Market (3 Districts)	Long term	Temporary	Moderate beneficial	Potential variance depending on recruitment	Enhancement	
Construction Supply Chain/Business	Long Term	Temporary	Moderate beneficial	Approach to contracting	Enhancement	
Accommodation Supply (60 minute zone)	Long Term	Temporary	Negligible	Numbers and concentrations of workforce	Accommodation Strategy including Housing Fund	Negligible/Minor Beneficial
Owner occupied Housing (60 Minute Zone)	Long Term	Temporary and Permanent	Negligible	Limited – could vary but not significant	None required	None
Private Rented Sector (60 minute zone and sensitive locations)	Long Term	Temporary	Negligible	Risk of concentrations and minor/moderate adverse impacts in specific locations	Accommodation Strategy including Housing Fund, Monitor and Manage	Negligible
Tourist Sector	Long term	Temporary	Negligible	Risk if greater demand for tourist accommodation in peak season	Accommodation Strategy including Housing Fund, Monitor and Manage	Negligible
Latent Sector	Long Term	Temporary	Minor beneficial	Potential for more to be brought forward or reduced uptake	None required	Minor beneficial

	Duration	Temporary/ Permanent	Significance	Uncertainty/ Sensitivity	Mitigation and Enhancement	Residual Impact
Education Capacity	Long term	Temporary	Negligible	Risk of higher child numbers or concentration in low capacity area	Preparatory financial contribution towards school places and support for management of children of workforce. Monitoring of impact and potential additional financial contribution	Negligible. Minor beneficial where additional places are provided.
Population Dynamics	Long term	Temporary	Major in Bridgwater and Stogursey/HPC	Possible variance in workforce locations	Various	Minor to Moderate
Social Services	None	None	Negligible	None	None	None
Leisure	Long term	Temporary	Negligible	Greater workforce or concentration in locations	Investment in provision	Moderate beneficial
Regulatory and Environmental Services	Long Term	Temporary	Negligible at District level, risk of Minor Negative at cluster/ settlement level	Greater workforce or concentration in locations	Monitoring of impact and financial contribution	Negligible
Crime, Anti-Social Behaviour and Policing	Long Term	Temporary	Negligible, possible minor adverse in Bridgwater	Greater workforce or concentration in locations	**Community Safety Management Plan**, Strategic Relationship Agreement (SRA) with the Police, monitoring and funding of services	Negligible
Fire Service	Long Term	Temporary	Negligible at Fire Service Level, risk of minor at cluster/ settlement level	Higher workforce or major incidents	SRA with Fire Service, Monitoring and Financial Contributions	Negligible

	Duration	Temporary/ Permanent	Significance	Uncertainty/ Sensitivity	Mitigation and Enhancement	Residual Impact
Health	Long Term	Temporary	Negligible	GP registration of workforce, size of workforce and dependents	Management and contracted service, service monitoring and financial contributions	Negligible
Ambulance Service	Long Term	Temporary	Negligible	Size of workforce, number of callouts	Monitoring of impact and financial contribution	Negligible
Operational Employment	Long term	Permanent	Major beneficial	None	Enhancement	Major beneficial
Operational: Supply Chain and Multiplier	Long Term	Permanent	Moderate beneficial	None	None required	Moderate beneficial

CHAPTER 10: TRANSPORT

CONTENTS

TABLES

PLATES

10. TRANSPORT

10.1 Introduction

10.1.1 This chapter of the Environmental Statement (ES) provides an assessment of the potential transport environmental impacts associated with the construction and operational phases of the proposed Hinkley Point C (HPC) Project. Detailed descriptions of the site, proposed development, construction, operational and decommissioning phases are provided in **Chapters 1** to **5** of this volume of the ES.

10.1.2 A glossary of the terminology used in this chapter is provided in **Volume 1** of this ES.

10.2 Scope and Objectives of Assessment

10.2.1 The scope of this assessment has been determined through a formal Environmental Impact Assessment (EIA) scoping process undertaken with the Infrastructure Planning Commission (IPC). It has also been informed by ongoing consultation with statutory consultees, including Somerset County Council (SCC), the Highways Agency (HA), Sedgemoor District Council (SDC) and West Somerset Council (WSC), the local community and the general public in response to the Stage 1, Stage 2, Stage 2 Update and M5 Junction 24 and Highway Improvements consultations. SCC and the HA are the highway authorities for the highways within the HPC study area.

10.2.2 The early sections of this chapter provide background on the scope of the assessment, the legislative and planning policy context, the assessment methodology and the key characteristics of the Hinkley Point C Project which inform the **Transport Assessment** as a whole. Section 10.7 describes the baseline transport conditions in the locality of the HPC development site and all associated development sites. Section 10.8 anticipates the future baseline condition taking into account the developments with planning approval and anticipated future traffic growth (but not the HPC development). Section 10.9 onward then discusses the transport impacts in the locality of the HPC development site and all associated development sites for the three assessment periods of 2013 (early construction), 2016 (peak construction) and 2021 (HPC operational phase with some remaining construction on site and deconstruction of some associated development).

10.2.3 This chapter is based upon the findings of the **Transport Assessment** which supports this application for Development Consent.

10.2.4 The assessment of transportation impacts has been undertaken adopting the methodologies described in **Volume 1**, **Chapter 7** of this ES, and Section 10.6 of this chapter.

10.2.5 This chapter focuses on the potential transport environmental impacts of:

- severance;
- driver delay;
- pedestrian delay;

- pedestrian amenity; and
- accidents and safety.

10.2.6 Other transport issues such as public transport, walking and cycling and travel planning are dealt with in the **Transport Assessment**.

10.2.7 The future baseline traffic conditions are compared with future With Development traffic conditions to assess the impact of the proposed HPC development on the transport networks. The traffic assessments used to inform this analysis assume implementation of the transport strategy and the proposed highway improvements which are both described in the **Transport Assessment** and summarised in this chapter. Any further mitigation measures are described in Section 10.10. An assessment of residual impacts following implementation of these mitigation measures is presented in Section 10.11.

10.2.8 Cumulative transportation impacts arising from the proposed HPC development in combination with other elements of the HPC Project and other relevant, committed projects are identified and assessed in this chapter of this ES. The traffic flows used in this chapter are those generated by committed developments and other predicted growth in the area plus those generated by the HPC Project (i.e. the HPC development site and all the associated development sites). In addition there are some other developments that have not been included in those assessments. These are dealt with in a qualitative way within **Volume 11** of this ES.

10.2.9 The objectives underlying the assessment are to:

- Identify the potential transport environmental impacts of the HPC Project, taking into account the characteristics of the development and the sensitivities of the local environment.
- Identify and describe measures which would be taken to mitigate any identified adverse environmental impacts.
- Predict and evaluate the extent and significance of residual effects taking into account the mitigation.

10.3 Legislation, Policy and Guidance

10.3.1 This section summarises the relevant policy at a national, regional and local level.

10.3.2 The Overarching National Policy Statement (NPS) for Energy (NPS EN-1) (Ref. 10.1) when combined with the NPS for Nuclear Power Generation (NPS EN-6) (Ref. 10.2) provides the primary basis for decisions by the IPC on applications for nuclear power generation developments that fall within the scope of the NPSs.

10.3.3 Notwithstanding this, the IPC may consider other matters that are both important and relevant to its decision making. This could include Planning Policy Statements (PPSs), Planning Policy Guidance Notes (PPGs), regional and local policy documents, although, if there is a conflict between these and the NPS, the NPS prevails for the purposes of IPC decision making.

10.3.4 Furthermore, the Planning Act 2008 (Ref. 10.3) provides that the IPC must, in making its decision on an application, have regard to any Local Impact Report (LIR) prepared by relevant local authorities. It is anticipated that the LIRs will rely in part on PPSs, PPGs, and regional and local policy to provide a context for their assessment. On this basis, regard has been given to these documents (where relevant to the technical assessment) since they are likely to inform the LIRs prepared by the relevant local authorities.

10.3.5 It is also noted that, on 25 July 2011, the Department for Communities and Local Government issued the consultation draft of the National Planning Policy Framework (NPPF) (Ref 10.4) which is intended to replace PPSs, PPGs and some Circulars within a single consolidated document. This provides another reason to attach primary weight to the policies of the NPSs. The consultation period concludes on 17 October 2011 and it is expected that the final NPPF will be adopted in 2012. The draft NPPF sets out a presumption in favour of sustainable development, and the need to support economic growth through the planning system. The draft NPPF also states that Nationally Significant Infrastructure Projects (NSIPs) are determined by the decision making framework set out in NPSs, which are part of the overall framework of planning policy (paragraph 6). The weight to be attached to different policy documents is addressed in the Planning Statement. For the purposes of this assessment, however, greatest weight is attached to the tests and guidance set out in the NPSs. Other policy documents are reviewed, however, as they may be relied on by others, including the IPC.

a) National Policy

10.3.6 In July 2011, parliament adopted the Overarching National Policy Statement for Energy (EN-1) which is the principal document for consideration of all new energy development and establishes the need for new energy infrastructure in the UK.

10.3.7 Paragraph 5.13.3 on Traffic and Transport Impacts sets out the requirement for a Transport Assessment in accordance with the NATA/WebTAG methodology stipulated in the Department for Transport's (DfT) 'Guidance on Transport Assessment' (March 2007) (Ref 10.5). Furthermore, clear direction is given on mitigation measures in paragraph 5.13.8 as follows:

> *"Where mitigation is needed, possible demand management measures must be considered and if feasible and operationally reasonable, required, before considering requirements for the provision of new inland transport infrastructure to deal with remaining transport impacts."*

10.3.8 Paragraph 5.13.10 states that:

> *"Water-borne or rail transport is preferred over road transport at all stages of the project, where cost-effective."*

10.3.9 Managing travel demand in this context can be broadly defined as prioritising the use of alternatives to private car use and road borne freight movements.

10.3.10 When referring to transport impacts the policy states at paragraph 5.13.7:

> *"Provided that the applicant is willing to enter into planning obligations or requirements can be imposed to mitigate transport impacts identified in the NATA/WebTAG transport assessment, with attribution of costs calculated in accordance with the Department for Transports guidance,*

then development consent should not be withheld, and appropriately limited weight should be applied to residual effects on the surrounding transport infrastructure"

10.3.11 Paragraph 5.13.5 also introduces the possibility of cost sharing between the applicant and Government for any third party benefits i.e. where the improvements provided more than offset the impact of the proposal.

10.3.12 Therefore the thrust of policy is that the applicant should take reasonable steps to provide mitigation so as to reduce impacts to an acceptable level but that limited weight should be applied to residual impacts.

i. Draft National Planning Policy Framework (July 2011) (Ref. 10.4)

10.3.13 Within the Transport Chapter, at paragraph 86 the NPPF advises:

"All developments that generate significant amounts of movement, as determined by local criteria, should be supported by a Transport Statement or Transport Assessment. Planning policies and decisions should consider whether:

- *the opportunities for sustainable transport modes have been taken up depending on the nature and location of the site, to reduce the need for major transport infrastructure.*
- *safe and suitable access to the site can be achieved for all people; and*
- *improvements can be undertaken within the transport network that cost effectively limit the significant impacts of the development. Subject to those considerations, development should not be prevented or refused on transport grounds unless the residual impacts of development are severe, and the need to encourage increased delivery of homes and sustainable economic development should be taken into account."*

ii. Planning Policy Statement 1: Delivering Sustainable Development (PPS1) (2005) (Ref 10.6)

10.3.14 Planning Policy Statement 1 (PPS1) was published in January 2005 and sets out the Government's overarching planning policies on the delivery of sustainable development through the town and country planning system.

10.3.15 PPS1 includes a number of key principles relating to development plans including the formulation of an integrated approach to development and the formulation of access policies.

10.3.16 Paragraph 27 (Delivering Sustainable Development) sets out the general approach to delivering sustainable development. In preparing development plans, planning authorities should, amongst other things,:

"Provide improved access for all to jobs, health, education, shops, leisure and community facilities, open space, sport and recreation, by ensuring that new development is located where everyone can access services or facilities on foot, bicycle or public transport rather than having to rely on

access by car, while recognising that this may be more difficult in rural areas."

iii. Planning Policy Guidance 13: Transport (PPG13) (2011) (Ref 10.7)

10.3.17 Originally published in March 2001 and revised in January 2011, Planning Policy Guidance 13 on Transport (PPG13) sets out the national context for planning for transport.

10.3.18 The objectives of PPG13 are to integrate planning and transport at the national, regional, strategic and local level to:

- "*promote more sustainable transport choices for both people and for moving freight*;
- *promote accessibility to jobs, shopping, leisure facilities and services by public transport, walking and cycling; and*
- *reduce the need to travel, especially by car."*

10.3.19 Paragraph 46 states:

"…Policies need to strike a balance between the interests of local residents and those of the wider community, including the need to protect the vitality of urban economies, local employment opportunities and the overall quality of life in towns and cities. Local authorities, freight operators, businesses and developers should work together, within the context of freight quality partnerships, to agree on lorry routes and loading and unloading facilities and on reducing vehicle emissions and vehicle and delivery noise levels, to enable a more efficient and sustainable approach to deliveries in such sensitive locations."

10.3.20 Annex C of PPG13 relates to transport infrastructure. It states that care must be taken to minimise the environmental impact of any new transport infrastructure projects, including the impacts which may be caused during construction (paragraph C1). Annex C goes on to state that particular emphasis should be given to the need to explore a full range of alternative solutions to problems, including solutions other than road enhancement (paragraph C4).

10.3.21 In a number of locations the PPG advises on the preference for using rail or sea to transport bulk goods. For example, at paragraph 47, when discussing minerals, the PPG states "*Local authorities should seek to enable the carrying of materials by rail or water wherever possible…"*

b) National Guidance

i. Circular 2/07 – Planning and the Strategic Road Network (Ref 10.8)

10.3.22 Circular 2/07 'Planning and the Strategic Road Network' published in 2007, details the Highways Agency's (HA) role and requirements in respect of the control of development in proximity to the Strategic Road Network (SRN), for which they are responsible. The Circular sets out:

- An approach adopted by the HA to encourage sustainable development while avoiding the potential for adverse effects on the SRN.

- A framework for collaborative working coordinating a number of organisations including Government Offices, regional and local planning authorities, local highway authorities, public transport providers and developers.
- How the HA will deal with planning applications. Although the Circular predates the Planning Act 2008, the collaborative approach which it advocates is firmly in line with the 'front loaded' approach to DCO applications.

10.3.23 The Circular draws on national policy and guidance and advocates the adoption of a demand management approach to development and promotes Travel Plans as an integral part of managing the capacity of the trunk road network.

ii. Department for Transport – Guidance on Transport Assessment

10.3.24 The DfT published its 'Guidance on Transport Assessment' (GTA) in March 2007. The guidance sets out the following principles:

- Reduce the need to travel, especially by car – thought should be given to reducing the need to travel; consider the types of uses (or mix of uses) and the scale of development in order to promote multi purpose or linked trips.
- Sustainable accessibility – promote accessibility by all modes of travel, in particular public transport, cycling and walking; assess the likely travel behaviour or travel pattern to and from the proposed site; and develop appropriate measures to influence travel behaviour.
- Mitigation measures – ensure as much as possible that the proposed mitigation measures avoid unnecessary physical improvements to highways and promote innovative and sustainable transport solutions.

iii. Highways Agency Protocol for Dealing with Planning Applications (Ref 10.9)

10.3.25 The HA has produced a protocol to assist developers in working with them when submitting a planning application for a development which could have an impact on the SRN.

10.3.26 The section titled 'Stage 2: Formal consultation by the Local Planning Authority' states that:

> *"For developments generating more than 30 two-way trips to the network during any peak period, a transport assessment and travel plan prepared in accordance with DfT and DCLG's 'Guidance on transport assessment' and meeting the requirements of DfT Circular 02/2007."*

10.3.27 This section also sets out the process that the HA requires regarding the consideration of mitigation measures:

- All reasonable steps shall be taken to minimise the level of physical mitigation required, through the use of measures such as travel plans, development phasing, heavy goods vehicle booking systems and encouraging flexible working.
- Physical measures on the local road network to minimise the impact on the strategic road network shall be utilised as far as is reasonably possible.
- Once all reasonable minimisation and off-network mitigation has been implemented, the HA will consider capacity improvements on the strategic road

network. The HA will not accept local capacity improvements where they would overload the wider network.

10.4 Regional Planning Policy

10.4.1 On 27 May 2010 the Secretary of State advised of the Government's intention to abolish regional planning policy and that this should be a material consideration in planning decisions. On 6 July 2010 the Secretary of State for Communities and Local Government revoked all Regional Strategies with immediate effect under section 79(6) of the Local Democracy, Economic Development and Construction Act 2009. This includes Regional Planning Guidance for the South West (RPG10) (Ref 10.10). However, following the High Court judgement on 10 November 2010 in a case brought by Cala Homes the Secretary of State's decision to revoke Regional Strategies was quashed.

10.4.2 As a result, on that same date, the Government wrote to the Chief Planning Officer to reiterate the Government's intention to abolish Regional Strategies through the Localism Bill.

10.4.3 This letter was also challenged on the grounds that the Government's intended revocation of Regional Strategies (including any Saved Structure Plan Policies) by the promotion of legislation for that purposes in the forthcoming Localism Bill was immaterial to the determination of planning applications and appeals prior to the revocation of Regional Strategies.

10.4.4 However, on 7 February 2011, the High Court held that the Government's advice to local authorities that the proposed revocation of regional strategies was to be regarded as a material consideration in their planning development control decisions should stand. The decision of the High Court was upheld by the Court of Appeal on 27 May 2011. The Court of Appeal clarified that it would be unlawful to have regard to the Government's intention to abolish regional strategies in the preparation and examination of Development Plan Documents. Therefore, the regional strategies remain in place but in the case of a development control decision it is for planning decision makers to decide on the weight to attach to the strategies taking into account, as a material consideration, the Government's stated intention to revoke them.

a) Regional Planning Guidance 10 for the South West 2001 – 2016 (RPG10) (2001) (Ref. 10.10)

10.4.5 Regional Planning Guidance for the South West (RPG10) sets out a broad strategy for the South West up to 2016.

10.4.6 Section 8 relates specifically to Transport and sets out the Regional Transport Strategy (RTS). The role of the RTS is to support the spatial strategy, to provide the strategic transport framework for the Local Transport Plans (LTPs) and development plans and to provide a framework for the investment and operational plans for relevant transport agencies/operators.

10.4.7 The RTS has 5 key objectives:

- *"To support the spatial strategy of RPG and to service existing and new development efficiently and in an integrated fashion;*

- *To reduce the impact of transport on the environment, by reducing the need to travel, encouraging travel by more sustainable means (especially by walking and cycling) and locating development at accessible locations, particularly by public transport; and to achieve environmental improvements by directing investment to those locations where infrastructure is required to offset the damaging effects arising from the impacts of traffic and transport;*
- *To secure improved accessibility to work, shopping, leisure and services by public transport, walking and cycling;*
- *To create a modern, efficient and integrated transport system that will meet the demands of a dynamic regional economy, help overcome regional peripherality and meet all travel needs; and*
- *To ensure the safe use of regional transport network and its associated facilities." (Page 83).*

10.4.8 Policy TRAN 1 (Reducing the Need to Travel) states that local authorities, developers and other agencies should work towards reducing the need to travel by private motor vehicle through the appropriate location of new development.

10.4.9 Policy TRAN 6 (Movement of Goods) states that local authorities, the business community, transport operators and other agencies should work together to achieve more sustainable patterns of distribution. Amongst other things, they should aim to locate major freight generating development close to the regional rail and road networks.

10.4.10 Policy TRAN10 (Walking, Cycling and Public Transport) states that:

"Local authorities, transport operators and other agencies should aim to increase the share of total travel by these modes and ensure that they provide attractive and reliable alternatives to the private car by:

- *Seeking transport assessments and travel plans for all new major developments and encouraging major organisations to prepare and implement such plans, having regard to sustainable transport objectives set by local authorities in the local transport plan; and*
- *Ensuring that major new development delivers (or sets out a clear and realistic strategy to deliver) a realistic choice of access by public transport, walking and cycling."*

b) The Draft Revised Regional Spatial Strategy for the South West Incorporating the Secretary of State's Proposed Changes 2008 – 2026 (July 2008) (Ref 10.11)

10.4.11 The Draft Regional Spatial Strategy (RSS) for the South West (2006-2026) was published by the South West Regional Assembly in 2006. In 2008 the Secretary of State published proposed changes to the draft RSS for further consultation.

10.4.12 If adopted, this document would replace the existing RTS, published in RPG10. Chapter 5 sets out the strategy's regional approach to transport. The main aim of the RTS is to support the RSS and reduce the rate of road traffic growth by:

- *"Supporting economic development (identified in the RES) by maintaining and improving the reliability and resilience of links from the region's Strategically Significant Cities and Towns (SSCTs) to other regions, international markets and connectivity within the region;*
- *Addressing social exclusion by improving accessibility to jobs and services;*
- *Making urban areas work effectively and creating attractive places to live by developing the transport network in support of the strategy to concentrate growth and development in the SSCTs; and*
- *Reducing negative impacts of transport on the environment including climate change." (Page 139).*

10.4.13 Policy RTS1 (Corridor Management) states that, in order to improve the reliability and resilience of journey times, to develop opportunities to facilitate a modal shift and support growth at the Strategically Significant Cities and Towns (SSCTs), which include Bridgwater and Taunton, provision will be made to manage the demand for long distance journeys and reduce the impacts of local trips on corridors of national and regional importance.

10.4.14 Policy RTS2 (Demand Management and Sustainable Travel Measures at the SSCTs) states that demand management measures should be introduced progressively at the SSCTs to reduce the growth of road traffic levels and congestion. This should be accompanied by a 'step change' in the prioritisation of sustainable travel measures serving these places.

10.4.15 Policy RTS3 (Parking) states that parking measures should be implemented to reduce reliance on the car and encourage the use of sustainable transport modes.

c) Somerset and Exmoor National Park Joint Structure Plan Review 1991 – 2011 (2000) (Policies 'saved' from 27 September 2007) (Ref 10.12)

10.4.16 The Somerset and Exmoor National Park Joint Structure Plan was adopted in 2000 with relevant policies saved from 27 September 2007. All policies have been saved with the exception of Policy 53 which related to the Department of the Environment, Transport and the Regions Road Schemes. The Plan provides a strategic base for all land use planning within the plan area for the period up to 2011.

10.4.17 The Structure Plan sets out a preferred strategy for development which includes the encouragement of a balanced and integrated transport system which emphasises alternatives to the private car, where practical (paragraph 3.8).

10.4.18 Policy STR1 (Sustainable Development) states that development should, amongst other things, develop a pattern of land use and transport which minimises the length of journeys and the need to travel and maximises the potential for the use of public transport, cycling and walking; and conserve biodiversity and environmental assets, particularly nationally and internationally designated areas.

10.4.19 Policy 39 (Transport and Development) states that proposals for development should be considered having regard to:

- The management of demand for transport.

- Achieving a shift in transport modes to alternatives to the private car and lorry wherever possible.
- The need for improvements to transport infrastructure.

10.4.20 Policy 45 (Bus) states that facilities for buses should be improved. This should include measures to give priority to buses and to introduce park and ride systems where these are the most sustainable option.

10.4.21 Policy 48 (Access and Parking) states that developments which generate significant transport movements should be located where provision may be made for access by walking, cycling and public transport. The level of parking provision in settlements should reflect their functions, the potential for the use of alternatives to the private car and the need to prevent harmful competitive provision of parking. The level of car parking provision associated with new development should first take account of the potential for access and provide for alternatives to the private car, and then, should be no more than is necessary to enable development to proceed.

10.4.22 Policy 49 (Transport Requirements of New Development) states that proposals for development should be compatible with the existing transport infrastructure, or, if not, provision should be made for improvements to infrastructure to enable development to proceed. In particular development should:

- Provide access for pedestrians, people with disabilities, cyclists and public transport.
- Provide safe access to roads of adequate standard within the route hierarchy and, unless the special need for and benefit of a particular development would warrant an exception, not derive access directly from a National Primary or County Route.
- In the case of development which will generate significant freight traffic, be located close to rail facilities and/or National Primary Routes or suitable County Routes subject to satisfying other Structure Plan policy requirements.

10.4.23 Policy 50 (Traffic Management) states that traffic management schemes which improve safety, travel conditions and the environment should be implemented to make the best possible use of the highway network. Such schemes should remove or reduce heavy or unnecessary vehicles from settlements or sensitive environments and improve conditions for pedestrians, cyclists and public transport users.

10.4.24 Policy 52 (Freight Traffic (Lorries in the Environment)) states that traffic, and particularly lorries, should be encouraged to use National Primary Routes wherever possible through appropriate measures such as positive signing and by discouraging the use of unsuitable roads through traffic management schemes.

10.4.25 Policy 54 (Transport Proposals and the Environment) states that new transport proposals and improvements, particularly road schemes must take into account the need to: minimise the impact of proposals through mitigation and compensation measures; improve or conserve the natural and built environment; avoid the risk of pollution to the water environment, including water resources; minimise the consumption of resources both in construction and operation; and, minimise conflict with adjoining land uses.

10.4.26 Policy 58 (Ports and Wharves) states that existing port and wharf facilities should be safeguarded from development which would prejudice their potential in the transport network. Any proposals for new facilities should be within or related to settlements.

10.5 Local Policy and Guidance

a) Local Policy

i. West Somerset Council Local Plan (2006) (Policies 'saved' from 17 April 2009) (Ref 10.13)

10.5.1 The West Somerset Local Plan forms part of the development plan for West Somerset. The Local Plan was adopted in 2006 (with relevant policies ‘saved’ from 17 April 2009). The key transport objectives of the West Somerset Local Plan are not saved as they are not policies, but were as follows:

- Reduce the need to travel and the distances travelled.
- Promote the best use of public transport routes and nodes, especially for journeys to work.
- Reduce environmental damage and promote environmental improvement by traffic management and calming measures, particularly in town and village centres.
- Promote the development of safe and convenient routes for cyclists and pedestrians.
- Ensure that new development proposals have appropriate access to public transport services.
- Safeguard the implementation of major highway schemes in the Structure Plan.

10.5.2 Policy T/3 (Transport Requirements of New Development) states that:

“New roads and improvement schemes should be designed to minimise their environmental impact. As far as the Local Planning Authority’s powers permit, planning permission will only be permitted where the proposal:

i) is of a design which both minimises the environmental impact and also the risk of accidents.

ii) has no adverse effects on the character of sensitive or distinctive landscapes, townscapes and areas of acknowledged historic or wildlife interest.

iii) uses materials and street furniture sympathetic to the locality.

iv) includes indigenous landscaping schemes to integrate into the surrounding area.

v) makes appropriate provision for pedestrians, cyclists the mobility impaired and for access to public transport.

vi) minimises the impact on the environment through mitigation and compensation measures where necessary; and

vii) conforms with national and county council design standards.”

10.5.3 Policy T/7 (Non-Residential Development Car Parking) states that:

> *"Car parking at non-residential development shall be provided on the following basis:*
>
> *i) Operational parking will be kept to the minimum necessary:*
>
> *ii) Non-operational parking will be set at a maximum of the level shown in Appendix 4, Table 3, reduced according to the availability of public transport and facilities for walking and cycling, as shown in Appendix 4, Tables 1 and 2; and*
>
> *iii) Where reduction in vehicle parking is appropriate, contributions will be sought for alternative modes of transport required to serve the development."*

10.5.4 Policy T/9 (Existing Footpaths) states that:

> *"Any development affecting an existing footpath will be required to incorporate the footpath into its design. Care should be taken to ensure that the footpath is attractive to users and safe."*

ii. West Somerset District Local Development Framework (LDF) Core Strategy (Options Paper) (January 2010) (Ref 10.14)

10.5.5 In accordance with the Planning and Compulsory Purchase Act 2004, West Somerset Council is in the process of producing its LDF, which, once adopted, will replace the Local Plan.

10.5.6 In January 2010, WSC published its Core Strategy Options Paper which is a material consideration for determining planning applications, although the weight attached to this document will be limited, given that it is at a relatively early stage of preparation.

10.5.7 The Options Paper does not include any specific policies relating to transport. The paper does however identify the types of policy that WSC considers could be included in the Core Strategy. In relation to transport, these are as follows:

- *"Reduce the threshold for travel plans to require them for medium sized as well as large development.*
- *Require contributions from new development to improve cycling and walking infrastructure.*
- *Locate new developments likely to give rise to significant numbers of trips in locations which are served by a range of modes of transport.*
- *Explore the opportunity offered by the West Somerset Railway to connect sites within the District to the national rail network for freight traffic.*

- *Examine the potential for a commuter train service to be offered using the West Somerset Railway.*
- *Any new major development to be of an appropriate mix of uses and facilities to offer the opportunity to reduce transport demand."*

iii. Sedgemoor District Local Plan 1991 – 2011 (2004) (Policies 'saved' from 27 September 2007) (Ref 10.15)

10.5.8 The Sedgemoor District Local Plan forms part of the Development Plan for Sedgemoor. The Local Plan was adopted in 2004 (with relevant policies 'saved' from 27 September 2007). The Transport and Movement chapter of the Local Plan states that an efficient transport system is vital to the economic and social well being of the District. It explains that policy on transport and movement will therefore support the Local Plan's strategy of balance between sustainability and controlled economic growth (paragraph 7.01).

10.5.9 Paragraph 7.05 states that the vision of the Local Plan is for an efficient, high quality and sustainable transport system, accessible to all sections of the community. This will be achieved by maintaining and improving transport infrastructure while reducing dependence on the private car.

10.5.10 Policy TM1 (Safe and Sustainable Transport) states:

"a) development will not be permitted which would prejudice the construction of cycle and pedestrian routes and bus lanes defined on the Proposals Map, unless suitable alternative routes are provided by the developer;

b) development will not be permitted which would reduce the convenience and safety of existing rights-of-way, bridle paths and cycle paths unless suitable alternative routes are provided by the developer;

c) development will only be permitted if the design makes adequate and safe provision for access by foot, cycle, public transport and vehicles so long as it's appropriate to the scale of the development and in accordance with National and County Council design standards and Somerset County Council's Highway hierarchy;

d) the Developer shall provide the transport infrastructure required by the development to an agreed phased programme. Where off-site works are required, these shall be appropriate to the scale and nature of the development and shall be funded by the developer; and

e) development will not be permitted for proposals which would have a significant impact on the highway network without the prior submission of a Traffic Impact Assessment."

10.5.11 The Local Plan states that current government guidance stresses the need to consider alternatives to building new roads. Proposals for construction of major new highways must therefore, meet the most rigorous levels of justification (paragraph 7.11).

iv. Sedgemoor Local Development Framework (LDF) Core Strategy (Proposed Submission) (September 2010) (Ref 10.16)

10.5.12 The Sedgemoor LDF Core Strategy (Proposed Submission) was consulted on from September to November 2010. An addendum to the Core Strategy was subject to a further consultation from 23 November 2010 until 18 January 2011. Changes prior to submission, proposed as a result of the consultation process were reported and endorsed by SDC's Executive Committee on 9 February 2011. The Core Strategy Proposed Submission was submitted to the Secretary of State on 3 March 2011 and an Examination in Public (EiP) was held in May 2011. Once adopted, the Core Strategy will form part of the Development Plan for Sedgemoor.

10.5.13 EDF Energy submitted representations objecting to the Core Strategy (Proposed Submission), relating to Chapter 4 'Major Infrastructure Projects' (and policies MIP1, MIP2 and MIP3 contained in that chapter) and those sections relating to housing and Hinkley Point. EDF Energy also participated at the relevant EiP hearings.

10.5.14 At the close of the hearing sessions on 26 May 2011, the Inspector agreed with SDC and EDF Energy that, in an attempt to reach agreement on the disputed Chapter 4, SDC would re-draft Chapter 4 and EDF Energy would have the opportunity to respond. The position of both parties in relation to the re-drafted Chapter 4 was set out in correspondence between SDC, EDF Energy and the Inspector. As a result of the correspondence invited by the Inspector, SDC has agreed to further changes to the Core Strategy which make clear that the Core Strategy does not set any policies, tests or requirements for the IPC to apply in deciding whether any element of the development comprised in an application for development consent is acceptable, nor the basis on which any such application should be approved. Instead, the Chapter is to set out those matters which SDC may take into account in preparing its LIR for the Hinkley Point C DCO application. These, therefore, represent aspirations of the Council, rather than formal planning policy for the Hinkley Point C DCO application. This status has now been confirmed in the Inspector's report on the examination of the Core Strategy, which was published on 27 September 2011.

10.5.15 Emerging policies MIP1, MIP2 and MIP3 relate specifically to the HPC Project, as set out in the re-drafted Chapter 4 (dated 29 July 2011).

10.5.16 Policy MIP1 (Major Infrastructure Proposals) explains that applications for major infrastructure development will be considered against the relevant national planning policy and the strategy and relevant policies of the development plan. The objective from the Council's perspective is that major infrastructure proposals should, where possible, contribute positively to the implementation of the spatial strategy and meet the underlying objectives of it.

10.5.17 Policy MIP2 (Hinkley Point C Associated and Ancillary Development) sets out the considerations that the Council will take into account in the preparation of a LIR in responding to proposals for development associated with, or ancillary or related to the HPC Project, where they are not the determining authority. Such considerations include: measures to avoid, minimise and then mitigate adverse impacts on the transport network; highway safety for all users should be maintained and where possible improved; investments that encourage travel by public transport, walking and cycling; and the delivery of investment in infrastructure, buildings and green infrastructure.

10.5.18 Policy MIP3 (Hinkley Point C: Planning Obligations and Mitigation) states that the Council will seek to ensure, wherever possible, that the proposals avoid, minimise and mitigate (including, where appropriate, compensate for) impacts during the construction, operation, decommissioning, and restoration phases.

10.5.19 In addition, the following emerging policies contained in the Core Strategy (Proposed Submission) are considered to be of potential relevance:

- Policy S1 (Spatial Strategy for Sedgemoor) states that development proposals will be expected to support the delivery of required infrastructure, including such things as transport infrastructure.
- Policy S2 (Infrastructure Delivery) states that all new development that generates a demand for infrastructure will only be permitted if the necessary on and off-site infrastructure required to support and mitigate the impact of the development site is either already in place or there is a reliable mechanism in place to ensure that it will be delivered at the time and in the location it is required.
- Policy S3 (Sustainable Development Principles) states that development proposals will be expected to, amongst other things, be located to minimise the need to travel and to encourage any journeys that remain necessary to be possible by alternative modes of travel including maximising opportunities for walking, cycling and the use of public transport.
- Policy S4 (Mitigating the Causes and Adapting to the Effects of Climate Change) states that development should mitigate the cause of climate change through, amongst other things, ensuring development encourages modes of transport other than the car.
- Policy D2 (Promoting High Quality and Inclusive Design) states, amongst other things, that development will need to demonstrate that it is accessible to all potential users using a range of transport modes, be integrated into existing patterns of movement and be permeable. Its design should create good connections to wider areas with a clear network of routes for walking and cycling.
- Policy D9 (Sustainable Transport and Movement) states, amongst other things, that travel management schemes and development proposals that reduce congestion, encourage an improved and integrated transport network and allow for a wide choice of modes of transport as a means of access to jobs, homes, leisure and recreation, services and facilities will be encouraged and supported.
- Policy D10 (Managing the Transport Impacts of Development) states that development proposals that will have a significant transport impact should, amongst other things: be supported by an appropriate Transport Assessment and Travel Plan; ensure inclusive, safe and convenient access for all; provide safe access to roads; ensure that the expected nature and volume of traffic and parked vehicles generated would not compromise road safety and/ or function; comprehensively address the transport impact of development and appropriately contribute to the delivery of necessary transport infrastructure; not prejudice safeguarded transport infrastructure; and enhance and develop rights of way.

b) Other Local Documents

i. Hinkley Point C Project Supplementary Planning Document Consultation Draft (February 2011) (Ref 10.17)

10.5.20 SDC and West Somerset Council (WSC) have jointly prepared draft supplementary planning guidance in relation to the HPC Project. Public consultation on the Consultation Draft version of the Hinkley Point C Project Supplementary Planning Document ("the draft HPC SPD") commenced on 1 March 2011 and concluded on 12 April 2011. EDF Energy has submitted representations which object to the draft HPC SPD.

10.5.21 Following the Sedgemoor Core Strategy EiP and subsequent correspondence with the Inspector, it is clear that the SPD cannot set tests, policies or requirements for the IPC to apply to the consideration of the Hinkley Point C project. If the Councils continue with the SPD preparation, its text will need to be considered in this light and it could not carry any weight in the determination of the DCO application. As it may be relied upon by some stakeholders, however, the principal contents of the draft SPD as it relates to the site are summarised below. In relation to transport, Box 8 of the draft HPC SPD states that the County Council and District Councils will expect the HPC Project promoter to:

- *"Align the Transport/Freight Strategy with other Council plans and strategies. The transport proposals for the HPC project during both the construction and operational phases of the power station should integrate with and contribute to the delivery of the approved transport strategies as set out in the Somerset Future Transport Plan and associated transport policies and implementation plan, the Bridgwater, Taunton and Wellington Future Transport Strategy, the Bridgwater Vision, Western Somerset Economic Development and Access Strategy and emerging Williton master-plan.*
- *Minimise the volume of road traffic associated with the development of the new power station at all times, but especially during peak hours and during the peak tourism season between the months of June, July and August. The efficient and safe functioning of key routes, including the M5, A38, A361, A370, A371 and A372 must be protected.*
- *Maximise the safe, efficient and sustainable movement of people and materials required for the proposed nuclear power station.*
- *Provide transport mitigation where additional traffic flows of the project exacerbate or cause highway congestion problems.*
- *Any new highway proposals are to be justified by a full New Approach to Appraisal (NATA) assessment. Appraisals should address potential impacts raised during consultation, such as the potential severance effect to Brymore School of the western by-pass option at Cannington.*
- *All proposed highway works are to be the subject of a full operational analysis and a road safety audit in accordance with then current guidance.*
- *Provide sustainable transport solutions for access to the site that workers and visitors will be required to use. This should include*

provision of public transport priority measures in the form of bus lanes and other bus priority measures on key routes from associated development sites to the main site for construction and other vehicles, providing a beneficial transport legacy.

- *Provide sustainable transport linkages to and from all associated development sites to provide access to employment, education, retail, leisure and healthcare facilities.*
- *Ensure the number of parking spaces provided at or near to the site during the construction phase is as close as possible to zero.*
- *Enable effective controls to be put in place to ensure workers and visitors do not park in inappropriate locations.*
- *Ensure as much construction material as possible is delivered by sea.*
- *Minimise the amount of waste materials, including topsoil, transported off-site.*
- *Provide necessary improvements to the transport network to mitigate against any adverse impacts on the community; including but not limited to congestion, air quality and road safety impacts. For example, include safety improvements where the additional traffic flows of the project exacerbate existing road safety problems.*
- *Minimise traffic disruption both for the local community and visitors to the area.*
- *Control and manage the flow of any road freight movement associated with the development in order to ensure appropriate routes are used, avoid peak hour movement and to respond to incidents on the transport network.*
- *Agree and enable deployment of robust plans for managing unforeseen incidents on the transport network, including but not limited to traffic management plans, diversionary routes and freight/ delivery management systems.*
- *Provide long-term, sustainable legacy benefits for the local community.*
- *Protect the natural and built environment and ensure the image of the area is not adversely affected.*
- *Ensure that public transport services are protected throughout the construction, operation and decommissioning of the Hinkley Point nuclear power stations.*
- *Ensure that the needs of cyclists and pedestrians are protected and enhanced throughout the construction and operation of the proposed nuclear power station. This should include enhanced pedestrian and cycle facilities from associated development sites to the centres of nearby towns and villages, including provision of the Bristol Road/(Bath Road) link and rail crossing in Bridgwater.*
- *Protect current Public Rights of Way (PRoW) in and around Hinkley Point and associated development sites, and where stop-ups are required, ensure that PRoW are implemented that do not result in significant diversion lengths.*

- *Develop and implement Travel Plans for the proposed power station and associated development that will be monitored during construction and operation of Hinkley Point C.*
- *Monitor all movement associated with the development to ensure agreed mode share targets and thresholds for traffic congestion, air quality and road safety are achieved during construction and operation.*
- *Fully mitigate against and compensate for the adverse environmental impact of development related traffic. This should involve providing sufficient funds through appropriate legal agreements to enable the relevant authorities and agencies to implement further mitigation measures should any unforeseen impacts occur during the construction of the development."*

ii. Somerset Future Transport Plan (Ref 10.18)

10.5.22 Somerset's Future Transport Plan 2011 – 2026 (FTP) replaced Somerset County Council's (SCC) Second Local Transport Plan (LTP2) in April 2011 and sets out a long-term strategy for helping to deliver transport priorities up until 2026.

10.5.23 The FTP contains the following statements:

- *"Help communities help themselves with regard to transport improvements;*
- *Assisting people to make smarter travel choices;*
- *Assisting people in being more active by providing more opportunities to travel in a healthy way;*
- *Manage the effect transport-related noise has on communities;*
- *Work with developers to ensure they take in to account the way people travel, and how people travel to access services;*
- *We will help hauliers choose the most appropriate routes and work to improve communication between communities and the hauliers that serve them;*
- *Encourage people to cycle and make more trips on foot."*

10.5.24 This demonstrates that local transport policy supports the provision of sustainable travel measures above new road building and capacity improvements.

iii. Technical Note 4 – Somerset County Council Transport Policies: Transport and Development (Ref 10.19)

10.5.25 The 'Technical Note 4 – Somerset County Council Transport Policies: Transport and Development – March 2010' document is a supporting Technical Document to the FTP.

10.5.26 Section 3 of the policy relates to Assessing Transport Impacts of Development.

10.5.27 Paragraph 3.19 states that:

"The Council will agree a suitable approach to determining the level of impact depending on the location and scale of the proposed development. In the main urban areas of Taunton, Bridgwater and Yeovil strategic traffic models are available and should be used in the first instance to identify potential development impacts. A useful starting point is to identify those junctions where the development traffic increases the modelled queue length by 5 or more vehicles on one or more arms of the junction. More detailed investigations into the impact of development traffic at these locations should then be undertaken using appropriate junction modelling tools. It should be noted that this is only a guideline value and the Case Officer may identify other junctions where detailed assessments will be required on a case–by-case basis."

10.5.28 Paragraph 3.21 states that:

"Once detailed investigations into the impact of development traffic have been undertaken at agreed locations the Council will consider whether measures are required to mitigate the impacts of the development. In considering the assessment and subsequent mitigation, the Council will seek to achieve the following outcomes. and will agree on a case by case basis how this will be assessed by the developer:

- *Nil-detriment to junction capacity and delay from development traffic where junctions currently operate at greater than 85% ratio of flow to capacity (RFC) for non-signalised junctions, or 90% for signalised junctions;*
- *Nil-detriment from development traffic on links where capacity is currently at 90% or more;*
- *Nil-detriment to journey times for traffic on agreed routes;*
- *Nil-detriment to journey times for public transport, walking or cycling;*
- *Nil-detriment to accident rates at clusters along key routes; and*
- *Agreed mode share targets for development related trips where travel plans are required (see Section 3.4)."*

10.5.29 Section 6 of this policy relates specifically to the proposed development at Hinkley. SCC should not seek to develop new planning policies to test a nationally significant infrastructure project (NSIP). NSIPs are subject to their own planning regime set out in the Planning Act 2008 and the primary consideration for NSIPs is the policy to be set out in the Energy and Nuclear National Policy Statement (NPS), in respect of both the HPC development site and the associated development.

10.5.30 Policy HIN 1: Transport requirements for new nuclear development states that Council will require the developer of new nuclear power stations in Somerset to:

- *"Minimise the volume of road traffic associated with the development of the new power station especially at peak hours.*

- *Provide sustainable transport solutions for access to the site that workers and visitors will be required to use.*
- *Provide sustainable transport linkages to and from all associated development sites.*
- *Ensure as close as possible to zero parking spaces are provided at or near to the site during the construction phase.*
- *Enable effective controls to be put in place to ensure workers and visitors do not park in inappropriate locations.*
- *Ensure as much construction material as possible is delivered by sea.*
- *Minimise the amount of waste materials transported off-site.*
- *Provide necessary improvements to the transport network to mitigate against any adverse impacts on the community; including but not limited to congestion, air quality and road safety impacts.*
- *Minimise disruption both for the local community and visitors to the area.*
- *Control and manage the flow of any road freight movement associated with the development in order to ensure appropriate routes are used, avoid peak hour movement and to respond to incidents on the transport network.*
- *Agree and enable deployment of robust plans for managing unforeseen incidents on the transport network; including but not limited to traffic management plans, diversionary routes and freight/delivery management systems.*
- *Provide long-term, sustainable legacy benefits for the local community.*
- *Protect the natural and built environment and ensure the image of the area is not adversely affected.*
- *Monitor all movement associated with the development to ensure agreed mode share targets and thresholds for traffic congestion, air quality and road safety are achieved during construction and operation.*
- *Provide sufficient funds through appropriate legal agreements to enable the relevant authorities and agencies to implement further mitigation measures should any unforeseen impacts occur during the construction of the development."*

10.5.31 Policy HIN 2 sets out the 'Requirement for an Evidence Based Approach' as follows:

"An evidence-based approach will be taken to determine the effectiveness of the proposed transport interventions for the implementation of the HPC transport/freight strategy. We will require the HPC project promoter to adhere to performance criteria in relation to key parts of the transport network. It should be noted that as such, a transport strategy package of measures will be expected to meet this approach, which would include:

- *Highway improvements, including junction improvements and more strategic network improvements identified through the transport assessment process and associated evidence base.*

- *Public transport provision, including waiting facilities, support for existing and additional services, and priority measures that will ensure public transport journey time reliability.*
- *Intelligent Transport Systems (ITS) to promote and support the use of public transport facilities.*
- *Road Safety Improvements.*
- *Infrastructure needs associated with deploying a Traffic Management Plan.*
- *Pedestrian and cyclist facilities, including those which support the use of public transport and support the provision of a high quality public realm.*
- *Motorcycle parking.*
- *Park and Ride facilities if demonstrated as necessary.*
- *Car parking management for the site, associated development and residential areas, including clearway provision.*
- *Coach and rail facilities.*
- *Provision and management of water-borne transport.*
- *Highways and bridge strengthening measures.*
- *Transport maintenance packages.*
- *Transport monitoring strategy to assess effectiveness of measures and identify further mitigation, where necessary."*

10.5.32 Policy HIN 3 summarises SCC's requirements for the 'Evidence for the Development Consent Application' as follows:

"Prior to the Development Consent Application to the IPC the Council will require the following evidence to be in place to enable the robust development of a Statement of Common Ground and a Local Impact Report:

- *A Transport Assessment to cover the construction and operation of the site and associated developments, including an assessment of the required access arrangements, likely impacts, appropriate mitigation and improvements to the transport system with completed technical audits.*
- *A Transport Strategy and associated evidential base for managing freight waste and people movements associated with the construction of the development.*
- *A Travel Plan for the construction phase; including mode share targets for access to and from the main site and each associated development site.*
- *Directly linked to parking standards, provision of access infrastructure, provision of sustainable transport linkages and design of development layouts.*
- *Full transport assessments and travel plans for any other significant related development proposals that emerge such as induction facilities.*

- *A Travel Plan to manage access to the development in its operational phase.*
- *A Visitor Management Plan to manage visitor access to the site and maximise access by sustainable transport.*
- *Traffic Management Plans to manage unforeseen incidents on the transport network.*
- *Construction Management Plan for HGV and construction worker movements.*
- *Agreed monitoring, control and enforcement proposals for all aspects of movement."*

10.5.33 Finally, Policy HIN 4 summarises SCC's requirements for 'Arrangements Prior to Commencement of Construction' as follows:

> *"Prior to commencement of construction the Council will require the following to be agreed with the relevant authorities and agencies:*
>
> - *Site specific travel plans for each associated development site.*
> - *Final detailed freight management plans based on actual materials sourcing.*
> - *Final detailed waste management plans.*
> - *Implementation of agreed access arrangements and necessary controls.*
> - *Implementation of an agreed transport mitigation package.*
> - *Implementation of visitor management, traffic management, monitoring and enforcement arrangements.*
> - *Any required financial contributions."*

iv. Bridgwater Vision (Ref 10.20)

10.5.34 Whilst not forming part of the statutory development plan for Sedgemoor, the Bridgwater Vision (2009) sets out a regeneration framework for Bridgwater, comprising a 50 year vision and seven transformational themes for the town.

10.5.35 The document makes specific reference to Hinkley Point as a strategic project and acknowledges the opportunities and challenges such development will have on the area.

10.5.36 Bridgwater's overall vision is encapsulated in Vision V1, which states:

> *"In 2060 Bridgwater will be an energy conscious town known for its ambitious approach to sustainability and low carbon living. Bridgwater will be seen as a place that has been re-energised into a confident town through its strong, innovative architecture, its vibrant town centre and its revitalised neighbourhoods – encouraging a greater sense of local community, wellbeing and civic pride.*
>
> *Bridgwater will have a reputation for successful, coordinated delivery of its ambitious place shaping programme. The town's people, businesses and agencies will continue to work in partnership to improve housing and*

transport, deliver its flooding solution; the Parrett barrier and provide outstanding health and recreation facilities. Bridgwater will continue to attract new investment, maintaining its new position as a regional centre of enterprise excellence. Its highly skilled workforce will be utilised by the many cutting edge employers in the town, encouraged by the focus on innovation and knowledge, offering quality job opportunities and training in new and emerging sectors."

10.5.37 Theme 5 of the Vision is 'An accessible and well connected Bridgwater'. The document explains that:

"This theme promotes measures to control traffic growth through improvements to public transport, improved facilities for pedestrians and cyclists, and creating better links to the wider network including Hinkley Point..." (page 38).

10.5.38 Section 4 (A New Direction for Bridgwater) gives further consideration to Hinkley Point:

"The planned construction of a new nuclear power station will not only bring many jobs, but also will require local businesses to improve their skills in order to prepare for future bidding, which in its own turn should contribute to the development of a knowledge economy.

It will also be essential to evaluate the environmental impact of proposals and the impact on local communities, both in construction and post construction. This may include for example, noise and disturbance from traffic and construction, the impact of abnormal loads, and the possible development of Combwich Wharf. It will also be important to assess the impact of the proposals on strong existing economic sectors such as tourism, where compensatory mitigation may be required to support the sector." (page 44)

10.5.39 The Strategic Spatial Diagram (pages 60-61) within the document identifies a potential new link road between Dunball roundabout and Hinkley Point.

10.5.40 The potential for road improvements to Hinkley from Junction 23 of the M5 motorway is identified as an opportunity, which may require a new link road running from the Dunball roundabout travelling west across the River Parrett towards Hinkley (page 106). The design principles for this include:

"Dunball roundabout provides a key gateway into the town from Junction 23 of the M5 motorway and potentially to Hinkley Point through a possible new link road.

The area will incorporate a possible new link road from the Dunball roundabout across the River Parrett connecting Hinkley Point to Junction 23 of the M5 motorway…"

10.5.41 The transport related design principles for the North Bridgwater character area (within which the Junction 23 site is located) are set out in the Vision as follows:

- Dunball roundabout provides a key gateway into the town from Junction 23 of the M5 motorway and potentially to Hinkley Point through a possible new link road.

- Bristol Road will be part of the key public transport corridor providing high frequency bus connections to the town centre from a sequence of bus stops along the route. The road corridor will also incorporate segregated pedestrian and cycle lanes providing safe, high quality connections to the town centre.
- A new link road into North East Bridgwater accessed directly from Bristol Road should be provided.
- A park and ride facility in conjunction with enhanced bus services will also provide connections from the North Bridgwater area to Bridgwater town centre (page 107).

10.5.42 The transport related design principles for North East Bridgwater character area (within which the Bridgwater A accommodation campus is located) are set out in the Vision as follows:

- The dismantled railway line should be retained as a key pedestrian/cycle green link east-west across North East Bridgwater.
- High quality cycle and pedestrian connections should be made to Sydenham, the town centre, the railway station, and the adjacent employment areas.
- A public transport route should be provided facilitating safe, easy and well-connected movement through and close to important amenities and high density areas of housing in particular (page 91).

10.5.43 The transport related design principles for the Sydenham and Bower character area (within which the Bridgwater C accommodation campus is located) are set out in the Vision as follows:

- Improved pedestrian and cycle routes will be promoted throughout the area to connect residents to local shops and services, community facilities, employment areas, the rail station and the town centre.
- The strategic role of Bower Lane will be strengthened as development occurs with connections between North East Bridgwater and South Bridgwater promoted (page 84).

10.5.44 The transport related design principles for the Huntworth character area (within which the Junction 24 site is located) are set out in the Vision as follows:

- Taunton Road will be promoted as a key public transport corridor with high frequency bus services giving workers in the area direct and frequent access to the town centre.
- A park and ride site adjacent to the A38 Taunton Road in conjunction with enhanced bus services will also provide connections to Bridgwater town centre.
- High quality, safe and legible pedestrian and cycle routes will be created through the area strengthening links back to the town centre particularly along the Canal corridor.
- Consideration should be given to improving pedestrian and cycle connections to the footbridge over the M5 to connect new development on the eastern side of the motorway into Bridgwater.

- A Travel Plan would be critical to the options presented for the site, with the potential for a bespoke public transport service and connecting pedestrian and cycle infrastructure back to the town centre (page 88).

v. Bridgwater, Taunton and Wellington Transport Strategy (Ref 10.21)

10.5.45 The Transport Strategy for Bridgwater, Taunton and Wellington for the period 2009 – 2026 was adopted by SCC in March 2010. The strategy indicates a number of infrastructure improvements that may be implemented during the strategy's lifespan in support of the draft Regional Spatial Strategy and will likely be a key component of the Third Somerset LTP.

10.5.46 At section 5.1 on Bridgwater the strategy states that SCC:

> *"…..will further investigate the potential for introducing park and ride sites on the edges of the town to reduce town centre congestion. We will seek to improve sustainable links to the railway station, as well as increasing opportunities for walking and cycling in the town by removing physical barriers created by roads, by providing new infrastructure and by improving the pedestrian environment in the town centre."*

10.5.47 SCC's transport strategy document also indicates a number of improvements that may be implemented during their strategy's life-span. Some of the improvements that are listed are advised to be development-related and will only be implemented should the site specific developments proceed.

10.6 Methodology

10.6.1 The Institute of Environmental Management and Assessment (IEMA) 'Guidelines for the Environmental Assessment of Road Traffic' (Ref.10.22) have been used to ensure that the environmental impacts arising due to predicted changes in traffic levels are properly and comprehensively addressed. In addition the Design Manual for Roads and Bridges (DMRB) Volume 11 has been referred to in the development of this chapter (Ref 10.23).

10.6.2 The IEMA guidelines advise the use of a 'check-list' of potential effects covering noise, vibration, visual impact, severance, driver delay, pedestrian delay, pedestrian amenity, accidents and safety, hazardous loads, air pollution, dust and dirt, ecological impact and heritage and conservation areas.

10.6.3 The guidelines acknowledge that for many developments some of the effects listed may not be widely relevant, but suggest that reasons should be provided for any exclusions.

10.6.4 This chapter deals only with the transport related effects i.e. severance; driver delay; pedestrian amenity; accidents and safety. Other effects such as noise and air quality are dealt with in other chapters of the Environmental Statement.

10.6.5 The sections below describe the information for the different elements of the assessment and then provide detail on the application of the IEMA methodology to the transport environmental effects of the HPC Project.

a) Study Area

10.6.6 In accordance with the IEMA guidelines, the study area has been defined by identifying any link or location where it is felt that significant environmental impacts may occur as a result of the HPC Project.

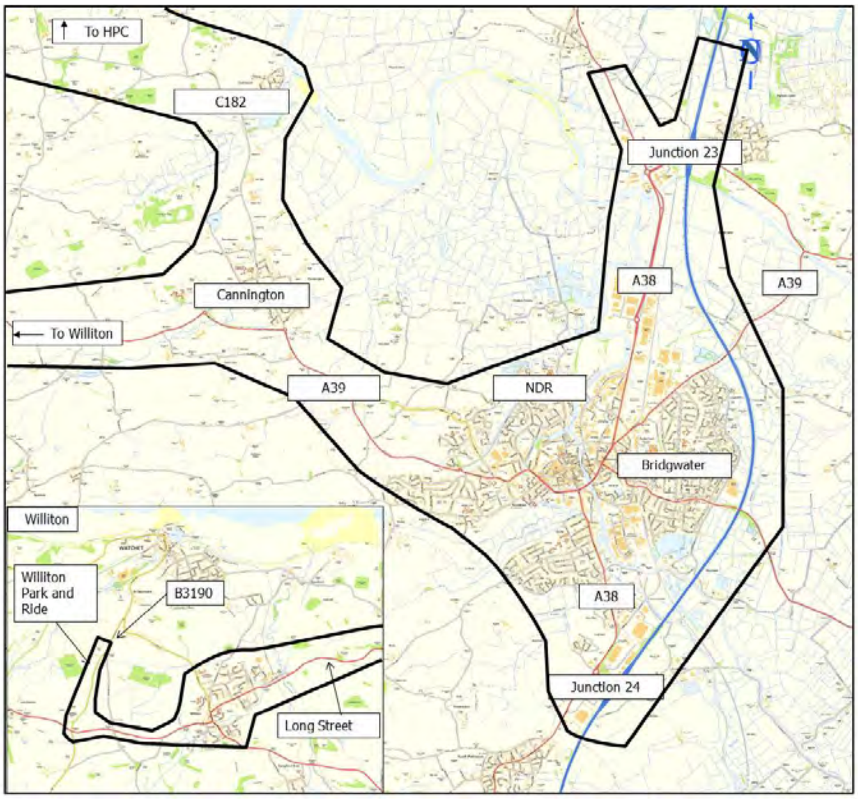
10.6.7 The geographical extent of the study area includes:

- The M5 motorway between and including Junction 23 and Junction 24.
- The A39 from the Crandon Bridge/Silverfish junction to the east of the M5 motorway to the A39 just to the west of A39/High Street junction in Cannington.
- The A38 from just to the north of Dunball roundabout to just to the south of Huntworth roundabout.
- Bridgwater town centre.
- Cannington village.
- C182 (Rodway) between Cannington and the HPC development site.
- Williton.

10.6.8 Links through Stogursey have not been included within the detailed assessment as it is not planned to route buses through the village except those that pick up workers from the village. The size of the buses that do pass through the village would be limited to 15 person vehicles. The small number of these vehicles would not have a material effect on the issues studied in this chapter.

10.6.9 The links modelled in the Paramics model (referred to hereafter as the model) are shown at **Plate 10.1**.

Plate 10.1: HPC Development Site Study Area



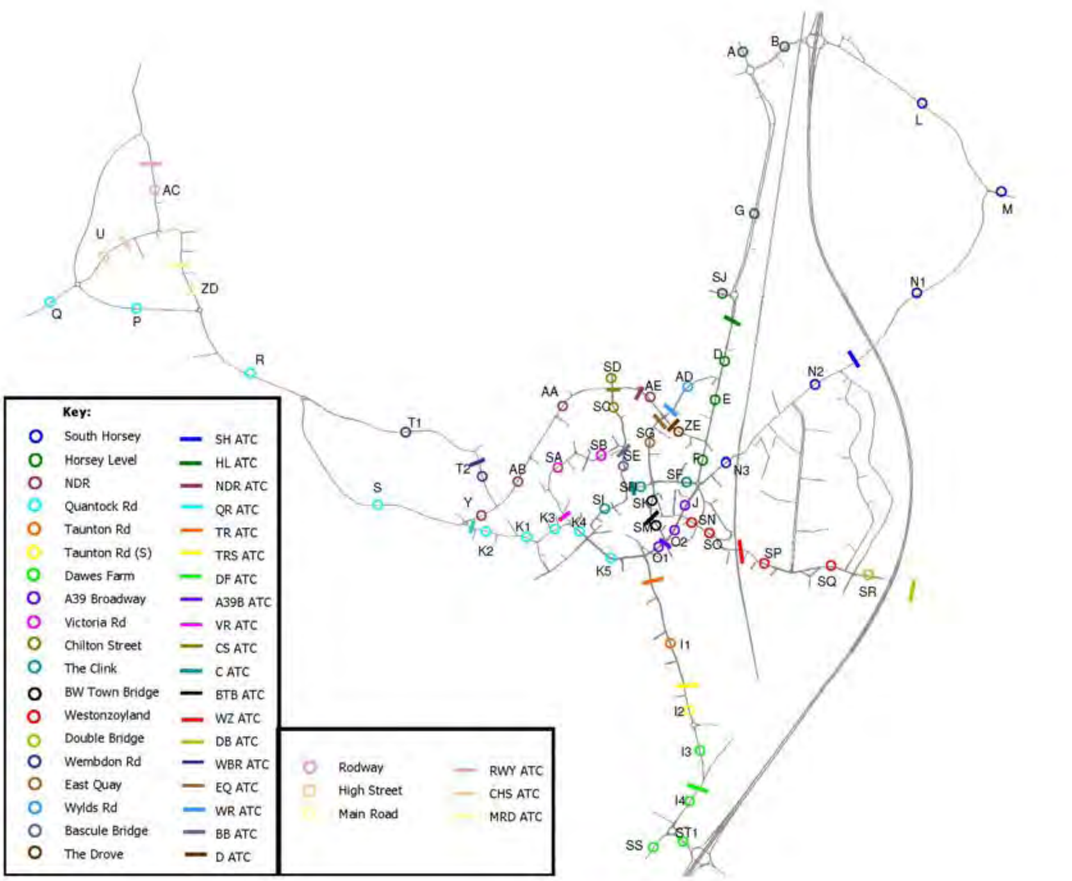
b) Traffic Assessment

10.6.10 This section summarises the methodology used to derive traffic flows used in the environmental assessment. Full details are included within the **Transport Assessment.**

10.6.11 The traffic assessment for the HPC Project has been undertaken using a model. The model has been used to predict changes in flow and junction performance as a result of the traffic generated by committed developments in the area and the HPC Project. It also predicts the effects of future changes to the highway network.

10.6.12 The links modelled are shown at **Plate 10.2**.

Plate 10.2: Paramics Modelled Links



i. Assessment Years and Quarters

10.6.13 The following assessment periods have been considered:

- 2009: Base Year.
- Quarter 3 2013.
- Quarter 4 2016.
- 2021.

10.6.14 2009 is the base year selected and is the year when the majority of traffic surveys were undertaken. This establishes the existing traffic conditions in the area.

10.6.15 Quarter 3 2013 is when the HPC development site construction would have commenced but the majority of the associated development sites would not be operational. At this stage park and ride and freight management facilities along with the temporary induction centre would be operational at Junction 24. The Cannington bypass would not completed at this stage.

10.6.16 Quarter 4 2016 is the assessment of peak construction impacts. At this stage all highway improvement measures would be in place, including the Cannington bypass. Based on the workforce and freight movement profiles, the fourth quarter is the period when traffic impacts are likely to be at their greatest.

10.6.17 In 2021 the HPC development site would be fully operational and some of the associated development sites would be being decommissioned. Junction 24 and Cannington park and ride would still be operational. In addition some construction activity would still be ongoing on the HPC development site (mainly the Intermediate Spent Fuel Store). The scenario used for assessment is a combination of the worst case quarter for construction workforce and the worst case quarter for operational staff.

10.6.18 Given that 2021 is not just an operational year, comment is made in the analysis about the likely effects when all construction activity would cease and there would be just the operational staff on site. This would at the end of 2022.

10.6.19 The first assessment in this chapter is for 2016 since this is the anticipated period of peak construction impact at the HPC development site. Following this, an assessment is made of the impacts in 2013 and 2021.

ii. Assessment Periods

10.6.20 The primary assessments have been undertaken on a daily basis (24 hour Annual Average Daily Traffic) since this reflects the impacts on severance, pedestrian amenity and safety. However, the peak network periods have also been assessed since these are relevant for pedestrian and driver delays. Vehicle delays have been assessed for all the hours modelled in the model i.e. 06:00 to 10:00 and 13:00 to 20:00.

iii. Baseline Traffic Flows

10.6.21 The baseline year for the purposes of this assessment is 2009.

10.6.22 The **Local Model Validation Report (LMVR)** appended to the **Transport Assessment** sets out all of the traffic data that has been collected to build the model. Further traffic data has been collected for junctions outside of the model as follows:

- A39 Long Street/North Street, Williton (turning count November 2009).
- A39 Fore Street/A358 High Street, Williton (turning count November 2009).
- A39/B3190 Washford Cross, Williton (turning count May 2011).
- A39 Fore Street south of Killick Way, Williton (Automatic Traffic Count (ATC) July 2010).

- A39 Priest Street to the west of Mamsey Lane (ATC July 2010).
- C182 (Rodway) near the Combwich Wharf access road (ATC October 2010).
- Proposed HPC development site access (permanent ATC count).

10.6.23 The surveyed traffic data is input to the model and a 2009 Base Model produced. This is validated against existing conditions – i.e. outputs from the model (traffic flows; queue lengths and journey times) are compared with actual conditions measured on site. The validated 2009 model has been agreed as fit for purpose by the transport authorities.

10.6.24 The model outputs hourly flows for the modelled hours (06:00-10:00 and 13:00-20:00). This data has been used to provide baseline environmental traffic data. The methodology for calculating 24 hour Annual Average Daily Traffic (AADT) and 18 hour Annual Average Weekday Traffic (AAWT) flows is summarised as follows:

- The agreed 2009 base model has been run 20 times and the results have been averaged. The need for 20 model runs of the 2009 base model is set out in the **LMVR** appended to the **Transport Assessment**. The total vehicles and percentage of Heavy Duty Vehicles (HDVs) i.e. Other Goods Vehicles 1 (OGV1), Other Goods Vehicles 2 (OGV2) and Public Service Vehicles (PSV) on each link in each direction have been obtained from the average results for the 11 model hours of 06:00-10:00 and 13:00-20:00.
- For the links at Junction 23 and Junction 24 of the M5, TRADS data from the HA has been used for the period between 01 January 2009 and 31 December 2009 to provide a factor to convert the 11 hours of model output data to 18 hour Annual Average Weekday Traffic (AAWT) (06:00-00:00) and 24 hour Annual Average Daily Traffic (AADT) flows. As the annual average traffic volumes have been taken from the HA's online database, a seasonality factor is not required for these links as it is already included.
- For the links on the local highway network a factor has been derived for each link to convert the 11 hours of modelled traffic data into 18 hour AWT and 24 hour AADT flows. The 18 hour AWT and 24 hour AADT factors for each link are based on the nearest ATC survey data available.
- The same 18 hour AWT and 24 hour AADT factors have been applied to provide the volume of HGVs by applying the factor to the total volume of HGVs provided by the base model between the hours of 06:00-10:00 hours and 13:00-20:00 hours. The ATC data collected does not provide a breakdown of vehicle classification therefore the proportion of HDVs is unknown. For this reason it is considered that the best alternative is to use the all vehicle factor for HGV proportions.
- The 18 hour AWT and 24 hour AADT flows have then been factored using a seasonality factor for the local highway network to provide 18 hour AAWT and 24 hour AADT flows. This is because the ATCs do not cover a full year.

iv. Future Year Baseline Traffic Flows

10.6.25 Baseline traffic models have been developed for 2013, 2016 and 2021. These incorporate the traffic generation from all committed developments in the area i.e.

those with planning permission. In addition, other growth has been allowed for by using TEMPRO and NTEM growth factors agreed with the transport authorities. Also included are any committed highway improvement schemes. These are as follows:

- Committed highway schemes implemented by 2013:
  - South Bridgwater Link Road
  - A39 Silverfish/Crandon Bridge
- Committed highway schemes implemented by 2016:
  - North East Bridgwater Link Road
- Committed highway schemes implemented by 2021:
  - Dunball roundabout improvement.

10.6.26 The future year base models for 2013, 2016 and 2021 have been agreed in principle by the transport authorities. These are referred to as the Reference Case Models.

v. Trip Generation

10.6.27 Given the bespoke nature of the proposed HPC development there are no UK Power Station land use trip rates available to determine the likely trip generation of the construction and operational phases of the HPC Project. Instead a first principles trip generation methodology has been employed as summarised below. The details of the methodology are set out in the **Transport Assessment**.

Workforce

10.6.28 The construction workforce required to construct the HPC Project has been derived from EDF Energy data collected from constructing similar reactors. It is anticipated it would take approximately nine years to complete the main construction works for the HPC Project when both units would be operational (including preliminary works); during this period it is forecast that the construction workforce would peak at 5,600 in 2016. Workforce numbers have been profiled for the construction period including the construction (2013) and deconstruction (2021) of the associated development sites.

10.6.29 A profile of the number of operational workers required to operate the two UK EPR Reactor Units has been derived based on data from similar existing UK EDF Energy managed power stations (i.e. Hinkley Point B (HPB) and Sizewell B). It is anticipated an operational workforce of 900 personnel would be required of which 810 would be present on site on any one day. Operational staff have been included in the workforce profile.

10.6.30 EDF Energy has developed a transport strategy that is described fully in the **Transport Assessment**. A summary of the strategy for the movement of construction staff is set out below:

- On-site parking at the HPC development site would be heavily constrained – with only 200 on-site parking spaces for contractors' staff. As such the large majority of the construction workforce would travel to and from the HPC development site by bus, either from park and ride sites or by direct bus services.

- Park and ride: park and ride facilities would be established near to Junction 23 and Junction 24 of the M5 motorway, and at Cannington and Williton. These would serve both home-based and non-home-based workers who would travel to the park and ride facilities and then be transferred by bus to the HPC development site or associated development site.
- Direct bus services: direct bus services would be provided from the accommodation campuses in Bridgwater and there would also be buses provided for workers on key routes to the HPC development site. The routes would need to align to the location of workers and would need to be reviewed on a regular basis in order to respond to fluctuations in the patterns of workforce demand and location.
- Walking and cycling: Walking and cycling forms an element of the strategy for workers. The elements of this are: directly to the HPC development site from suitable locations; to the park and ride sites; and to bus routes. In conjunction with SCC an audit of relevant cycling and walking routes has been undertaken and a number of proposed improvements identified
- Major infrastructure interventions: Even with the transport strategy and **Freight Management Strategy** there would inevitably be an increase in traffic movements (freight; buses and cars) on the local network. After careful consideration and consultation, EDF Energy has concluded that a bypass around Cannington should form part of the proposals. This is in order to mitigate the impacts of additional traffic and in particular HGVs and buses through the village.
- Highway network improvements: A series of highway improvements have been developed in conjunction with stakeholders and the local community. These measures include those that assist safety as well as capacity. These improvements are included in the HPC project as associated development.
- Travel Plans: Travel planning would form an integral part of the transport strategy. The **Framework Travel Plan** requires the use of sustainable modes and seeks to minimise use of the private car where practicable. One of the key features of the transport strategy is that workers would be required to use certain modes. For example, if a worker lives at an accommodation campus they would be required to use a direct bus to get to the HPC development site

10.6.31 The people trip generation has been based on the workforce profiles and the transport strategy described above. The mode assigned to workers (walk, cycle, direct bus, park and ride) has been based on an assessment of the distribution of the staff and the most suitable mode for them. Workers would be prescribed a mode of travel by EDF Energy. For example, workers assigned to a particular park and ride site would be required to use that site for their onward journey to the HPC development site.

10.6.32 The number of buses estimated to use the road network is based on a high frequency timetable of buses allowing workers to arrive at the pick up point over a period of time. When the detailed bus operations are refined the number of buses is likely to reduce significantly since there would be more precise adjustment of buses to match demand.

Freight

10.6.33 The development of the new nuclear power station would require significant quantities of construction materials to be delivered to the HPC development site. EDF Energy has developed a **Freight Management Strategy** (**FMS**) which is appended to the **Transport Assessment.**

10.6.34 The proposed freight measures aim to reduce and control the use of road freight traffic during the construction phase, especially in the peak hours. As for worker movements, a range of options have been investigated and further details are provided in the **FMS**.

10.6.35 A summary of the **FMS** is shown below:

- The re-use and storage of excavated materials on-site to avoid exporting off-site.
- The use of water for delivery of bulk materials and the largest abnormal indivisible loads (AILs) through the construction of a temporary jetty at HPC, the refurbishment and extension of Combwich Wharf and the construction of a new freight laydown facility at Combwich.
- Introducing off-site freight management facilities at Junction 23 and Junction 24, to control incoming freight traffic flow and holding freight vehicles in case of an incident on the local network or on-site.
- Regulating traffic flow by using a project-wide delivery management system (DMS) to regulate flows and move away from peak time congestion.
- Reducing small vehicle movements through consolidation of postal and courier deliveries at the freight management facilities.

10.6.36 EDF Energy is committed to bringing at least 80% of bulk materials required for HPC development site concrete production by sea. In accordance with EDF Energy's objectives, the use of water would be maximised to what is practicable. However, it must be recognised that there are constraints to the use of water and in particular tides and poor weather can affect use.

10.6.37 The freight generation and material quantities figures are based on EDF Energy's extensive experience of constructing Pressurised Water Reactors in France as well as information from the construction of Sizewell B in the UK. It is also augmented by data emerging from the on-going construction of Flamanville 3 in France. Where additional materials are required due to site specific elements of the HPC Project (e.g. for such items as the construction of the jetty and sea wall) estimates have been made by the engineering team based on the design of the infrastructure.

10.6.38 The quantum of materials required to construct the associated developments has been derived based on the proposed layout and construction specification.

10.6.39 The material and waste quantities have been profiled over the construction phase in accordance with the construction programme. The material and waste have then been assigned a mode of transport (i.e. Jetty, Combwich Wharf or by road). Any material or waste to be delivered or removed by road has been converted to freight vehicle movements by applying average vehicle payload assumptions to each type of material and waste.

10.6.40 For the purpose of quantifying freight traffic the freight vehicles associated with the construction of the HPC Project have been categorised as follows:

- Heavy Goods Vehicles – HGVs: all vehicles exceeding a maximum gross weight of 3.5 tonnes (maximum allowable total weight when loaded). These include medium goods vehicles (maximum gross weight between 3.5 and 7.5 tonnes) and heavier 2, 3 or more axle lorries.
- Light Goods Vehicles – LGVs: vans, pickups, 4x4s and cars with a maximum gross weight of 3.5 tonnes.

10.6.41 It has been assumed that the construction materials, plant and equipment for the project would be transported by HGVs while LGVs would be used for transporting food and consumables, small items and specialist tools/equipment. LGVs would also include Contractors' fleet vehicles.

10.6.42 The above categorisation is important. As can be seen the definition of HGVs used includes Medium Goods Vehicles (MGVs). Therefore, when the numbers and impacts of HGVs are discussed later in this chapter they include MGVs.

10.6.43 The number of HGVs per day would fluctuate around the average figure depending on the type of on-site activities and delivery requirements. It is considered that a factor of ±50% applied to the average would provide an adequate range to cater for these variations e.g. an average of 250 HGVs (500 movements) per day over a quarter may result in the number of HGVs per day varying between 125 (250 movements) and 375 (750 movements).

Overall Trip Generation

10.6.44 In overall terms it is considered that the trip generation for both people and freight is robust for at least the following reasons:

- Assessment in Quarter 4 2016 is for the peak of the construction process and that level of activity lasts only approximately 5 months.
- Traffic using the park and ride sites includes a contingency of 10%.
- HGV movement estimates are based on conservative assumptions on the use of sea for deliveries and on the payloads per HGV.
- A 20% contingency has been included in the estimate of HGV numbers for construction of all associated developments.
- The definition of a HGV used includes Medium Goods Vehicles.
- Bus numbers are based on a high frequency timetable. Numbers will reduce when bus timetables are more precisely matched to worker demand and location.
- No allowance has been made for the fact that the Bridgwater A accommodation campus is on land allocated for housing and for which a traffic allowance is already made in the Reference Case flows. Similarly, no reductions have been made for traffic that would cease to be generated as the existing use of the Somerfield Site at Junction 24 has come to an end.

vi. Trip Distribution

10.6.45 The detailed methodology for estimating the trip distribution is set out in the **Transport Assessment** and is summarised in this section.

Workforce Distribution

10.6.46 Given the bespoke and complex nature of the HPC Project, there is no historical data that can be used to establish a robust trip distribution for employees who would be working on the construction of the HPC Project. Instead a gravity model has been built using data from the socio-economics impact assessment. A detailed methodology is included in the **Transport Assessment.**

10.6.47 In terms of skills, the construction workforce can be divided predominantly into civil operatives and mechanical and electrical operatives with the remaining workforce comprising supervisory, managerial and clerical staff, plus site services and security employees.

10.6.48 The existing skills profile in the local area does not fully meet the specialised requirements of the construction of the HPC Project and therefore there would be two types of construction workers, as follows:

- Home-based workers, who would commute to and from work on a daily basis from their home address.
- Non-home-based workers who cannot feasibly commute to and from work on a daily basis from their home address and would therefore require temporary accommodation in the vicinity of the HPC development site.

10.6.49 The split of home-based and non-home-based workers would change over the course of the construction phase as the nature of the construction evolves. As the construction progresses, a different, more specialised, workforce would be required. These workers would most likely need to be attracted from further afield, resulting in an increase in the number of workers occupying local temporary accommodation.

10.6.50 In order to assist with the housing of the non-home-based workers, EDF Energy proposes to provide accommodation campuses both on the HPC development site and within Bridgwater. A total of 1,510 spaces would be provided. In addition to the campus provision, non-home-based workers would also live in existing accommodation in the vicinity of the HPC development site.

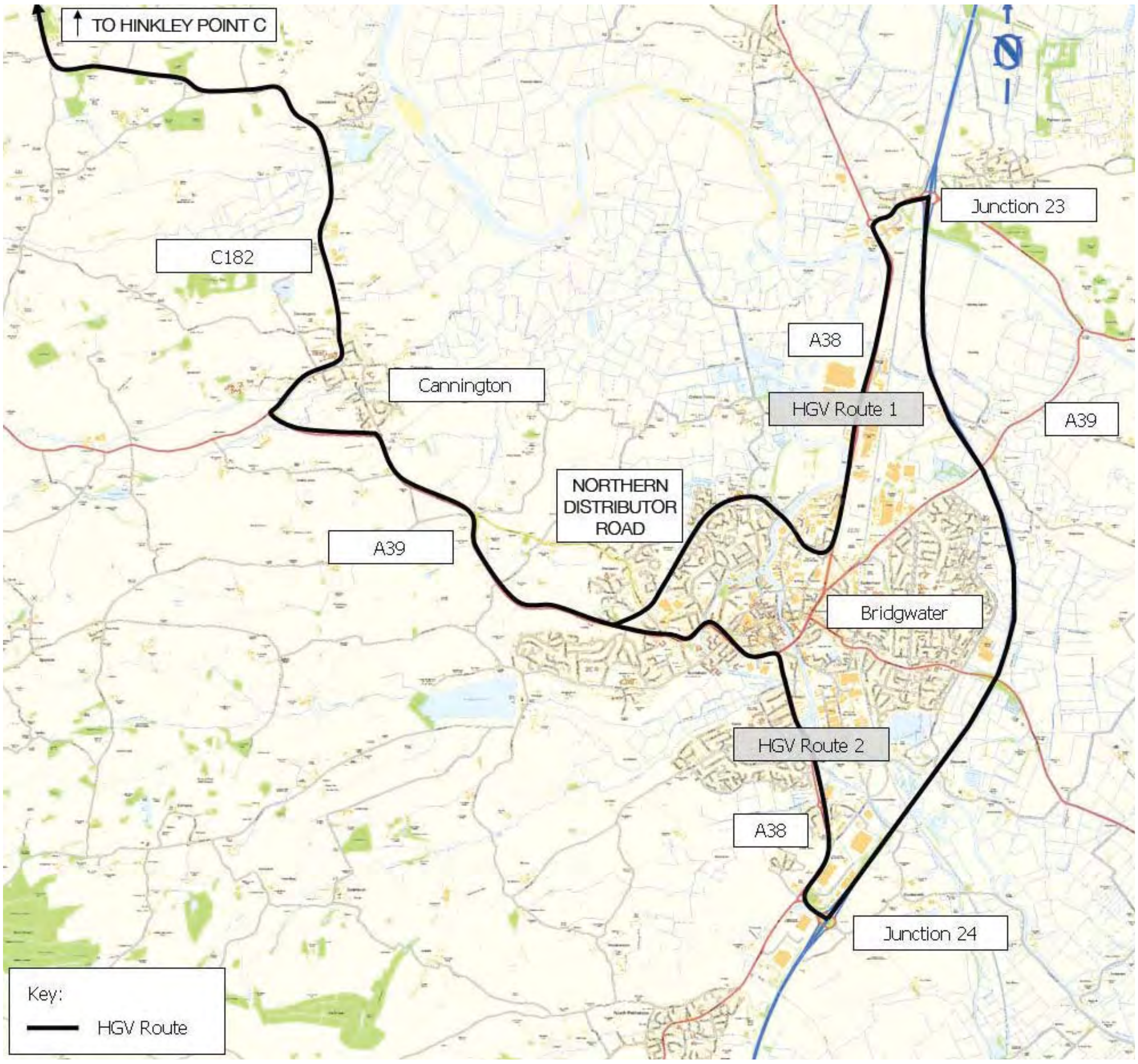
10.6.51 Research within the UK construction industry has demonstrated that construction workers would tend to commute daily up to 90 minutes. It has therefore been assumed that the home-based workers would commute up to 90 minutes from their home to the HPC development site. It is considered that the non-home-based workers would tend to live closer to the HPC development site as they are moving into the area primarily for work and the travel time to work would be a material factor when choosing accommodation. It has therefore been assumed that the non-home-based workers would commute up to 60 minutes from their accommodation to the HPC development site.

Freight Distribution

10.6.52 Full details of the freight distribution are set out in the **Transport Assessment** and appended **Freight Management Strategy.**

10.6.53 It has been assumed that all HGV movements associated with construction at the HPC development site would travel via the M5 motorway and through Bridgwater. HGVs travelling to the HPC development site would pass through freight management facilities at Junction 23 or Junction 24 of the M5 and then use the routes shown in **Plate 10.3** to access the HPC development site. Prior to completion of the Cannington bypass, HGVs would pass along High Street Cannington. After completion of the Cannington bypass, all HGVs connected with the HPC Project would route via the Cannington bypass. In 2013, when only the freight management facility at Junction 24 is operational, some HGVs would travel from Junction 24 via the M5 to Junction 23 and then use the northern HGV route via Bristol Road and the Northern Distributor Road to access the HPC development site.

Plate 10.3: Designated HGV Routes to the HPC development site



vii.Impact Assessment

10.6.54 The trip generation and trip distribution have been used to derive a matrix of vehicular trip origins and destinations. These are then added to the Reference Case models for 2013, 2016 and 2021 to give the ‘with-development’ models.

10.6.55 Examination of the 2016 Reference Case and 2016 with-development models identified certain capacity issues in both scenarios. Therefore mitigation measures were introduced to seek to assist traffic movements. In addition, certain safety enhancements were agreed with the transport stakeholders and local community. A list of the proposed highway improvements is shown below. These improvements are in addition to accesses provided to the HPC development site and associated development sites. For the purposes of this assessment, they are mitigation incorporated as part of the HPC Project.

- M5 Junction 23 roundabout.
- A38 Bristol Road/Wylds Road junction.
- A38 Bristol Road/The Drove junction.
- Wylds Road/The Drove junction.
- A38 Bristol Road/A39 (Bath Road) (Cross Rifles) junction (see note below).
- A39 Broadway/A38 Taunton Road junction*.
- A39 New Road/B3339 Sandford Hill roundabout*.
- Washford Cross roundabout*.
- Huntworth roundabout*.
- Claylands Corner junction*.
- Cannington traffic calming measures*.
- C182 Farringdon Hill Lane horse crossing*.
- Cannington bypass.

10.6.56 These changes to the highway network were added to the model for 2016 and 2021. In 2013 only the improvements shown with a (*) above were included although it would be EDF Energy’s intention to implement as many schemes as possible by the end of 2013.

10.6.57 The HPC generated traffic flows have a very small impact on Cross Rifles roundabout. However, a proposed improvement scheme has been introduced in the model to assist traffic flow at this critical node which currently experiences congestion. This is a scheme derived by EDF Energy that is all within the highway boundary. However, it is proposed that EDF Energy make a contribution to SCC to allow them to promote their own larger scheme using funding from other development contributions in the area.

10.6.58 Adding the proposed highway improvements to the With Development models leads to the production of the With Development and Mitigation models.

10.6.59 Extensive output can be derived from a run of the model and this is discussed in detail in the **Transport Assessment**. For the purposes of this assessment, the outputs used have been the changes in traffic flows on sections of the highway network (known as links). Outputs have been shown in this chapter for:

- All vehicles.
- HGVs and buses.

viii. Accidents and Safety

10.6.60 The **Road Safety Strategy** prepared for the HPC Project is provided as an appendix to the **Transport Assessment**. This section summarises the agreed methodology used for the study to assess the impact of the HPC Project on road safety.

10.6.61 Accident data for the five years up to the end of June 2010 has been obtained from SCC and the HA for the study area.

10.6.62 The accident data has been compared against the national accident rates to determine if any links have rates significantly higher than would otherwise be expected.

10.6.63 The local road network has then been broken down into parishes and accident clusters identified using the definitions developed by the Somerset Road Safety Partnership (SRSP) as follows:

- an accident cluster in an urban location is where at least seven accidents have occurred within a 50 metre radius in a five year period; and
- an accident cluster in a rural location is where at least seven accidents have occurred within a 100 metre radius in a five year period.

10.6.64 The accident data relating to the M5 has also been analysed to determine if there are any sites that have experienced a high number of accidents, when compared to the national average.

10.6.65 An assessment has then been made of the likely impact of the proposed HPC Project on road safety in the study area. This has been done based on the likely changes in traffic flows as a result of the proposed development. However, it is important to note that traffic flows would also increase as a result of increases in traffic flows excluding HPC (i.e. due to committed developments and general growth).

10.6.66 Measures to mitigate the impact on road safety in the study area have been identified. These aim to address issues at existing sites that have experienced a higher than average accident rate that could be exacerbated by any increase in traffic flow generated by the HPC Project. However, suggested measures recognise improvements to be brought forward by EDF Energy to address capacity issues and SCC's own safety improvement programme.

c) Consultation

10.6.67 Extensive consultation has been undertaken throughout the EIA process. As a result of the consultation process, comments have been received from the highway authorities and have informed this assessment. In addition meetings and discussions with the highway authorities have been extensive and on-going to agree the scope of the assessment. The highway authorities have agreed the methodology for estimating the traffic flows for this assessment, in addition to other traffic data required for the noise and air quality assessments. For further details, refer to the **Consultation Report**.

d) Detailed Assessment Methodology

10.6.68 The following paragraphs provide a detailed methodology of how the IEMA 'Guidelines for the Environmental Assessment of Road Traffic' (1992) (Ref. 10.1) have been applied in this assessment.

i. Screening Process

10.6.69 The potential effects of the HPC Project have been determined by comparing the With Development and Mitigation scenario to the Reference Case scenario in the assessment years. Within the IEMA guidance, two broad rules are suggested which can be used as a screening process to limit the scale and extent of the assessment:

- Rule 1: include highway links where traffic flows would increase by more than 30% (or the number of heavy goods vehicles would increase by more than 30%).
- Rule 2: include any other specifically sensitive areas where traffic flows have increased by 10% or more.

10.6.70 Where the predicted increase in traffic flows is lower than the above thresholds, the IEMA guidelines suggest the significance of the effects can be stated to be negligible and further detailed assessments are not warranted. Increases in traffic flows below 10% are generally considered to be insignificant in environmental terms given that daily variations in background traffic flow may vary by this amount.

ii. Sensitivity of Receptors

10.6.71 The sensitivity of a road can be defined by the vulnerability of the user groups who may use it, e.g. elderly people or children. A sensitive area may be where pedestrian activity may be high, for example in the vicinity of a school or where there is already an existing accident issue. It should be noted that the sensitivity of the receptor is judged on the sensitivity of road users (primarily pedestrians). It also takes account of the existing nature of the road e.g. an existing "A" road is likely to have a lower sensitivity than a minor residential road. **Table 10.1** below provides a summary of the types of receptors and the sensitivity of each, defined as substantial, moderate, minor or negligible.

Table 10.1: Sensitivity of Receptors

Receptor Type	Receptor Sensitivity
Receptors of greatest sensitivity to traffic flow: schools, colleges, playgrounds, accident clusters, retirement homes, roads without footways that are used by pedestrians.	Substantial
Traffic flow sensitive receptors: congested junctions, doctors' surgeries, hospitals, shopping areas with roadside frontage, roads with narrow footways, recreation facilities	Moderate
Receptors with some sensitivity to traffic flow: places of worship, public open space, tourist attractions and residential areas with adequate footway provision	Minor
Receptors with low sensitivity to traffic flows and those sufficiently distant from affected roads and junctions	Negligible

10.6.72 A desktop exercise augmented by a number of site visits has been undertaken to identify the sensitive receptors in the study area. All road links within the study area have been assessed and assigned sensitivity. Recognising the quantity of road links within the study area, for ease of review the assessment narratives have focused on the road links that would lead to highest impact. The results of the analysis are shown at **Table 10.2** below. A plan of the link locations is shown earlier in this chapter at **Plate 10.2**.

Table 10.2: Study Area Receptor Sensitivity

Link	Link Ref.	Sensitivity
M5 Junction 23 northbound on-slip	V1	Minor
M5 Junction 23 southbound off-slip	V2	Minor
M5 Junction 23 northbound off-slip	V3	Minor
M5 Junction 23 southbound on-slip	V4	Minor
A39 spur east of Dunball	B	Minor
A39 east of J23	L	Minor
A38 north of Dunball	A	Minor
A38 south of Dunball	G	Minor

Main Road, Cannington	ZD	Substantial
Rodway south of bypass	AC	Substantial
Rodway north of bypass	12	Minor
Cannington bypass	Z1	Minor
A39 Williton	2	Substantial

iii. Magnitude of Impact

10.6.73 To assist with the judgement of magnitude of impact, reference has been made to the IEMA guidelines (Ref. 10.1). This guidance sets out consideration, and in some cases, thresholds, in respect to changes in the volume and composition of traffic to facilitate a subjective judgement of traffic impact and significance. These thresholds are guidance only and provide a starting point by which a detailed analysis will inform a subjective analysis of the impact magnitude.

10.6.74 It is important to note that the impacts assessed are temporary, not permanent, and this affects the significance attached to them. In 2016 the maximum workforce would be present at the HPC development site for approximately five months. Similarly, the peak HGV flows in 2013 occur for only a few months. However, it is also recognised that, whilst it would be below the peaks which have been assessed here, there would be sustained traffic generation arising from the HPC construction phase for a significant number of years and therefore that the temporary effects associated with the construction of HPC would continue for longer than would normally be the case for the construction phase of most developments. The period of relatively high levels of traffic generation related to the construction of HPC and the operation of the associated developments is approximately 5-6 years and, as a worst case assumption, it can therefore be assumed that the impacts assessed for the 2016 period would persist for that length of time. In reality traffic flows would often be at a somewhat lower level than have been assessed for 2016, and where it is considered that the period for which the 2016 impact is likely to persist is materially shorter or longer, comment is included in the text.

10.6.75 As described earlier in this chapter, within any quarter the number of HGV movements would vary from the average for that quarter. Some days the number would be above average and some days below. The hour by hour modelling has been undertaken on the basis of a peak day within the quarter under analysis. However, the daily flows (AADT) are for an average day to be consistent with other analysis within the Environmental Statement (e.g. air quality) and because it is normal practice to assess the average i.e. the most likely set of circumstances. However, where there is likely to be a significant impact, a commentary on the peak day for HGVs is also provided.

iv. Types of Impact

10.6.76 The following paragraphs cover each of the impacts that are considered in this chapter.

Severance

10.6.77 Severance is defined as the perceived division that can occur within a community when it becomes separated by a major traffic artery and describes a series of factors that separate people from places and other people. Such division may result from the difficulty of crossing a heavily trafficked road or a physical barrier created by the road itself.

10.6.78 The measurement and prediction of severance is difficult, but relevant factors include road width, traffic flow, speed, the presence of crossing facilities and the number of movements across the affected route.

10.6.79 IEMA guidelines refer to the Department of Transport's 'Manual of Environmental Appraisal' (Ref. 10.1), which suggests that changes in traffic flow of 30%, 60% and 90% would be likely to produce 'slight', 'moderate' and 'substantial' changes in severance, respectively. It is advised that these broad indicators should be used with care and regard paid to specific local conditions.

Pedestrian Delay

10.6.80 IEMA guidelines note that changes in the volume, composition and or speed of traffic may affect the ability of people to cross roads. Typically, increases in traffic levels result in increased pedestrian delay, although increased pedestrian activity itself also contributes. The guidelines do not set any thresholds, recommending instead that assessors use their judgement to determine the significance of the impact.

10.6.81 The IEMA guidelines refer to a report published by the Transport Research Laboratory (TRL SR356, Goldschmidt, 1976) as providing a useful approximation for determining pedestrian delay. The TRL research concluded that mean pedestrian delay was found to be eight seconds at flows of 1,000 vehicles per hour and below 20 seconds at 2,000 vehicles per hour for various types of crossing condition. This research has been reproduced in DMRB Volume 11, Section 3, Part 8. Figure 1 of Part 8 provides predictive mean pedestrian delay based on empirical data taking into account traffic flow and a range of parameters such as crossing width and vehicle speeds.

10.6.82 A two-way flow of 1,400 vehicles per hour has been adopted as a lower threshold for assessment (equating to a mean 10 second delay for a link with no pedestrian facilities in the TRL report). Below this flow pedestrian delay is unlikely to be a significant factor. This is deemed a robust starting point for narrowing down the modelled routes within the study area and ensuring the routes selected exceeded the suggested threshold of analysis in DMRB Volume 11. It should be noted that for controlled forms of pedestrian crossing the pedestrian delays are less.

Pedestrian Amenity

10.6.83 IEMA guidelines define pedestrian amenity as the relative pleasantness of a journey and can include fear and intimidation if they are relevant. As with pedestrian delay, amenity is affected by traffic volumes and composition along with pavement width and pedestrian activity. The guidelines suggest tentative thresholds of significance would be where the traffic flow is halved or doubled.

Driver Delay

10.6.84 IEMA guidelines note that driver delay can occur at several points on the network, although the effects are only likely to be significant when the traffic on the highway network is predicted to be at or close to the capacity of the system.

10.6.85 A comparison of journey times on key routes in the model has been undertaken to establish the increase in driver delay as a result of the HPC Project. These are reported in full in the **Transport Assessment** and summarised in this chapter.

Accidents and Safety

10.6.86 IEMA guidelines do not include any definition in relation to accidents and safety, suggesting that professional judgement will be needed to assess the implications of local circumstance, or factors which may increase or decrease the risk of accidents. The full results of the **Road Safety Strategy** are reported in the **Transport Assessment** and are summarised in this chapter.

10.6.87 **Table 10.3** summarises the criteria that has been used to determine magnitude of impacts. However, the absolute level of an impact is also important e.g. the total flow of traffic or HGVs on a link. Comment is made on this in the analysis.

Table 10.3: Magnitude of Impact Criteria

Impact	Magnitude of Impact			
	Negligible	Minor	Moderate	Substantial
Severance	Change in total traffic or HGV flows of less than 30%	Change in total traffic or HGV flows of 30-60%	Change in total traffic or HGV flows of 60-90%	Change in total traffic or HGV flows over 90%
Pedestrian Delay	Two way traffic flow < 1,400 vehicles per hour	A judgement based on the road links with two way traffic flow exceeding 1,400 vehicles per hour in context of the individual characteristics		
Pedestrian Amenity	Change in total traffic or HGV flows < 100%	A judgement based on the routes with >100% change in context of their individual characteristics		
Driver Delay	A judgement based on the journey time assessment			
Accidents and Safety	A judgement based on analysis detailed in the **Road Safety Strategy**			

v. Significance of Impacts

10.6.88 The significance of the impact is judged on the relationship of the magnitude of impact to the assessed sensitivity and/or importance of the receptor. The predicted significance of the impacts is outlined in **Volume 1**, **Chapter 7** and summarised in **Table 10.4** below:

Table 10.4: Significance of Impacts

Sensitivity of Receptor	Magnitude of Impact			
	Negligible	Minor	Moderate	Substantial
Negligible	Negligible	Negligible	Negligible	Minor
Minor	Negligible	Negligible	Minor	Moderate
Moderate	Negligible	Minor	Moderate	Substantial
Substantial	Minor	Moderate	Substantial	Substantial

10.6.89 Potential effects are therefore concluded to be of negligible, minor, moderate or substantial significance. Moderate and substantial significance effects are considered to be significant in terms of EIA guidance.

vi. Cumulative Impacts

10.6.90 The assessments for each of the elements of the HPC Project, i.e. the HPC development site and associated development sites (see **Volume 2**, **Chapter 10** and **Chapter 8** in each of **Volumes 3** to **10** of this ES), include all flows associated with the overall HPC Project i.e. flows to and from the HPC development site and the associated development sites. Furthermore, these assessments include other committed, non-HPC, developments for the area. In addition there are some other developments that have not been included in those assessments. These are dealt with in a qualitative way within **Volume 11** of this ES.

vii.Limitations, Constraints and Assumption.

10.6.91 The main limitation in baseline conditions presented in this chapter is the precision of traffic counts. Such counts are recorded over a day or a week and are subject to an accuracy of + or – 10%. However conditions predicted by the model have been validated using standard criteria and are therefore considered to provide a representative estimate.

10.6.92 Traffic generation estimates for HPC are based on a number of assumptions on matters such as materials quantities, number of workers and construction programme. However, worst case assumptions have been made in a number of instances. For example, the peak construction quarter in 2016 is assessed and conservative assumptions are made on goods vehicle payloads. Furthermore, the expected use of the park and ride sites has been increased by a contingency of 10%.

10.7 Baseline Conditions

10.7.1 The transport effects of the construction and operation of the HPC Project cover the full study area described earlier in this chapter. Furthermore, the effects during the construction phase are closely linked with activities at the associated development sites. Therefore, the transport baseline conditions at the HPC development site and all associated development sites are described in this chapter of the ES.

a) HPC Development Site

i. Pedestrian Network

10.7.2 Paragraph 74 of PPG13, advises that walking offers the greatest potential to replace short car trips, particularly those under 2km. Facilities and infrastructure for pedestrian movement along existing highways in the immediate vicinity of the proposed HPC development site are extremely limited to the site. There are no pedestrian facilities adjacent to the local roads within a 2km isochrone except within the village of Shurton.

10.7.3 There is, however, a network of Public Rights of Way (PRoW) within the local area. Within the HPC development site the following PRoW exist:

- A portion of the West Somerset Coast Path which links the River Parrett Trail at Steart in Bridgwater Bay with the South West Coast Path National Trail at Minehead.
- The Green Lane which is an east-west track that runs along the ridge through the middle of the HPC development site.
- A number of smaller, interconnecting footpaths running north-south and east-west.

ii. Cycling Network

10.7.4 Paragraph 77 of PPG13 advises that cycling also has potential to substitute for short car trips, particularly those under 5km, and to form part of a longer journey by public transport.

10.7.5 There is no dedicated cycling infrastructure present within a 5km isochrone of the HPC development site. The traffic volumes on the roads within the cycle catchment are currently low. The roads within the cycle catchment are generally subject to the national speed limit of 60mph with the exception of sections through the local villages, where the speed limit reduces to 30mph. The roads are also unlit outside of the villages.

iii. Bus Network

10.7.6 The Institute of Highways and Transportation (IHT) ‘Guidelines for Planning for Public Transport in Developments’, published in 1999 (Ref. 10.24), recommends a maximum walking distance to bus stops of 400m. At present there are no bus stops within the recommended walking distance to the HPC development site. There are also currently no bus services that serve the existing Hinkley Point Power Station Complex.

10.7.7 The only bus stop located within a 2km radius from the HPC development site is Lower House Farm bus stop located on Shurton Lane. This stop is served by the First Group service 614 that operates on ‘college days’ only and travels between Shurton and Bridgwater College. It has one outbound service at 07:55 and one inbound service at 17:30.

10.7.8 A second bus stop is located in Stogursey, at Acland Hood Arms. Four bus services serve this stop, the 614, 14, 23A and 23B. Further details on these services are provided in **Table 10.5** below.

Table 10.5: Existing Bus Services

Route	Route Description	Days of Operation	Time	Peak	Off Peak
614	Bridgwater College, Cannington, Stogursey, Shurton via Wembdon	Mon-Fri	17:30	N/A	N/A
614	Shurton via Wembdon, Stogursey, Cannington, Bridgwater College	Mon-Fri	07:55	N/A	N/A
14	Bridgwater (Polden Meadows), Cannington, Watchet via Bus Station, Wembdon, Nether Stowey	Mon-Sun	10:41-16:41, 18:11	N/A	2 hourly
14	Nether Stowey, Wembdon, Watchet via Bus Station, Cannington, Bridgwater (Polden Meadows)	Mon-Sun	08:18-16:18	2 hourly	2 hourly
23A	Bridgwater, Taunton via Stogursey, Nether Stowey, Kingston St. Mary	Mon-Fri	09:28	N/A	N/A
23A	Kingston St. Mary, Nether Stowey, Taunton via Stogursey, Bridgwater	Mon-Fri	13:45	N/A	N/A
23B	Williton, Taunton via Stogursey, Nether Stowey, Kingston St. Mary	Mon-Fri	07:43	N/A	N/A
23B	Kingston St. Mary, Nether Stowey, Taunton via Stogursey, Williton	Mon-Fri	17:30	N/A	N/A

10.7.9 There is a bus lay-over facility located near the junction of Brookside Road and Withycombe Hill in Combwich where buses stand between services.

iv. Rail Network

10.7.10 The nearest effective railhead is at Bridgwater, some 16km from the proposed HPC development site. Bridgwater railway station is located on the main rail network on the route between Bristol and Exeter and links the major population centres in the region.

10.7.11 There is another railway line that passes some 12km to the west of the proposed HPC development site which is one that is privately operated by West Somerset Railway. This line starts at Minehead and terminates at Bishops Lydeard.

10.7.12 Passenger services through Bridgwater station are operated by First Great Western and Cross Country train operating companies. The basic service pattern between Cardiff Central and Taunton is one train per hour in each direction Monday to Sunday.

10.7.13 Direct services from Bridgwater to Exeter are limited with one train service in the morning at 07:10 and one night service at 00:04. Further details on train services are provided in **Table 10.6** below:

Table 10.6: Train Services from Bridgwater Railway Station

Destination	Days of Operation	AM Peak Times (06:00-10:00)	PM Peak Times (16:00-20:00)
Taunton	Mon-Fri	06:09, 07:10, 08:09, 09:19, 09:48	16:45, 17:46, 18:46, 19:15, 19:48
	Sat	06:09, 07:06, 08:10, 09:52	06:42, 17:42, 18:42, 19:42
	Sun	08:24, 09:15	06:48, 18:54, 19:59
Bristol	Mon-Fri	06:14, 06:48, 07:05, 07:25, 07:40, 08:48, 09:49	16:28, 17:17, 18:19, 19:24
	Sat	07:05, 07:44, 08:09, 09:10	16:19, 17:19, 18:19, 19:19
	Sun	08:55	17:30, 18:34, 19:16
Cardiff	Mon-Fri	06:14, 06:48, 07:05, 07:25, 07:40, 08:48, 09:49	16:28, 17:17, 18:19, 19:24
	Sat	07:05, 07:44, 08:09, 09:10	16:19, 17:19, 18:19, 19:18
	Sun	N/A	N/A
Exeter (indirect)	Mon-Fri	06:09, 07:10, 08:09, 09:19, 09:48	16:45, 17:46, 18:46, 19:15, 19:48
	Sat	06:09, 08:10, 09:52	16:12, 17:42, 18:42, 19:42
	Sun	08:24, 09:15	06:48, 18:54, 19:59

v. Maritime

10.7.14 EDF Energy owns a Roll-on Roll-off facility at Combwich Wharf on the River Parrett some 6km from Hinkley Point which is described in the Combwich Wharf section below.

vi. Highway Network

10.7.15 **Plate 10.1** at the beginning of this chapter illustrates the highway network in the vicinity of the HPC development site and wider local area. The transportation network surrounding the HPC development site is commensurate with a rural location with a network of country lanes linking scattered residences, farmhouses and a number of small hamlets.

10.7.16 The main access road serving the existing Hinkley Point Power Station Complex is the C182 which is a single carriageway road passing from Hinkley Point south-east to the village of Cannington. The C182 routes to the east of Shurton and to the west of Combwich and passes through the centre of Cannington to join the A39 to the south of the village.

10.7.17 The C182 is an unlit, single-carriageway rural road generally subject to the national speed limit for such roads i.e. 60mph for most of its length. There are sections where lower speed limits are in force and the C182 is subject to a speed limit of 30mph through the village of Cannington. There is a limit of 40mph immediately to the north of the village.

10.7.18 The A39 runs westwards towards Williton and Minehead and south-eastwards towards Bridgwater and then eastward to Glastonbury.

10.7.19 The A38 routes through Bridgwater on a predominantly north-south alignment. The A38 provides access to Bristol to the north and Taunton to the south. The M5 motorway bypasses Bridgwater to the east of the town with two interchanges at Junction 23 and Junction 24. Junction 23 is located north of Bridgwater and Junction 24 of the motorway is located south-east of Bridgwater.

10.7.20 The Northern Distributor Road (NDR) was built during 2001/02 and links the A38 with the A39 to the west of Bridgwater. The NDR was built to route traffic around central Bridgwater to reduce congestion and HGV flows through central Bridgwater as well as act as a distributor road for new housing. The NDR has recently been reclassified as the A39.

10.7.21 Two of the key junctions in the area are the Cross Rifles roundabout at the junction of the A39 (Bath Road) and A38 Bristol Road and the A38 Taunton Road/A39 Broadway junction.

10.7.22 The baseline traffic flows for the highway network are shown in **Table 10.7** below.

Table 10.7: 2009 Baseline Two-way Daily (24 hour AADT) Vehicular Traffic Flows

Link	Link Ref.	2009 Base

b) Combwich Wharf

i. Pedestrian and Cycle Networks

10.7.24 A narrow footway with grass verges on each side runs along the east side of the C182 between Cannington village and Brookside Road, the vehicular access road to Combwich village. A footway runs along the southern side of Brookside Road from the C182 to the edge of Combwich village from which point footways are provided on both sides of the road throughout most of Combwich village.

ii. Bus Networks

10.7.25 The nearest set of bus stops to Combwich Wharf is at the junction of C182/Brookside Road, approximately 400m to the north of the Combwich Wharf private access road. The bus stops are served by Routes 14, 23A and 614.

iii. Maritime

10.7.26 The Roll-on and Roll-off facility was mainly used during the construction of Hinkley Point A (HPA) and Hinkley Point B (HPB), and its use for the import of occasional Abnormal Indivisible Loads (AILs) by EDF Energy and National Grid has continued. In the early 1990s the facility was upgraded and a new private road linking it to the C182 was constructed. Use of the facility therefore necessitates the onward transfer of loads to the site by road.

10.7.27 As use of the Combwich Wharf facility by the existing HPA and HPB operations and National Grid is infrequent, there is no current baseline with regard to movement by this mode which can be quantified.

iv. Highway Network

10.7.28 Combwich is a small village with roads unsuitable for the passage of large vehicles and therefore a private access road has been built from Combwich Wharf, which passes to the south of the village and connects to the C182. EDF Energy owns Combwich Wharf and the private access road.

c) M5 Junction 23

10.7.29 The proposed park and ride facility, freight management facility, induction centre and consolidation facility for postal/courier deliveries in close proximity to M5 Junction 23 would be located off the A38 Dunball roundabout with access provided off the Bridgwater Business Park arm.

i. Pedestrian and Cycle Networks

10.7.30 There are no controlled pedestrian or cycle crossing facilities within the vicinity of the A38 Dunball roundabout. A narrow footway routes along the southern side of the A39 spur road arm of the roundabout. A footway routes along both sides of the A38 Bristol Road south arm and along the western side of the A38 Bristol Road north arm. A footway is also provided along the southern side of the Bridgwater Business Park arm.

ii. Bus Network

10.7.31 A set of bus stops is currently located on the A38 Bristol Road south arm, approximately 100m south of the A38 Dunball roundabout. There are dedicated bus laybys on both the north and southbound carriageways providing safe places for buses to stop without affecting the flow of traffic. These bus stops are served by Route 21/21A, the Taunton to Burnham on Sea service. The bus stops are simple flag stops without covered waiting facilities. There is also a set of bus stops on the A38 Bristol Road north arm, approximately 400m to the north of the A38 Dunball roundabout. These stops are served by Routes 21/21A, 102 and 375.

iii. Rail Network

10.7.32 Bridgwater railway station is approximately 4.5km from the Junction 23 site via A38 Bristol Road, (Bath Road), Polden Street and Wellington Road. **Table 10.6** summarises the services stopping at Bridgwater railway station.

iv. Highway Network

10.7.33 The A38 Dunball roundabout is a four arm roundabout. The four arms of this roundabout are the A38 Bristol Road north, the A39 spur road (i.e. the road between the A38 Dunball roundabout and the M5), the A38 Bristol Road south and the access road to the Bridgwater Business Park.

10.7.34 M5 Junction 23 is a four arm grade separated roundabout with the M5 motorway running north-south beneath the roundabout. The four arms of the roundabout are the M5 on and off-slip roads to the north and south, A39 Puriton Hill to the east and the A39 spur road to the west.

d) M5 Junction 24

10.7.35 The proposed park and ride facility and freight management facility in close proximity to M5 Junction 24 would be located near the A38/Huntworth roundabout on the former Somerfield Distribution Centre site. Access would be from the arm of the roundabout giving access to the Motorway Service Area and industrial area.

i. Pedestrian and Cycle Networks

10.7.36 There are no controlled pedestrian or cycle crossing facilities at the Huntworth roundabout. A footway routes along the southern side of the A38 spur road arm, along the eastern side of A38 Taunton Road north and south arms and along the northern side of the Stockmoor Village residential access road and the Bridgwater Motorway Service Area access road. There are no controlled pedestrian or cycle crossing facilities at the M5 Junction 24.

ii. Bus Network

10.7.37 The nearest bus stops to the Junction 24 site are a set of bus laybys located approximately 100m south of the Huntworth roundabout on the A38 Taunton Road south, which are served by Route 21/21A.

iii. Rail Network

10.7.38 Bridgwater railway station is approximately 4km from the Junction 24 site via A38 Taunton Road, Broadway, St. John Street and Wellington Road. **Table 10.6** summarises the services stopping at Bridgwater railway station.

iv. Highway Network

10.7.39 The Huntworth roundabout is a five arm roundabout to the west of the M5 Junction 24. The five arms are the A38 Taunton Road north, the Bridgwater Motorway Service Area access, the A38 spur road (i.e. road between A38 roundabout and M5), the A38 Taunton Road south and the access to the Stockmoor Village residential development to the west.

10.7.40 M5 Junction 24 is a four arm grade separated roundabout with the M5 motorway running north-south beneath the roundabout. The four arms of the roundabout are the M5 on and off-slip roads to the north and south, an unclassified road to the east and the A38 spur road to the west.

e) Cannington Bypass

i. Pedestrian and Cycle Networks

10.7.41 The proposed bypass passes through open fields and bisects Public Right of Way BW5/8.

ii. Bus Network

10.7.42 The nearest bus stops to the proposed development are located on High Street close to the Memorial junction.

iii. Rail Network

10.7.43 The nearest railway station to Cannington is at Bridgwater, approximately 6km to the south-east of the proposed development. Bridgwater railway station is located on the mainline rail network on the route between Bristol and Exeter.

iv. Highway Network

10.7.44 The A39/Main Road (western) roundabout is a three arm roundabout with the AA39 forming the southern and western arms and Main Road forming the northern arm, which leads to Cannington village. The A39/High Street roundabout is a three arm roundabout with the A39 forming the eastern and southern arms and High Street forming the northern arm, which leads to Cannington village.

f) Cannington Park and Ride Site

10.7.45 The proposed park and ride facility at Cannington would be located to the north of the A39 between the A39/Main Road and A39/High Street roundabouts.

i. Pedestrian and Cycle Networks

10.7.46 There are no controlled pedestrian or cycle crossings within the vicinity of the proposed Cannington park and ride facility. There are footways around the A39/Main Road roundabout connecting local properties to the south of the junction with the footway network in Cannington. A footway is provided on the eastern side of the A39 between the A39/Main Road roundabout and Sandford Hill, beyond which the footway reduces in width to be unusable. There are no footways in the vicinity of the A39/High Street roundabout and no footways on either side of the A39 near to the proposed Cannington park and ride facility.

ii. Bus Network

10.7.47 The nearest set of bus stops to the proposed Cannington park and ride facility are a set of bus stops located on Main Road approximately 100m north of the A39 roundabout, in the vicinity of Southbrook. These bus stops are served by Routes 14, 23A and 615.

iii. Rail Network

10.7.48 The nearest railway station to Cannington is at Bridgwater, approximately 6km to the south-east of the proposed park and ride facility. Bridgwater railway station is located on the mainline rail network on the route between Bristol and Exeter. **Table 10.6** summarises the services stopping at Bridgwater railway station.

iv. Highway Network

10.7.49 The A39/Main Road roundabout is a three arm roundabout with the A39 forming the southern and western arms and Main Road forming the northern arm, which leads to Cannington village. The A39/High Street roundabout is a three arm roundabout with the A39 forming the eastern and southern arms and High Street forming the northern arm, which leads to Cannington village.

g) Williton Park and Ride

10.7.50 The proposed park and ride facility at Williton is to be located on an existing lorry park site on the B3190 to the west of Williton.

i. Pedestrian and Cycle Network

10.7.51 There are no footways on the B3190 in the vicinity of the site. There are no designated cycle facilities although cyclists can use local roads.

ii. Bus Network

10.7.52 The B3190 is a bus route served by the 14, 18, 28, 105 services which travel via Watchet.

iii. Rail Network

10.7.53 Williton railway station forms part of the West Somerset Railway, a heritage railway line. Williton station is located on Station Road, off the A39 to the east of Williton village centre. Trains run between Minehead and Bishops Lydeard, via Williton, daily during the late Spring and Summer and less frequently in the Winter months.

iv. Highway Network

10.7.54 The B3190 is a typical rural road of approximately 5-6m width. It joins the A39 at an uncontrolled crossroads.

h) Bridgwater Accommodation Campuses

10.7.55 Bridgwater A site is located to the north of the A39 (Bath Road). The Bridgwater C site is located to the west of College Way, to the south of the A39.

i. Pedestrian Network

10.7.56 There are footways along both sides of A39 (Bath Road), approximately 2m in width. A zebra crossing is provided to the west of Union Street and a further zebra crossing is provided to the west of College Way. Over the railway bridge on A39 (Bath Road) there is a footway on the northern side approximately 2m wide. A separate footbridge is provided on the southern side of (Bath Road), which is approximately 3m in width.

10.7.57 There is a zebra crossing approximately 30m north of the Cross Rifles roundabout on the A38 Bristol Road that provides pedestrian access to the nearby Sainsbury's supermarket. There are footways on both sides of the A38 Bristol Road and two arms of the A38/Bristol Road/The Drove junction have signal controlled pedestrian crossing facilities (i.e. The Drove and A38 Bristol Road south arm).

ii. Cycle Network

10.7.58 The existing cycle facilities within a 5km cycle catchment of the Bridgwater accommodation campus sites include:

- A signed cycle route provides a connection between Bridgwater railway station and the town centre via St. John Street and Eastover.
- A high quality segregated cycle/footpath along one side of the northern section of Feversham Road.
- A high quality off-road cycle route connecting the NDR to Crowpill Lane.
- An off-road shared pedestrian and cycle route is provided in the Sydenham part of Bridgwater, connecting Redgate Street to Longstone Avenue.
- A high quality segregated cycle/footpath along at least one but in parts on both sides of the NDR between A39 and the junction with Wylds Road.
- As the NDR segregated cycle/footpath approaches the River Parrett, it routes south to connect to Linham Road. The cycle route runs south along Linham Road and at the Marina the route divides in two with one route heading west along the Bridgwater to Taunton Canal to connect to Victoria Road. The other part of the route heads south off-road along the River Parrett, over The Clink (no formal crossing facilities provided) and then continues along West Quay and Binford Place. At the southern end of Binford Place the cycle route continues off-road through Blake Gardens, under the A39 Broadway and connects to Old Taunton Road and then connects back onto the Canal towpath, which forms part of the River Parrett Trail (National Cycle Network Route 3).

iii. Bus Network

10.7.59 Within Bridgwater there is a bus and coach station at Watsons Lane, near to the ASDA supermarket. The bus and coach station was opened in 2004 and is operated by First Group.

10.7.60 With regard to bus stops near to the proposed accommodation campus sites in Bridgwater, there is a set of bus stops immediately to the west of the A39 (Bath Road)/Union Street/Lower (Bath Road) junction and these are served by Route 1, the Sydenham/Wyndham Road Circular.

10.7.61 There is also a set of bus stops on A39 (Bath Road), adjacent to Frederick Road, which are served by Route 1, Route 102 to Burnham on Sea and Route 375 to Wells and Bristol.

10.7.62 There are also a number of bus stops on the A38 Bristol Road, the nearest of which to the accommodation campus sites is a set of bus stops to the south of Union Road. These are served by Route 21/21A from Taunton to Burnham on Sea.

iv. Rail Network

10.7.63 Bridgwater railway station is approximately 1.5km from the Bridgwater A site and 1.3km from the Bridgwater C site. The shortest walking route from the accommodation campuses to the railway station is via A39 (Bath Road), Polden Street and Wellington Road.

v. Highway Network

10.7.64 The A39 (Bath Road), within the vicinity of the proposed accommodation campus sites, is a 7.3m single carriageway with street lighting.

10.7.65 There is a bridge over the Bridgwater to Highbridge (part of the Bristol to Penzance) railway line, where it is crossed by the A39. The bridge carriageway has a reduced width and there is signage advising that eastbound traffic has priority over westbound traffic over the bridge.

10.7.66 The junction of A39 (Bath Road)/A38 Bristol Road is referred to as the 'Cross Rifles' roundabout. This is a four arm roundabout with the A38 Bristol Road joining from the north, the A39 (Bath Road) joining from the east, A39 Broadway joining from the south and The Clink joining from the west.

10.7.67 The A38 Bristol Road is a main arterial route into Bridgwater and, as such, carries significant volumes of traffic especially in the peak periods. During peak periods queues form on the A38 into Bridgwater, which affect the operation of the A38/Express Park roundabout as the queues extend across the circulatory carriageway.

10.7.68 To the south of Express Park is the A38/Wylds Road priority junction, which provides vehicular access to a major industrial/commercial area of Bridgwater. Wylds Road is restricted and vehicles are only permitted to turn left from Wylds Road to the A38 Bristol Road. Immediately to the west of the junction, on Wylds Road is Allerton Road and the operation of this minor junction can impede the flow of traffic turning to and from the A38, particularly as Wylds Road is used by a significant volume of heavy goods vehicles accessing/egressing the industrial areas nearby. It should also be noted that Wylds Road is also used by southbound traffic heading into Bridgwater who are avoiding the delays further south at the Cross Rifles roundabout.

10.7.69 Further south, is the signal controlled junction of A38 Bristol Road/The Drove. The operation of this junction is complicated by the proximity of Union Street on the eastern side of the A38 immediately to the south of the signal controlled junction. Union Street is a 'left-in left-out' priority junction and its bellmouth kerbs encroach into the traffic signal controlled junction. The Drove forms part of what is referred to as the 'Northern Distributor Road' (NDR), which was built in 1992.

10.8 Future Baseline Conditions

10.8.1 As set out earlier in this chapter, the assessment years selected are 2013, 2016 and 2021. Therefore future baseline conditions have been assessed for these years. Future baseline conditions are referred to as the Reference Case.

10.8.2 For 2016 the Reference Case flows are shown below along with the comparison to the 2009 Base Case flows. For 2013 and 2021 the Reference Case flows are shown in the Assessment of Impacts section.

10.8.3 **Table 10.9, Table 10.10** and **Table 10.11** summarise the 2009 Base and 2016 Reference Case flows for the daily (24 hour AADT), AM peak (08:00 to 09:00) and PM peak (17:00 to 18:00) hours. These are two way flows (e.g. sum of the eastbound and westbound flows). It should be emphasised that these are flows that occur without the HPC development. The increases in flow compared with the 2009 Base Case are due to other planned developments in the area and application of DfT growth factors.

10.8.4 Changes in predicted flows on a link can take place for a number of reasons. Additional traffic from planned developments would add traffic to a link. However, if congestion and delay on one link increase this can lead to traffic diverting to an alternative route. This then leads to an increase in flow on the diversion route but a decrease on the congested link from which traffic diverts.

Table 10.9: 2009 Base vs. 2016 Reference Case Two-way Daily (24 Hour AADT) Vehicular Traffic Flows

Link	Link Ref.	2009 Base	2016 Ref Case	Increase (Numerical)	Increase (%)

Williton	2	440	474	34	8%

10.8.5 As can be seen there are general increases of flow on the network. Flows on the M5 Junction 23 southbound and northbound slip roads increase as do flows on the A38 south of Dunball. There are also increases albeit smaller at Junction 24 and Taunton Road.

10.9 Assessment of Impacts

10.9.1 As noted earlier in this chapter, the assessments have been undertaken for three assessment periods: 2013 when construction of the HPC development site would have commenced and the associated development sites would be under construction; 2016 which is the year of maximum construction impacts; and 2021 when the power station would be fully operational and some of the associated development sites would be being deconstructed. The assessment also includes the implementation of the transport strategy as described in the **Transport Assessment**.

a) 2016

10.9.2 As noted earlier in this chapter, the assessments have been undertaken assuming implementation of EDF Energy's transport strategy as summarised earlier in this chapter. In addition, the proposed highway improvement package as described in the Methodology (Impact Assessment) section is assumed to be in place.

10.9.3 **Tables 10.12** to **10.15** show the 2016 With Development and Mitigation scenario compared with the 2016 Reference Case daily and network peak hour flows are shown for All Vehicles. Daily flows are also shown for HGVs and buses. Further detailed information is included in the **Transport Assessment**.

10.9.4 As with the 2009 Base Case and 2016 Reference Case comparison above, flow changes are not only due to HPC traffic but also re-routing due to the highway improvements. For example, improvements to the Cross Rifles junction would lead to re-routing of traffic where the route is currently influenced by capacity constraints at the junction.

Rodway south of bypass	AC	6,779	3,446	-3,333	-49.2%
Rodway north of bypass	11	6,779	8,316	1,537	22.7%
Cannington bypass	Z1	0	6,244	6,244	
B3190	10	1,412	1,619	207	14.7%
Williton	2	6,150	6,977	827	13.4%

10.9.5 As can be seen, flows increase on the main routes from Junction 23 and Junction 24 to HPC development site i.e. the A38 South of Dunball (G), Western Way (AA), A39 Taunton Road (I1), A39 Broadway (K5), A39 west of Quantock roundabout (S) and A39 south of Cannington (P). Flows then use the Cannington bypass (Z1) with consequent reductions through Cannington on Main Road (ZD), High Street (U) and Rodway (AC). The decreases are less on High Street partly because some buses remain using this route.

10.9.6 However, flows also increase on, for example, (Bath Road) (N3) even though little HPC traffic is expected to use this road. This is likely to be due to re-assignment of traffic because of capacity improvements at Cross Rifles. This is further corroborated by the reduction in flow on the A39 east of M5 Junction 23 (Link L).

10.9.7 Overall the highway improvement package increases capacity in Bridgwater. One consequence of this appears to be that some traffic that is currently using the M5 as a bypass of Bridgwater now uses the A38/39 through the town. This is shown in the reduction in flows on the south facing slip roads at Junction 23 and the north facing slip roads at Junction 24.

10.9.8 In general the changes in HGV and bus flows due to the HPC Project reflect the total vehicle changes. Some buses are routed down Wylds Road (in order to reduce impacts in the sensitive hours on residential properties on Bristol Road) whilst HGVs use The Drove as requested by SCC.

10.9.9 On High Street Cannington there is a small increase in flow due to buses which remain routed through Cannington offsetting the small reduction in HGV flows since only a small number of HGVs use High Street in the Reference Case.

i. Severance

10.9.10 Only the A39 south of Cannington would experience an increase in daily traffic flows above 30% as a result of the HPC development. Therefore on the remaining links which experience an increase in traffic, the impact from all traffic flows is judged to be negligible.

10.9.11 The 101% increase in flows on the A39 to the south of Cannington would represent a substantial impact. This impact arises due to traffic diverting from Main Road Cannington to the A39 before using the bypass and from HPC traffic. The sensitivity of this route is minor (due to there being little pedestrian activity) leading to an initial appraisal of significance of moderate adverse. However, given the nature of the A39 at this point and the temporary nature of the peak impacts it is considered that the correct assessment is **minor adverse** impact.

10.9.12 Both Main Road and Rodway (south of Cannington bypass) experience reductions in daily traffic flow of between 30% and 60% as a result of the construction of the Cannington bypass as part of the HPC Project. This level of reduction represents a minor impact. These routes have substantial sensitivity receptors and therefore the significance of impact on both of these links is considered to be of **moderate beneficial** significance.

10.9.13 In terms of HGV's and buses, the only links that experience an increase in daily flows of between 30% and 60% are shown below. This is a minor magnitude of impact.

- A38 between Wylds Road and the Drove.
- Wylds Road.
- Williton.

10.9.14 Wylds Road and the A38 between Wylds Road and The Drove are judged to be minor in sensitivity and therefore the significance of the impact is **negligible.** Williton is judged to be substantial in sensitivity and therefore the significance of the impact is **moderate adverse**.

10.9.15 The only link to have an impact of between 60% and 90% is A39 Broadway. This is a moderate magnitude of impact and A39 Broadway is a moderate sensitivity receptor. Therefore the significance of the impact is **moderate adverse**.

10.9.16 The following links have a magnitude of impact of greater than 90% which is considered substantial and arises from the consideration that these links are on the HGV/bus routes to the site:

- The Drove.
- Western Way west of Chilton Street.
- A39 west of Quantock Road.
- A39 south-east of Cannington.
- A39 south of Cannington.
- Rodway north of Cannington bypass.

10.9.17 The Drove, and A39 south-east and south of Cannington and Rodway North of Cannington are all judged as minor receptors and therefore the significance of the impact is **moderate adverse**. In fact these links are either through industrial areas or are rural in nature with very little pedestrian activity and very few adjacent residential properties.

10.9.18 The assessment tables above include the link (Link 11 – Rodway North of Cannington) which covers the area to the north of the village. However, to the north of the Combwich freight laydown facility there would be some additional HGV movements transferring goods between the freight laydown facility and the HPC development site. These flows are estimated to be 300 movements per average day spread evenly through the day between 07.00 and 20.00 i.e. 27 movements per hour. Peak day movements could increase up to a maximum of 400 movements per day. However, there would also be days when the flow is considerably less than 300. Therefore the average flow of 300 HGVs per day has been used in the assessment.

10.9.19 Furthermore, there are some HGVs that would travel from the freight management facilities at either Junction 23 or Junction 24 and deliver goods to the Combwich freight laydown facility and return to the motorway without continuing to the HPC development site. This would tend to reduce the flow to the north of the freight laydown facility but this factor has not been taken into account in the analysis in order to give a robust assessment.

10.9.20 Therefore to the north of the freight laydown facility the total HGV plus bus flow would increase to 1,452 movements per day (1,152 + 300). The sensitivity of the receptor at this location is still minor and therefore the significance of the impact is **moderate adverse.**

10.9.21 Western Way, the A39 Broadway and the A39 to the west of Quantock roundabout are all moderate sensitivity receptors and therefore from an initial assessment the significance of the impacts is substantial. These links are examined in turn below.

Western Way:

10.9.22 This road already creates severance between the residential properties on either side. Properties do not front onto the road and this reduces the level of pedestrian activity. There are guardrails along sections of the road and pedestrian crossing of the road tends to be at controlled crossing points. It should be remembered that Western Way is an A road and the signed route from the A39 west of Quantock roundabout to the M5.

10.9.23 The figures reported in the table above are for HGVs and buses. It is considered that whilst buses still have an impact on severance, the perceived impact is less than for HGVs. Therefore the impact of just HGVs has also been considered.

10.9.24 For just HGVs, the increase over a day due to HPC is 330 per day which is an average of 22 vehicles per hour during the permitted hours for HGV operations (07.00 to 22.00) or approximately one HGV every three minutes.

10.9.25 It is also important to recognise the absolute level of HGVs. At present the proportion that HGVs represent of the total flow along Western Way is 1.7% which is a low percentage especially for an "A" road. The national average is 7% although it is around 5% if certain road categories are excluded. Even with the addition of HPC HGVs the proportion would only increase to 3.7%, still a low figure for this type of road.

10.9.26 If buses are also included then the proportion of HGVs plus buses is approximately 7% i.e. no greater than the national average.

10.9.27 On a peak day for HGVs, the HGV increase would be 495 HGVs per day (330 X 1.5). This is one vehicle every 2 minutes. HGVs would then represent 4.9% of the total flow, still below the national average. Taking all of the above into account including the nature of Western Way and the fact that the impacts assessed would be temporary in nature and the estimates are robust, it is considered that the significance of the impact is **moderate adverse.**

A39 west of Quantock Road:

10.9.28 At this point the HGV route from Junction 23 and that from Junction 24 combine. There would be 1145 extra HGVs and buses per day, which is an average of less than 1 vehicle per minute.

10.9.29 For just HGVs the increase would be 532 HGVs per day or one vehicle every 2 minutes.

10.9.30 Currently HGVs represent 3.3% of the total flow and this would increase to 5.8% which is below the national average of 7%.

10.9.31 With buses included, the future proportion that HGVs and buses represent of the total flow is 10.3%.

10.9.32 On a peak day for HGVs, the HGV increase would be limited to 750 movements since this is the limit that EDF Energy propose for the peak daily flow. This is equivalent to one vehicle every minute. In this case HGVs would represent 7% of the total flow.

10.9.33 Only approximately 20 houses front onto Quantock Road on this link and the houses on the north side do not front onto the road. Therefore, the level of pedestrian activity is likely to be low.

10.9.34 Taking the above factors into account and the temporary nature of the peak impacts the significance of the impact on this short stretch of Quantock Road is judged to be **substantial adverse**. Further to the west where there are virtually no properties close to the road, the significance of the impacts would reduce considerably.

10.9.35 Looking at severance in the round there would be some adverse impacts in Bridgwater but benefits in Cannington. The impacts are over a temporary period and the roads affected are all A roads which are expected to take HGV traffic. In general these roads have only a small number of residential properties fronting onto them. The estimated number of vehicles is a robust estimate, particularly for buses and the HGV numbers include Medium Goods Vehicles. Taking all of the above into account the overall impact on Severance is judged to be **moderate adverse.**

ii. Pedestrian Delay

10.9.36 Those highway links with a two-way flow greater than 1,400 vehicles per hour include The Clink and various locations on the A38 and A39 in and around Bridgwater. However, none of these links experience traffic flow increases of greater than 30% and therefore the magnitude of impact on all of these links as a result of the HPC development with respect to pedestrian delay is **negligible.**

10.9.37 On Cannington High Street, improvements to the pedestrian crossing facilities are proposed. These comprise re-siting the location of the existing zebra crossing nearer to the Memorial Junction and its conversion to a pelican crossing and installation of a new crossing on Rodway close to Bridgwater College. Furthermore, the traffic flows would reduce significantly due to the completion of the bypass. These changes would lead to a **moderate beneficial** impact on pedestrian delay.

iii. Pedestrian Amenity

10.9.38 Based on advice in the IEMA Guidelines, the change in flows at which pedestrian amenity changes become material are a doubling or halving in the flow of all traffic or HGVs.

10.9.39 Only the A39 south of Cannington experiences a general traffic flow increase of greater than 100% in association with the HPC site. However, the receptor sensitivity for the route is minor as the route has no frontage access or pedestrian activity. The overall effects are therefore concluded to be **negligible** in terms of significance.

10.9.40 In terms of HGV's and buses the links that experience a daily flow increase of greater than 100% and where the sensitivity of the receptors are other than minor are shown below along with the % change in HGVs only as a result of HPC shown in brackets:

- Western Way west of Chilton Street (161%).
- A39 west of Quantock Road (125%).

10.9.41 On a peak day HGVs would increase by 227% and 192% respectively. However the number of days of peak HGVs would be relatively small and the vast majority of time the flows would be less than the peak.

10.9.42 The existing level of pedestrian amenity also needs to be taken into account. All three roads are A roads carrying significant levels of traffic and the pedestrian amenity level is therefore already low.

10.9.43 In Cannington, whilst there is not a halving in traffic flows, the effects of the bypass in removing traffic are considered to be material and are judged to be **moderate beneficial.**

10.9.44 Taking the above into account, and the fact that the sensitivity of the receptors is judged to be moderate and the level of impact assessed is temporary, the significance of the impact is considered to be **moderate adverse** in Bridgwater and **moderate beneficial** in Cannington.

iv. Driver Delay

10.9.45 The **Transport Assessment** includes a detailed analysis of journey times on various routes in Bridgwater and surrounding areas and demonstrates that there is no material detriment to journey times within Bridgwater as a whole. Overall journey speeds are maintained. During the modelled hours (06:00 to 10:00 and 13:00 to 20:00 the average speed of a vehicle through the modelled network is 29.1 miles per hour in the 2016 Reference Case and 29.0 miles per hour in the With Development and Mitigation Case. Hence there is no material change.

10.9.46 The key routes for journey times are the two HGV routes from the M5 to the HPC site since these take the great majority of HPC generated traffic. Charts showing the changes in journey times on these two routes are shown below.

10.9.47 Journey Time 10 is the route from Huntworth roundabout (i.e. the access to Junction 24 site), via A38 Taunton Road, A39 Broadway, to Quantock roundabout.

10.9.48 The route from the Junction 23 facilities comprises two routes. Route 6 is from Junction 23 facilities to Cross Rifles whilst Route 1 is from the A38/The Drove junction to the Quantock roundabout.

10.9.49 Plans of the journey time routes are included in the **Transport Assessment**.

10.9.50 The red line on the graphs shows the 2016 Reference Case i.e. what happens without HPC but with other growth. The green line shows the journey times if HPC traffic is added but with no highway improvements. The blue line shows the situation if the highway improvements are added. Twenty model runs are undertaken to produce the results for each scenario. The range of results is shown by the dotted lines with the average being shown by the solid line. The range of results is known as the confidence interval. The period between 10.00 and 13.00 hours has not been modelled (as agreed with the transport authorities) and therefore the graphs should be ignored for these periods. A change is only considered statistically significant if the confidence intervals (i.e. the range of results from the multiple runs undertaken) between two scenarios do not overlap.

10.9.51 The first two graphs show the journey times for Route 10.

Plate 10.4: 2016 Journey Time Analysis: Route 10 – Southbound

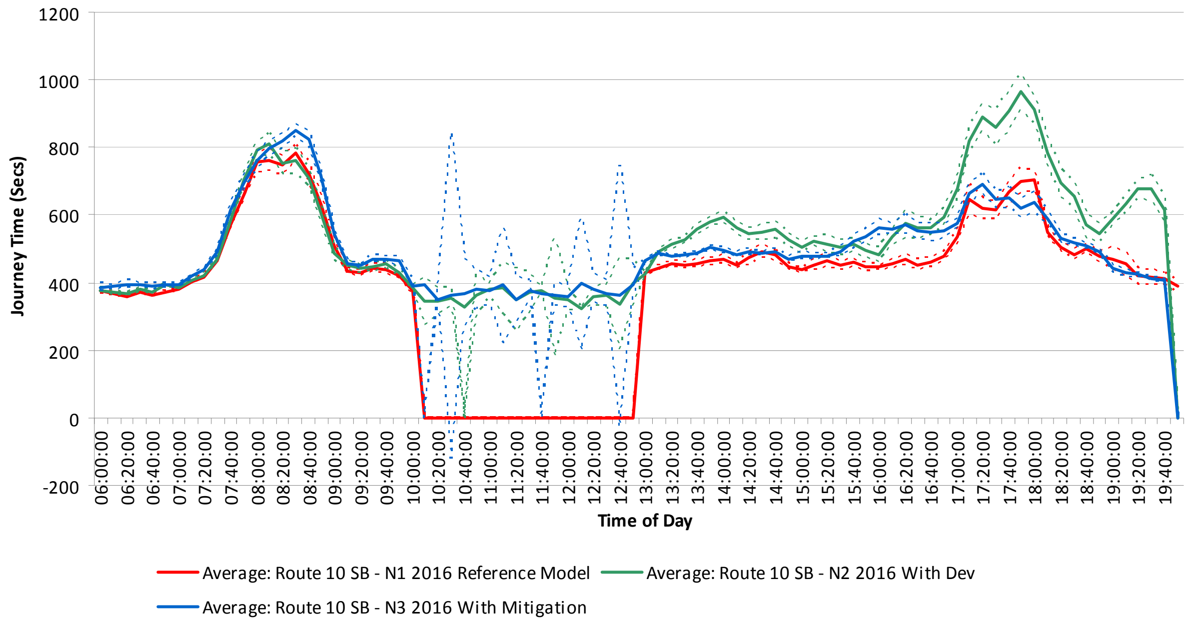

Plate 10.5: 2016 Journey Time Analysis: Route 10 – Northbound

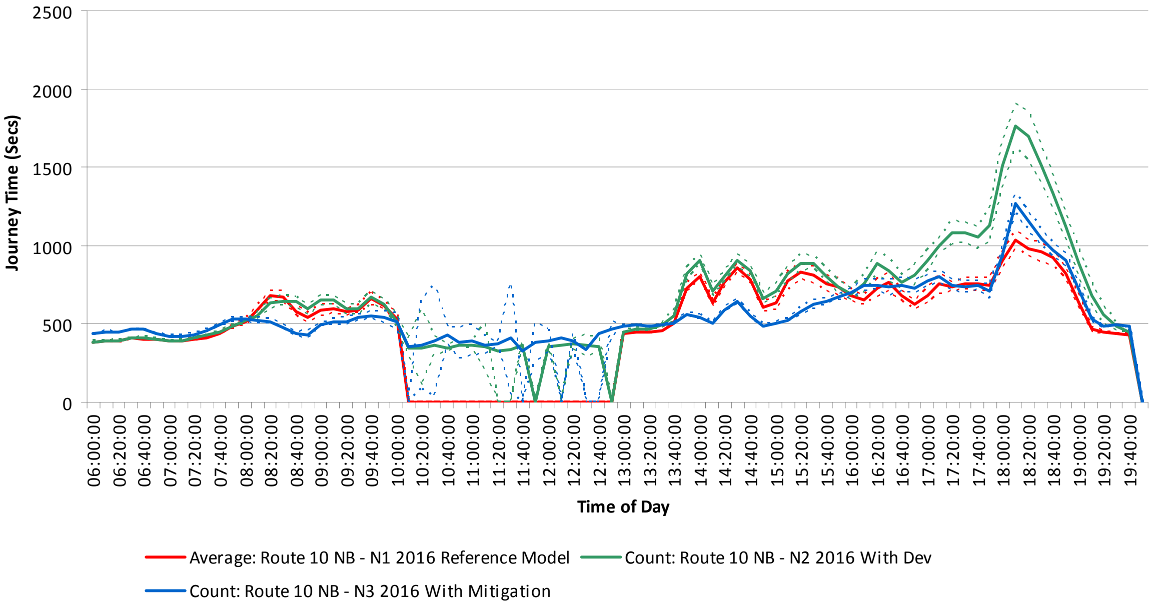

10.9.52 As can be seen on the journey time analysis for Route 10, without any mitigation there is a significant detriment to journey times in both the southbound direction (i.e. away from HPC) and northbound direction in the evening peak period.

10.9.53 With the proposed highway improvements in place the southbound direction journey times are broadly neutral between the Reference Case and the With Development and Mitigation Case. In the northbound direction (towards HPC) there is an improvement in the morning peak and early afternoon but some detriment around 18.00 hours.

10.9.54 Shown below are the journey times for Routes 6 and 1.

Plate 10.6: 2016 Journey Time Analysis: Route 6 – Southbound

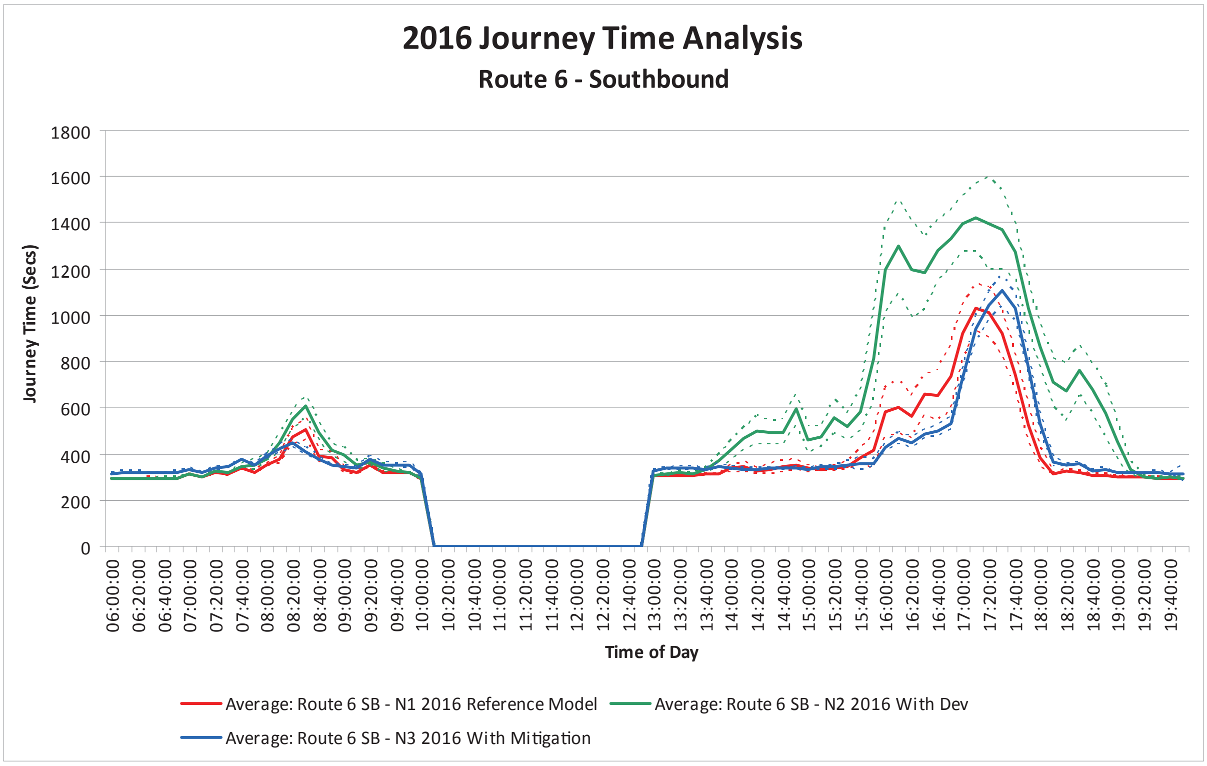

Plate 10.7: 2016 Journey Time Analysis: Route 6 – Northbound

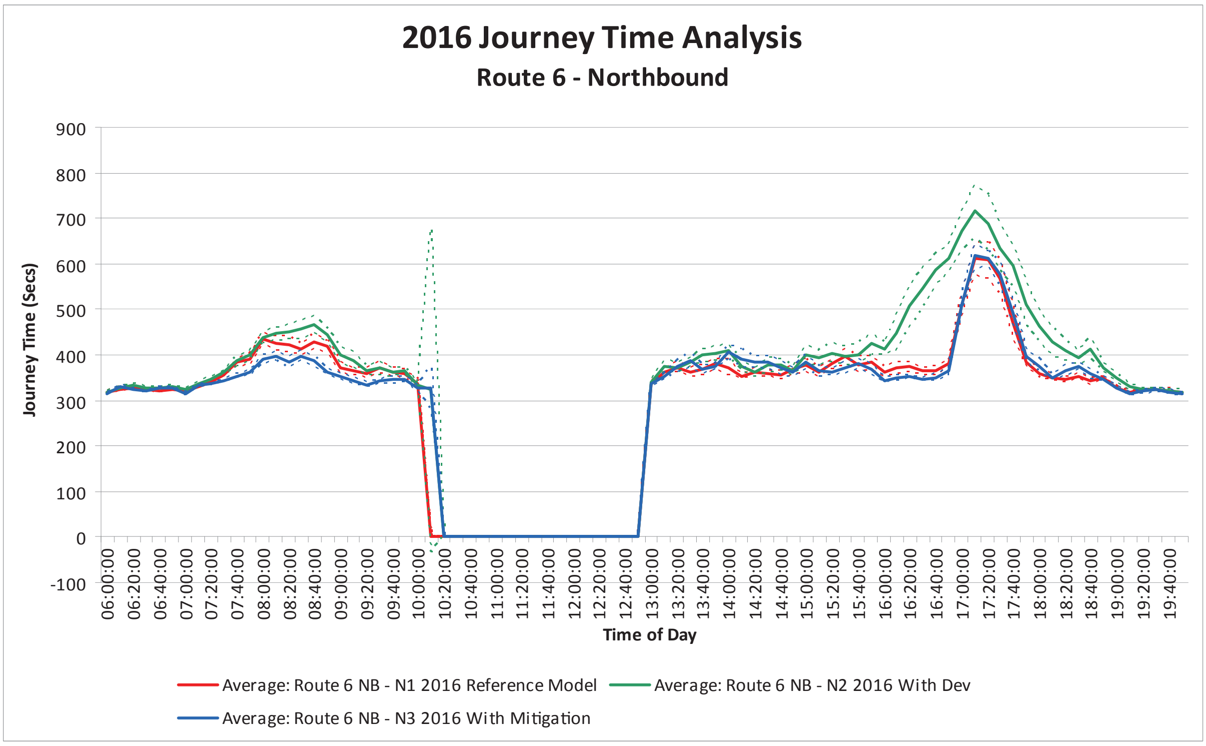

Plate 10.8: 2016 Journey Time Analysis: Route 1 – Eastbound

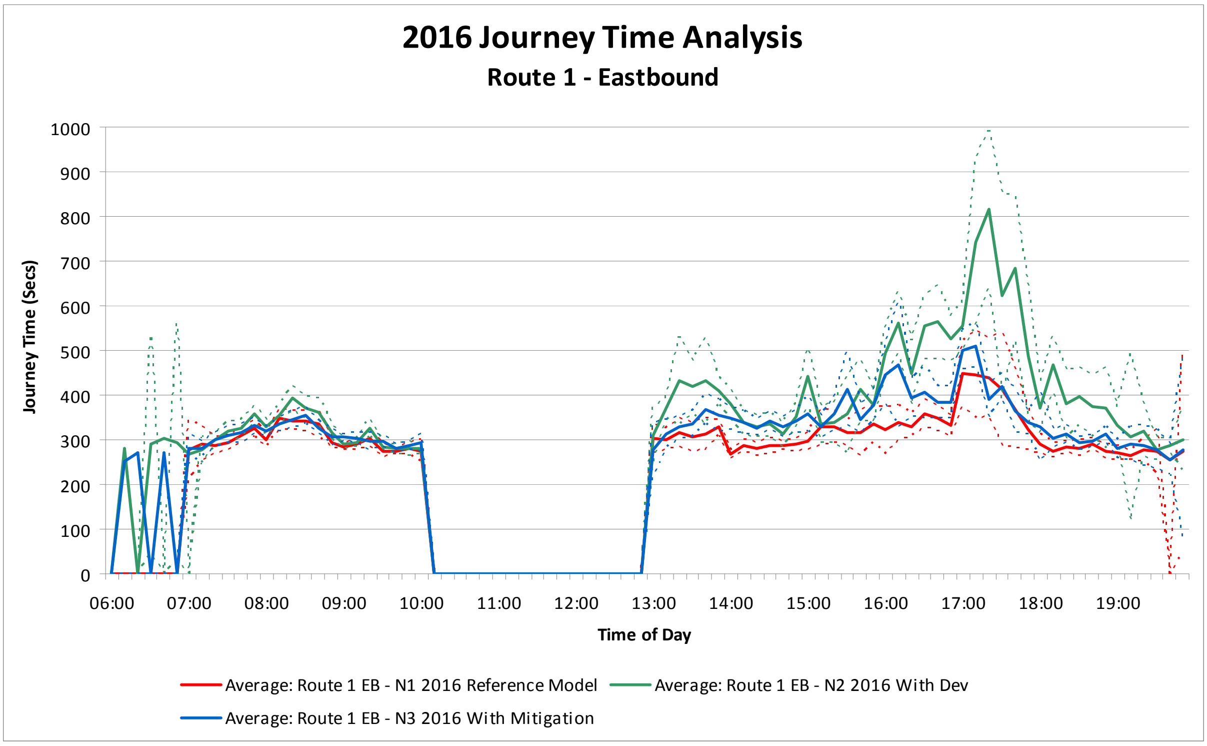

Plate 10.9: 2016 Journey Time Analysis: Route 1 – Westbound

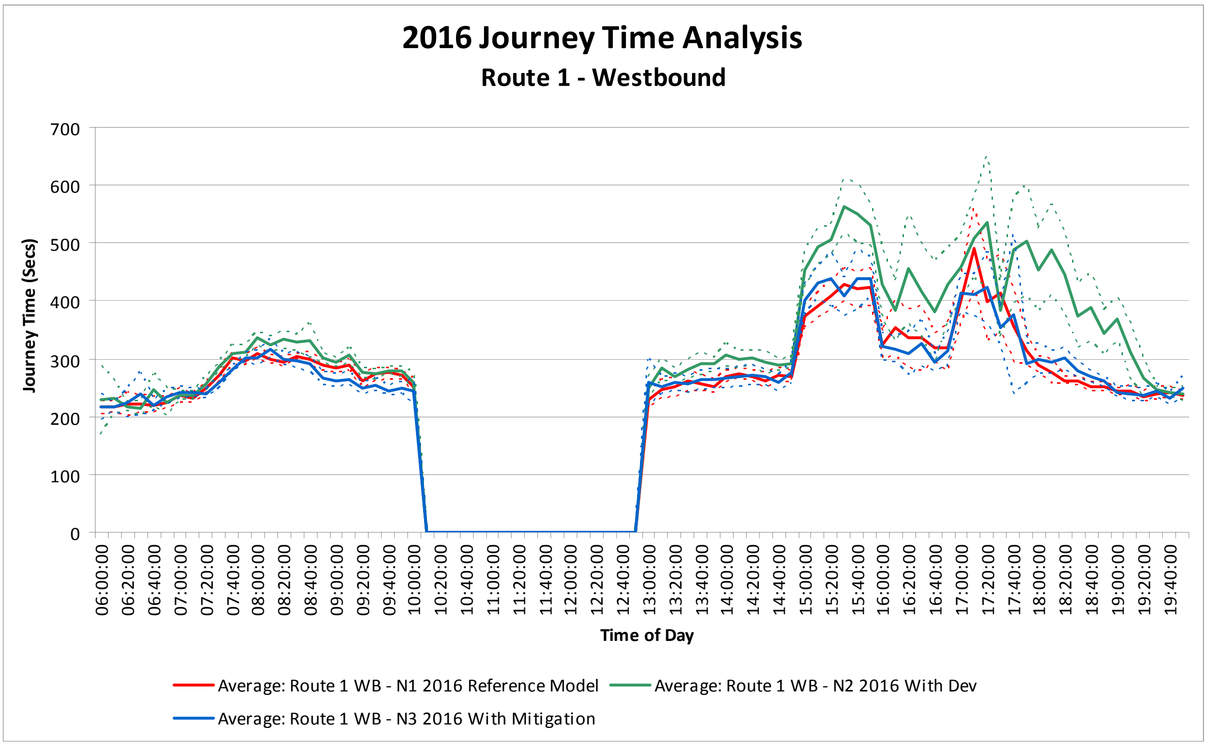

10.9.55 On journey time Route 6 southbound, HPC traffic plus mitigation leads to a small increase in journey time in the morning peak and a small reduction in the evening peak. In the northbound direction there is a small improvement in the morning peak and no change in the evening peak.

10.9.56 On Route 1 there is no statistically significant change in journey times when the scenario with HPC traffic plus mitigation is compared with the Reference Case in either the eastbound or westbound directions.

10.9.57 On the basis of the above, the impact of HPC with highway mitigation on driver delay is considered to be **negligible**.

v. Accidents and Safety

10.9.58 As noted earlier in this chapter, a full safety study has been undertaken and the results are reported in the **Road Safety Strategy** appended to the **Transport Assessment.**

10.9.59 The study demonstrates that there are a number of accident clusters where traffic flows would increase due to committed development schemes and other traffic growth as well as HPC. Somerset County Council themselves have an ongoing safety improvement programme in Bridgwater which is looking at a number of the clusters.

10.9.60 The study demonstrates that a number of the highway improvements proposed by EDF Energy bring forward safety enhancements. In particular this is the case at A39 New Road/B3339 Sandford Hill roundabout, Taunton Road/Broadway and Wylds Road/The Drove junctions.

10.9.61 As noted earlier in this chapter the increases in total traffic flows through Bridgwater as a result of HPC are all less than 30% although HGV and bus flows increase by greater than 30% in some locations.

10.9.62 Taking all the above into account the potential impact on safety is judged to be **minor adverse**.

b) 2013

10.9.63 As noted earlier in this chapter, 2013 represents the early construction phase of the HPC Project before all the associated development sites would be operational. The park and ride site and freight management facility located at the Junction 24 site close to M5 Junction 24 would be operational but other associated developments would still be under construction. Some freight vehicles and buses would still be routed from Junction 24 up the M5 to Junction 23 and then along the northern HGV route via the Northern Distributor Road. As well as vehicle movements relating to the construction of the HPC development site, movements relating to the construction of associated developments have also been included in the analysis.

10.9.64 In terms of highway improvements, the analysis has been undertaken on the basis of only the site preparation works improvements plus Huntworth roundabout being in place. The Cannington bypass would not be operational until Quarter 4 2014.

10.9.65 Therefore the highway improvements assessed are:

- A39 Broadway/A38 Taunton Road junction.
- A39 New Road/B3339 Sandford Hill roundabout.
- Washford Cross roundabout.

- Huntworth roundabout.
- Claylands Corner junction.
- Cannington Traffic Calming Measures.
- C182 Farringdon Hill Lane horse crossing.

10.9.66 However, EDF Energy would seek to implement the entire highway improvement package as soon as possible and therefore some additional improvement measures may be in place before the assessment period of Quarter 3 2013.

10.9.67 The results of the analysis are shown in the **Tables 10.16** to **10.19**. These cover daily all vehicle flows, peak hour all vehicle flows and daily HGV and bus flows. More detailed information is included in the **Transport Assessment**.

Table 10.16: 2013 Reference Case vs. 2013 With Development and Mitigation Daily (24 Hour AADT) 2 Way All Vehicles Traffic Flows

B3190	10	1,412	1,619	207	14.7%
Williton	2	6,150	6,977	39	0.6%

10.9.68 As can be seen the great majority of flow increases are less than in 2016. For example, on Western Way the increase in daily flows is 827 vehicles (6.7%) compared with 1,845 vehicles (14.6%) in 2016.

10.9.69 In Cannington, the bypass would not be in place and therefore there would be increases in flows on roads through the village. On High Street the daily all vehicles flow would increase by 1391 vehicles or 64% of the existing flow.

10.9.70 The most significant change in HGV and bus flows compared to 2016 would be in Cannington where HGVs and buses would be routed along High Street until the bypass is complete.

i. Severance

10.9.71 Examining daily flows, there are no increases greater than 30% except on High Street Cannington. Therefore on this criteria, on all links other than High Street, the impacts are expected to be negligible.

10.9.72 In terms of HGV's and buses, the links that experience an increase in daily flows of between 30% and 60% are shown below. This is a minor magnitude of impact.

- A38 between Wylds Road and The Drove.
- A39 Taunton Road (south of Showground).
- A39 south of Broadway.
- Wylds Road.
- M5 Junction 24 southbound off-slip.

10.9.73 All of these links are judged to be minor or moderate in sensitivity and therefore the significance of the impact is **negligible or minor adverse**.

10.9.74 No links experience a magnitude of impact between 60% and 90%

10.9.75 The following have a magnitude of impact of greater than 90% which is considered substantial and arises from the consideration that these links are on the HGV/bus routes to the site :

- The Drove.
- Western Way west of Chilton Street.
- A39 Broadway.

- A39 west of Quantock Road.
- A39 south-east of Cannington.
- A39 south of Cannington.
- High Street Cannington.
- Rodway (north and south of Cannington bypass).

10.9.76 The Drove, and A39 south-east and south of Cannington and Rodway north of Cannington bypass are all judged as minor receptors and therefore the significance of the impact is **moderate adverse**. In fact these links are either through industrial areas or are rural in nature with virtually no pedestrian activity or adjacent residential properties.

10.9.77 For Western Way, the increase in HGVs and buses is 559 vehicles per day which is less than in 2016. The increase represents an average of 23 vehicles per hour or one every three minutes. If just HGVs are considered the increase is 333 per day or one vehicle every four minutes.

10.9.78 Taking into account the comments made in the 2016 analysis and the fact that the HGV plus bus increase is lower than in 2016, the significance of the impact is considered **moderate adverse**.

10.9.79 For Broadway, the impacts are similar to those in 2016 and therefore the significance is judged as **moderate adverse**.

10.9.80 On A39 west of Quantock roundabout, the increase in HGVs and buses is 1139 vehicles compared to 1145 in 2016. The increase represents one vehicle per minute. Looking at just HGVs the increase is 543 HGVs per day compared with 531 in 2016) which is 23 per hour or just over one vehicle every three minutes.

10.9.81 Overall the significance of the severance impact along the short stretch of Quantock Road with residential properties close by is similar to that in 2016 and is considered to be **substantial adverse**. Looking at severance in the round across the main HGV and bus routes through Bridgwater the impact overall is considered to be **moderate adverse**.

10.9.82 In Cannington, there are significant increases in HGV and bus flows on High Street and C182 Rodway. On High Street HGVs increase by 552 vehicles per day (up to 750 on a peak day) and buses increase by 698 vehicles per day. No such vehicles to/from the HPC development site would be permitted on Main Road and therefore there is no effective increase in such vehicles on that road.

10.9.83 The increases are substantial in magnitude and the receptor sensitivity is also substantial leading to a significance of impact that is considered **substantial adverse**. However, it should be remembered that HGVs as defined here include Medium Goods Vehicles and that bus numbers are likely to be significantly lower once detailed timetabling is undertaken.

10.9.84 EDF Energy recognises the impact that traffic travelling through Cannington would have and has therefore included provision of the Cannington bypass within its proposals. It is expected that the bypass would be open to traffic in Quarter 4 2014. As noted in the 2016 analysis, once the bypass is complete there would be a beneficial effect compared to existing and Reference Case conditions within Cannington.

10.9.85 Recognising the increases in traffic, EDF Energy has proposed traffic management measures within Cannington which would be implemented as part of the site preparation works. These works would control traffic and improve the pedestrian environment.

10.9.86 Notwithstanding the above, the impacts are still considered **substantial adverse** albeit for a temporary period.

10.9.87 Therefore, in overall terms the significance of the severance impacts are considered **moderate adverse** except in Cannington where they are considered **substantial adverse**.

ii. Pedestrian Delay

10.9.88 The analysis in 2013 is similar as in 2016 i.e. no links where the hourly flow is greater than 1400 vehicles per hour experience an increase in flow due to HPC of more than 30% Therefore the effects on pedestrian delay are considered negligible.

10.9.89 On Cannington High Street, the improvements to pedestrian facilities described earlier would assist pedestrians crossing the roads. However, due to the increases in flows there could be delays for those crossing elsewhere. Therefore the overall effect is judged to be **negligible**.

10.9.90 Therefore, the significance of the pedestrian delay impact is considered **negligible**.

iii. Pedestrian Amenity

10.9.91 Based on advice in the IEMA Guidelines, the change at which pedestrian amenity changes become material are a doubling or halving in the flow of all traffic or HGVs.

10.9.92 No link experiences a general traffic flow increase of greater than 100% in association as a result of the HPC Project.

10.9.93 In terms of HGV's and buses the links that experience a daily flow increase of greater than 100% and where the sensitivity of the receptors are other than minor are shown below along with the % change in HGVs as a result of HPC shown in brackets:

- Western Way west of Chilton Street (161%).
- A39 Broadway (70%).
- A39 west of Quantock Road (125%).
- Cannington High Street.
- C182 Rodway.

10.9.94 Other than in Cannington, the impacts are similar to or less than in 2016. However, the significance of the impacts are still **moderate adverse**.

10.9.95 In Cannington, on the High Street and Rodway the magnitude of the impacts is considered substantial. However, the proposed improvement scheme in Cannington would improve the pedestrian environment by creating wider footways, and improved crossing facilities. On this basis the significance of the impact is considered **moderate adverse.**

iv. Driver Delay

10.9.96 The basis of the assessment of driver delay is as in 2016. Overall through the network there is a small decrease in average speeds from 31.5 miles per hour to 30.3 miles per hour, a reduction of 4% which is not considered significant.

10.9.97 The results of the journey time analysis for Route 10 are shown below.

Plate 10.10: 2013 Journey Time Analysis: Route 10 – Southbound

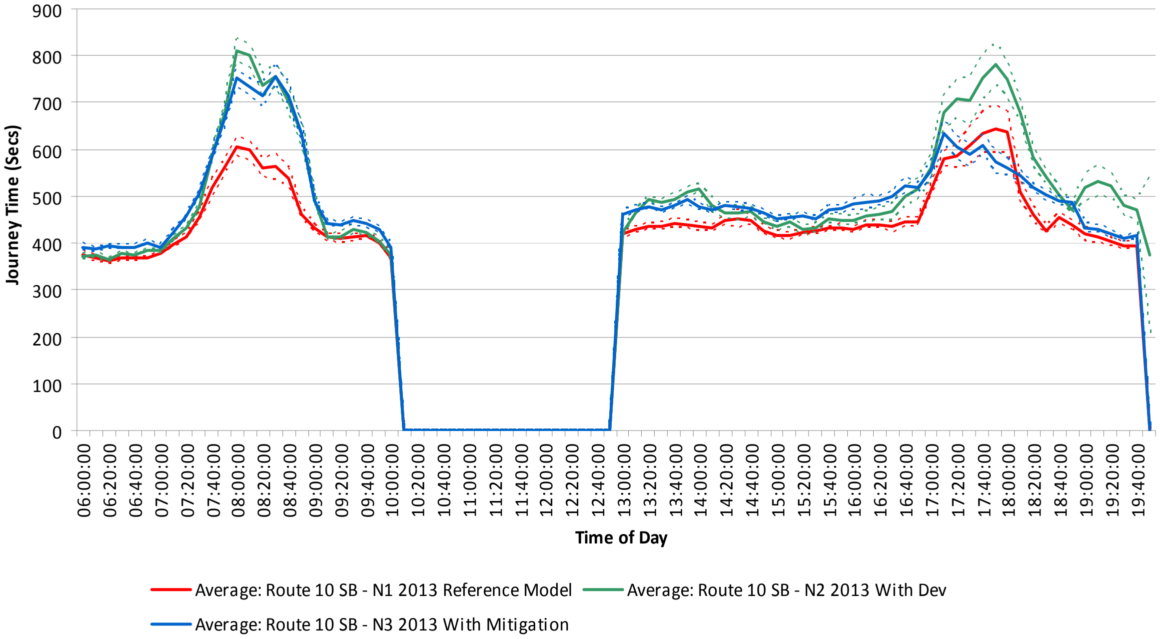

Plate 10.11: 2013 Journey Time Analysis: Route 10 – Northbound

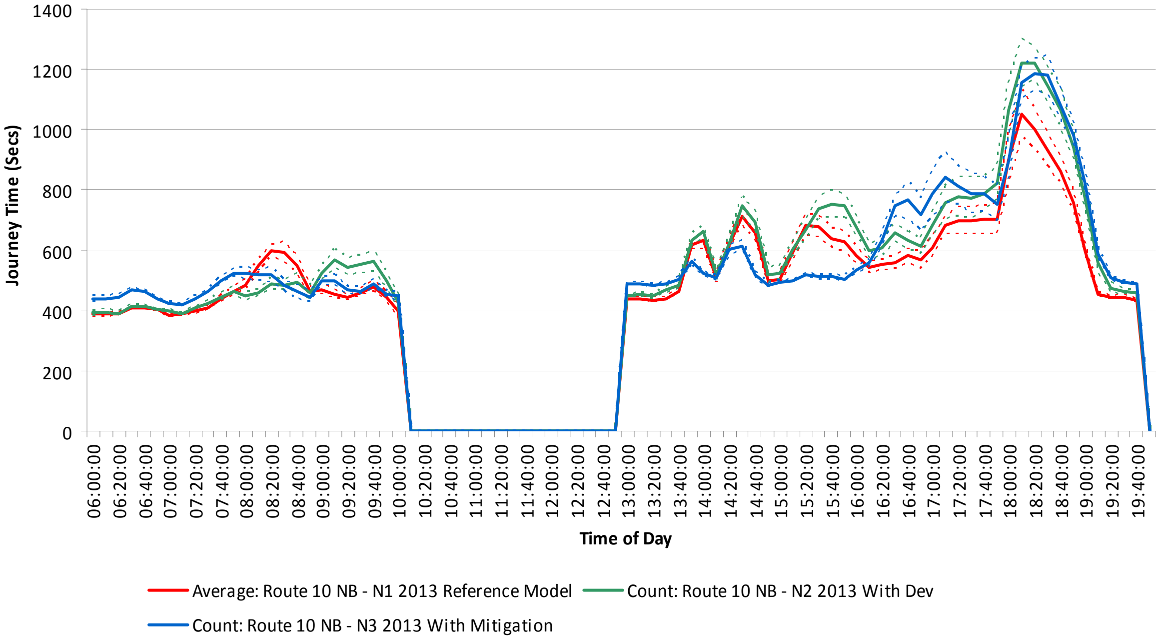

10.9.98 As can be seen, in the southbound direction, there is some increase in journey time in the morning peak and a negligible effect in the evening peak.

10.9.99 In the northbound direction the effects of HPC are neutral in the morning peak and show an increase in journey times in the evening peak.

Plate 10.12: 2013 Journey Time Analysis: Route 6 – Southbound

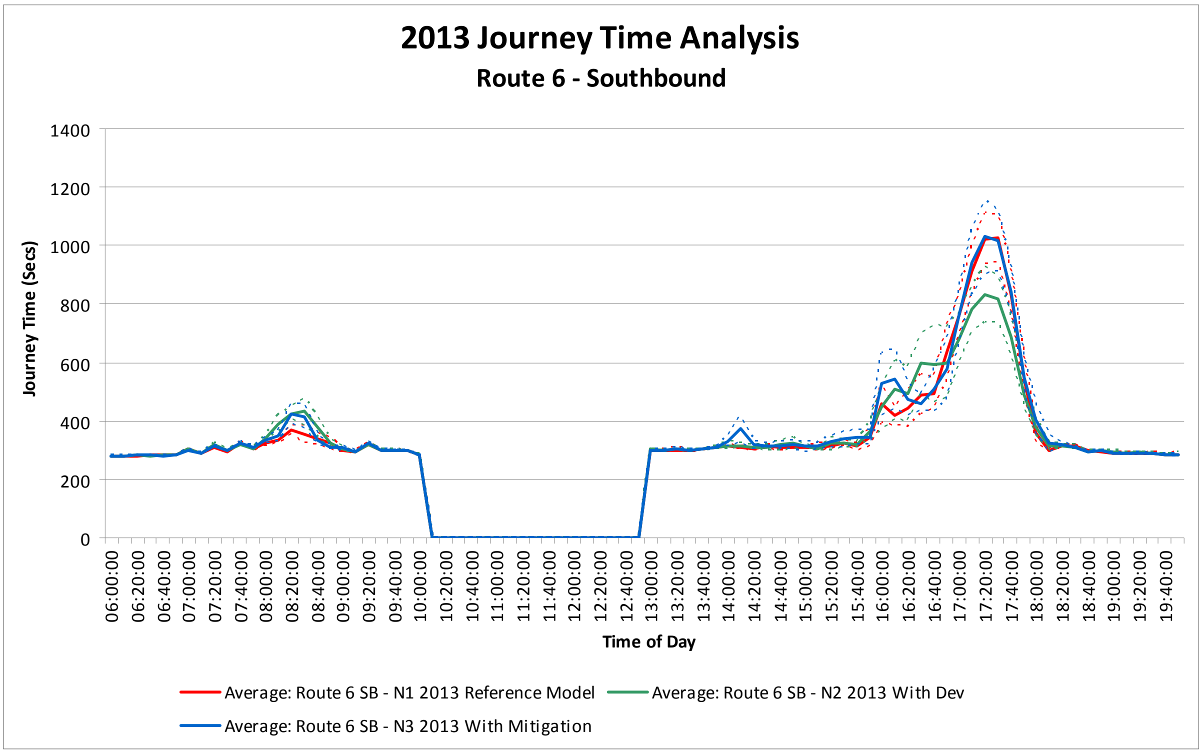

Plate 10.13: 2013 Journey Time Analysis: Route 6 – Northbound

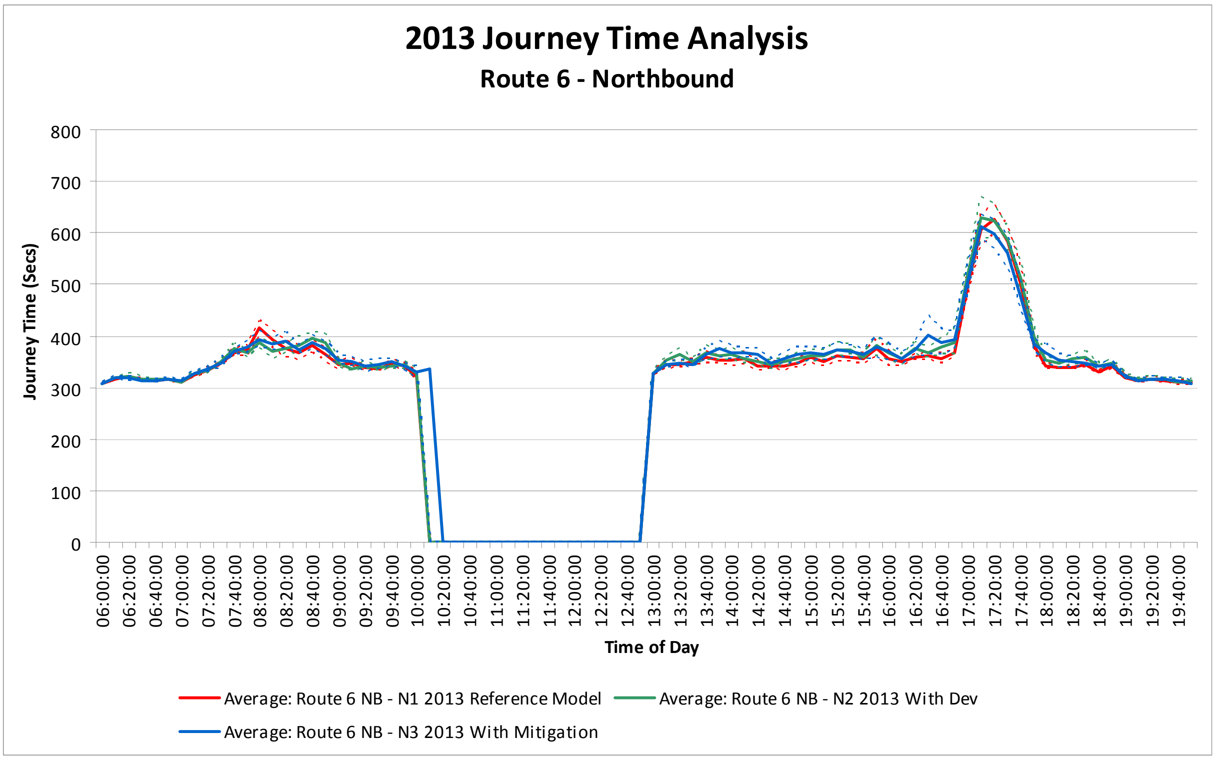

Plate 10.14: 2013 Journey Time Analysis: Route 1 – Eastbound

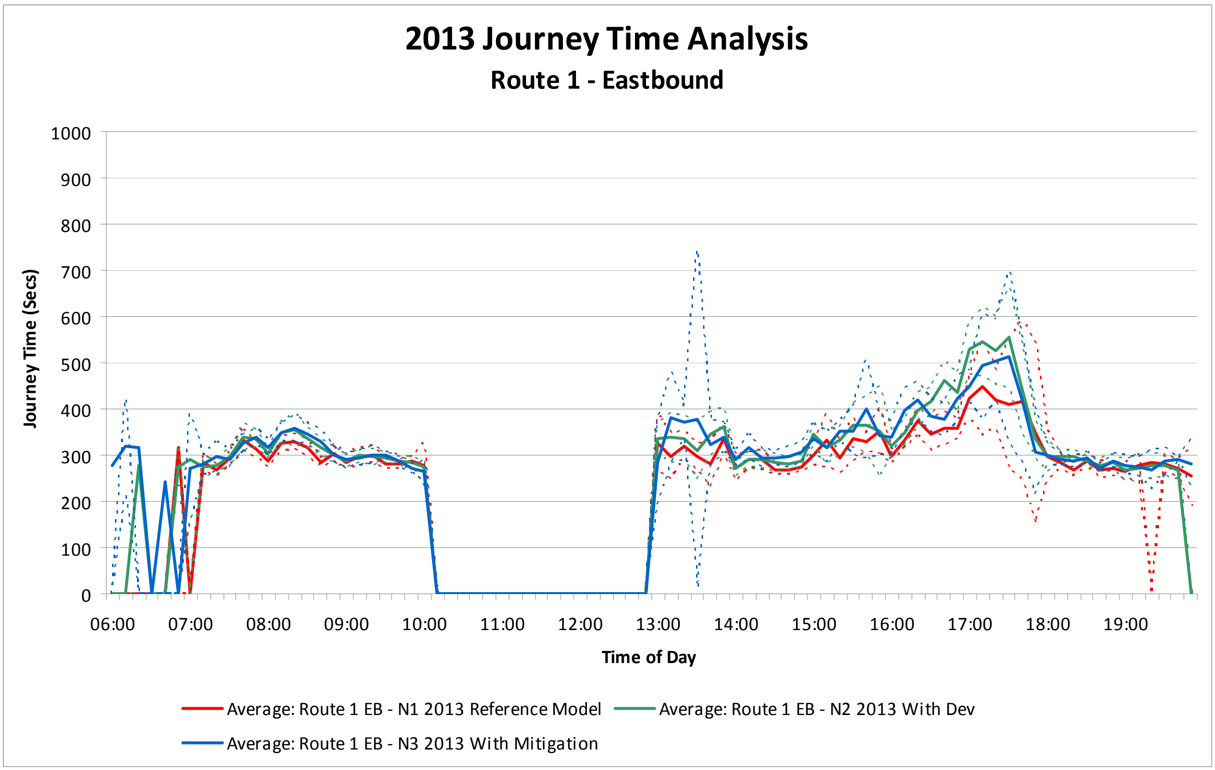

Plate 10.15: 2013 Journey Time Analysis: Route 1 – Westbound

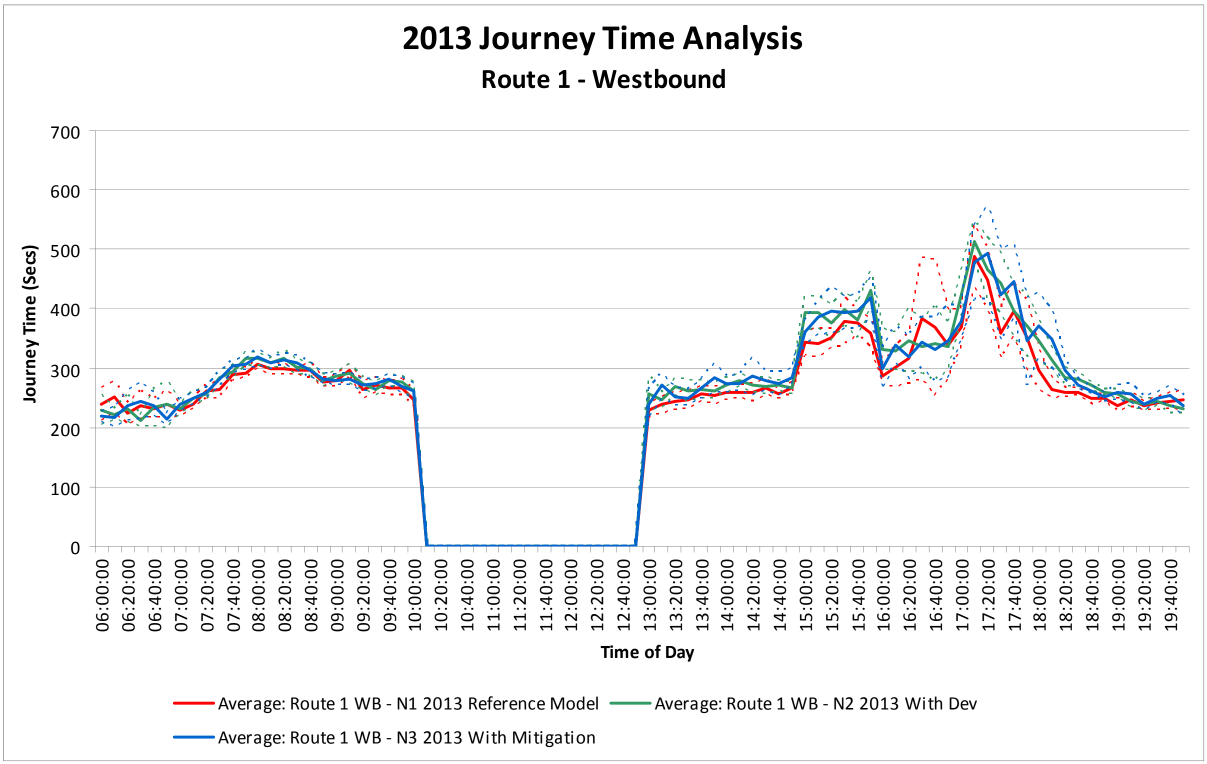

10.9.100 On Routes 1 and 6 in both directions there are no statistically significant differences in journey times between the with HPC traffic plus mitigation scenario and the Reference Case. In all cases the confidence limits of the two scenarios overlap.

10.9.101 In overall terms the significance of the impact on driver delay is considered **minor adverse.**

v. Accidents and Safety

10.9.102 The accident and safety analysis in 2013 is very similar to that in 2016. The main difference would be in Cannington. Whilst the increases in flow are substantial, as noted above the improvement package is designed to control traffic and improve pedestrian amenity and safety. Therefore the significance of the safety impact is considered **minor adverse**.

c) 2021

10.9.103 In 2021 there would be a full complement of operational staff on site (900 personnel with a maximum of 810 on site on any one day). However, in addition there would still be some construction activity on the HPC development site (associated with the spent fuel store) and some of the associated development sites would potentially be being decommissioned. However, construction activity on the HPC development site would be modest compared with 2016. The Junction 24 park and ride and freight management facility would be operational in 2021 as would Cannington park and ride.

10.9.104 The results of the modelling are shown in the tables below. More detailed information is included in the **Transport Assessment**.

Table 10.20: 2021 Reference Case vs. 2021 With Development and Mitigation Daily (24 Hour AADT) 2 way All Vehicles Traffic Flows

i. Severance

10.9.106 Examining daily flows, there are no increases greater than 30% except on the A39 to the south of Cannington. The increase of 72.6% is moderate. However, the receptor is minor and so the significance of the impact is **minor adverse**.

10.9.107 In Cannington there is a reduction in flow on Main Road of 3,489 vehicles per day and on Rodway south of bypass of 3,952 vehicles per day. The reductions are classified as minor and the receptors as substantial leading to a significance of **moderate beneficial.** However, it is considered this may undervalue the relief provided to these roads by the bypass. Furthermore, it may be possible to introduce further traffic calming within Cannington once the bypass is complete including reducing the speed limit to 20mph. This would encourage more traffic to use the bypass and therefore further reduce the flows through the village.

10.9.108 In terms of HGV’s and buses, the only link in Bridgwater that experiences an increase in daily flows of between 30% and 60% is A39 Broadway. This is a minor magnitude of impact on a moderate sensitivity receptor and therefore the significance of the impact is **minor adverse**.

10.9.109 The following have a magnitude of impact of between 60-90% which is considered moderate:

- Western Way (west of Chilton Street).
- A39 west of Quantock Road.
- A39 south-east of Cannington.

10.9.110 The A39 south-east of Cannington, Western Way and the A39 west of Quantock Road are all judged as minor or moderate receptors and therefore the significance of the impact is **moderate adverse.**

10.9.111 For Western Way the total of the HGV plus bus increase is 291 vehicles per day which compares with an increase of 710 vehicles per day in 2016. Whilst the increase in HGV flows is less than in 2016, the impact is still considered to be **moderate adverse**.

10.9.112 For the A39 west of Quantock roundabout the increase in HGVs and buses is 528 vehicles which compares with 1145 in 2016. Again, whilst the increase is less than in 2016, the impact is still considered to be **moderate adverse**

10.9.113 The following have a magnitude of impact of greater than 90% which is considered substantial and arises from the consideration that these links are on the HGV/bus routes to the site:

- A39 south of Cannington.
- Rodway north of bypass.

10.9.114 The A39 south of Cannington and Rodway north of the bypass are judged as minor receptors and therefore the significance of the impact is **moderate adverse**, as in 2016.

10.9.115 For the C182 to the north of the Combwich freight laydown facility there may still be additional HGVs travelling between the freight laydown facility and the HPC development site. In 2016 these have been estimated to be 300 per average day. In 2021 there are likely to be fewer movements. However even if they were maintained at 300 per day this would not affect the assessment of the impact as being **moderate adverse**

ii. Pedestrian Delay

10.9.116 The analysis in 2021 is similar to that in 2016 i.e. there are no links where the hourly flow is greater than 1400 vehicles per hour and which experience an increase in flow due to HPC of more than 30% Therefore, the effects on pedestrian delay are considered **negligible**.

10.9.117 On Cannington High Street, the traffic flows would reduce significantly due to the completion of the bypass. These changes would lead to a **moderate beneficial** impact on pedestrian delay.

iii. Pedestrian Amenity

10.9.118 Based on advice in the IEMA Guidelines, the change at which pedestrian amenity changes become material are a doubling or halving in the flow of all traffic or HGVs.

10.9.119 No links experience a general traffic flow increase of greater than 100% as a result of the HPC Project and therefore there is no material impact.

10.9.120 In terms of HGV's and buses there are no links that experience a daily flow increase of greater than 100% and where the sensitivity of the receptors are other than minor. The significance of the impacts are considered to be **negligible**.

10.9.121 In Cannington, whilst there is not a halving in traffic flows, the effects of the bypass in removing traffic are considered to be material and are judged to be **moderate beneficial.**

iv. Driver Delay

10.9.122 The average speeds through the assessment network improve in 2021 due to the highway improvements introduced. In the morning peak, the average speed increases from 22.5mph to 24.7mph. In the evening peak the average speed increases significantly from 18.7mph to 25.6mph. Over the whole of the modelled period the average speed increases from 26.9mph to 29.9mph.

10.9.123 The outputs from the journey time analysis are shown below.

Plate 10.16: 2021 Journey Time Analysis: Route 10 – Southbound

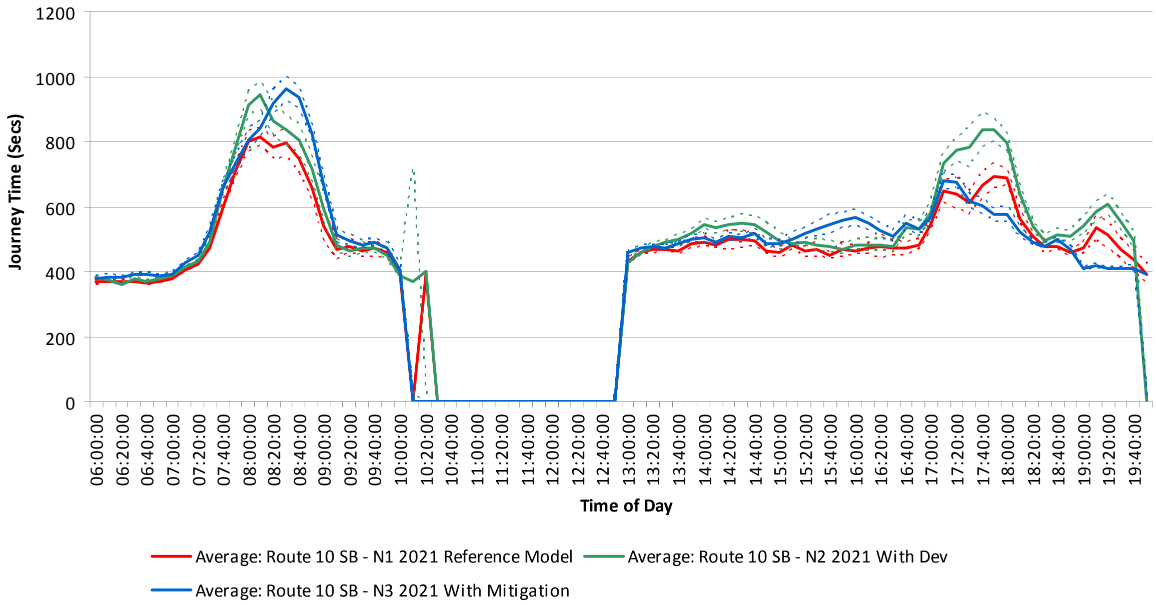

Plate 10.17: 2021 Journey Time Analysis: Route 10 – Northbound

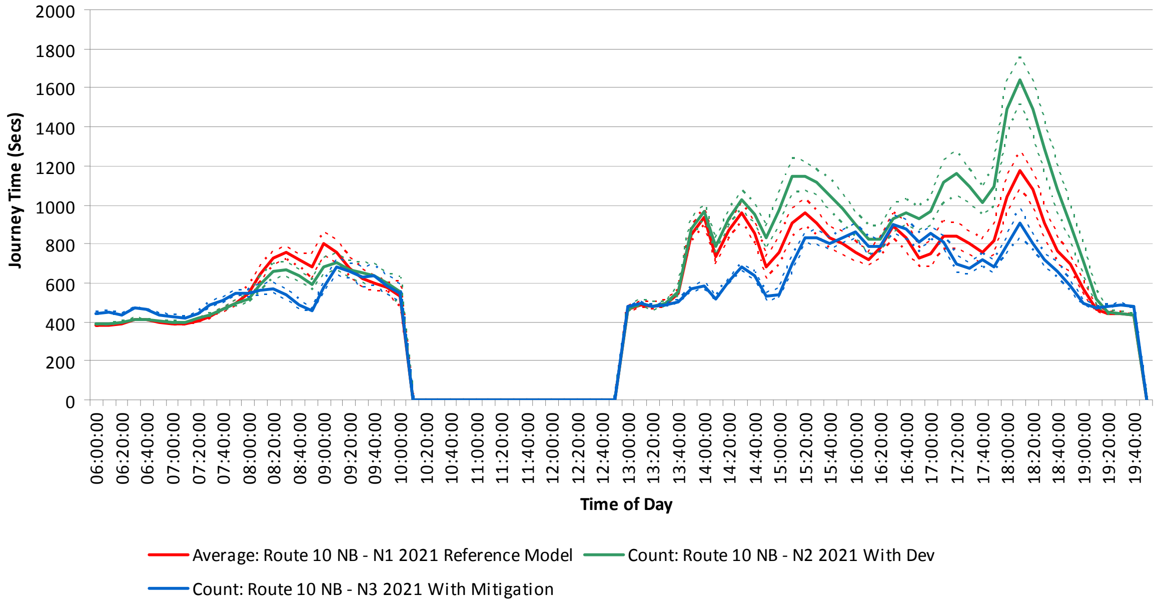

10.9.124 As can be seen in the southbound direction on Route 10 there is a small increase in the journey time in the morning peak and a reduction in the evening peak.

10.9.125 In the northbound direction there are improvements in the morning and evening peaks.

Plate 10.18: 2021 Journey Time Analysis: Route 6 – Southbound

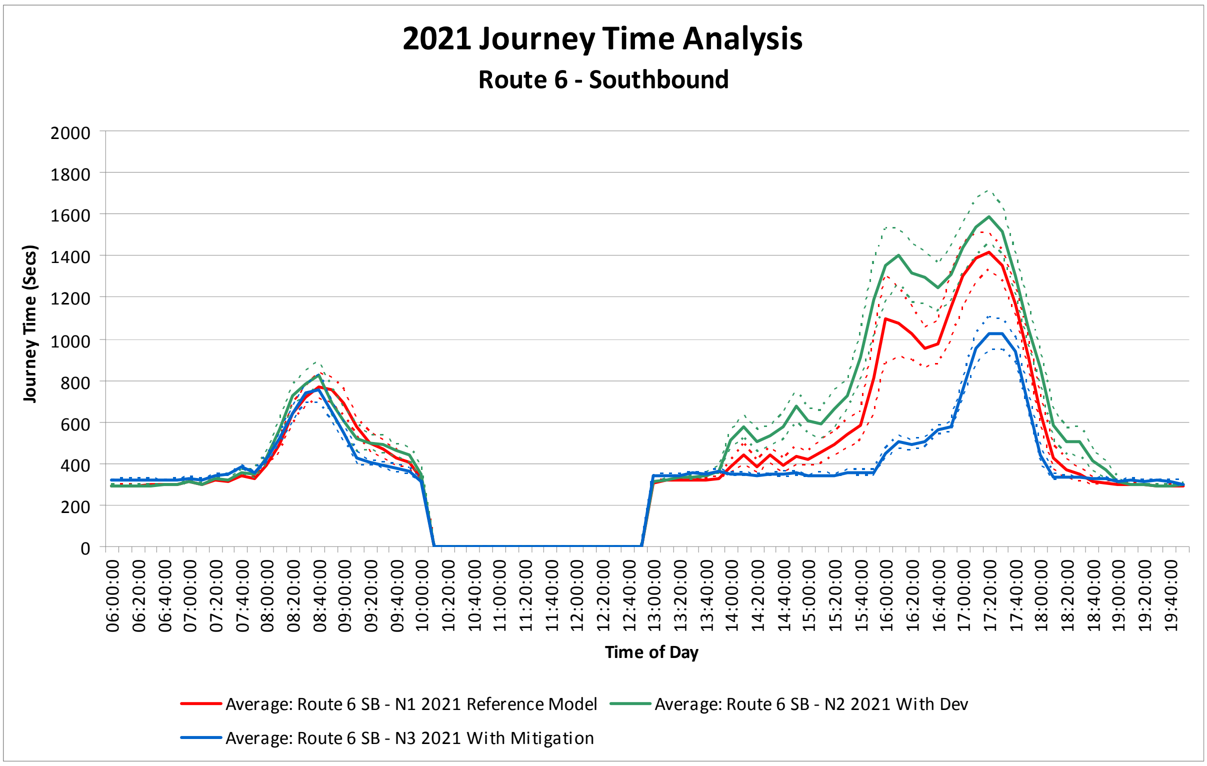

Plate 10.19: 2021 Journey Time Analysis: Route 6 – Northbound

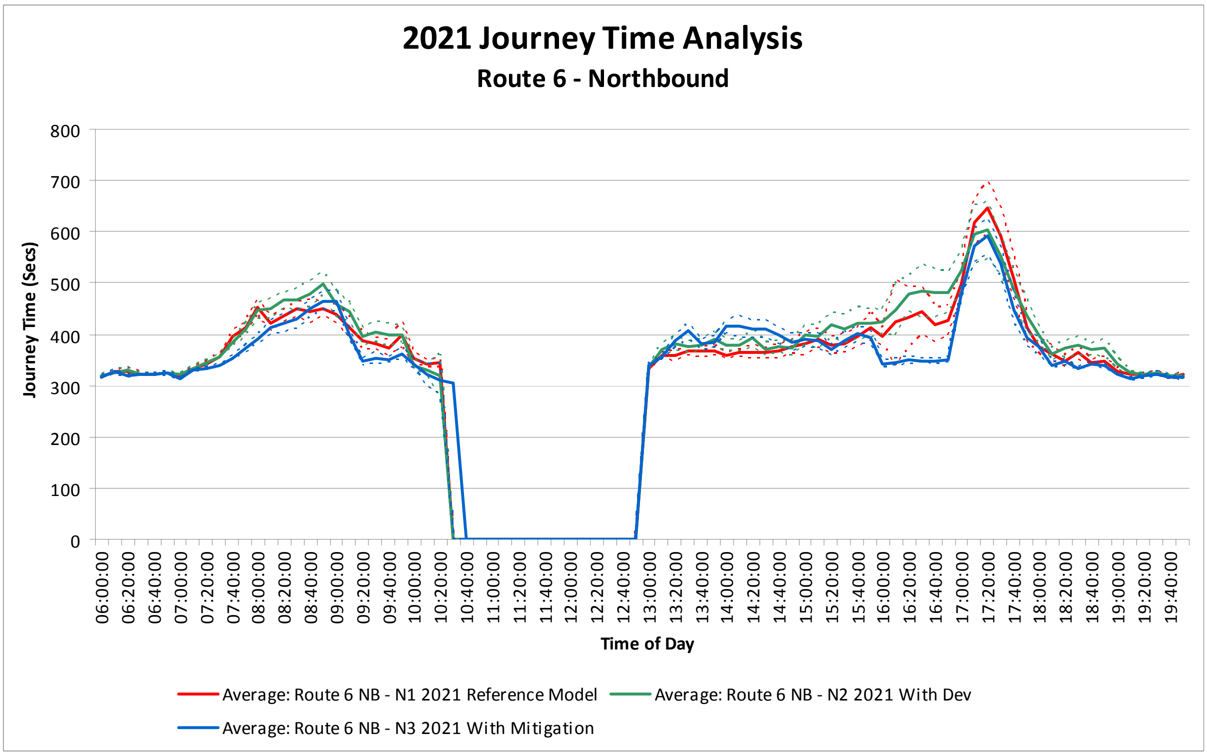

Plate 10.20: 2021 Journey Time Analysis: Route 1 – Eastbound

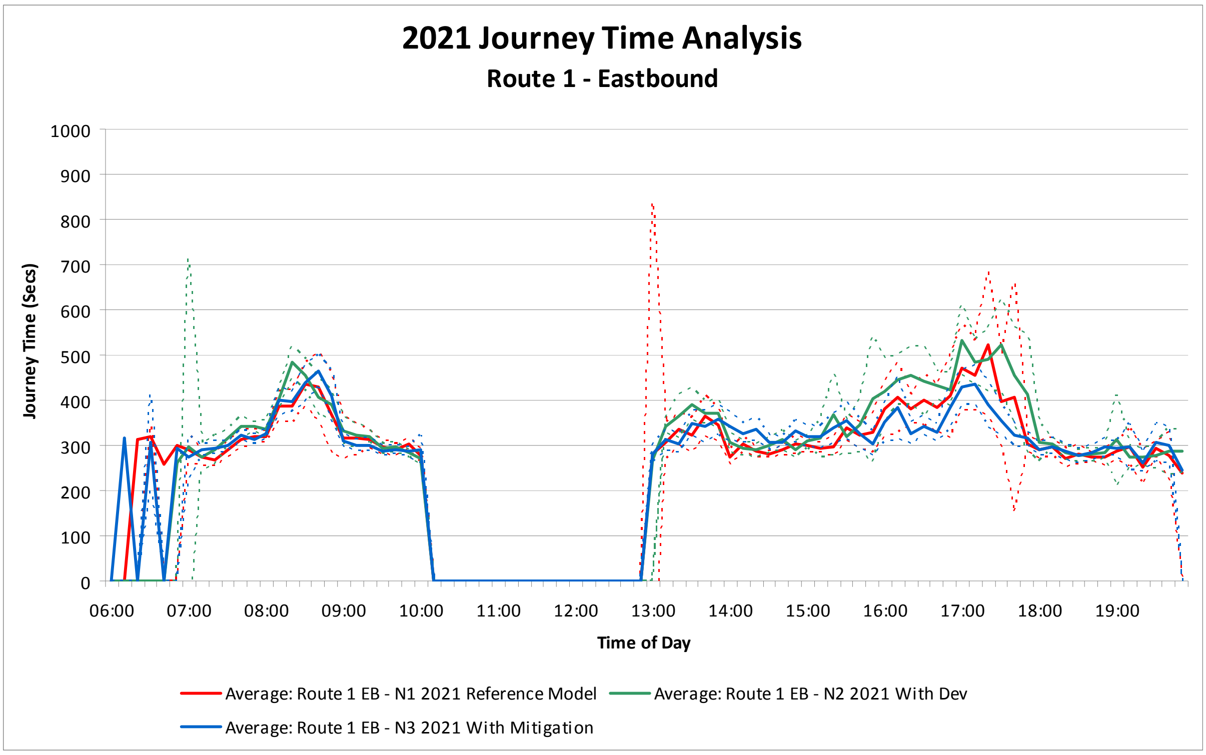

Plate 10.21: 2021 Journey Time Analysis: Route 1 – Westbound

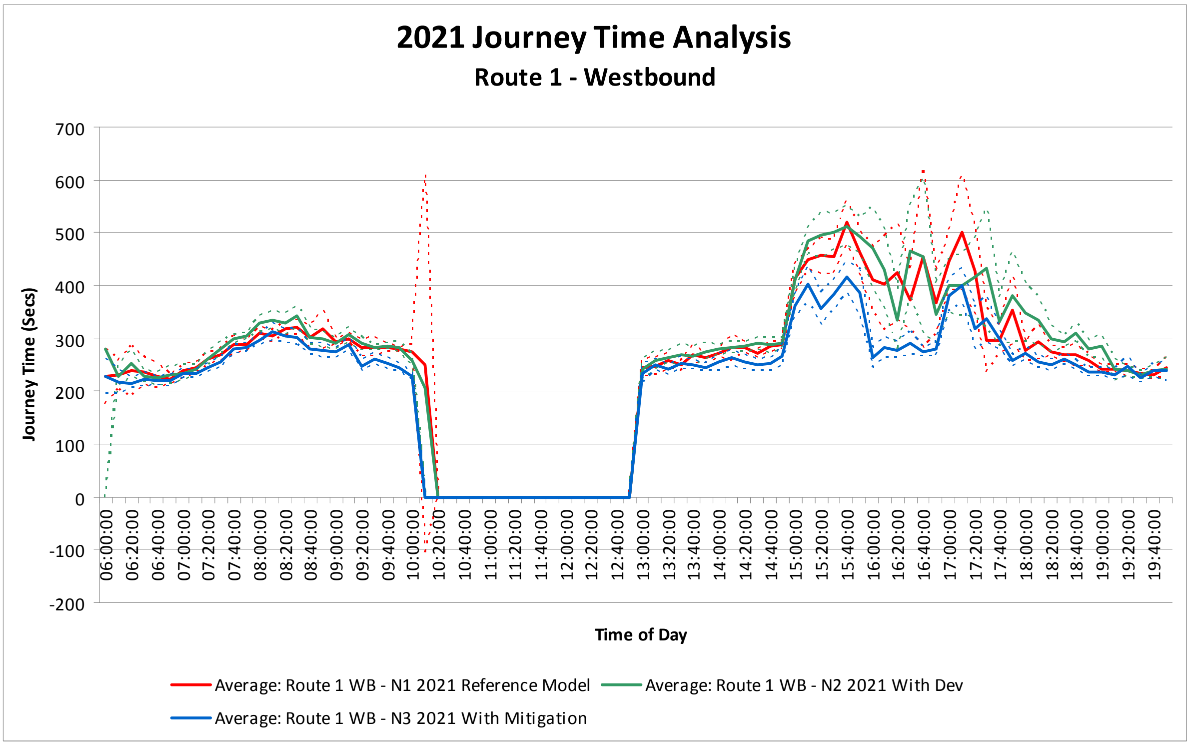

10.9.126 On Route 6 southbound there is some improvement in the journey time around 09:00 with the HPC plus mitigation scenario compared with the Reference Case. In the evening peak there is a more significant improvement. In the northbound direction there is a small improvement around 08:00 and no change in the evening peak.

10.9.127 On Route 1 in the eastbound direction the comparison is neutral. In the westbound direction the comparison is neutral in the morning peak and there is a small improvement in journey time for the HPC plus mitigation scenario around 16:30.

10.9.128 Taking all the above into account and in particular the change in average speeds, there is judged to be a **moderate beneficial** effect on driver delay in 2021 as a result of the proposals.

v. Accidents and Safety

10.9.129 The accident and safety analysis in 2021 is very similar to that in 2016. The significance of the safety impact is considered **minor adverse**.

10.10 Mitigation of Impacts

10.10.1 As stated earlier in this chapter, the main part of the transport mitigation comprises the transport strategy and the highway improvements. These both form part of EDF Energy's application for development consent and have therefore been included in the "Assessment of Impacts".

10.10.2 In addition to the proposed highway improvements, EDF Energy propose to contribute to potential safety enhancements and pedestrian and cycle improvements within Bridgwater that Somerset County Council are progressing as part of their ongoing programme of improvements.

10.10.3 Junctions where potential safety improvements have been identified within the **Road Safety Strategy** are listed below. The junctions shown with an asterisk (*) are those where EDF Energy are promoting improvements as part of the application for development consent.

- A39
  - A39 Broadway/A38 Taunton Road*.
  - A39 Broadway/A372 St. John Street.
  - A39 North Street/Albert Street.
  - A39 North Street/West Street.
  - A39/A38 Dunball roundabout.
  - A39 Sandford Corner*.
- A38
  - A38 Bristol Road/A39 (Bath Road)/The Clink (Cross Rifles roundabout).
  - A38 Taunton Road/Rhode Lane.
  - The A38/M5 Junction 24 Huntworth roundabout*.
  - The A38 Taunton Road/Wills Road Junction.
- NDR
  - (Wylds Road/The Drove).

10.10.4 In addition, the effects of the construction of the HPC Project would be monitored throughout and if any unforeseen impacts are identified, EDF Energy would work with the authorities to mitigate their impact.

10.10.5 Whilst not strictly a mitigation, further traffic calming measures in Cannington could also be introduced which would encourage more traffic to use the bypass and thus increase the benefits in the centre of the village.

10.11 Residual Impacts

10.11.1 The additional mitigation measures identified above would further improve the safety in Bridgwater and the residual safety impact is therefore considered to be **negligible**. Similarly, the contribution towards pedestrian and cycle enhancements would improve pedestrian amenity. The impact is still considered to be **negligible.**

10.11.2 In Cannington it is considered that with additional traffic calming measures, the benefits of the bypass could become **substantial beneficial** in terms of Severance and Pedestrian Amenity

10.11.3 All other impacts remain as reported in the Assessment of Impacts section.

10.12 Summary of Impacts

10.12.1 A summary of the impacts and residual impacts for each of the three assessment years are provided in **Table 10.21**. When construction on the site is completed and there are just operational staff, it can be concluded that there would be no material adverse impact on the criteria considered within this chapter as a result of the operational phase of HPC. There would be substantial benefits in Cannington due to the introduction of the bypass and **moderate beneficial** impacts on journey times through Bridgwater.

10.12.2 **Table 10.24, Table 10.25** and **Table 10.26** below summarise the impact for each assessment year.

10.12.3 In Bridgwater, the tables demonstrate that for the key impacts of severance and pedestrian amenity, the residual impacts are generally **moderate adverse** since the roads affected are all A roads which already carry substantial volumes of traffic. The effect on pedestrian delay is considered **negligible** and most crossings of the A roads take place at controlled crossings. There are **negligible** changes to driver delay in 2016 and these become a **beneficial** effect in 2021. However, in 2013 there is a **minor adverse** impact on driver delay since it has been assumed in the analysis that not all of the highway improvement schemes are in place by Quarter 3 2013.

10.12.4 The impact on accidents is minor adverse but this becomes **negligible** when the funding from EDF Energy towards Somerset County Council's safety programme is taken into account.

10.12.5 In Cannington there are **substantial adverse** impacts in 2013 since the bypass would have not yet been completed and therefore construction traffic would be passing through the village. However, these impacts are for a limited period, prior to the bypass becoming operational in Quarter 4 2014. Once the bypass is operational then Cannington enjoys the benefits of significantly less traffic. These benefits are judged to be **moderate beneficial** rising to **substantial beneficial** if additional traffic calming is introduced in the village since more traffic would be diverted to the bypass.

10.12.6 When construction on the site is completed and there are just operational staff, it can be concluded that there would be no material adverse impact on the criteria considered within this chapter as a result of the operational phase of HPC. There would be **substantial benefits** in Cannington due to the introduction of the bypass and **moderate beneficial impacts** on journey times through Bridgwater.

10.12.7 In some instances the assessment for Cannington is different to that for Bridgwater. In such instances the Cannington assessment is shown in *italics* in the tables below.

Table 10.24: Summary of Impacts 2016

Description of Impact	Impact	Mitigation Measure	Residual Impact
Severance	Moderate Adverse *Moderate Beneficial*	Additional Traffic calming in Cannington	Moderate Adverse *Substantial Beneficial*
Driver Delay	Negligible	N/A	Negligible
Pedestrian Delay	Negligible *Moderate Beneficial*	N/A	Negligible *Moderate Beneficial*
Pedestrian Amenity	Moderate Adverse *Moderate Beneficial*	Contribution to SCC programme. Additional traffic calming in Cannington	Moderate Adverse *Substantial Beneficial*
Accidents and Safety	Minor Adverse	Contribution to SCC programme	Negligible

Table 10.25: Summary of Impacts 2013

Description of Impact	Impact	Mitigation Measure	Residual Impact
Severance	Moderate Adverse *Substantial Adverse*	N/A	Moderate Adverse *Substantial Adverse*
Driver Delay	Minor Adverse	N/A	Minor Adverse
Pedestrian Delay	Negligible	N/A	Negligible
Pedestrian Amenity	Moderate Adverse	Contribution to SCC programme.	Moderate Adverse
Accidents and Safety	Minor Adverse	Contribution to SCC programme	Negligible

Table 10.26: Summary of Impacts 2021

Description of Impact	Impact	Mitigation Measure	Residual Impact
Severance	Moderate Adverse *Moderate Beneficial*	Additional traffic calming in Cannington	Moderate Adverse *Substantial Beneficial*
Driver Delay	Moderate Beneficial	N/A	Moderate Beneficial
Pedestrian Delay	Negligible *Moderate Beneficial*	N/A	Negligible *Moderate Beneficial*
Pedestrian Amenity	Negligible *Moderate Beneficial*	Contribution to SCC programme. Additional traffic calming in Cannington	Negligible *Substantial Beneficial*
Accidents and Safety	Minor Adverse	Contribution to SCC programme	Negligible

APPENDICES

11. NOISE AND VIBRATION

11.1 Introduction

11.1.1 This chapter of the Environmental Statement (ES) assesses the potential noise and vibration impacts associated with the construction and operation of Hinkley Point C (HPC) on human receptors. Potential noise and vibration impacts on marine and terrestrial ecological receptors are addressed in **Chapters 19** and **20** of this volume respectively. Detailed descriptions of the site, proposed development, construction and operational phases are provided in **Chapters 1** to **5** of this volume of the ES.

11.1.2 Potential sources of noise during the construction and operation of HPC include the following:

- site preparation and ground terracing activities (preliminary works);
- construction and operation of the temporary jetty (preliminary works);
- construction operations including the movement and operation of a wide range of mobile or stationary construction plant equipment, and specifically with regard to ground compaction, piling activities or blasting;
- on-site vehicular movements;
- off-site transport movements, including construction workforce and freight movements;
- operation of HPC; and
- off-site operational transport movements.

11.2 Scope and Objectives of Assessment

11.2.1 The scope of the assessment has been determined through a formal Environmental Impact Assessment (EIA) scoping process undertaken with the Infrastructure Planning Commission (IPC). It has also been informed by ongoing consultation with statutory consultees including Sedgemoor District Council (SDC), West Somerset Council (WSC), Somerset County Council (SCC), the local community and the general public in response to the formal pre-application consultation process.

11.2.2 The assessment of noise and vibration impacts has been undertaken adopting the methodologies described in **Volume 1**, **Chapter 7** and Section 11.4 below. This section is complemented by a baseline noise survey report, henceforth referred to as the 'Factual Noise Report' (see **Appendix 11A**), and a baseline and blasting trial vibration survey report, henceforth referred to as the 'Trial Blast Noise and Vibration Report' (see **Appendix 11B**). The Factual Noise Report includes details of background noise monitoring completed at representative receptor locations in the vicinity of the HPC development site as well as additional locations that could be affected during the development construction.

11.2.3 Noise and vibration impacts are presented in Section 11.6, and appropriate mitigation measures aimed at preventing, reducing or off-setting any potential adverse impacts that are identified to be of significance are identified in Section 11.7. An assessment of residual impacts following implementation of these mitigation measures is presented in Section 11.8.

11.2.4 **Volume 1**, **Chapter 7** of this ES refers to the methodology used to assess cumulative impacts. Additive and interactive effects between impacts generated within the site boundary and study area are assessed within this chapter. Construction and operational traffic noise impacts, as assessed in this chapter, considers all affected highways, for which the base scenarios include traffic generated by consented future developments. Cumulative impacts that consider on-site construction and operational activities associated with proposed HPC developments and proposed or reasonably foreseeable non-HPC developments are considered in **Volume 11** of this ES.

11.2.5 The objectives underlying the noise and vibration assessment were to:

- predict the noise and vibration generation and propagation during the site preparation, construction and operation of the temporary jetty, and construction of two UK EPR units (C1 and C2) and ancillary buildings;
- predict the potential noise impacts associated with road traffic at key stages of the construction phase; and
- predict, by computational modelling, noise propagation from the main components of HPC during the operational phase

11.2.6 It is unlikely that the construction and operation of the development will lead to immediate ‘acute’ noise or vibration effects, (i.e. hearing damage), as these are generally confined to work places with very high levels of noise and vibration. What effects there may be, will generally be associated with disturbance to living conditions and amenity value, either due to short-term (a few months) to long-term (greater than five years), temporary activities or permanent operational sources.

11.2.7 Noise impacts associated with helicopters travelling to and from the proposed helipad are not expected to be significant due to the infrequency of occurrence. It is expected that no more than three helicopter visits per year would occur, and these will be scheduled during weekday periods only. Whilst these fly-over, landing and take-off events are likely to be audible at residential receptors in neighbouring villages and hamlets, the impacts would be no more significant than the existing and historic situation associated with visits to the Hinkley Point A and B sites. Furthermore, naval and coastguard helicopter movements within the Bristol Channel area are relatively commonplace. No further detailed assessment of helicopter noise impacts has therefore been undertaken.

11.3 Legislation, Policy and Guidance

11.3.1 This section identifies and describes legislation, policy and guidance of relevance to the assessment of potential noise impacts associated with the construction, operation and post-operational phases of the proposed development.

11.3.2 As stated in **Volume 1**, **Chapter 4**, the Overarching National Policy Statement for Energy (NPS EN-1) when combined with the NPS for Nuclear Power Generation (NPS EN-6) provides the primary basis for decisions by the IPC on applications for nuclear power generation developments that fall within the scope of the NPSs.

11.3.3 Notwithstanding this, the IPC may consider other matters that are both important and relevant to its decision-making. This could include Planning Policy Statements (PPSs), Planning Policy Guidance Notes (PPGs), regional and local policy documents, although, if there is a conflict between these and the NPS, the NPS prevails for the purposes of IPC decision making.

11.3.4 Further, the Planning Act 2008 provides that the IPC must, in making its decision on an application, have regard to any Local Impact Report (LIR) prepared by relevant local authorities. It is anticipated that the LIRs will rely in part on PPSs, PPGs, regional and local policy to provide a context for their assessment. On this basis, regard has been given to these documents (where relevant to the technical assessment) since they are likely to inform the LIRs prepared by the relevant local authorities.

a) International

i. World Health Organization ‘Guidelines for Community Noise’ (WHO,1999)

11.3.5 The WHO ‘Guidelines for Community Noise’ (Ref. 11.1) provides health-based guidance on suitable noise levels in the form of ‘guideline values’, intended to avoid or minimise community annoyance by noise. Guidance is provided on noise levels for both indoor and outdoor areas.

11.3.6 **Table 4.1** of the WHO document recommends environmental daytime and evening limits of 55dB L_{Aeq} or less over the 16-hour daytime period (07:00-23:00) to avoid minimal serious annoyance, and 50dB L_{Aeq} *“to avoid minimal moderate annoyance”.*

11.3.7 However, it is important to note that the WHO recommendations represent the onset of health effects such as annoyance and sleep disturbance from such noise exposure, and that exposure in excess of these is not necessarily indicative of significant adverse impacts.

ii. World Health Organization ‘Night Noise Guidelines for Europe’ (WHO, 2009)

11.3.8 The ‘Night Noise Guidelines for Europe’ (Ref. 11.2) is again concerned with the potential health effects of environmental night noise, based on a review of available research by a working group of experts.

11.3.9 It recommends a target of 40dB $L_{night,outside}$ ‘at a residential façade (incident noise level) to protect the public, including the most vulnerable groups such as children, the chronically ill and the elderly’. The $L_{night,outside}$ indicator relates to the annual average night-time noise level and takes account of the varying need to open windows at night throughout the year. An interim target of 55dB $L_{night,outside}$ was also recommended for countries where the 40dB $L_{night,outside}$ guideline is not achievable.

11.3.10 The night noise guidelines assume a sound insulation of 21dB for an average building envelope, allowing for those that wish to sleep with windows slightly open, and acknowledges that if noise levels increase, people may close their windows.

11.3.11 The guidelines provided indicate, from available research, the levels above which an effect starts to occur or shows itself to be dependent on the exposure level. However, these observed effect thresholds do not establish the significance of effects, which may not become significant until much higher degrees of noise exposure.

11.3.12 A 'National Noise Incidence Study' (Ref. 11.3) in 2000 identified through an ambient noise monitoring survey at 1160 locations that 95% of the properties in the UK exceeded the 40dB $L_{night,outside}$ level.

b) National

i. Noise Policy Statement for England (NPSE) 2010

11.3.13 The Noise Policy Statement for England (NPSE) (Ref. 11.4), published in March 2010, sets out the long-term aims of Government noise policy. The Noise Policy Aims, as presented within this document, are:

> *"Through the effective management and control of environmental, neighbour and neighbourhood noise within the context of Government policy on sustainable development:*
>
> - *avoid significant adverse effects on health and quality of life;*
> - *mitigate and minimise adverse effects on health and quality of life; and*
> - *where possible, contribute to the improvement of health and quality of life."*

11.3.14 The NPSE draws on two established concepts from toxicology that are currently being applied to noise effects, for example, by the World Health Organisation, namely NOEL – No Observed Effect Level and LOAEL – Lowest Observed Adverse Effect Level. The NPSE extends these concepts and introduces the concept of a Significant Observed Adverse Effect Level (SOAEL). This is the level above which significant adverse effects on health and quality of life are understood to occur.

11.3.15 The second aim of the NPSE refers to the situation where the effect lies somewhere between LOAEL and SOAEL. It requires that all reasonable steps should be taken to mitigate and minimise adverse effects on health and quality of life while also taking into account the guiding principles of sustainable development (Paragraph 1.8 of the NPSE). This does not mean that such adverse effects cannot occur.

11.3.16 The third aim seeks, where possible, positively to improve health and quality of life through the pro-active management of noise while also taking into account the guiding principles of sustainable development, recognising that there will be opportunities for such measures to be taken and that they will deliver potential benefits to society. The protection of quiet places and quiet times as well as the enhancement of the acoustic environment will assist with delivering this aim.

ii. The Control of Pollution Act, 1974 (COPA)

11.3.17 Section 60 of the Control of Pollution Act, 1974 (Ref. 11.5) provides powers to local authority officers to serve an abatement notice in respect of noise nuisance from construction works, whilst Section 61 provides a method by which a contractor can avoid such action by applying for a consent to conduct construction activities in advance of their occurrence (a 'prior consent'). The prior consent is drawn up between the local authority and the contractor and may contain a range of agreed working conditions designed to minimise or prevent the occurrence of noise nuisance from construction activities. Application for Section 61 'prior consent' is a commonly used mitigation technique in respect of potential noise and vibration impacts from major construction works.

iii. Planning Policy Guidance 24: Planning and Noise (PPG 24) (1994)

11.3.18 PPG24 (Ref. 11.6) was introduced by the Department of the Environment (now the Department for Communities and Local Government) in 1994. Paragraph 1 on Page 1 of PPG 24 indicates that it was issued to:

> *"…provide advice on how the planning system can be used to minimise the adverse impact of noise without placing unreasonable restrictions on development or adding unduly to the costs and administrative burdens of business. It outlines some of the main considerations which local planning authorities should take into account in drawing up development plan policies and when determining planning applications for development which will either generate noise or be exposed to existing noise sources".*

11.3.19 For new developments that will introduce noise into an area, PPG24 confirms (in Annex 3) that it is appropriate to use previously established assessment methodologies. Further guidance is given in relation to 'Noise from road traffic' (Annex 3, Paragraph 1), 'Noise from industrial and commercial developments' (Annex 3, Paragraphs 19-20) and 'Noise from construction sites' (Annex 3, Paragraph 21). The appropriate assessment methodologies are discussed in the relevant sections below.

c) Regional

11.3.20 The Government's revocation of regional strategies was quashed in the High Court on 10 November 2010. However, on that same date the Government reiterated in a letter to Chief Planners its intention to revoke regional strategies through the Localism Bill. This letter was also challenged but, on 7 February 2011, the High Court held that the Government's advice to local authorities that the proposed revocation of regional strategies was to be regarded as a material consideration in their planning development control decisions should stand. The decision of the High Court was upheld by the Court of Appeal on 27 May 2011. Therefore, the regional strategies remain in place but in the case of development control decisions it is for planning decision makers to decide on the weight to attach to the strategies (see **Volume 1, Chapter 4** for a full summary of the position regarding the status of regional planning policy).

i. Regional Planning Guidance 10 for the South +West 2001-2016 (RPG10) (2001)

11.3.21 RPG 10 (Ref. 11.7) sets out the broad development strategy for the period to 2016 and beyond. With specific reference to noise, RPG10 calls for Local Authorities and others to improve the local environment by reducing incidents of noise pollution (Paragraph 4.23) and reduce the impact of transport on the environment (which in turn can increase the occurrence of noise) (Paragraph 8.5). There is no specific guidance or policies for assessing noise for new developments.

ii. Draft Revised Regional Spatial Strategy (RSS) for the South West Incorporating the Secretary of State's Proposed Changes for Public Consultation (July 2008) (Ref. 11.8)

11.3.22 There are no specific policies relating to noise within the draft RSS.

iii. Somerset & Exmoor National Park Joint Structure Plan Review 1991-2011 (2000) (Policies 'saved' from 27 September 2007) (Ref. 11.9)

11.3.23 **Chapter 7** deals with transport and identifies noise as an occurrence of greater mobility (Paragraph 7.1). There are no specific policies relating to noise within the Structure Plan.

d) Local

i. West Somerset Local Plan (2006) (Policies 'saved' from 17 April 2009)

11.3.24 The West Somerset Local Plan forms part of the Development Plan for West Somerset. The Local Plan (Ref. 11.10) was adopted in April 2006 (with relevant policies 'saved' from 17 April 2009). The Proposals Map indicates that the site is not subject to any specific noise designations. The site lies outside of the defined Development Boundary.

11.3.25 The following saved policy is considered to be potentially relevant:

11.3.26 Policy PC/2 (Noise Pollution) states:

11.3.27 "Proposals for developments involving potential noise nuisance to existing occupiers of land or buildings will only be permitted when measures to minimise the impact of noise likely to be generated are incorporated as part of the development."

ii. West Somerset District Local Development Framework (LDF) Core Strategy (Options Paper) (January 2010)

11.3.28 The Core Strategy is at a preliminary stage of preparation and the Options Paper does not include any specific policies relating to environmental noise.

e) Supplementary Planning Guidance

11.3.29 Sedgemoor District Council and West Somerset Council have jointly prepared draft supplementary planning guidance in relation to the HPC Project. Public consultation on the Consultation Draft version of the Hinkley Point C Project Supplementary Planning Document (the draft HPC SPD) commenced on 1 March 2011 and concluded on 12 April 2011. EDF Energy has submitted representations which object to the draft HPC SPD. See **Volume 1**, **Chapter 4** for a full summary of the position regarding the status of the draft HPC SPD.

11.3.30 With regards to the approach to Main Site accommodation campus, Box 20 in the draft HPC SPD states that impacts on neighbouring residents of Shurton and Burton should be avoided, including noise (Page 38).

i. Sedgemoor District Local Plan 1991-2011 (2004) (Policies 'saved' from 27 September 2007)

11.3.31 The Sedgemoor District Local Plan forms part of the Development Plan for Sedgemoor. The Local Plan was adopted in September 2004 (with relevant policies 'saved' from 27 September 2007). The Proposals Map (Southern Sheet and Inset Map No. 20) indicates that the site is not subject to any specific noise designations. The site lies outside of the defined Development Boundary.

11.3.32 The following saved policy is considered to be potentially relevant:

11.3.33 Policy PCS15 (Noise Pollution) states:

"Noise generating development will not be permitted if it would:

(a) be liable to unacceptably increase the level or disruptive character of noise experienced in any area to the detriment of its character; or

(b) be liable to unacceptably increase the noise experienced by the users of existing or proposed noise sensitive development to the detriment of those users.

Noise sensitive development will not be permitted if its users will be unacceptably affected by noise generating uses."

ii. Sedgemoor District Council Local Development Framework (LDF) Core Strategy (Proposed Submission) (September 2010)

11.3.34 The Sedgemoor LDF Core Strategy (Proposed Submission) was consulted on from September to November 2010. Changes prior to submission proposed as a result of the consultation process were reported and endorsed by the Council's Executive Committee on 9 February 2011. The Core Strategy (Proposed Submission) was submitted to the Secretary of State on 3 March 2011 and an Examination in Public (EiP) was held in May 2011. Once adopted, the Core Strategy will form part of the Development Plan for Sedgemoor.

11.3.35 EDF Energy submitted representations objecting to the Core Strategy (Proposed Submission), relating to Chapter 4 'Major Infrastructure Projects' (and policies MIP1, MIP2 and MIP3 contained in that chapter) and those sections relating to housing and Hinkley Point. EDF Energy also participated at the relevant EiP hearings. See **Volume 1**, **Chapter 4** for a full summary of the position regarding the status of the Core Strategy.

11.3.36 The following Core Strategy (Proposed Submission) policies are of potential relevance:

11.3.37 Policy D4 deals (Renewable and Low Carbon Energy Generation) states that the Council will support such proposals provided that such installations would not have significant adverse impact taking into account, amongst other things, any unreasonable adverse impact on users and residents of the local area including the generation of noise.

11.3.38 Policy D9 (Sustainable Transport and Movement) states that proposals should contribute to reducing adverse environmental issues, including noise pollution and vibration.

11.3.39 Policy D10 (Managing the Transport Impacts of Development) states that development proposals that will have a significant transport impact should be supported by an appropriate Noise and Vibration Assessment.

11.3.40 Policy D16 (Pollution Impacts of Development and Protecting Residential Amenity) states:

> *"Development proposals that are likely to result in levels of air, noise, light or water pollution (including groundwater) vibration or soil contamination that would be harmful to other land uses, human health, tranquillity or the built and natural environment will not be supported.*
>
> *Where there are reasonable grounds to suggest that a development proposal may result in a significant adverse environmental impact, the Council will require planning applications to be supported by assessments relating to (amongst other things):*
>
> - *Noise pollution and/or vibration...*
>
> *Where it is demonstrated that it is possible to manage the potential adverse impacts of the development proposals through its design or mitigation measures, the Council will, by means of condition or legal agreement, seek to ensure such measures are effective, for example improving limitations on matters including hours of operation, emissions of fumes, noise and light, parking and servicing for both construction and operational stages…*
>
> *Development proposals that would result in the loss of land of recreational and/or amenity value or unacceptably impact upon the residential amenity of occupants of nearby dwellings and any potential future occupants will not be supported. Particular consideration will be given to the extent that the proposal could result in unacceptable noise and disturbance, overshadowing, overlooking and/or visual dominance."*

11.4 Methodology

a) Noise and Vibration Principles

11.4.1 The noise and vibration principles which have formed the basis of this noise and vibration impact assessment are detailed in **Appendix 11C**.

b) Study Area

11.4.2 The study area, including the location of sensitive receptors in the locality of the HPC Development which has been considered for the assessment construction and operational phases of HPC is illustrated in **Figure 11.1**. The purpose of the assessment was to determine the potential worst-case impacts associated with the proposed development. Therefore, it is reasonable to assume that the nearest (unscreened) receptor locations to the proposed development are those likely to experience the greatest noise and vibration impacts.

11.4.3 For the assessment of the off-site highway improvements schemes, the working areas within the site boundary, together with a study area of 600m around them were considered. As above, the purpose of the assessment was to determine the potential worst-case impacts associated with the proposed highway improvements. In general this was represented by assessments of potential noise and vibration impacts at the nearest residential dwelling or any sites of amenity value.

11.4.4 The study area assessed for impacts resulting from the movement of construction (including HGVs and buses) and operational traffic considers the designated public highway routes (see **Chapter 10** of this volume). In addition, other public roads included in the traffic forecast model were included for completeness.

c) Baseline Noise Monitoring

11.4.5 A combination of short-term attended and unattended environmental noise measurements were undertaken at the following locations:

- North of the HPC development site on the site boundary adjacent to the coastal path to assist the determination of potential impacts to this public amenity;
- Knighton Farm approximately 450m to the south-west of the HPC development site for the assessment of potential impacts from predicted noise levels to residents in Knighton and Burton;
- Doggetts approximately 30m to the south-east of the HPC development site for the assessment of potential impacts from predicted noise levels to residents in Shurton;
- Wick House approximately 810m to the east of the HPC development site for the assessment of potential impacts from predicted noise levels to residents in Wick;
- South of the HPC development site on the site boundary, approximately 180m north of the nearest residential receptor location (Bishops Farm House) for the assessment of potential impacts from predicted noise levels to residents in Shurton; and

- Hinkley Point Power Station Visitor Centre at the HPC development site eastern boundary to assist the determination of potential impacts to public amenity at Pixies Mound.

11.4.6 Further details on the monitoring programme and details of the microphone positions, as well as a commentary of the significant noise sources at each location are provided in the Factual Noise Report provided in **Appendix 11A**.

d) Consultation

11.4.7 Consultations have been undertaken with Environmental Health Officers (EHOs) of West Somerset Council (WSC) and Sedgemoor District Council (SDC). A scoping consultation meeting with both parties was held in December 2008. During this meeting the specific requirements for the assessment of noise impacts were discussed. This included agreements regarding the choice of noise sensitive reference positions to be used for determining noise impacts at residential and public amenity locations closest to the proposed HPC development site.

11.4.8 A second consultation meeting was held with WSC and SDC in October 2009. At this meeting, the progress of the impact assessment was described and a presentation of a summary of the baseline noise monitoring survey was given. The proposed construction noise limits as detailed in **Table 11.2** were presented to the consultees, as well as the proposed operational noise threshold (amended since this meeting). The methodology and scenario assumptions for the operational noise prediction modelling for the HPC development (presented in detail in **Appendix 11F**) were also discussed.

11.4.9 Following the second consultation meeting, WSC and SDC requested further clarification on the derivation of the proposed noise threshold values for the construction and operational phases of HPC. This further detail was provided in March 2010 (see **Appendix 11G**).

11.4.10 The following advice and direction was provided by WSC and SDC, which has been taken into account within this assessment:

- baseline noise survey scope and methodology were agreed (refer to Factual Noise Report in **Appendix 11A**);
- impacts of plant noise during the operational phase should be assessed in accordance with BS 4142:1997, with a target criterion of 5dB above the prevailing background not to be exceeded; and
- due to the large separation distance, vibration due to construction and operation was considered by the consultees to be unlikely to significantly affect the nearest residential locations. It was agreed that a baseline vibration assessment was not required.

11.4.11 In February 2011, a third consultation meeting was held with WSC and SDC. The purpose of this meeting was to:

- present additional work undertaken since Stage 2 Consultation;
- set out the scope of further work to be undertaken;
- identify consultation undertaken to date;
- review consultation comments received at Stage 2 Consultation and how these had been, or were intended to be addressed; and
- review proposed mitigation measures, and management and monitoring procedures.

11.4.12 At this meeting, the rationale for the proposed change to the operational noise limit from 43dB $L_{Aeq,T}$ as presented at the Stage 2 Consultation to a limit of 38dB $L_{Aeq,T}$ (façade) was discussed. It was also confirmed that the limit value should represent the 'Rating Level', in accordance with BS4142 (Ref. 11.23), and therefore a +5dB penalty should be applied to the predicted noise level if such noise emission from the operational nuclear power station comprises distinct acoustic features.

11.4.13 The methodology for the determination of the effects of varying wind conditions on noise propagation within the model was also discussed. This methodology was changed from the CONCAWE methodology to the method within ISO 9613-2 (see **Appendix 11F**). A technical note was provided to SDC and WSC accompanying the minutes to the meeting outlining this change as well as a summary of the significant changes to the operational noise model since the Stage 2 Consultation (see **Appendix 11H**).

11.4.14 A noise impact assessment for the HPC development was included within the submitted Stage 2 Consultation documentation. Following this, considered responses to the noise and vibration assessments were provided by the following consultees:

- WSC and SDC;
- Somerset County Council (SCC);
- Stogursey Parish Council (SPC);
- The Environment Agency (EA);
- The Highways Agency (HA);
- Countryside Council for Wales (CCW);
- Fairfield Estate;
- North Petherton Town Council;
- Otterhampton Parish Council; and
- Stringston Parish Council.

11.4.15 Comments received have been reviewed and, where appropriate, additional clarification has been provided within this chapter. For further information, detailed responses to all comments are provided in the **Consultation Report**.

e) Assessment Methodology

i. Value and Sensitivity

11.4.16 With regard to noise and vibration effects, the standard impact assessment methodology, as set out in **Volume 1**, **Chapter 7**, is not readily applicable. This is largely due to the fact that noise and vibration effects are assessed in relation to quantitative noise level criteria and thresholds (see sections below). However, for the purposes of this assessment the overall sensitivity and value, relating to human beings living in proximity to either the HPC development site or affected highways, have been nominally rated.

11.4.17 The potential for noise disturbance has also been considered in outdoor public places, such as footpaths or historical features (such as 'Pixies Mound', south of the Hinkley Point A nuclear power station). **Table 11.1** below provides a summary of the sensitivity of receptors to predicted noise levels, used to determine the significance of potential noise and vibration impacts.

Table 11.1: Summary of Receptor Sensitivity

Receptor	Exposure	Sensitivity
Permanent		
Residents at Doggetts (private dwelling)	Continuous long-term	Medium
Residents of Shurton Village	Continuous long-term	Medium
Residents of Shells Cottages, Williton	Continuous, Short-term (highway improvements)	Medium
Schools (Brymore School)	Continuous long-term	High
Non-Permanent		
Users of footpaths and PRoWs (Casual walkers and hikers)	Transient short-term	Low
Visitors to Pixies Mound	Transient short-term	Low
Visitors to Tropiquaria Zoo and child play area	Transient short-term	Low
Visitors to places of worship/cemeteries	Transient short-term	Medium

11.4.18 Private residential properties are categorised as being of 'Medium' sensitivity, with 'High' sensitivity reserved for locations where very good communication and resting conditions are essential (schools, hospitals, care homes for the elderly or people with learning disabilities). This is based upon guidance provided by the WHO (Ref. 9.1). Outdoor public amenity receptor locations were categorised as 'Low' due to the transient presence of human receptors in these locations, and the options that such receptors would have available allowing them to select other locations at any given time.

11.4.19 The significance of identified impacts can therefore be related to the Impact Significance Matrix presented in **Volume 1**, **Chapter 7**, once the magnitude of each impact has been predicted in accordance with the relevant guidance methodologies described below.

ii. Magnitude

11.4.20 The magnitude of impact has been based on the consequences that the proposed development would have based upon predicted noise and vibration levels, and has been considered in terms of high, medium, low and very low. The magnitude criteria used in this assessment are detailed in the methodology sections below for each phase of the proposed development.

iii. Construction – Noise from On-Site Construction Activities

11.4.21 Construction site noise is assessed differently from noise from permanent installations, as it is recognised that the former is an inevitable by-product of required works and its effects are limited in duration. As defined in **Volume 1, Chapter 7**, the durations of temporary impacts are categorised as:

- short-term – less than one year;
- medium-term – one to five years; and
- long-term – greater than five years.

11.4.22 Advice is contained within British Standard BS 5228: 2009 'Noise and vibration control on construction and open sites' – Part 1 'Noise' (Ref. 11.11). This document contains a database of the noise emissions from individual items of equipment and certain activities to allow the prediction of noise from construction (and demolition) works to identified receptors. The prediction method provides guidance on the effects of different types of ground and barrier attenuation and on how to assess the impact of fixed and mobile plant. Whilst not mandatory, Annex E of this document provides informative advice to aid the development of noise assessment criteria based on previous published guidance and methodologies adopted successfully for other planning applications.

11.4.23 In assessing the requirement for noise limits, or operating period controls relating to construction works, Government Agencies and Local Authorities generally give consideration to the following aspects of the planned works, all of which have a bearing on the 'significance' of the impact:

- duration of planned activities (weeks, months, years);
- whether activities are planned for the night-time period;
- proximity of development to residential areas; and
- predicted source-term noise levels and noise impacts at residential areas.

11.4.24 The proposed noise magnitude criteria for construction works on the development site, in general, offer tighter control over noise emissions than recommended in BS 5228-1: 2009 (Ref. 11.11), Annex E, in light of the proposed duration of construction works. Recommended criteria for construction works are typically referenced to longer time periods (i.e. 12-hour daytime, 4-hour evening or 8-hour night), which allow for more intensive, and more noisy work over shorter periods if the working schedule is well managed. The shorter reference period of 1-hour for all periods as proposed would therefore provide better control on construction noise emissions throughout the long-term (up to 10 years) construction schedule. This takes account of the recommendation, in BS 5228-1: 2009 Annex E, for a 1-hour reference period to be adopted for long-term earthworks (i.e. for working periods greater than 6-months).

11.4.25 The proposed noise emission limits for construction activities undertaken within the HPC development site are presented in **Table 11.2** below. This includes proposed construction noise limits outside of typical daytime working periods, including preparatory and maintenance works to be undertaken during the reduced night-shift.

Table 11.2: Proposed Noise Limits for Site Preparation and Construction Works Associated with Hinkley Point C

Assessment Period		**Construction Noise Threshold (Free-Field)***
Day of Week	**Time of Day**	**dB $L_{Aeq,1hour}$**
Monday – Friday	07:00 – 19:00 19:00 – 23:00 23:00 – 07:00	65 60 45
Saturday	07:00 – 19:00 19:00 – 23:00 23:00 – 07:00	65 60 45
Sunday and Bank Holidays	07:00 – 19:00 19:00 – 23:00 23:00 – 07:00	60 55 45

Notes: dB re: 20µPa

** Determined at a noise sensitive receptor location (free-field). Predicted construction noise levels should include the typical existing ambient noise level (dB $L_{Aeq,T}$), as advised in BS5228-1, Annex E.*

Where L_{Aeq} = the equivalent continuous A-weighted sound pressure level, being the single number that represents the total sound energy measured over that period

Noise levels may be permitted up to 75dB $L_{Aeq,1hour}$ for specific works of short duration (such as blasting) where 'best practicable means' have been demonstrated to WSC and noise sensitive premises have been informed at least 48-hours in advance.

11.4.26 It should be noted that the noise levels presented in **Table 11.2** are limits rather than target values. As the majority of works will occur at a significant distance from receptors in the locality of the HPC development site, construction noise levels are, on the whole, predicted to be well below the proposed threshold values.

11.4.27 Based on these values, the noise magnitude scale for use in the prediction of potential impacts has been determined as presented in **Table 11.3**.

Table 11.3: Noise Magnitude Scale for Construction of Hinkley Point C

Assessment Period		**Construction Noise Magnitude – (Associated with UK Epr Development Site) dB $L_{Aeq,1hour}$ (Free-Field)**			
Day of Week	**Time of Day**	**Very Low**	**Low**	**Medium**	**High**
Monday – Friday	07:00 – 19:00 19:00 – 23:00 23:00 – 07:00	<55 <50 <35	55-65 50-60 35-45	65-70 60-65 45-50	>70 >65 >50
Saturday	07:00 – 19:00 19:00 – 23:00 23.00 – 07:00	<55 <50 <35	55-65 50-60 35-45	65-70 60-65 45-50	>70 >65 >50
Sunday and Bank Holidays	07:00 – 19:00 19:00 – 23:00 23:00 – 07:00	<50 <45 <35	50-60 45-55 35-45	60-65 55-60 45-50	>65 >60 >50

Notes: dB re: 20µPa

Two separate approaches have been adopted for the prediction of construction noise using the BS5228 (Ref. 11.17) methodology. These include worst-case calculations of noise from individual activities, such as construction of the Nuclear Island as well as detailed computational modelling which considers numerous activities being undertaken concurrently.

11.4.28 The individual activities assessed include:

- site preparation works (preliminary works);
- construction of temporary jetty and aggregates handling facility (preliminary works);
- upgrade of roads at the northern site access;
- sea wall construction;
- construction of emergency access road including the bridge over Bum Brook;
- deep excavation and concrete substitution to form Nuclear Island building foundations;
- construction of temporary and permanent buildings (non-nuclear);
- tunnelling (cooling water intake and outfall infrastructure);
- construction of nuclear island buildings;
- construction of temporary accommodation campus;
- construction of the National Grid 400kV substation;
- early landscaping; and
- final landscaping.

11.4.29 The detailed noise prediction calculations presented in **Appendix 11D** and summarised below consider each activity independently. In reality, many of these activities will occur concurrently, and therefore an additional noise prediction modelling exercise has been undertaken to enable a prediction of the effects of these concurrent activities. Details and outputs from this modelling study are provided in **Appendix 11E**. The following five discrete modelling scenarios (each representing a point in time during the HPC preliminary works and construction programme) were considered (Scenarios A-D represent daytime works):

- Scenario A – two months into site preparation works;
- Scenario B – six months into site preparation works;
- Scenario C – deep excavation (approx. Q3 2013);
- Scenario D – UK EPR construction (approx. Q4 2014); and
- Scenario E – night-time construction/maintenance activities (approx. Q4 2014).

11.4.30 **Table 11.4** provides detail of the assumed activities being undertaken for each construction noise modelling scenario.

Table 11.4: Assessed Construction-related Activities for Each Model Scenario

Activity	Scenario				
	A	B	C	D	E
Residual vegetation removal (hedges and trees)	✓	×	×	×	×
Stripping of topsoil	✓	×	×	×	×
Topsoil stockpiling at both the southern operational extent of the Southern Construction Phase Area (latitude 144750mN) and at the western boundary of the Southern Construction Phase Area	✓	×	×	×	×
Preparation works for construction of the northern roundabout close to Pixies Mound	✓	×	×	×	×
Deep (rock) excavation at UK EPR Units 1 and 2	×	✓	✓	×	×
Transporting of excavated materials to the stockpiles within the Southern Construction Phase Area using western haul road	×	✓	×	×	×*
Dump truck using circular haul route between northern and southern land areas	×	✓	✓	✓	×
Site levelling at the site of the proposed southern access roundabout	×	✓	×	×	×
Construction of temporary and permanent (non-nuclear) buildings	×	×	✓	✓	✓
Operation of temporary jetty	×	×	✓	✓	✓
Tunnelling and construction of the cooling water inlet and outlets	×	×	✓	✓	✓
Construction of the National Grid 400kV substation	×	×	✓	✓	
Construction of the on-site accommodation campus	×	×	✓	×	×
Construction of nuclear island buildings	×	×	×	✓	✓
Occupation of the on-site accommodation campus	×	×	×	✓	✓

*Note: * Transportation of excavated spoil during tunnelling operations at night would be limited to the fresh rock stockpile area, north of 145100mN.*

11.4.31 Construction plant and equipment type and numbers assumed for each modelled scenario were in accordance with the equipment list for the respective activities presented in **Table 11D.9** of **Appendix 11D**.

iv. Construction – Noise from Off-Site Traffic

11.4.32 There is no specific guidance for assessing the noise impact of construction traffic on public highways. However, given the duration of the proposed construction programme, an assessment has been undertaken using the methodology usually employed for permanent operational road traffic noise impacts.

11.4.33 The Design Manual for Roads and Bridges (DMRB) **Volume 11**, Section 3, Part 7 (HD 213/11) 'Noise and Vibration' (Ref. 11.12) provides an appropriate method for evaluating both the immediate and long-term impact of changes in the 18-hour traffic flow (06:00-24:00) in terms of the impacts on people and, principally, occupiers of residential property.

11.4.34 DMRB requires that an assessment is undertaken where an increase in a road traffic flow of 25% or greater is predicted (equivalent to an increase or decrease in road traffic noise of approximately 1dB L_A), implying that road traffic flow increases of up to 25% result in no significant impacts in environmental noise terms.

11.4.35 It is generally accepted that changes in road traffic noise levels of up to 3dB L_A are not widely perceptible. This is equivalent to a road traffic flow increase or reduction of 100%. Confirmation is provided in Department of Transport 'Transport Analysis Guidance' (2007 update) (Ref. 11.13), where it is stated:

> *"For freely flowing traffic, a difference of about 3dB in noise level is required before there is a statistically significant change in the average assessment of nuisance. The assessment of nuisance however could still be affected even if there is only a 1dB change in the noise level if the change is associated with changes in the view of traffic, or if the change occurs suddenly."*

11.4.36 In order to assess the level of community disturbance from potential changes in local road traffic characteristics during the construction phase of the proposed development, an assessment has been undertaken based on the principles of the DMRB Simple Assessment methodology. Although this methodology is designed for the assessment of permanent operational traffic impacts, it is also considered the most appropriate tool available for the assessment of the relatively long construction phase proposed for HPC.

11.4.37 The change (either an increase or decrease) in basic noise level (BNL), calculated according to the methods given in Calculation of Road Traffic Noise (CRTN) (Ref. 11.14), for each road section affected (refer to **Table 11I.1** of **Appendix 11I**) can then be compared with noise impact criteria presented in **Table 11.5**.

Table 11.5: Guidelines for the Assessment of Magnitude for 18-hour Traffic Noise

Magnitude	Guidelines
High	Considerable increase in the perceived noise levels typified as a difference of more than 5dB $L_{A10,T}$ from the existing ambient level.
Medium	Significant change in the perceived noise levels, typified as a difference of 3 to 4.9dB $L_{A10,T}$ from the existing ambient level.
Low	Change in the perceived noise levels, typified as a difference of 1 to 2.9dB $L_{A10,T}$ from the existing ambient level.
Very low	Generally imperceptible change in the perceived noise levels typified as a difference of 0.1 to 0.9dB $L_{A10,T}$ from the existing ambient level.

11.4.38 The traffic data used for the road traffic noise impact assessment has been taken from the Paramics micro-simulation traffic model built to assess the effects of the HPC Project proposals. The Paramics model includes Cannington and Bridgwater and Junctions 23 and 24 of the M5 motorway. The bus and Heavy Goods Vehicle (HGV) trips are fixed to the network and the remaining development trips are dynamically assigned through the network. For each modelling scenario the output traffic data from the Paramics model was factored using Automatic Traffic Count data to provide 18-hour Annual Average Weekly Traffic (AAWT) data.

11.4.39 In order to determine the overall potential road traffic noise impacts of construction of the HPC Project, the following assessment scenarios have been examined:

- 2009 ‘Baseline Year’ **(09BY)**;
- 2013 ‘Do-Nothing’ **(13DN)**, including:
  - forecast traffic growth including committed development only.
- 2016 ‘Do-Nothing’ **(16DN)**, including:
  - forecast traffic growth including committed development only.
- 2013 ‘Do-Something’ **(13DS)**, including:
  - forecast traffic growth including committed development;
  - construction of HPC power station (peak HGV trip generation);
  - operation of proposed park and ride, freight management facilities and temporary courier consolidation facility and induction centre at Junction J24 of the M5; and
  - construction of other associated development sites.
- 2016 Do-Something **(16DS)**, including:
  - forecast traffic growth including committed development;
  - construction of HPC power station (peak workforce demand);
  - operation of a western bypass of Cannington; and
  - operation of associated development sites.

11.4.40 The year 2009 was chosen as the baseline year for the assessment as this is the most recent year for which full traffic data was available. The years 2013 and 2016 were selected to represent the worst-case construction years (i.e. the years with peak construction traffic relating to the HPC Project).

11.4.41 For use in this assessment, the forecast daily (18-hour AAWT) traffic data in 2013 considers the **average day**, during the **peak quarter** of the **peak year** for HGV movements.

11.4.42 Comparison of impacts determined for each of the scenarios described above will therefore represent an assessment of the overall impacts of construction traffic relating to the HPC Project.

11.4.43 The forecast 2016 'Do-Something' (16DS) scenario uses data from the 'with development' road traffic scenario (**Table 11I.2** of **Appendix 11I**) provided from the transport studies. This assumes that a number of travel plan measures are in place during the construction phase of the HPC Project. These additional measures (which include certain of the associated developments) have been designed to alleviate impacts on the local highway network. As well as reducing traffic congestion, these measures will help to reduce noise and vibration impacts from road traffic during the proposed HPC construction phase. The relevant associated developments include:

- J23 Park and ride facility and freight management facility close to Junction 23 of the M5 Motorway;
- J24 Park and ride facility and freight management facility close to Junction 24 of the M5 Motorway;
- Cannington Park and ride facility located off the A39, south of Cannington village;
- Williton Park and ride facility located off the B3190, west of Williton;
- Combwich upgrade of the existing wharf, and construction of a water-borne freight set-down and storage area;
- HPC development site contractor accommodation campus including associated residential facilities for construction workers within the Southern Construction Phase Area (SCPA); and
- Western bypass of Cannington Village, connecting the A39/High Street roundabout with the C182 (Rodway), south of Putnell Barn.

11.4.44 In addition to the above sites, a number of road congestion mitigation measures (see 'Construction – Noise from Highway Improvements' in Section 11.6b) are assumed to be in place. Whilst these measures help to reduce congestion issues, they can encourage higher traffic flows in some locations as driver patterns change. Subsequently, changes (increases or decreases) in road traffic noise may result directly from these improvements.

11.4.45 Short-term noise and vibration impacts during peak hours for construction workforce movements (particularly early morning between 05:00 and 07:00 hours) have been assessed separately, due to the greater sensitivity to noise during these periods. This assessment is also based upon forecast traffic data for the scenarios identified above.

11.4.46 The assessment of hourly road traffic noise resulting during the daytime is considered to be an absolute worst-case, taking the forecast **peak day** for HGV movements in each of the assessment years (2013 and 2016), including the **peak year** (2016) for HGV traffic. This was assessed in this way primarily so that the transport assessment could ensure that junctions had the capacity to cope throughout the HPC construction phase. For the large majority of the HPC construction phase, hourly noise impacts (particularly those assessed during the night-time period) will be less significant than has been assessed.

11.4.47 The magnitude criteria presented in **Table 11.5** are only relevant for 18-hour traffic data, as these criteria are influenced by a number of factors, such as: the time of the day, the hourly traffic volume and ultimately, the absolute noise levels.

11.4.48 As undertaken for 18-hour traffic data, the change in hourly basic noise level (BNL), again calculated according to the methods given in CTRN (Ref. 11.14), for each road section affected, has been used to assess the potential impacts. However, it should be noted that CRTN is less reliable for low traffic flows (less than 200 vehicles per hour).

11.4.49 A range of noise impact magnitude scales, presented in **Table 11.6**, were therefore adopted taking into account the actual number of predicted vehicle movements (the resultant change can be an increase or decrease of noise).

Table 11.6: Guidelines for the Assessment of Magnitude for 1-hour Traffic Noise

Magnitude	Change in Predicted Noise Level, dB $L_{A10,1\ hour}$	
	Predicted with Development Traffic <200 Vehicles per Hour	Predicted with Development Traffic >200 Vehicles per Hour
High	> 10	> 5
Medium	5 – 9.9	3 – 4.9
Low	2 – 4.9	1 – 2.9
Very low	0.1 – 1.9	0.1 – 0.9

11.4.50 The magnitude changes presented in **Table 11.6** for road sections with predicted 'with development' traffic flows in excess of 200 vehicles per hour are as advised in DMRB (Ref. 11.12), and correlate with those presented in

11.4.51 **Table 11.5:** Given the limitations of the CRTN (Ref. 11.14) methodology, further magnitude change criteria have been adopted for road sections with predicted 'with development' traffic flows below 200 vehicles per hour. In the absence of published guidance, this criteria is designed to reflect the change in frequency of vehicle movements (an average of less than four vehicles per minute), and the perception by the receiver in terms of absolute noise exposure levels.

11.4.52 Therefore, the absolute road traffic noise level has also been considered in relation to published guidance values. With reference to potential road traffic noise impacts during the night, DMRB recognises the current limitations of research into the dose-response relationship for exposure. It therefore recommends that *"…only those sensitive receptors predicted to be subject to a $L_{night,outside}$ of 55dB should be considered"*. This level corresponds to the Interim Target level specified in the WHO NNGE (Ref. 11.2), and is an incident level (free-field) at the façade of a dwelling, presented as an annual average.

11.4.53 Based on this principle, road traffic noise impacts along highway sections for which the BNL is predicted to be below 55dB $L_{Aeq,1hr}$ (free-field), during HPC construction, should be assessed as being of minor significance, regardless of the predicted noise change. The level of 55dB $L_{Aeq,T}$ corresponds with the interpretation of the earlier WHO guidance (Ref. 11.15) by the National Physical Laboratory (NPL) together with the Institute of Sound and Vibration Research (ISVR) at Southampton University (Ref. 11.16), as requested by the UK Department of Environment (DETR) in 1998.

11.4.54 The NPL/ISVR report states that:

> *"In essence, the WHO guidelines (Ref. 11.15) represent a consensus view of international expert opinion on the lowest threshold noise levels below which the occurrence rates of particular effects can be assumed to be negligible. Exceedances of the WHO guideline values do not necessarily imply significant noise impact and indeed, it may be that significant impacts do not occur until much higher degrees of noise exposure are reached. One difficulty here is the true importance of the different noise effects considered when placed in an overall context relating to quality of life, and the extent to which noise control might have excessive consequences in other areas of human experience."*

11.4.55 Therefore, by applying the principle that greater levels of exposure are required to result in a significant impact, it is considered that noise levels of at least 10dB higher than the WHO guideline of 45dB $L_{Aeq,1\ hour}$ should be required before a receptor would experience *"…much higher degrees of noise exposure"*. The NPL/ISVR continues:

> *"As such, it would be unwise to use the WHO guidelines as targets for any form of strategic assessment, since, given the prevalence of existing noise exposure at higher noise levels, there might be little opportunity for and little real need for any across the board major improvements. On the other hand, the most constructive use for the WHO guidelines will be to set thresholds above which greater attention should be paid to the various possibilities for noise control action when planning new developments. It is important to make clear at this point that exceedances do not necessarily imply an over-riding need for noise control, merely that the relative advantages and disadvantages of noise control action should be weighed in the balance. It is all a question of balance and mere exceedance of the WHO guidelines just starts to tip the scales."*

11.4.56 Elsewhere in the NPL/ISVR document it explains that the limit of unacceptability is essentially a political decision. However, the document does identify a zone of intermediate impact which lies above the WHO criteria (below which the effects of noise are considered to be negligible), and below the level that noise effects are considered to be significant. Within this region, it is reasonable to conclude that, whilst attenuation measures should be considered, the actual noise impacts are not a restrictive factor to development.

11.4.57 In order to determine a representative road traffic noise level for each assessed road section, a simplified calculation methodology was adopted, using individual sound exposure levels (SEL) for each assigned vehicle movement. The traffic flows were divided into two categories in accordance with CRTN (Ref. 11.14): cars and other light vehicles with an assumed SEL of 67dB L_{AE} at 10m (based on previous measurements); and, heavy vehicles (HGVs and buses) with an assumed SEL of 80dB L_{AE} at 10m (based on previous measurements and data provided in BS 5228-1 (Ref. 11.11).

v. Construction – Noise from Highway Improvement Works

11.4.58 Construction noise calculations were also undertaken for significant highway improvement schemes on the local highway network (i.e. those that involve works beyond the existing highway boundary), using the BS 5228-1 (Ref. 11.11) methodology described above.

11.4.59 The proposed noise magnitude criteria for highway improvement works are presented in **Table 11.7**. The limits are based on advice provided in BS 5228-1.

11.4.60 It should be noted that no highways improvement works are proposed during the evening (19:00-23:00) or night-time periods (23:00-07:00), on Saturday afternoons (13:00-23:00), Sundays or public holidays.

Table 11.7: Guidelines for the Assessment of Magnitude for Highway Improvements Noise

Magnitude	Guideline
High	Generation of daytime façade noise levels (predicted construction noise plus measured ambient noise) in excess of 75dB(A) $L_{eq,12hr}$
Medium	Generation of daytime façade noise levels (predicted construction noise plus measured ambient noise) that are in the range of 65 to 75dB(A) $L_{eq,12hr}$
Low	Generation of daytime façade noise levels (predicted construction noise plus measured ambient noise) that are in the range of 55 to 65dB(A) $L_{eq,12hr}$
Very low	Generation of daytime façade noise levels (predicted construction noise plus measured ambient noise) that are below 55dB(A) $L_{eq,12hr}$

vi. Construction – Vibration from On-Site Construction Activities and Highway Improvement Works

11.4.61 Guidance on the assessment of the potential vibration impacts associated with construction activities is provided within British Standard BS 5228: 2009 ‘Code of practice for the control of noise and vibration on construction and open sites’ – Part 2 ‘Vibration’ (Ref. 11.17). This document refers to the measurement and assessment guidance provided in BS 6472 ‘Guide to evaluation of human exposure to vibration in buildings’ – Part 1: 2008 ‘Vibration sources other than blasting‘ (Ref. 11.18) and BS ISO 4866 ‘Mechanical vibration and shock – Vibration of fixed structures – Guidelines for measurement of vibrations and evaluation of their effects on structures’ (Ref. 11.19) (supersedes BS 7385-1: 1990), and BS 7385: Part 2: 1993 ‘Guide to damage levels from ground-borne vibration’ (Ref. 11.20).

11.4.62 For the type of development proposed, plant such as piling equipment, compressors, pumps, generators and HGVs are likely to be the most significant sources of low frequency noise with the potential to cause resonance in nearby buildings, which is often perceived as vibration by occupants.

11.4.63 Bulk earthworks and construction activities generally give rise to impulsive and intermittent vibration. In such circumstances, it is necessary to be able to quickly compare levels against simple criteria to give an immediate evaluation of the likelihood of a problem without recourse to complex post-processing of results. Under these conditions, assessment criteria based on peak particle velocities (PPVs) are most appropriate.

11.4.64 Based on Table B.1 of BS 5228-2 (Ref. 11.17), the proposed PPV significance criteria for typical demolition and construction activities (excluding blasting), measured at a sensitive receptor location, are presented in **Table 11.8**.

Table 11.8: Construction Vibration Magnitude Criteria (excludes blasting)

Magnitude	Vibration Level (mm/s PPV)	Impact
High	10.00	Vibration is likely to be intolerable for any more than a very brief exposure to this level
Medium	1.00	It is likely that vibration of this level in residential environment will cause complaint, but can be tolerated if prior warning and explanation has been given to residents
Low	0.30	Vibration might be just perceptible in residential environments
Very Low	0.14	Vibration might be just perceptible in the most sensitive situations for most vibration frequencies associated with construction. At lower frequencies, people are less sensitive to vibration.

11.4.65 In the case of ripping and blasting (the latter of which may be required) operations that will be undertaken during the deep foundation excavations for the Nuclear Island and other deep structures, the potential impacts have been assessed in accordance with British Standard BS 6472 ‘Guide to evaluation of human exposure to vibration in buildings’ – Part 2: 2008 ‘Blast-induced vibration’ (Ref. 11.21). This document provides a methodology for the prediction of the likely vibration magnitude based on the Maximum Instantaneous Charge (MIC) in kg, and the slant distance from the blast to the receptor in metres.

11.4.66 Based on Table 1 of BS 6472-2, the proposed PPV significance criteria for blasting operations, measured at a residential receptor location, are presented in **Table 11.9**.

Table 11.9: Vibration Magnitude Assessment Criteria (blasting operations)

Magnitude	Guidelines
High	Generation of PPV in excess of 24mm/s
Medium	Generation of PPV in the range of >10 to <24mm/s
Low	Generation of PPV in the range of >6 to <10mm/s
Very Low	Generation of PPV below 6mm/s

11.4.67 The above assumes that blasting and ripping will only be undertaken during daytime hours (08:00-18:00 Monday-Friday, 08:00-13:00 Saturday), and that there will be no more than three blast events per day.

vii. Construction – Vibration from Off-Site Traffic

11.4.68 Air-borne vibration from traffic is generally produced by the engines or exhausts of road vehicles and these are dominant in the audible frequency range (50Hz to 100Hz). Ground-borne vibration is more often in the 8Hz to 20Hz range and is produced by the interaction between rolling wheels and the road surface as well as by the jolting of HGVs over surface irregularities.

11.4.69 The potential impact of airborne vibration resulting from the change in traffic levels on other affected highways was assessed using guidance in the DMRB (Ref. 11.12). The DMRB identifies that the annoyance from vibration correlates well to $L_{A10\ (18\text{-hour})}$ levels. However:

11.4.70 *"For a given level of noise exposure the percentage of people bothered very much or quite a lot by vibration is 10% lower than the corresponding figure for noise nuisance."*

11.4.71 At predicted road traffic noise exposure below 58dB $L_{A10\ (18\text{-hour})}$ DMRB states the percentage of people bothered by vibration should be considered to be zero.

11.4.72 With respect to ground-borne vibration which is only likely to result if there are significant surface irregularities in the road surface, DMRB identifies that:

> *"Such vibrations are unlikely to be important when considering disturbance from new roads and an assessment will only be necessary in exceptional circumstances."*

viii. Operation – Industrial Noise

11.4.73 The propagation of operational noise emissions from sources on the proposed HPC development site (including: machinery; building vents; and building façades) has been predicted in accordance with the International Standards Organisation (ISO) 9613: 'Attenuation of sound during propagation outdoors' – Part 2 'General method of calculation' (Ref. 11.22). The operational noise emissions have been modelled using Cadna computational predictive software.

11.4.74 This section provides a summary of the modelling undertaken and full details, including assumptions made. Input and output data are provided in **Appendix 11F**. Cadna noise modelling has been used to predict the levels of environmental noise at a distance from a variety of sources. Parameters used within the noise modelling include:

- Topography: The existing topography within the site boundary was modelled using 1m LiDAR (Light Detection and Ranging) data and beyond this area, 10m Ordnance Survey contours were imported into the model. The local topography of the HPC development site was adjusted to reflect the proposed platform levels. Landforms associated with final landscaping in the southern section of the SCPA (south of 144750mN) have also been incorporated into the model.
- Buildings and other topography: Proposed and existing buildings and cylinders (including chimney stacks) were incorporated within the model. The height of buildings located within the existing Hinkley Point A and B nuclear power generation sites have been estimated, whilst the height of all sensitive receptor buildings has been set to 6m, allowing for properties up to two storeys.
- Noise sources (emission points): Three types of noise sources were included in the model including point sources, area sources and line sources. The directivity of noise emissions was based upon the source type (e.g. chimney stack exit or building façade) and the source location (openings in building façades).
- Ground absorption: All land outside of the HPC development site and the existing Hinkle Point power station complex was assigned a sound absorption factor of 1.00 (soft ground) for the purpose of noise propagation calculations. The remaining ground was assigned a ground absorption factor of 0.20, to account for hard surfaces and small obstacles (machinery, vehicles). Areas supporting EDF Energy pylons and electrical plant on the proposed National Grid 400kV substation site were assigned a ground absorption factor of 0.5 as these will be covered by stone chippings.
- Meteorological conditions: Annual hourly sequential meteorological data which was generated using the United Kingdom Meteorological Office (UKMO) Numerical Weather Prediction Model for the Hinkley Point site was used to define meteorological conditions in the noise propagation model. The industrial noise calculation utilises the ISO 9613-2 (Ref. 11.22) methodology for the determination of meteorological correction (C_{met}).
- Foliage/woodland areas: Areas of existing foliage have been identified within the model. However, these areas have no acoustic features and are therefore not accounted for within noise propagation calculations.
- Reflections: Given the distance separation between the built development areas and the nearest noise sensitive receptors, a single order of reflection was permitted within the model.
- Noise sensitive locations: Noise sensitive receptors included Knighton Farm, Doggetts, and Wick Farm (see **Figure 11.1**). The baseline noise conditions for these receptors are described in the Factual Noise Report in **Appendix 11A**.

11.4.75 British Standard BS 4142: 1997 'Method for rating industrial noise affecting mixed residential and industrial areas' (Ref. 11.23) provides a method of assessing the likelihood of complaint from a noise source by comparing the rating level of that source with the background noise level L_{A90} at noise-sensitive receptors affected by noise from existing or proposed fixed developments including factories and commercial/industrial units.

11.4.76 In Section 9 of BS4142: 1997 'Assessment Method' it is stated that an excess above the existing background noise level L_{A90} of up to 5dB L_A due to the rating noise level from fixed plant at a new development is of 'marginal significance'. This has been interpreted since the introduction of the Standard in 1967, that a 5dB L_A excess due to new, fixed plant noise sources is, in general, acceptable. For this reason, Environmental Health Officers of WSC and SDC recommended this assessment criterion for this assessment.

11.4.77 For the calculation of noise propagation from the built plant, three meteorological scenarios were used:

- average wind speed and direction based on hourly data (2004-2008);
- downwind conditions; and
- neutral (no wind).

11.4.78 However, BS 4142 does not specify how wind effects should be accounted for in propagation predictions, only that the calculation method should be reported and reasoned appropriately. Operational noise propagation has been determined based upon all three scenarios to provide an indication of the meteorological effects.

11.4.79 Furthermore, BS 4142 is not suitable for assessing the noise impacts when the background and rating noise levels are both very low (below 30$L_{A90,T}$ and 35dB $L_{Aeq,T}$ respectively), as occurs around the HPC development site (refer to Factual Noise Report in **Appendix 11A**). Given the rural setting, it is proposed to set a fixed target criterion for all plant at the façade of nearest noise sensitive receptors, taking into account meteorological conditions that are likely to promote noise propagation from the site to the receptors. Operational noise impacts have been assessed based upon the average wind direction and the worst-case downwind scenario for comparison with the proposed criterion.

11.4.80 The assessed noise emissions from the operational HPC site were assumed to be constant; therefore the determined impact during the night-time will dictate the overall operational noise impact. The proposed target noise level should minimise the potential for sleep disturbance in accordance with guidance provided in the World Health Organisation (WHO) document 'Guidelines for Community Noise' (1999) (Ref. 11.1) and British Standard BS 8233: 1999 'Sound insulation and noise reduction for buildings – Code of practice' (Ref. 11.24), even with windows open.

11.4.81 In 2009, the WHO published its 'Night Noise Guidelines for Europe' (NNGE) (Ref. 11.2) in which it recommends a target of 40dB $L_{night,outside}$ at a residential façade ('free-field' incident level) to protect the public, including the most vulnerable groups such as children, the chronically ill and the elderly. The $L_{night,outside}$ indicator relates to the annual average night-time noise level and takes account of the varying need to open windows at night throughout the year. This parameter is therefore comparable with the operational noise rating level predicted using the average wind conditions.

11.4.82 It is therefore proposed that a rating noise criterion of 38dB $L_{Aeq,T}$ (façade) is adopted. With the façade correction, this level is 5dB below the annual average value recommended in WHO NNGE document and would result in an internal noise level of less than 30dB $L_{Aeq,night}$ within bedrooms. The WHO Guidelines for Community Noise (Ref. 11.1) indicate that this represents the noise level at which it is possible to start detecting sleep disturbance and below which effects can be assumed to be negligible. In this regard, the advice provided by the NPL/ISVR interpretation report (Ref. 11.16), as discussed above is relevant.

11.4.83 In terms of potential daytime disturbance, this proposed threshold criterion is 12dB below the level at which the WHO considers there to be the onset of moderate annoyance in a small minority (10%) of the population (50dB $L_{Aeq,16hours}$).

11.4.84 **Table 11.10** shows the proposed operational noise magnitude assessment criteria (as adopted in this assessment), determined at a residential receptor location.

Table 11.10: Operational Noise Magnitude Assessment Criteria

Magnitude	Sound Pressure Level (Façade) Under Annual Average Wind Conditions, Db L_{at}(Lt) – Assumes Continuous Noise Emissions Throughout The Day and Night
High	> 40
Medium	38 – 40
Low	35 – 38
Very Low	<35

ix. Operation – Noise from Off-Site Traffic

11.4.85 An assessment of the road traffic noise impacts during the early operational phase of HPC has been undertaken using the same methodology as described for construction-related traffic above. The relevant criteria for 18-hour and 1-hour traffic noise magnitude levels presented in **Table 11.5** and **Table 11.6**, respectively, were used.

11.4.86 In order to determine the overall potential road traffic noise impacts of early operation of HPC, the following assessment scenarios have been examined:

- 2009 'Baseline Year' **(09BY);**
- 2021 'Do-Nothing' **(21DN)**, including:
  - forecast traffic growth including committed development only.
- 2021 'Do-Something' **(21DS)**, including:
  - forecast traffic growth including committed development;
  - ongoing construction of the Interim Spent Fuel Store (ISFS) building;
  - deconstruction of temporary associated developments;
  - early operation of HPC power station; and
  - operation of a western bypass of Cannington.

11.4.87 The traffic data used for the road traffic noise impact assessment has been taken from the validated Paramics micro-simulation traffic model built to assess the effect of the HPC Project (see **Chapter 10** of this volume). For each modelling scenario, the output traffic data from the Paramics model were factored using Automatic Traffic Count data to provide 18-hour AAWT data.

x. Significance of Impacts

11.4.88 Within this chapter, the generic descriptions used to define the level of impact significance and the likelihood of occurrence are the same as those provided in **Volume 1**, **Chapter 7**, where an Impact Assessment Matrix (IAM) is presented which compares the magnitude of an impact with the sensitivity of the receptor to determine the level of impact significance.

11.4.89 For the purpose of this assessment, mitigation measures have been proposed where there is an adverse impact of greater than minor significance and the impact magnitude, spatial scope and temporal nature make it appropriate to do so.

xi. Cumulative Impacts

11.4.90 Cumulative impacts of the HPC development are considered in **Volume 11**. This includes potential cumulative effects of construction works associated with the HPC development site and concurrent construction and operation of proposed associated development sites and/or other planned or reasonably foreseeable projects.

11.4.91 The cumulative assessment of all HPC construction and operation traffic is detailed in this chapter. All traffic noise impact assessments have assessed the 'Do-Something' scenario with future base ('Do-Nothing') scenarios. Future base (Reference Case) scenarios have included additional road traffic resulting from committed development. Individual road traffic noise impacts associated with these committed developments are therefore excluded from the cumulative assessment process detailed in **Volume 11**.

11.4.92 An assessment of potential in-combination effects of different noise sources during construction (road traffic on public highways and on-site construction machinery) is presented in this chapter.

f) Limitations, Constraints and Assumptions

11.4.93 Assumptions have been made about the type of equipment and machinery to be used during the construction works based upon likely methods to be adopted and previous development project experience, but contractors may adopt different working methods to reach execute the works. The assessment presented herein has therefore adopted a worst-case scenario wherever possible.

11.4.94 The use and number of fixed mechanical service plant associated with on-site accommodation campus buildings was informed by design details. Individual plant model and type were assumed, with typical sound power output data obtained from manufacturer publications.

11.4.95 A general noise emission rate (65dBA/m^2) was assumed for use of the two 5-a-side football pitches, based upon previous measurements, and use of these facilities prohibited between the hours of 08:00 and 22:00.

11.4.96 The permanent operational road traffic noise impacts associated with the HPC Project were assessed in 2021, when some residual activities associated with its construction would still be ongoing (deconstruction of associated development site, and construction of the ISFS building). Whilst this therefore does not represent a true operational scenario, it provides a worst-case assessment, following which the impacts would be reasonably assessed to be of lower significance.

11.4.97 It should be noted that CRTN is less reliable for low traffic flows. However, in the absence of an appropriate alternative standard with which to assess 'low flow traffic segments', CRTN was used. The magnitude criteria in **Table 11.6** have been developed to allow some consideration of this limitation in the methodology.

11.5 Baseline Environmental Characteristics

a) Introduction

11.5.1 This section presents the baseline environmental characteristics for the proposed HPC development site and surrounding area with specific reference to noise and vibration.

11.5.2 Eleven off-site highway improvements schemes will be included in the HPC Project DCO application. They are presented in the project description in **Volume 1**, **Chapter 2** of this ES. The schemes concern land that is presently within the highway, on highway land, such as verges, limited areas of hard surfacing and urban greenspace. Only two of the schemes (construction of new roundabouts at Washford Cross near Williton, and Sandford Corner, south of Cannington) have any potential to generate significant noise and vibration impacts and these are included within this baseline section. The location of the proposed works at Washford Cross, including the receptor locations is shown on **Figure 11.2a** with Sandford Corner shown on **Figure 11.2b**.

b) Noise Sensitive Receptors

11.5.3 A noise sensitive receptor is identified as a location where significant changes in environmental noise levels have potential to cause either detrimental or beneficial impacts. Considered effects typically include influence on the amenity of an area or location, potential disturbance to sleep, comfortable conversation or entertainment; degradation of an educational environment; or interruption of a religious ceremony.

11.5.4 Noise sensitive receptors in the vicinity of the HPC development site have principally been selected according to the likelihood of the impacts listed above to occur, and also to represent a group of locations, on a 'worst-case' basis, where similar impacts may occur.

11.5.5 Receptor locations are free-field (i.e. greater than 3.5m from any reflecting surface other than the ground) at three residential receptor locations and four public amenity locations (footpaths, permissive routes and Pixies Mound). The coastal footpath (the West Somerset Coast Path – see **Chapter 25** of this volume of the ES, Amenity and Recreation) baseline noise monitoring location is also considered to be representative of the intertidal zone for the assessment of the potential impacts to marine ecology and terrestrial ecology and ornithology discussed in **Chapters 19** and **20** of this volume of the ES.

11.5.6 The locations of noise sensitive receptor locations are identified in **Plates 11F.6** and **11F.8** of **Appendix 11F**.

11.5.7 The area around the HPC development site is primarily farmland, punctuated by scattered residences, farmhouses, and a number of small hamlets. Three noise sensitive receptors were selected from these, each at a distance greater than 1km from the nearest proposed UK EPR reactor unit. However, it is proposed that land within the operational extent of the SCPA (north of 144750mN) is used to enable construction, including spoil and rock storage areas, contractor works areas and a contractors accommodation campus. Activities in these locations will be at a closer approach (up to 80m to the nearest residential dwelling).

11.5.8 A summary of the key elements of each phase with respect to potential noise impacts on nearby receptor locations is provided below so that appropriateness of monitoring location selection is apparent.

c) Baseline Noise and Vibration Surveys

11.5.9 An initial baseline noise survey was undertaken between 27 April and 7 May 2009. The survey methodology and the identification of appropriate monitoring locations were agreed with EHOs of WSC and SDC prior to the survey.

11.5.10 The baseline noise survey was undertaken to establish the baseline acoustic climate at the nearest noise sensitive receptors. Full details of the survey are provided in the Factual Noise Report in **Appendix 11A** along with a complete set of monitoring data. **Table 11.11** below provides a summary of the range in measured daytime and night-time L_{Aeq} and L_{A90} sound level data.

Table 11.11: Summary of the Range in Baseline Noise Measurements at Key Noise Sensitive Receptors (Baseline noise survey April – May 2009)

Monitoring Location	Sound Pressure Level, dB (Free-Field)					
	Day (07:00-23:00)		Evening (19:00-23:00)		Night (23:00-07:00)	
	$L_{Aeq,T}$	$L_{A90,T}$	$L_{Aeq,T}$	$L_{A90,T}$	$L_{Aeq,T}$	$L_{A90,T}$
Northern HPC development site boundary (Coastal footpath)	42 – 45	36 – 37	45	41	47	42
Knighton Farm (residential)	44 – 48	30 – 33	37 – 41	26 – 31	43 – 46	26 – 31
Doggetts (residential)	40 – 59	32 – 45	35 – 63	30 – 37	35 – 52	27 – 45
Wick Farm (residential)	46 – 60	37 – 46	41 – 45	35 – 41	44 – 47	36 – 38
Southern boundary of the Southern Construction Phase Area	40 – 50	32 – 35	37	29	39	29
Hinkley Point power station – visitors centre	49 – 50	46 – 48	50	48	56	50

11.5.11 Baseline noise measurements were undertaken at a height of between 1.2m and 1.5m above ground level, in free-field conditions, in accordance with BS 7445:2003 Part 1 'Description and measurement of environmental noise – Guide to quantities and procedures' (Ref. 11.25). All measurements were undertaken during suitable meteorological conditions, conducive to obtaining reliable and accurate baseline data, in accordance with the relevant guidance documents.

11.5.12 Monitoring locations were selected to be representative of the nearest noise sensitive receptors, which are primarily residential dwellings in a rural setting. In addition, baseline noise measurements were also undertaken at a location in proximity to the coastal public footpath immediately to the north of the HPC development site, to assess the potential impacts on this public amenity.

11.5.13 The dominant noise sources identified during the baseline noise survey included local road traffic, birdsong and surf movement (at the coastal monitoring location). The determined ambient noise levels were typical of a rural environment, dropping very low during the night-time, and wind noise masking having an observable effect.

11.5.14 Although distant road traffic was occasionally audible due to the very low background noise levels, it is not considered a significant contributor to the acoustic environment at these rural locations. (Doggetts and Wick House are located over 5km north of the A39.) The baseline survey at Doggetts and Wick House included a bank holiday week-end, however, the measured ambient noise levels at these receptor locations were not notably dissimilar from those measured at Knighton Farm or in proximity to Bishops Farm House (southern boundary of the SCPA). The exception to this was elevated noise levels due to decking construction at Doggetts on the Saturday and Sunday (2 and 3 May 2009). It is therefore considered that neither school holiday nor bank holiday traffic is likely to significantly affect the acoustic climate at Doggetts or Wick House.

11.5.15 Increased wind speeds (up to 5-8m/s) occurred between 23:30 and 10:30 on the 4-5 May 2009 during the measurement survey at Doggetts and Wick House. Noise from the movement of nearby foliage in the wind is likely to have contributed to these measured noise levels, which are therefore represented by the upper night-time values in **Table 11.11** for the locations.

11.5.16 Further details of baseline noise levels and existing localised noise sources can be found in the Factual Noise Report (**Appendix 11A**).

11.5.17 In addition to the ambient noise monitoring locations identified in **Table 11.11**, a 24-hour survey was also undertaken at Mamsey House residential care home in Williton, located adjacent to the A39. The ambient noise levels at this location were therefore considered representative of the baseline conditions at Tropiquaria Zoo, which represents the closest potential noise sensitive receptor to the proposed Washford Cross roundabout construction. The ambient daytime noise level at this location was determined to be 62dB $L_{Aeq,16hr}$ (63dB $L_{Aeq,07:00\text{-}19:00}$).

11.5.18 **Table 11.12** provides typical existing daytime ambient noise level at each monitoring location, derived from the logarithmic average of the measured $L_{Aeq,15min}$ values between 07:00 and 19:00 hours. This data were used to determine predicted ambient noise levels during the construction phase (see **Table 11.18** and **Table 11.19**).

Table 11.12: Typical Existing Daytime Ambient Noise Level at Each Baseline Monitoring Location (Baseline noise survey April – May 2009)

Monitoring Location	Typical* Daytime Ambient Noise Level, dB $L_{Aeq,T}$
Northern development site boundary (Coastal footpath)	43
Knighton Farm (residential)	46
Doggetts (residential)	45
Wick Farm (residential)	46
Southern boundary of the Southern Construction Phase Area	41
Hinkley Point power station – visitors centre	49
Benhole Lane (south)	41
Benhole Lane (north)	43
Coastal footpath	43
Pixies Mound	49
Tropiquaria Zoo	63

Note: ** Derived from the arithmetic average of the measured $L_{Aeq,15min}$ values between 07:00 and 19:00 hours.*

11.5.19 Given the rural setting, the baseline noise monitoring data obtained at the southern boundary of the SCPA (see **Table 11.11** and **Table 11.12**) are assumed to be representative of the ambient noise climate at Bishops Farm House in Shurton (approximately 210m to the south of the monitoring location).

11.5.20 Further noise and vibration surveys were undertaken between 20 and 29 April 2010 in relation to trials to determine noise and vibration levels that might be associated with blasting works. The survey comprised continuous monitoring at Bayleys Brook House, approximately 1.6km south of the trial blasting pits within the Built Development Area West as illustrated in **Appendix A** to **Appendix 11B (**see **Figure A.1**). A second continuous monitoring location was approximately 800m east of the trial blasting pits and approximately 30m west of the Hinkley Point A boundary fence and access gate.

11.5.21 Throughout the monitoring period, the weather was generally dry and with above average temperatures for the time of year. On the day of the blasting tests (22 April 2010), an easterly wind prevailed at a speed of 2-7mph; the ambient temperature just exceeded the average maximum high (13˚C); and, there was no rainfall.

11.5.22 The results of this noise monitoring survey are presented in **Table 11.13** and **Table 11.14** and the results of the vibration measurements are presented in **Table 11.15** and **Table 11.16.**

Table 11.13: Summary of Ambient Noise Levels during Blasting Trials – Bayleys Brook House

Monitoring Period (Start Date)	Measurement Duration (T)	Sound Pressure Level, dB (Fast Time-Weighting)		
		$L_{Aeq,T}$	$L_{A90,T}$ *	$L_{Amax,T}$

11.5.23 The baseline noise levels used in the assessment of off-site traffic impacts have been calculated according to the CRTN methodology and are provided in **Appendix 11I**.

11.6 Assessment of Impacts

a) Introduction

11.6.1 For the proposed development, the impact assessment with respect to noise and vibration on the existing environment covers the following aspects:

- Potential increase in noise during the construction works associated with HPC (including site preparation and construction and operation of the temporary jetty);
- Potential vibration generated by the construction works associated with HPC (including site preparation and construction and operation of the temporary jetty);
- Potential change in off-site road traffic noise and vibration during the construction phase of HPC including the construction, operation and post-operation of associated development sites, and early operation of the HPC project; and
- Potential increase in noise from the operational HPC site.

11.6.2 Due to the typically low vibration levels that are likely to be generated (primarily by on-site vehicle movements), it is expected that operational activities would not result in perceptible vibration impacts on any of the sensitive receptors. Therefore, no further assessment of this operational vibration was undertaken. This was agreed in consultation meetings held with the EHO at WSC (see Section 11.4d).

b) Best Practice

11.6.3 Best practice measures will be undertaken and are considered to form part of the proposed development. They will be based on the principles set out in the **Environmental Management and Monitoring Plan** (**EMMP)** with further information provided within the **Subject Specific Management Plan: Noise and Vibration (SSMP)**. Measures forming part of the proposed development have been taken into account in the assessment of impacts. Measures will include the following.

i. Construction and Post-Operational Noise

11.6.4 The standard of good practice outlined in BS 5228-1 (Ref. 11.11) would be followed. This includes:

- continuous noisy plant to be housed in acoustic enclosures (where practicable);
- use of electrical items of plant instead of diesel plant in especially sensitive locations (where practicable);
- exhaust silencing and plant muffling equipment to be maintained in good working order;
- avoid unnecessary revving of engines and switch off equipment;
- minimise drop heights of materials; and
- start up plant sequentially rather than all together.

11.6.5 In addition, a formal system would be put in place during the works which identifies the roles and responsibilities of site staff regarding a noise and vibration complaint action procedure. Site logs will be maintained; detailing all complaints received relating to noise and/or vibration disturbance impacts and the corresponding action taken including the response made to each complainant. Liaison would be undertaken with the local community ensuring they have advance notice of the schedule of works.

ii. Construction Vibration

11.6.6 BS 5228-2 (Ref 11.17) gives detailed advice on standard good construction practice for minimising impacts from construction vibration. It would be a requirement of any construction contract that the constructors comply with the recommendations in these standards, in order to achieve specific vibration emissions criteria for the site.

11.6.7 Measures to reduce the predicted impact from piling activities on site would include:

- pre-boring of the upper strata; and
- informing residents in advance of piling operations.

iii. Operational Noise

11.6.8 The 'rating' of a noise automatically increases when tones, whines or impulses are noticed in the audible noise. Care will therefore be taken, both in identifying particular tonal and impulsive sources on the plant and to ensure that these will be adequately silenced by design. The most significant sources of tonal energy are likely to be fans, which will produce tonal noise typically at blade passing frequency. Transformers will also contain middle to low frequency tonal energy at the second and fourth harmonics (100Hz and 200Hz).

11.6.9 Sound attenuation, in the form of acoustic barriers and enclosures, will be considered where safety and other operational requirements permit. This will include enclosures to the refrigeration units mounted at roof level on nuclear island buildings. Other noise control treatments that will be considered during detailed design and installation are listed below:

- acoustic attenuators on exhaust stacks, ventilation intakes and discharge points;
- steam vents to be fitted with vent silencers; and
- lagging of steam pipes and control valves.

c) Construction Impacts

11.6.10 The assessment of construction activities was undertaken with regard to potential noise and vibration impacts to local residential properties, and noise-sensitive public amenity receptors.

i. Construction – Noise from On-Site Construction Activities

11.6.11 The primary noise and vibration sources during the HPC construction phase are those typical of an industrial construction site. Potential impacts will vary through the following major stages of the development:

- mobilisation;
- excavation, levelling and preparation of working platforms;
- construction of a temporary jetty;
- construction of temporary and permanent access roads and parking areas;
- construction of the sea wall defences;
- deep excavations and tunnelling;
- construction of a workers accommodation campus;
- building construction;
- construction of the National Grid 400kV substation; and,
- EPR commissioning.

11.6.12 Throughout the construction phase the volume of construction traffic on the road network will vary considerably, with the potential to affect noise sensitive receptors along the roads connecting the HPC development site with the M5 motorway to the south-east.

11.6.13 In addition to the above construction activities, noise resulting from occupation of the proposed workers accommodation campus on the SCPA will have the potential to impact upon existing nearby dwellings.

11.6.14 In order to evaluate the noise generation during the HPC construction phase it is necessary to define the various activities that will be undertaken. Construction contractors may use different working methods and plant. However, it is possible to undertake a generic construction assessment of noise and vibration impacts based on expected methods of working gained from experience with previous similar developments.

11.6.15 For the purpose of predicting construction noise levels a series of typical activities have been assessed based on likely closest approach and typical plant working.

11.6.16 As detailed in **Appendix 11D**, typical construction plant that are likely to be used on-site include the following:

- excavators;
- cranes;
- earthmoving plant;
- batching plant;
- compressors;
- diesel generators;
- road-going HGVs removing spoils and delivering material (to be minimised by the construction of a jetty to be used for aggregates and cement delivery);
- hand held tools such as disc cutters, grinders and nut runners;
- piling plant;
- concrete pumping plant and trucks;
- rock breakers and crushing plant;
- dewatering pumps; and
- tunnel boring plant.

11.6.17 In addition to the above, blasting of fresh rock may be required during excavations. Whilst blasting might generate significant noise emissions, they will be very short-term. Provided that local residents are given prior notification of blasting events, thereby reducing the potential startle effect, the overall significance in terms of noise impacts is far less significant than longer term activities, assessed below.

11.6.18 The detailed noise prediction calculations presented in **Appendix 11D** and summarised below consider each activity independently. In reality, many of these activities will occur concurrently, and therefore an additional noise prediction modelling exercise has been undertaken to enable a prediction of the effects of these concurrent activities. Details and outputs from this modelling study are provided in **Appendix 11E**. As described above, the following five discrete modelling scenarios (each representing a single point during the HPC site preparation works and construction programme) were considered (see **Table 11.4** for details of assumed activities in each scenario):

- Scenario A – Approximately two months into the site preparation works;
- Scenario B – Approximately six months into the site preparation works;
- Scenario C – Deep excavation (anticipated to commence 2013);
- Scenario D – UK EPR reactor unit construction (anticipated to commence 2014); and
- Scenario E – Night-time construction/maintenance activities (anticipated to commence Q4 2014).

11.6.19 For each scenario, a full complement of assumed plant and equipment, associated sound power level (SWL) and prediction routines, to the requirements of BS 5228-1 (Ref. 11.11), is included in the tables in **Appendix 11D**.

11.6.20 The BS 5228-1 prediction method uses the shortest distance from the receptor to the construction activities. The nearest edge of the relevant construction works site has been used as the calculation point for equipment/plant classed as 'mobile' (loaders and excavators) and similarly the edge of the site has been used as the calculation point for equipment/plant classed as 'fixed' (generators and compressors.).

11.6.21 Predictions of construction activity noise levels at the receptor locations has taken account of features that may affect propagation, such as ground absorption; and, screening by the natural and/or formed topography. Other factors, such as the length of the working traverse and the machinery 'on-time' are also included within the calculations.

Construction Noise from Individual Activities

11.6.22 Predicted noise levels, detailed in **Appendix 11D** and summarised in **Table 11.17**, are therefore worst-case and in practice, the actual noise levels may not attain those predicted. It should be noted that predicted noise levels are based upon the assumption that standard good construction practice measures will be applied. Such measures to control noise impacts are outlined in BS 5228-1:2009. Therefore, source noise data, used in the construction noise calculations, for specified plant (provided in BS 5228-1:2009) is based upon well-maintained equipment, and where appropriate integral acoustic enclosures.

Table 11.17: Summary of Worst-case Predicted Construction Noise Levels at the Nearest Receptor Locations to Hinkley Point C Construction Works based on BS 5228 Calculations (excluding existing ambient noise)

Predicted Worst-Case Daytime Noise Levels#, dB $L_{Aeq,1h}$								
Construction Phase (see key)	Receptor Location

1 Upgrade of roads
2 Sea defence construction (using current design)
3 Construction of bridge over Bum Brook
4 Construction of emergency access road
5 Deep excavation and concrete substitution
6 Construction of temporary and permanent buildings (non-nuclear)
7 Tunnelling
8 Construction of Nuclear Island buildings
9 Construction of accommodation campus
10 Construction of the National Grid 400kV substation
11 Final landscaping
12 Early landscaping
13 Construction of temporary jetty and aggregates handling facility

Predicted construction noise levels do not include existing ambient noise levels

Receptor (R) locations shown in Figure 11.1

11.6.23 The predicted construction noise levels do not include existing ambient noise levels at the respective receptor locations and are therefore not measurable for comparison with the proposed noise limits in **Table 11.3**. Baseline ambient noise levels have therefore been added to the predicted construction noise levels above, and presented in **Table 11.18** below. The baseline ambient values used are the arithmetic mean of the measured daytime (07:00-19:00) $L_{Aeq,15min}$ values.

Table 11.18: Summary of Worst-case Predicted Daytime Construction Noise Levels at the Nearest Receptor Locations to Hinkley Point C Construction Works based on BS 5228 Calculations

11 Final landscaping
12 Early restoration landscaping
13 Construction of temporary jetty and aggregates handling facility

Predicted construction noise levels do not include existing ambient noise levels (see **Table 11.12**)

Receptor (**R**) locations shown in **Figure 11.1**

11.6.24 From **Table 11.17** and **Table 11.18** and the calculations in **Appendix 11D**, it can be seen that, during short-term activities associated with construction of the emergency access road, close to Bishops Farm House, the daytime 65dB $L_{Aeq,1h}$ criterion is likely to be exceeded.

11.6.25 Similarly, worst-case predicted noise levels during early landscaping and final landscaping operations at the closest approach to the southern boundary of the SCPA are likely to exceed the adopted 65dB $L_{Aeq,1h}$ daytime criterion at Doggetts. Due to their proximity to residential dwellings, these activities will be restricted to normal working daytime only.

11.6.26 As a result of this worst-case assessment with all plant working at the closest approach, the overall impact of construction noise during daytime construction of the emergency access road and for short periods during the final landscaping operations is assessed as being of **major adverse** significance at the assessed residential receptor locations.

11.6.27 The noise impact at the assessed residential receptor locations of all other construction activities, individually, associated with the HPC development site is assessed as being of **minor** to **moderate adverse** significance due to a combination of the additional distance attenuation and physical screening by the natural and formed topographical features. This assessment is applicable for both daytime and evening periods, as defined in **Table 11.13**. It is evident however, that some activities would result in more significant impacts at residential dwellings if undertaken at night. Based on this, the following activities would be prohibited at night (23:00-07:00 hours):

- construction of the emergency access road and its bridge over Bum Brook;
- landscaping works south of the 144750mN site boundary;
- some activities associated with deep excavation works (rock ripping and crushing); and
- construction of the temporary accommodation campus.

11.6.28 At the assessed public amenity receptor location at Pixies Mound, short-term high magnitude construction noise levels are predicted during the nearby upgrade of roads (two to three months). The significance of this noise magnitude to an outdoor amenity location is assessed as being of **moderate adverse** significance, using the magnitude criteria and sensitivity defined in **Table 11.3** and **Table 11.1**, respectively. Similarly, at the assessed coastal footpath location during construction of the temporary jetty, high magnitude noise levels are predicted. As a worst-case assessment, the significance of this noise magnitude is also assessed as **moderate adverse**.

11.6.29 Due to the availability of suitable tide levels, it is proposed that construction of the jetty in the marine environment would continue during the night. The predicted construction noise level presented in **Table 11.18** includes earthworks associated with the landward aggregates handling facility (daytime only), and therefore does not represent the night-time noise impacts of jetty construction. At night, seaward jetty construction, which would be a further 700m north of the nearest residential dwellings (approximately 1.9km) than the assessed works at the aggregates handling facility, with significant noise screening provided by the coastal cliffs (up to 15m high). The night-time jetty construction noise would therefore be well below the threshold criterion of 45dB $L_{Aeq,1hr}$ (refer to **Table 11.2**), and the impact significance is therefore assessed as **minor adverse**.

11.6.30 During final landscaping activities close to the site boundary, short-term noise impacts of **moderate adverse** significance are also predicted at all three assessed public footpath receptors. However, it should be noted that, for the majority of this phase of works, when plant are operating further within the site boundary, the noise impacts will be less significant.

11.6.31 The magnitude assigned to public amenity receptors is given as if the receptors at these locations would be stationary. However, human receptors at these amenity locations will be transient and are therefore very unlikely to be subject to the same exposure duration as defined for fixed property receptor locations. Therefore, whilst the predicted noise levels might result in short-term disturbance, the impact on a person's enjoyment of these amenities is likely to be less significant than has been assessed.

11.6.32 At each of the assessed outdoor public amenity receptor locations, during all other assessed phases of works, the noise magnitude will vary between very low and medium. Therefore the impact significance is predicted to be **negligible** to **minor adverse**, using the magnitude criteria and sensitivity defined in **Table 11.3** and **Table 11.1**.

Construction Noise from Concurrent Activities

11.6.33 The prediction of noise from individual construction activities in the section above provides a robust assessment of acute impacts with all respective noise-generating sources located at the shortest distance to respective sensitive receptors. In order to better understand what the long-term construction noise impacts are likely to be, a detailed noise prediction model was developed (**Appendix 11E**) which assumed all anticipated operational construction plant and equipment at a given time. For each assessed scenario, the location of operational construction plant was therefore not necessarily at the closest possible working area to individual receptors.

11.6.34 **Table 11.19**, below, provides a summary of the predicted ambient noise levels during concurrent construction activities. By their nature, scenarios that assess later phases of the construction works take into account earlier construction works which effect noise propagation. This includes the formation of landscape features, including early restoration south of the 144750mN boundary and the formation of a boundary earth bund, west of the aggregates handling facility. These design features therefore provide additional acoustic screening to later construction phases.

11.6.35 As presented in **Table 11.18**, the predicted construction noise levels in **Table 11.19**, determined by detailed noise propagation modelling, include typical baseline ambient noise levels (see **Table 11.12**). Predicted noise contours, which exclude baseline ambient noise levels, for the assessed scenarios are shown in **Figures 11.3** to **11.7**.

Table 11.19: Summary of Predicted Ambient Noise Levels at Identified Sensitive Receptor Locations during Combined Hinkley Point C Construction Activities (including existing ambient noise)

Receptor Location	Type	Predicted $L_{Aeq,T}$ Sound Pressure Level#, dB (Free-Field)				
		Scenario (See Notes Below)

Notes: *# Including typical ambient daytime noise level (see **Table 11.12**)*

** Night-time works excluding ambient noise levels*

Scenario A includes site preparation activities (second month).

Scenario B includes site preparation activities (sixth month).

*Scenario C includes construction activities 5, 6, 7, 9 and 10 (Ref. **Table 11.18**), and operation of the aggregates jetty.*

*Scenario D includes construction activities 6, 7, 8 and 10 (Ref. **Table 11.18**), and operation of the aggregates jetty.*

*Scenario E includes construction activities 6, 7 and 8 (Ref. **Table 11.18**), and operation of the aggregates jetty.*

*Receptor (R) locations shown in **Figure 11.1***

11.6.36 The predicted noise levels represent the coincidence of five discrete and specific moments in time assumed during the site preparation works and main HPC construction phases. They were selected to assess the most substantial works activities (in terms of duration) on the site, such as deep excavation and power station construction. Some activities identified in **Table 11.18** were not, however, captured in the modelled assessments due to their short-term nature (early landscaping will be less than six months duration). In addition, later works phases, including internal mechanical and electrical plant installation, were not considered significant noise sources in contrast with the assessed earthworks and building construction phases.

11.6.37 Activities associated with construction of the proposed aggregates jetty were also not included within the assessed detailed noise prediction model. It is anticipated that these works would commence after the assessed 'Scenario B' (6-months into the site preparation works) and would be complete prior to 'Scenario C' when the site preparation works are complete and the deeper excavations and other main construction works are underway. The potential noise impacts of the construction activities associated with the jetty during the day would be most significant at the coastal footpath receptor location. At other assessed locations, noise from other ongoing activities associated with the site preparation works would be of far greater significance.

11.6.38 Construction of the jetty would be the only night-time activity undertaken during the preliminary works, and therefore the individual construction noise assessment presented in the section above is applicable. Jetty construction at night would result in an impact of **minor adverse** significance to the nearest residential properties.

11.6.39 At residential dwellings, the detailed modelling predicts low to very low magnitude ambient noise levels during these substantial construction works phases (note that Scenarios A and B assess only site preparation works undertaken during daytime periods only). This is assessed to result in a noise impact of **minor adverse** significance at all assessed residential receptors locations.

11.6.40 Similarly, during the night-time (Scenario E only) the predictions in **Table 11.19** indicate a low construction noise magnitude at all assessed residential dwellings. The significance of noise from night-time construction activities is therefore assessed as **minor adverse**.

11.6.41 At the assessed public amenity receptor locations at Benhole Lane (north) and at Pixies Mound, medium magnitude site preparation works noise levels (daytime only) are predicted for 'Scenario A'. These result from earthworks close to the site boundary, comprising cutting and forming of the working platforms in the northern Built Development Areas. The significance of the noise impact to these public amenity locations during these periods is assessed as **minor adverse**, using the magnitude criteria and sensitivity defined in **Table 11.13** and **Table 11.1**, respectively.

11.6.42 At the coastal footpath, very low to low noise magnitude levels are predicted during the assessed scenarios (at a receptor of low sensitivity) and, therefore, the significance of the impact is assessed as **minor adverse**. As noted above, the assessed scenarios do not include construction of the temporary jetty. During jetty construction, it is predicted (see **Table 11.18**) that a medium-term impact of **moderate adverse** significance would result at the coastal footpath,

11.6.43 During the evening period (Mon-Sat), a medium noise magnitude is determined for 'Scenario D' at Benhole Lane (north), due to bulldozers operating in the area of the aggregates handling facility, and at Pixies Mound, due to the National Grid 400kV substation construction (cranes, compressors and electric bolters associated with mechanical and electrical (plant installation). The significance of these impacts is assessed as **minor adverse**.

11.6.44 Walkers using these amenity locations are likely to be transient and are unlikely to be subject to the same exposure duration as defined for fixed property receptor locations. Therefore, whilst the predicted noise levels might result in periodic disturbance, the impact on a person's enjoyment of the amenity is likely to be less significant than has been assessed.

11.6.45 The nature of construction work means that the worst-case situation with the plant working at closest approach may exist for only a matter of days or even hours and there would be regular periods, even during the course of a single day, when the assumed noise generating plant would not be in operation during breaks or changes of working routine.

11.6.46 Blasting of the bedrock (if required) during excavation works in unweathered rock at the two UK EPR reactor unit sites would be approximately 1km north of the nearest private residential property (Doggetts). Given the low magnitude blasts that would be created, and this separation distance, the short-term noise impacts of these events is unlikely to be significant in the context of the proposed noise emission limits in **Table 11.2**. It is also unlikely that impulsive noise from these events would be sufficient to cause a startle response from local residents.

ii. Construction – Noise from Occupation and Use of On-Site Campus Accommodation and Associated Leisure Facilities

11.6.47 This contractor's accommodation campus will be located north of the proposed earth bund which will provide acoustic screening, with the nearest residential accommodation blocks positioned approximately 100m north of Doggetts.

11.6.48 The closest campus amenities (such as shops and leisure facilities) will be approximately 180m north of Doggetts. Mechanical service units (including air-conditioning and refrigeration plant) associated with amenity buildings will therefore be located at a significant distance from existing residential dwellings. Furthermore, there is the opportunity for these items of plant to be located on the northern façades of the respective buildings, thereby providing significant acoustic screening. Similarly, building elements of the proposed amenity blocks will be designed to sufficiently reduce noise breakout.

11.6.49 Acoustic design and control measures will be incorporated to ensure that noise emissions from occupation and amenity use do not exceed 5dB above the $L_{A90,T}$ background level (or 30dB, whichever is greater) at the nearest existing residential properties. The overall noise impact upon existing residential dwellings is therefore assessed as **minor adverse**.

11.6.50 In addition to existing noise sensitive receptors, potential noise impacts to residents of the proposed on-site campus accommodation and associated leisure facilities may occur. Given that this facility will represent the closest residential receptor location to the proposed construction works, noise levels at the campus are likely to exceed those predicted above. However, as the campus forms part of the construction, it will be managed by the contractor's site management, who will be responsible for ensuring adequate living and amenity conditions. Design of the campus buildings, and in particular glazing and ventilation design, will ensure that internal noise levels (in sensitive rooms) are adequate for reasonable resting and sleeping conditions to prevail. This will take account of the need to provide suitable internal amenity during the daytime, when night-shift staff are resting or sleeping (should night-shift staff be accommodated at this campus).

iii. Construction – Noise from Off-Site Traffic

11.6.51 Noise from road traffic generated during the HPC construction phase will have the potential to impact upon occupants of residential dwellings and other sensitive receptors, such as schools and places of worship, on the highway network. The peak levels of construction related traffic are predicted to be 2013 (peak HGV movements) and 2016 (peak workforce numbers). The predicted distribution of the construction works traffic on the highway network in these years has been used to assess the potential noise impacts by comparison of the ‘Do-Nothing’ scenario with the respective ‘Do-Something’ scenarios, as described in Section 11.4.

Daily (18-Hour) Road Traffic Noise

11.6.52 The assessed daily (18-hour AAWT) traffic data in 2013 is based upon the **average day**, during the **peak quarter** of the **peak year** for HGV movements. Although the assessment specifically considers this peak period, i.e. a reasonable worst-case scenario, it should be recognised that, throughout the long-term HPC construction phase there would be a sustained level of generated road traffic (notably HGVs and buses).

11.6.53 **Table 11I.1** in **Appendix 11I** provides a list of assessed road sections. **Table 11I.2** of **Appendix 11I** presents the base and forecast traffic flows. **Table 11I.3** of **Appendix 11I** presents the calculated Basic Noise Level (BNL), including correction for percentage HGV content and average vehicle speed, for each assessed road section.

11.6.54 Comparison between the calculated daily BNL for the 2013 ‘Do-Nothing’ and ‘Do-Something’ scenarios indicates that the greatest change in daily road traffic noise is predicted on High Street in Cannington, where an increase of +7.0dB(A) is predicted. Using the criteria presented in **Table 11.5**, this represents a high magnitude of change for receptors of medium value and sensitivity. The significance of impact for this assessed road section is therefore predicted to be **major adverse**.

11.6.55 Again, in 2013, before the Cannington bypass is operational, a medium magnitude change in daily road traffic noise is predicted on the C182 (Rodway) within Cannington. This impact is therefore assessed as being of **moderate adverse** significance.

11.6.56 A daily road traffic noise impact of **moderate adverse** significance is also predicted on the A39 southern bypass of Cannington throughout the HPC construction period.

11.6.57 For all other assessed roads on the network, a potential increase in daily road traffic noise due to HPC construction traffic ranging from +0.1 to +2.7dB(A) is predicted in 2013. Using the criteria presented in **Table 11.5**, the magnitude of change is assessed as either low or very low on receptors of medium value and sensitivity. This represents a predicted impact of **minor adverse** significance.

11.6.58 A comparison has also been undertaken of the potential change in daily road traffic noise between the calculated BNL in the 2016 'Do-Nothing' and 'Do-Something' scenarios. During this period, the A39 southern Cannington bypass is predicted to experience the greatest change of +4.3dB(A), due to diversion of HPC and public traffic on to the western bypass. This represents a medium magnitude of change and therefore an impact of **moderate adverse** significance on receptors of medium value and sensitivity along this road. Along all other assessed links, the magnitude of change in daily road traffic noise is assessed as either low or very low on receptors of medium value and sensitivity in 2016. The significance of impact is therefore assessed as **minor adverse**.

11.6.59 Beneficial impacts are predicted in 2016 in Cannington with the bypass in place on the C182 (Rodway) south of the northern roundabout of the bypass and Main Road/Fore Street through Cannington. On these links a daily road traffic noise reduction of -2.6dB(A) and -2.1dB(A) respectively is predicted, due to diversion of HPC and public traffic on to the western bypass. This represents a medium and low magnitude change (on receptors of medium value and sensitivity) when compared with the criteria presented in **Table 11.5**. The noise impact is assessed as being of **moderate** and **minor beneficial** significance, respectively.

Hourly Road Traffic Noise

11.6.60 In addition to the above assessment of noise from 18-hour traffic flows over the highway network during HPC construction, it is necessary to undertake an assessment of potential impacts of vehicle movements, associated with changes of shift at the HPC development site during sensitive periods, as well as peak HGV movements during the day. **Tables 11I.4** to **11I.10** in **Appendix 11I** presents the forecast hourly traffic flows on all assessed road sections for the following periods:

- 05:00-07:00 – bus movements (start of shift 1) in the early morning development peak;
- 12:00-13:00 – peak HGV movements during the day; and
- 23:00-01:00 – bus movements (end of shift 2) in the late evening development peak.

11.6.61 The hourly road traffic noise assessments of these periods are therefore worst-case periods taking account of the greatest sensitivity (early morning and late evening), and peak total traffic flows (HGVs during the daytime). The movement of HGVs, from the HPC development site and the proposed freight logistic facilities would be prohibited between the hours of 22:00-07:00.

11.6.62 The assessment of hourly road traffic noise between the hours of 12:00-13:00 is an absolute worst-case, taking the forecast **peak day** in the assessed **peak year**. This was assessed in this way primarily so that the transport assessment ensured that junctions had sufficient capacity throughout the HPC construction phase.

11.6.63 The assessment of hourly road traffic noise in the assessed early morning and late evening periods is a worst-case, based on a regular bus timetable for transporting the workforce to and from the HPC development site.

11.6.64 **Tables 11I.19** and **11I.20** in **Appendix 11I** show the predicted change in the BNL for each assessed hour in 2013 and 2016, respectively. **Tables 11I.29** and **11I.30** in **Appendix 11I** show the noise change magnitude for each assessed hour in 2013 and 2016, respectively.

HPC Construction – 2013 Hourly Traffic Noise Impacts

11.6.65 In 2013, prior to the opening of the proposed Cannington bypass, the greatest changes in hourly BNL are predicted in Cannington. The C182 (Rodway) (AC) and High Street (U) are predicted to experience **major adverse** (on receptors of medium value and sensitivity) impacts during the assessed early morning and late evening hours. This impact would last approximately 18 months prior to the opening of the Cannington bypass.

11.6.66 The A39 eastwards, from the southern Cannington bypass (P) through Sandford Hill (R) and Wembdon Rise (S) are predicted to experience a **major adverse** impact during the assessed early morning and late evening hours.

11.6.67 In Bridgwater, along the A39 Broadway (K5), the significance of impact is assessed as **major adverse** (on receptors of medium value and sensitivity) between the hours of 05:00-06:00 and 23:00-00:00. A **moderate adverse** early morning and late evening road traffic noise impact is predicted on other sections of the A39 through Bridgwater (links K1-K4).

11.6.68 Early morning and late evening road traffic noise impacts of **moderate** to **major adverse** significance were determined on the Western Way Northern Distributor Route (NDR) between Wylds Road at the Quantock Roundabout (links AE, AA, AB and Y). Whilst, an impact of **moderate adverse** significance is predicted along Wylds Road (AD), which is an industrial zone and therefore the designated route for night-time bus movements.

11.6.69 A **moderate adverse** traffic noise impact is also predicted between the hours of 05:00-06:00 and 23:00-00:00 on the A38 Bristol Road (links D and G) between Bridgwater and the proposed J23 development.

11.6.70 A medium magnitude of change is predicted on the Stogursey link between the hours of 06:00-07:00, on receptors of medium value and sensitivity. The significance of impact is therefore assessed as **moderate adverse**. During other assessed night-time hours, the predicted $L_{Aeq\ 1hour}$ is below 55dB, and therefore the road traffic noise impact is assessed as being of **minor adverse** significance. It should be noted that this assessment assumes that all transport of HPC workforce to and from the Williton park and ride site would use this route. In reality, some of these services will route via the A39, through Cannington, with others (minibus only) travelling through Stringston and Stogursey to pick up construction staff that are resident there.

11.6.71 A medium magnitude of change is also predicted for some of the assessed late-evening hours on roads through Williton (Links 2, 3, 4, 6, and 10). This represents an impact of **moderate adverse** significance.

11.6.72 During the daytime, in the hour during which peak vehicles movements associated with the HPC development would occur, the C182 (Rodway) (AC) and High Street (U) are predicted to experience **moderate** and **major adverse** significance impacts, respectively (on receptors of medium value and sensitivity). These impacts would last approximately 18 months, until the western Cannington bypass is operational.

11.6.73 Daytime road traffic noise impacts of **moderate adverse** significance are also predicted on the A39, southern Cannington bypass (P) and Wembdon Rise (S).

11.6.74 On all other assessed roads, in 2013, the magnitude of daytime road traffic noise change is assessed as either low or very low on receptors of medium value and sensitivity. Therefore, the impact is assessed as being of **minor adverse** significance on these links.

HPC Construction – 2016 Hourly Traffic Noise Impacts

11.6.75 In 2016, following the opening of the proposed Cannington bypass, an impact of **major adverse** significance (on receptors of medium value and sensitivity) is predicted on the A39 southern Cannington bypass (P) eastwards towards Bridgwater to Wembdon Rise (links R and S) during the majority of assessed early morning/late evening hours. An impact of this significance is also predicted along the proposed bypass.

11.6.76 Within Cannington village, impacts of **minor** to **moderate beneficial** significance are predicted on the C182 (Rodway) (AC), High Street (U) and Main Road/Fore Street (ZD) on receptors of medium value and sensitivity (as a result of HPC traffic and other vehicles using the proposed Cannington bypass).

11.6.77 In Bridgwater, early morning/late-evening road traffic impacts of **moderate** to **major adverse** significance are predicted along both designated routes for HPC construction traffic. Namely along the A39 between Taunton Road and Wembdon Road (links K1-K5) and between the A38 Bristol Road and Wembdon Road (links AA, AB, AD, AE and Y).

11.6.78 A **moderate adverse** traffic noise impact is also predicted on the A38 Bristol Road between Bridgwater and the proposed J23 development. These impacts are predicted occur between the hours of 05:00-06:00 and 23:00-00:00 (link D), and 05:00-06:00 (link G).

11.6.79 The impact of hourly traffic movements in Williton during the assessed hours is **moderate adverse** on the routes (mainly the A39) through Williton (Links 2-4, 6 and 10) on receptors of medium value and sensitivity.

11.6.80 In addition, the impact along the route that minibuses from the proposed Williton park and ride site will take (through Stringston and Stogursey) is assessed as being of **moderate adverse** significance during all hours excluding 00:00-01:00. A medium magnitude of noise level change is also predicted on the Stogursey link between the hours of 05:00-06:00 and 23:00-00:00, on receptors of medium value and sensitivity. The significance of impact is therefore assessed as **moderate adverse**. Between the hours of 00:00-01:00, the predicted $L_{Aeq\ 1hour}$ is below 55dB, and therefore the road traffic noise impact is assessed as being of **minor adverse** significance. It should be noted that this assessment assumes that all transport of HPC workforce to and from the Williton park and ride site would use this route. In reality, some of these services will route via the A39, through Cannington, with others (minibus only) travelling through Stringston and Stogursey to pick up construction staff that are resident there.

11.6.81 On all other assessed roads, in 2016, the magnitude of road traffic noise change is assessed as either low or very low on receptors of medium value and sensitivity. Therefore, the impact is assessed as being of **minor adverse** significance on these links.

11.6.82 During the daytime, in the hour during which peak HGV movements associated with the HPC development would occur, the A39 southern Cannington bypass (P) predicted to experience an impact of **major adverse** significance (on receptors of medium value and sensitivity). This is due to the diversion of HPC and public traffic towards the western Cannington bypass.

11.6.83 Daytime road traffic noise impacts during the peak hour of HGV movements of **moderate adverse** significance are predicted on the Northern Distributor Route in Bridgwater (links AA, AB, AE, Y and ZE), as well as the A39 between Bridgwater and Cannington (links R and S).

11.6.84 The C182 (Rodway) (AC) is predicted to experience an impact of **moderate beneficial** significance, due to HPC construction and public traffic diverting away from the village centre and on to the western Cannington bypass.

11.6.85 On all other assessed roads, in 2016, the magnitude of daytime road traffic noise change is assessed as either low or very low on receptors of medium value and sensitivity. Therefore, the impact is assessed as being of **minor adverse** significance on these links.

Construction – Noise from Highway Improvements

11.6.86 As part of the proposed HPC development, eleven highway improvements schemes are proposed to existing public highways. The proposed works, are described in **Volume 1**, **Chapter 2**.

11.6.87 For the eleven schemes the only works considered to be of sufficient scale to cause significant adverse noise effects are associated with construction of new roundabouts; at the junction of the A39 and B3190 at Washford Cross, near the proposed Williton park and ride site, and at the junction of the A39 and B3339 at Sandford Corner, south of Cannington. All other proposed highways improvements would require small-scale works lasting for very short periods, and would be completed entirely within the existing highway boundaries.

11.6.88 Construction of the Washford Cross roundabout, which will replace the existing priority junction, is expected to last a maximum of 6 months. The closest noise sensitive receptor to this proposed work is Tropiquaria Zoo (25m to the north-west). The predicted noise level (see **Table 11D.10** of **Appendix 11D**) associated with road construction works at the closest outdoor area of Tropiquaria Zoo is 74dB $L_{Aeq,12h}$ which includes a typical ambient noise level of 63dB $L_{Aeq,day}$ (see **Table 11.2**).

11.6.89 This construction noise magnitude is therefore assessed as high (see **Table 11.7**) on receptors of low importance and sensitivity. The impact of these short-term activities is predicted to be of **moderate adverse** significance. However, human receptors at this location will be transient and are therefore very unlikely to be subject to the same exposure duration as defined for fixed residential receptor locations. Therefore, whilst the predicted noise levels might result in short-term disturbance, the impact on a person's enjoyment of the amenity is likely to be less significant than has been assessed.

11.6.90 The closest residential noise sensitive receptors to the proposed work are Shells Cottages (approximately 200m south-west). At these properties, the predicted road construction noise level (see **Table 11D.11** of **Appendix 11D**) is 54dB $L_{Aeq,12h}$ excluding ambient noise level. This construction noise magnitude is therefore likely to be assessed as low (see **Table 11.7**) on receptors of medium importance and sensitivity. The impact of these short-term activities is predicted to be of **minor adverse** significance.

11.6.91 Construction of the Sandford Corner roundabout, which will replace the existing priority junctions, is also expected to last a maximum of 6 months. The closest noise sensitive receptor to this proposed work is a single residential dwelling approximately 25m to the east and south-east. The predicted noise level (see **Table 11D.12** of **Appendix 11D**) associated with road construction works at this property is 73dB $L_{Aeq,12h}$ excluding ambient noise level. This construction noise magnitude is therefore likely to be assessed as medium (see **Table 11.7** on receptors of medium importance and sensitivity. The impact of these short-term activities is predicted to be of **moderate adverse** significance.

11.6.92 The nature of the construction works means that the conservative situation predicted may exist for only a matter of days, or even hours. There would be regular periods, even during the course of a single day, when the assumed plant would not be in operation, for example during breaks or changes of working routine.

iv. Construction – Vibration from On-Site Construction Activities (excluding blasting) and Highway Improvements Works

11.6.93 Surface plant such as cranes, compressors and generators are not recognised as sources of high levels of environmental vibration. Reference to Figure 1 of 'Control of Vibration and Noise during Piling' (British Steel, 1998 (Ref. 11.26) confirms that, even at a closest distance of 10m, peak particle velocities (PPV) significantly less than 5mm/s are generated by such plant. For example, a bulldozer may generate a PPV of approximately 0.6mm/s and a 'heavy lorry on poor road surface' a PPV of less than 0.1mm/s at 10m. These values are well below limits at which even cosmetic building damage becomes likely (15mm/s (BS 5228-2 (Ref. 11.17)).

11.6.94 Two methods of piling are presently proposed on the HPC development site. These are vibratory sheet piling and continuous flight augur (CFA) piling. Each of these generate relatively low levels of vibration compared with hammer driven piling techniques. Given the distance separations between the site of potential piling operations and the nearest residential dwellings (greater than 1km), vibration levels generated during normal construction activities on the SCPA are likely to be well below the perceptibility level. Notwithstanding this, vibration impacts will be minimised to ensure sensitive activities and machinery associated with nuclear power generation at the operational Hinkley Point B site (approximately 600m to the east) are not adversely affected by the works. Vibration impacts of typical construction activities on the development site are assessed as **minor adverse** at the nearest residential receptors and buildings at the Hinkley Point A and B stations.

v. Construction – Vibration from Blasting

11.6.95 During deep excavation, blasting of the bedrock will be required. This is likely to involve the drilling of a number of boreholes within a rock face, into which are placed the necessary explosive charges. Blast events will be localised and therefore a minimum explosive charge will used to achieve the required rock extraction rate.

11.6.96 Blasting events, however, can be a cause for concern for neighbouring residents due to firstly the sound, which will heighten senses, followed by the possibility of secondary vibrations at audible frequencies caused by air overpressure. This is only likely to occur following surface blasting, where topographical screening of the air overpressure is minimal. In respect of possible effects of this, BS 6472-2 (Ref. 11.21) states that there is *"…no known evidence of structural damage occurring in the United Kingdom as a result of air overpressure levels from blasting associated with mineral extraction"*. The subjective response of a receiver to this air overpressure is often unrelated to the magnitude of the associated ground-borne vibration, which in some cases is not actually perceptible. A well designed blast would, by its very nature minimise the generation of air overpressure, and at distances of greater than 500m, it would not be measureable, except in completely calm meteorological conditions.

11.6.97 Three trial blasts (B-BBH1, B-BBH2 and B-BBH3) were undertaken within the Built Development Area West in April 2010, to determine the reaction of the bedrock to blasting, and to assess the potential vibration impacts. During this time continuous monitoring of both noise and vibration was undertaken at two locations:

- West of the Hinkley Point A site boundary; and
- Bayleys Brook House (residential dwelling) in Shurton.

11.6.98 The monitoring results are presented in the Trial Blast Noise and Vibration Report (see **Appendix 11B**).

11.6.99 **Plate 11.1** to **Plate 11.4** present the noise and vibration levels measured during trial blasting tests within the HPC development site which were undertaken to determine the nature of the levels that could occur at potentially sensitive receptors. For the measurements which were undertaken at Bayleys Brook House and close to the boundary of Hinkley Point A the figures clearly indicate that vibration levels from blasting operations are unlikely to exceed the very low magnitude criterion (6mm/s) identified in **Table 11.9**. Only blast event B-BBH2 registered an observable increase in vibration above the background level at Bayleys Brook House. This maximum recorded PPV level (0.201mm/s) is below the 0.3mm/s level that BS 5228-2 (Ref. 11.21) suggests "…*might be just perceptible in residential environments*". It is however, above 0.14mm/s, the level at which BS 5228-2 states that "…*might be just perceptible in most sensitive situations for most vibration frequencies associated with construction."*

11.6.100 It should be noted that good practice for community relations and health and safety, i.e. notifying the community of planned blast events, and the pre-blast alarm, both serve to raise the sensitivity of local residents to both noise and vibration. Therefore, vibrations may have been perceived by alerted residents.

11.6.101 Peak vibration levels from the blast events are more clearly discernible in the measurement data obtained at the Hinkley Point A monitoring location, approximately half the separation distance than that to Bayleys Brook House (but in a different direction) from the blast site. However, the generated vibration levels at this location were again well below the very low magnitude criterion (6mm/s).

11.6.102 It is difficult to be certain of the exact cause of the measured L_{Amax} during a given one-minute measurement period. However, the maximum A-weighted instantaneous noise level at Bayleys Brook House did not exceed 65dB $L_{Amax,T}$ as a result of the trial blast.

11.6.103 Overall, it is concluded that the vibration magnitude events, although possibly perceptible to alerted residents, was determined to be 'Very Low' in relation to disturbance impacts. Cosmetic damage to buildings is highly unlikely as threshold values for buildings are much higher than those for perception, and disturbance is used in this assessment.

11.6.104 It is therefore predicted that the blasting noise and vibration would have a **minor adverse** impact on the nearest potentially affected receptors of low to medium importance and sensitivity.

Plate 11.1: Measured Noise and Vibration Levels at Bayleys Brook House during Blast Event B-BBH2

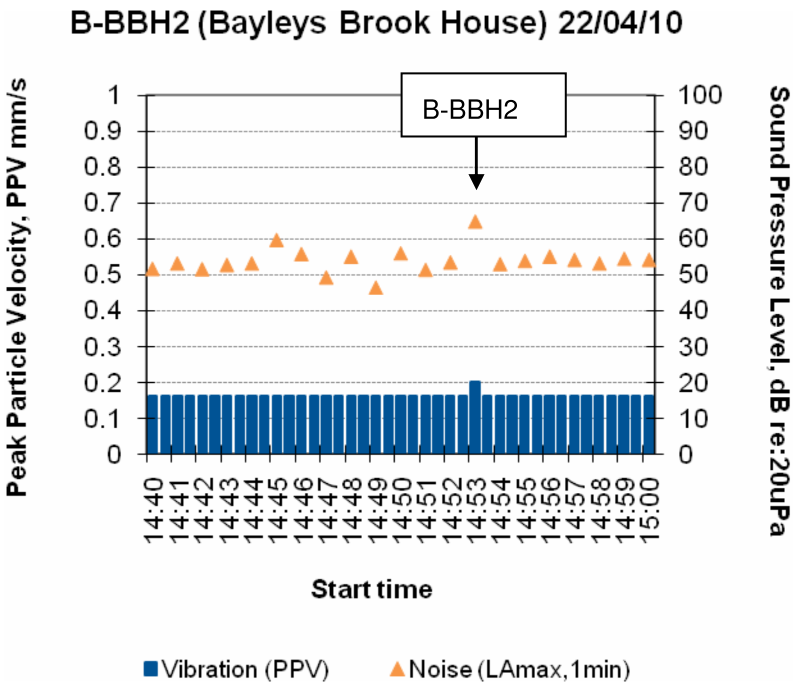

Plate 11.2: Measured Noise and Vibration Levels at Hinkley Point A during Blast Event B-BBH2

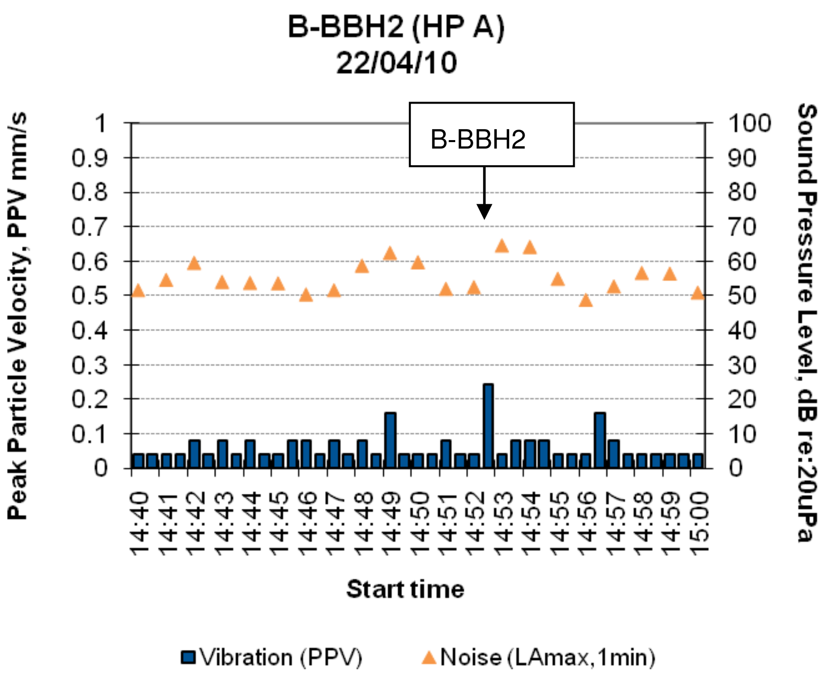

Plate 11.3: Measured Noise and Vibration Levels at Bayleys Brook House during Blast Event B-BBH3 and B-BBH1

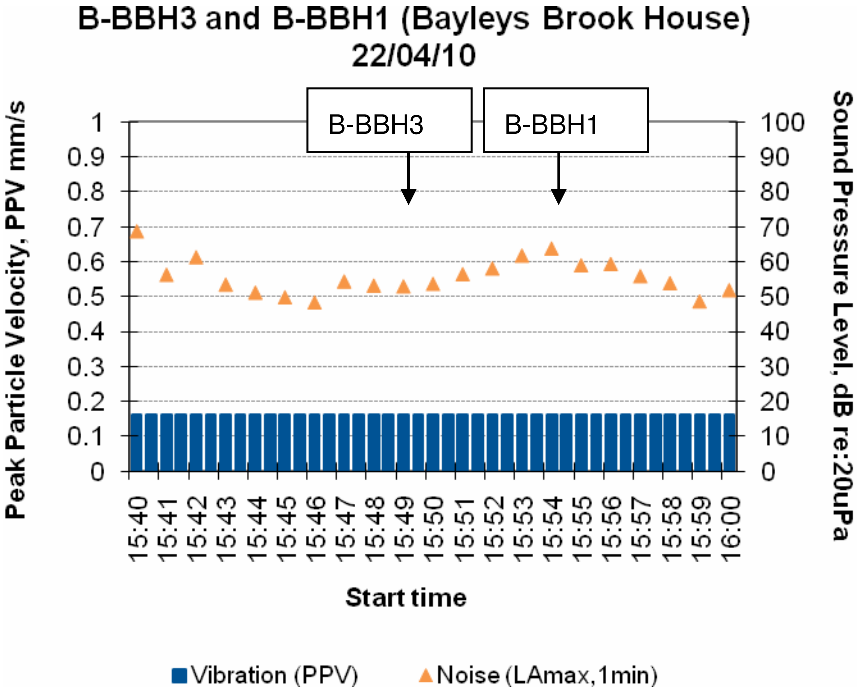

Plate 11.4: Measured Noise and Vibration Levels at Hinkley Point A during Blast Event B-BBH3 and B-BBH1

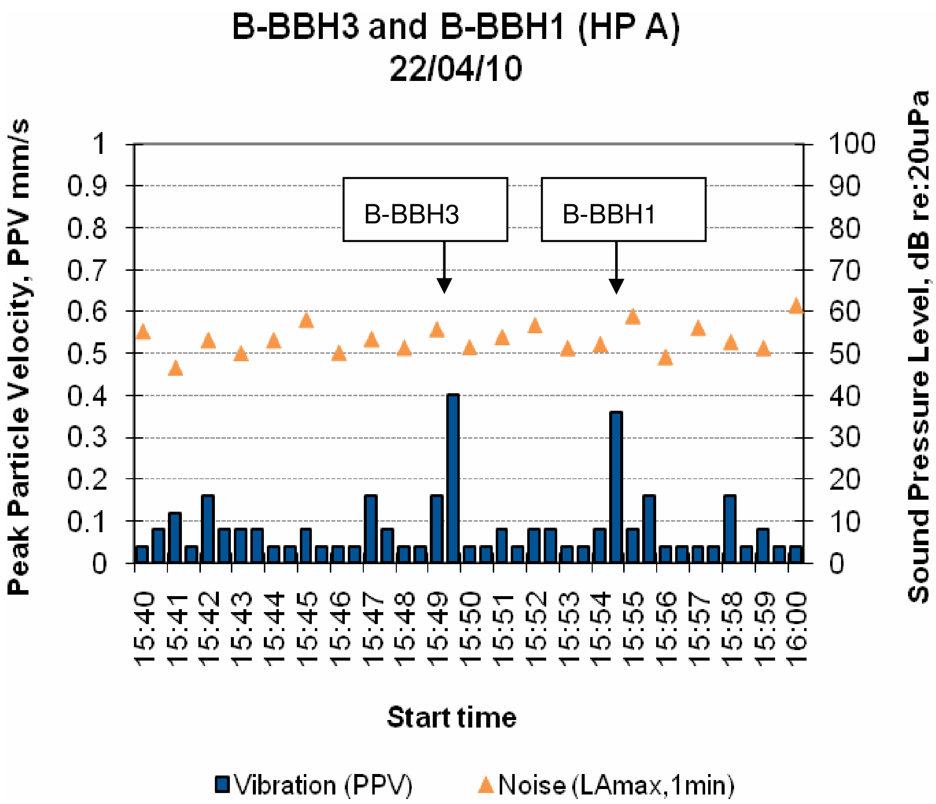

vi. Construction – Vibration from Off-Site Traffic

11.6.105 Along public highways, passing HGVs, including trucks and buses, may cause occasional building excitation through ground-borne vibration as the vehicle traverses discontinuities, such as rough surfaces or speed-humps. Ground-borne vibration levels generated by HGV traffic will vary depending upon a number of factors (e.g. loading, road surface abnormalities, distance to property, and ground conditions). It is therefore not feasible to quantify potential ground-borne vibration magnitude. However, it is highly unlikely that vibration levels would be sufficient to cause even cosmetic damage to buildings.

11.6.106 The overall impact of ground-borne vibration resulting from road traffic associated with the HPC construction is assessed as being of **minor adverse** significance, on receptors of medium value and sensitivity.

11.6.107 The assessment of 18-hour road traffic flow in 2013 has shown that an increase in traffic is predicted on the A39 southern bypass (P), the A39 between Quantock Roundabout and Sandford Corner (S) and on the route through Stringston and Stogursey. Using the guidance in DMRB (Ref. 11.12), and based on the predicted change in traffic noise, it was determined that the percentage of people *"bothered very much or quite a lot"* by airborne vibration within 40m of these routes will increase by a further 6-10%.

11.6.108 The assessment of 18-hour road traffic flow in 2016 has shown that an increase in traffic is predicted on the A39 southern bypass (P), the A39 between Quantock Roundabout and Sandford Corner (S) and on the route through Stringston and Stogursey. Using the guidance in DMRB (Ref. 11.12), and based on the predicted change in traffic noise, it was determined that the percentage of people *"bothered very much or quite a lot"* by airborne vibration within 40m of these routes will increase by a further 4-11%.

11.6.109 Overall, the impact of airborne vibration resulting from road traffic associated with the HPC construction is assessed as being of **minor adverse** significance, on receptors of medium value and sensitivity.

d) Cumulative Construction Impacts

11.6.110 Major construction activities have the potential to result in cumulative noise and vibration impacts at neighbouring sensitive receptors in terms of disturbance to amenity. The construction vibration assessment above determined that impacts, even during blasting events, at the nearest residential dwellings will be of no greater than minor adverse significance. Vibration may however be perceptible in residential properties, which can lead to feelings of anxiety and/or annoyance in sensitive individuals with strong feelings towards the proposed HPC Project. In this context, the combination of construction noise and vibration could potentially exacerbate an individual's aggravation, thereby heightening their senses to subsequent activities.

11.6.111 Overall, impacts resulting from construction noise will result in the most significant adverse effects to local residents throughout the construction phase, with vibration impacts being of negligible to minor significance. The cumulative impacts are therefore assessed as being no greater than has been assessed for the construction noise.

11.6.112 Noise and vibration from both construction machinery on-site and from construction vehicles on public highways has the potential to result in combined impacts at sensitive receptor locations. These combined effects are therefore not fully addressed in the detailed impact assessment sections above. However, of the neighbouring residential dwellings, only Doggetts would be potentially affected by such in-combination effects (noise only), due to the relative short separation distance from the C182 (Wick Moor Drove).

11.6.113 At a distance of approximately 170m west of the C182, the predicted daily road traffic noise level at Doggetts (Receptor 7 in **Figure 11.1**) would be 50dB $L_{Aeq,16hr}$ in the 2016 'Do-Something' scenario, calculated in accordance with CRTN (Ref. 11.14) and PPG 24 (Ref. 11.6) guidance. Based on the findings presented in **Table 11.7**, for the majority of the HPC construction phase, road traffic noise on the C182 will be the slightly dominant noise source at Doggetts. However, during construction of the accommodation campus, and during early and final landscaping, the noise generated by on-site machinery will be most significant.

11.6.114 Noise exposure from on-site construction machinery will vary significantly dependent upon activity intensity and location. For periods, noise levels generated by on-site construction and by off-site road traffic will be similar, the combined effect would therefore be a slightly more adverse effect. In accordance with the threshold criteria for construction (**Table 11.3**), the magnitude of noise from the combined sources during these periods would be no greater than has been assessed for the construction works alone.

11.6.115 Road traffic, even including HGVs, does not generate significant ground-borne vibration. At the nearest sensitive receptor (Doggetts), vibration from road traffic will not be perceptible. Therefore, overall the worst-case potential impact of combined vibration sources throughout the HPC construction phase is assessed as being of **minor adverse** significance.

e) Operational Impacts

i. Potential Noise-generating Activities during the Operational Phase

11.6.116 Once the construction phases are complete for each UK EPR reactor unit, they will undergo commissioning which will last approximately two years per unit. The commissioning phase will involve a number of activities that are likely to generate noise emissions with atypical characteristics; especially during the testing of essential standby plant such as the diesel generators and the overspeed tests of the steam turbines, which may emit high frequency sounds during high pressure leak tests of water circulation and nuclear steam supply systems.

11.6.117 The primary sources of noise during the operation of HPC relate to the operation of UK EPR reactor units, including the following:

- the discharge stack;
- air entry and exit openings;
- ventilation openings;
- pumping stations;
- steam pipes situated on the Reactor building; and
- equipment situated in the Turbine Hall (such as transformers and alternator).

11.6.118 In addition to site plant noise, there will also be operational traffic-related noise effects. The operation of HPC will require a workforce of approximately 900 staff in total, which will generate additional traffic on the highway network. Additional heavy vehicular traffic and workforce traffic will also be generated for materials delivery during maintenance and refuelling outages, where it is anticipated that a further 600-1,000 staff would be required.

ii. Operation – Commissioning Activities

11.6.119 During the commissioning tests, some activities are likely to generate noise emissions with atypical characteristics; such as high frequency sounds during high pressure leak tests of water circulation and nuclear steam supply systems. It is expected that on-site commissioning tests will require operation of the eight essential diesel generators (EDGs) and four Stand-by Black-out generators (SBOs) for 245-hours per generator.

11.6.120 Release of stored pressure following these tests may be audible at a number of the nearest receptor locations given the possible magnitude of sound pressure levels and the distinctive nature of the sound likely to be generated. However, events are likely to be very short-term (no more than a few minutes each) and can be managed to occur within daytime periods only. Other activities undertaken during the commissioning phase are unlikely to generate noise emissions in excess of those which would occur for the fully operational HPC. Given the short-term nature of these activities, the overall noise impact of commissioning testing is assessed as being of **minor adverse** significance.

11.6.121 Coincident with the commissioning phase, the jetty will be dismantled and removed from site. Dismantling of the jetty development would require similar activities to its construction (except blasting). The predicted noise levels presented in **Table 11.17** are therefore considered representative of a worst-case scenario for this phase of the jetty development. The potential noise impacts are therefore assessed as being of **minor adverse** significance.

11.6.122 Similarly, vibration generated during this phase would be no more significant than assessed for the jetty construction phase, which was also assessed as being of **minor adverse** significance.

iii. Operation – Noise from HPC Operation

11.6.123 The propagation of operational noise emissions from sources on the HPC site, including: machinery; building vents; and building façades, have been modelled using CadnaA computational predictive software. The model scenarios and assumptions of this modelling study are described in detail in **Appendix 11F**. **Table 11.20** below provides a summary of the predicted façade noise level at three neighbouring noise sensitive receptor locations. These locations correspond to background noise measurement locations detailed in the Factual Noise Report (see **Appendix 11A**) (note: background measurements were undertaken in free-field conditions).

Table 11.20: Predicted Operational Noise Level at Nearest Receptor Dwellings (façade) in Proximity to the development site based on Prediction Modelling

Ref.*	Receptor	Predicted Sound Pressure Level, dB (Façade)		
		L_{AT}(LT) (Average wind direction)	L_{AT}(DW) Downwind	L_{AT} Neutral (no wind)
ML2	Knighton Farm (R9)	33.7	36.6	35.2
ML3	Doggetts (R7)	29.6	32.3	30.9
ML4	Wick Farm (R6)	32.2	34.9	33.4

Note: * Refer to Factual Noise Report (**Appendix 11A**) for baseline monitoring location identifiers. Receptor (R) locations shown in **Figure 11.1**.

11.6.124 Calculations were undertaken using three meteorological scenarios:

- average wind direction based on hourly data (2004-2008);
- downwind conditions; and
- neutral (no wind).

11.6.125 BS 4142: 1997 (Ref. 11.23) does not specify how wind effects should be accounted for in propagation predictions, only that the calculation method should be reported and reasoned appropriately. Operational noise propagation has been determined based upon all three scenarios to provide an indication of the meteorological effects. Noise propagation calculations were undertaken in accordance with the International Standards Organisation guidance document ISO 9613: Part 2: 1996 'Attenuation of sound during propagation outdoors' (Ref. 11.22) and the results are presented as noise contours for the neutral and average wind scenarios in **Figure 11.8** and **11.9**.

11.6.126 As would normally be expected, the modelling predictions indicate that noise levels at each assessed receptor location due to operation of the Hinkley Point C site will be greatest under downwind conditions. However, based on meteorological data recorded between 2004 and 2008, wind blowing from the direction of the operational areas of the site to the three assessed receptor locations is infrequent. Knighton Farm was downwind (wind direction from 30°-60°) for just 6.7% of the time, equating to an equivalent of less than 25 days per year. At Doggetts, this was even less common, with downwind conditions occurring for just 3.4% of time (less than 13 days). With a prevailing wind (23.3%) from the west to north-west (270°-300°), there is a slightly greater occurrence of downwind conditions (300°-330°) at Wick Farm, however, this only amounts to 10.2% of the year (approximately 37 days).

11.6.127 Under neutral conditions (no wind), the noise levels are predicted to be 1.4-1.5dB lower. The annual average site noise levels are predicted to be even lower due to the prevailing winds which will inhibit noise propagation to the assessed receptor locations for the majority of the year. The acceptable operational noise criterion typically recommended by WSC is 5dB above background. However, this criterion is based upon the BS 4142: 1997 assessment methodology which states that it is not applicable *"when background and rating noise levels are both very low"* (below 30dB $L_{A90,T}$ and 35dB $L_{Ar,T}$). The baseline noise survey, detailed in the Factual Noise Report (**Appendix 11A**), subsequently determined that background noise levels do fall below the 30dB $L_{A90,T}$ criterion at night (refer to **Table 11.11**), as is typical of a rural location. **Table 11.21** shows the predicted impacts under neutral conditions which neither favour nor discriminate against propagation from source to receiver, in accordance with this methodology. The background noise levels used in this assessment are the lowest measured values to provide an absolute worst-case assessment.

Table 11.21: Assessment of Predicted Specific Noise Levels during Operation of two UK EPR Units at HPC against the Lowest Measured Background Noise Levels at the Nearest Receptor Locations

Ref.*	Receptor	Sound Pressure Level, dB (Free-field)			Difference, dB		Predicted noise less than 5dB above background
		Predicted specific noise level, $L_{Aeq,T}$ (neutral wind)	Lowest measured background level, $L_{A90,T}$ #				
			Day	Night	Day	Night	
ML2/R9	Knighton Farm	32.2	30	30	+2.2	+2.2	Yes
ML3/R7	Doggetts	27.9	32	30	-4.1	-2.1	Yes
ML4/R6	Wick Farm	30.4	37	36	-6.6	-5.6	Yes

Note: * Reference receptor (R) locations identified in **Figure 11.1**, and baseline monitoring locations (ML) referred to in the Factual Noise Report (**Appendix 11A**).
Minimum value of 30dB $L_{A90,T}$ due to limitations of BS4142 methodology.

11.6.128 The assessment indicates that, taking into account the limitations of BS4142, predicted noise levels under neutral wind conditions will be acceptable.

11.6.129 Adoption of the specific target criterion of 38dB $L_{Aeq,T}$ (façade) is proposed for the total noise emissions from all plant operating on the proposed HPC site, determined at the nearest residential properties. The predictions in **Table 11.20** indicate that in the worst-case the annual average noise level outside the assessed receptor dwellings during the night will be well below this criterion. Thus, in accordance with the World Health Organisation guidance document 'Night Noise Guidelines for Europe' (2009) (Ref. 11.2), no observable adverse effects on sleeping conditions are predicted to occur. Therefore, the overall noise impact of operation of the HPC power station will be of **minor adverse** significance.

11.6.130 The detailed noise propagation modelling exercise identified that the most significant noise sources include the two main stack exhaust points (one for each UK EPR reactor), roof-mounted refrigeration units, the main transformer buildings, and heat exchangers associated with the Interim Spent Fuel Store (ISFS) building. However, it should be noted that two of these identified sources will not operate continuously. Ventilation from the two main stacks will only occur as required to maintain appropriate and safe internal conditions. Similarly, it is assumed that eight of the 12 heat exchangers associated with the ISFS building are in operation. However, ventilation will only be required during periods of high ambient air temperature and/or on occasions of a large inventory being stored in the cooling ponds. It should be noted that operation of all 12 heat exchangers would only occur in the event of an emergency.

11.6.131 Furthermore, it was assumed that four of the eight essential diesel generators (EDGs) and two of four Station Black Out (SBO) generators are in operation. This is safety equipment, providing backup power supply in the unlikely event of loss of the main off-site power supply when house load operation fails, so that the UK EPR units can be secured and the reactor cooled. These backup generators routinely operate during periodic tests, which represent an estimated 60-hours per year for each of the EDG and SBO generators.

11.6.132 Mitigation measures will ensure that no noise emissions contain acoustic features which may accentuate the likelihood of disturbance, as defined in Section 8 of BS 4142: 1997. Possible acoustic features include:

- a distinguishable, discrete, continuous note (whine, hiss, screech and hum);
- distinct impulses (bangs, clicks, clatters, or thumps); or
- noise emissions which are irregular enough to attract attention.

11.6.133 Potential sound mitigation to minimise the possible long-term impacts of operational noise are discussed in Section 11.7 below.

iv. Operation – Vibration Noise from HPC Operation

11.6.134 Due to the separation distance (greater than 1.0km), the operation HPC will not result in significant adverse vibration impacts at the nearest residential dwellings in Shurton, Burton, Knighton and Wick. Operational safety requirements implemented at the detailed design stage will ensure that moving parts or machinery will be sufficiently isolated from the ground to ensure that ground-borne vibration is not detrimental to processes either on the operational HPC site or the operational Hinkley Point B site (approximately 0.6km to the west). Operational vibration impacts are therefore assessed as being of **minor adverse** significance.

v. Operation – Noise from Off-Site Traffic

11.6.135 Noise from road traffic generated during the early operation of HPC will have the potential to impact upon occupants of residential dwellings and other sensitive receptors, such as schools and places of worship, aligning the highway network. Whilst traffic generation will be significantly reduced, the assessed year (2021) does not represent only HPC operation, but also residual activities associated with its construction phase. This includes dismantling and restoration of the temporary associated development sites, as well as the construction of the ISFS which will continue to be constructed once the two UK EPR reactor units become operational.

11.6.136 **Table 11I.1** in **Appendix 11I** provides a list of assessed road sections. **Table 11I.2** of **Appendix 11I** presents the base and forecast traffic flows. **Table 11I.3** of **Appendix 11I** presents the calculated Basic Noise Level (BNL), including correction for percentage HGV content and average vehicle speed, for each assessed road section.

11.6.137 Comparison between the calculated daily BNL for the 2021 'Do-Nothing' and 'Do-Something' scenarios indicates that the greatest change in daily road traffic noise is predicted on the A39 southern Cannington bypass, where an increase of +3.0dB(A) is predicted. Using the criteria presented in **Table 11.5** this represents a medium magnitude of change for receptors of medium value and sensitivity. The significance of impact for this assessed road section is therefore predicted to be **moderate adverse**. The level of daily road traffic noise impact significance is predicted to be no worse than **minor adverse** for all other assessed road sections.

11.6.138 Beneficial impacts are predicted in 2021 in Cannington, due to legacy use of the proposed bypass, on roads through Cannington. On these links, a daily road traffic noise reduction of -0.7 to -3.6dB(A) is predicted. This represents a very low to medium magnitude change (on receptors of medium value and sensitivity) when compared with the criteria presented in **Table 11.5**. The noise impact is assessed as being of **minor** to **moderate** beneficial significance.

11.6.139 In addition to the above assessment of noise from 18-hour traffic flows over the highway network during early operation of HPC, it is necessary to undertake an assessment of potential impacts of vehicle movements, including a single construction shift (spent fuel building) and daytime deconstruction of associated development sites. **Tables 11I.4** to **11I.10** in **Appendix 11I** presents the forecast hourly traffic flows on all assessed road sections for the following periods:

- 05:00-07:00;
- 12:00-13:00; and
- 23:00-01:00.

11.6.140 **Table 11I.21** in **Appendix 11I** shows the predicted change in the BNL, whilst **Table 11I.31** shows the noise change magnitude for each assessed hour in 2021.

vi. HPC Early Operation – 2021 Hourly Traffic Noise Impacts

11.6.141 In 2021, when the HPC is fully operational, but construction of the ISFS building and deconstruction of the associated development sites is continuing, the night-time noise impacts from road traffic was determined to be of **minor adverse** significance on all but one route. This is because the remaining construction workforce would operate on a single-shift, therefore removing the requirement for late evening bus movements.

11.6.142 The exception is between the hours of 06:00-07:00 on the existing A39 south Cannington bypass, where a road traffic noise impact of **moderate adverse** significance is predicted.

11.6.143 During the daytime, a noise change of medium magnitude is also predicted on this route, on receptors of medium value and sensitivity, due mainly to HGV traffic associated with ISFS construction. The daytime road traffic noise impact on this section of road is therefore assessed as being of **moderate adverse** significance.

11.6.144 In 2021, the daytime road traffic noise impact was assessed as being no worse than **minor adverse** significance on all other roads, and indeed, with the western Cannington bypass remaining (after the main HPC construction works are complete and both units are operational), hourly road traffic noise impacts of **minor beneficial** significance were determined along many of the assessed routes. This is most notable during the assessed night-time periods, especially within Cannington Village.

vii.HPC Permanent Operation

11.6.145 Upon completion of construction of the ISFS building, and deconstruction of associated development sites, where applicable, the vehicular traffic generation by the HPC site will reduce further. Most significantly, the number of HGV movements between HPC and the M5 Motorway will reduce to negligible levels. Under normal operation, traffic generation will result from commuting site staff (peak operational workforce will be 900 during the dayshift 08:00-16:30), with a short-term increase (600 dayshift, and 400 night-shift for approximately 1-month) during planned outages, at approximately 18 month intervals.

11.6.146 As a result, remaining road traffic noise impacts would be significantly less adverse than was assessed in 2021.

viii. Operation – Vibration from Off-Site Traffic

11.6.147 Along public highways, passing HGVs, including trucks and buses, may cause occasional building excitation through ground-borne vibration as the vehicle traverses discontinuities, such as rough surfaces or speed-humps. Ground-borne vibration levels generated by HGV traffic will vary depending upon a number of factors (e.g. loading, road surface abnormalities, distance to property, and ground conditions). It is therefore not feasible to quantify potential ground-borne vibration magnitude. However, it is highly unlikely that vibration levels would be sufficient to cause even cosmetic damage to buildings.

11.6.148 The overall impact of ground-borne vibration resulting from road traffic associated with the early operation of HPC is assessed as being of **minor adverse** significance, on receptors of medium value and sensitivity.

11.6.149 The overall impact of airborne vibration resulting from road traffic associated with the early operation, and throughout HPC operation, is assessed as being of **minor adverse** significance, on receptors of medium value and sensitivity.

11.7 Mitigation of Impacts

a) Mitigation of Construction Impacts

11.7.1 British Standard BS 5228: Part 1: 2009 (Ref. 11.11) gives detailed advice on standard good construction practice for minimising effects of construction noise. This can take the form of reduction at source, control of noise spread, and in areas of very high noise levels, insulation at receptors. It is likely to be a requirement of any construction contract that the constructors comply with the recommendations in this standard, in order to achieve specific noise limit criteria for each site. The adoption of Best practice construction measures has been taken into account within the assessments set out above.

11.7.2 With regard to blasting operations, as with standard construction activities, blasting events (if required) will be designed to ensure Hinkley Point B operations are not adversely affected. This provision will also ensure that impacts at the nearest residential dwellings (a further 400m from events) are suitably minimised.

11.7.3 During the early stages of HPC construction, early landscaping will raise the elevation of land in the south of the SCPAto the south of the main construction fence line at 144750mN providing screening of all future works. These amended elevations were included within the later modelled scenarios (Scenarios C, D and E), described in Section 11.4.

- Additional, site-specific mitigation measures may be agreed with Officers of WSC and SDC through the use of their prior approval powers under Section 61 of the Control of Pollution Act 1974 (Ref. 11.5).

11.7.4 Measures to be incorporated will be included within the **Noise and Vibration Management Plan** (**NVMP**) for the HPC development site. This will include details of the requirements for ambient noise monitoring throughout the HPC construction programme. Long-term noise monitoring stations will be established at a number of locations within the villages of Shurton, Knighton and Wick. The **NVMP** will also describe the formal procedures for reporting measured ambient noise levels and responding to noise and/or vibration complaints.

11.7.5 In recognition of the overall scale of the proposed HPC construction, EDF Energy has already committed to a Neighbourhood Support Scheme which comprises a Property Price Support Scheme and a Noise Insulation Scheme. These voluntary schemes allow residential property owners in the villages of Shurton, Burton, Knighton, Wick and Stolford to apply for either secondary glazing or new double-glazing, with acoustic ventilation, to be fitted. These schemes are offered irrespective of the significance of the noise impacts as determined in the ES, but demonstrate a fair and responsible action as a commitment to being a good neighbour.

11.7.6 Construction works associated with highway improvements schemes will be restricted to standard daytime working hours only, between the hours of 07:00-19:00 Monday to Friday, and 07:00-13:00 on Saturdays. As such, no works will take place on Sundays or public holidays.

b) Mitigation of Off-Site Traffic Impacts

11.7.7 The associated development sites form part of a transport strategy proposed to alleviate construction traffic impacts associated with the development of the HPC Project. As well as limiting traffic congestion and other potential environmental impacts, such as impacts on local air quality, these mitigation measures are intended to help reduce noise and vibration impacts from road traffic during construction of the HPC Project. The traffic data used in the assessment has made a range of worst-case assumptions which make the assessment robust.

11.7.8 Once operational, the proposed Cannington bypass would reduce the predicted noise impacts from HPC construction traffic in Cannington village. As a result of the proposed bypass, beneficial impacts are predicted along the route through Cannington in the 2016 and 2021 assessment scenarios.

11.7.9 The assessment has assumed that the **Freight Management Strategy** (appended to the **Transport Assessment**) would be in place to minimise as far as is practicable the disturbance from HGVs accessing the HPC development site. There would be no HGVs travelling to the HPC development site during these sensitive periods (between the hours of 22:00 and 07:00).

11.7.10 The two designated routes from Junction 23 and 24 of the M5 through Bridgwater have been designed, where practicable, to use main roads and commercial/industrial routes avoiding more sensitive residential areas. During the night-time periods, buses travelling to and from the J23 development would be diverted from the designated route. Buses would use Wylds Road instead of A38 and The Drove onto Wylds Road. This diversion avoids sensitive residential areas along the A38 in preference for the industrial areas on Wylds Road which would not be occupied during these hours.

c) Mitigation of Operational Impacts

11.7.11 The assessment assumes that, where applicable and permissible in terms of operational and safety requirements, the detailed design of the HPC Project, including plant selection and location, would reduce noise emissions at source as far as reasonably practicable. The assessment set out above assumes that the operational noise emissions would not include tonal or distinct characteristics.

11.8 Residual Impacts

a) On-site Construction

11.8.1 During short-term activities associated with construction of the emergency access road, as well as early and final landscaping south of the 144750mN main construction fence line, the adverse noise impact is assessed as being of short-term **major adverse** significance. This assessment was based on worst-case assumptions with all machinery operating at the closest point to the assessed dwellings. During all other construction activities, including combined on-site works elements during construction of HPC, the residual noise impact is assessed as being of long-term **minor adverse** significance at all assessed residential dwellings and public outdoor amenity locations.

11.8.2 During the night-time, the reduced shift and restricted working will ensure that construction noise impacts are significantly less than during the daytime. Overall, it is assessed that the residual impact of night-time working north of Green Lane will be of long-term **minor adverse** significance to all residential receptor locations.

11.8.3 The residual noise impact to visitors to Pixies Mound during short-term road upgrading works nearby is assessed as being of short-term **moderate adverse** significance. However, this is based upon a one-hour exposure period. In reality, receptors (primarily walkers) are likely to be continually mobile, and are therefore unlikely to experience the predicted noise level for sufficient time for the proposed noise threshold for construction works to be exceeded.

11.8.4 The residual noise impact to the users of the public footpaths along the western boundary of the HPC development site and the coastal footpath to the north of the site is assessed as being of long-term **negligible** to **minor adverse** significance.

11.8.5 Control measures adopted to ensure no adverse construction vibration impacts to ongoing nuclear power generation at Hinkley Point B should provide sufficient protection to the nearest sensitive receptors. It is therefore assessed that the residual vibration impact during the construction phase will be of long-term **minor adverse** significance.

11.8.6 Occupation of the contractor's accommodation campus, including operation and use of the proposed amenities will result in a long-term **minor adverse** noise impact at the nearest noise-sensitive receptor.

b) Off-site Construction Traffic

11.8.7 In relation to noise from road traffic, the impact assessment during construction has been conducted for the years of 2013 and 2016. These are the years that have been assessed in the **Transport Assessment** and represent the peak periods of traffic generation during HPC construction. The 2013 assessment includes the peak period of HGV movements and the 2016 assessment includes the peak period in terms of workforce numbers.

11.8.8 It should be noted that there will be relatively high levels of sustained traffic generation for a period of approximately five to six years within the overall construction programme for HPC. While the 2013 and 2016 assessments represent the peaks in terms of anticipated traffic generation (and thus the worst-case in terms of associated noise impacts) some remaining but lower level of adverse impacts will persist through the main years of the construction programme.

11.8.9 The adverse impacts that have been identified essentially fall into two categories. The first of these is daytime noise impacts which arise principally from the HGV movements to and from the HPC development site. These movements will be limited to the two authorised HGV Routes, and HGV movements on these routes will be restricted to between the hours of 07:00-22:00. Worse-case assumptions have been made for HGV movements in the transport modelling which has been used for the noise impact assessment.

11.8.10 The second area of impacts is noise which arises early in the morning or late in the evening from bus movements required to transport HPC construction workforce to and from the HPC development site. These movements will not occur through the night but will align with the beginning of the first construction shift and the end of the second construction shift and will be limited to a window of approximately 1.5 to 2 hours. As with HGV movements, the modelling of bus movements has been made on robust assumptions which assume that very regular timetables operate on all direct, campus and park & ride bus routes associated with the beginning and end of each construction shift. These timetables are not fixed at this stage and will be finalised once a bus operator has been appointed to provide the bus services. In practice, bus provision and timetables will be regularly adjusted to match the changing patterns of demand and the actual number of buses on many routes is likely to be significantly less than has been modelled at many points in the construction programme. However, at this stage and for the purpose of providing a very robust assessment of transport and noise impacts, fixed timetables on all routes have been used in the modelling.

11.8.11 More generally it should also be noted that EDF Energy's transport strategy has been developed with a significant focus on reducing the traffic impacts during the construction phase of the development. A wide range of measures are being implemented to reduce the volume of traffic movements in relation to both freight and people. While not specifically discussed in this chapter, these measures substantially reduce the scale of traffic – and thus potential noise impacts – which would otherwise occur in their absence. Further information on the transport strategy and the robust nature of the HGV and bus movement assumptions is contained in **Chapter 10** of this volume and in the **Transport Assessment**.

11.8.12 With respect to the absolute noise levels which will arise from HPC related traffic, with the exception of four properties north of Cannington on the C182 (Rodway), these are not predicted, at any point in the construction programme, to breach any statutory limits in relation to road traffic noise or exceed levels at which there would be a statutory requirement to provide mitigation in the form of noise insulation.

11.8.13 A further consideration is that, due to the natural reduction in traffic noise with distance, the adverse impacts that have been assessed will only apply to residential properties and any other receptors which are located adjacent to the road on the affected road links. Any properties that are screened from the road by buildings or other features, or that are set back from the road, will experience substantially reduced impacts which are not likely to be more than long-term **minor adverse** in nature. It is also relevant in this context that on some of the links which are assessed as experiencing adverse impacts there are very few residential properties, or other receptors, which are close to the road – an example of this would be stretches of the A39 between Cannington and Bridgwater.

11.8.14 The two locations where significant numbers of residential properties are assessed as experiencing adverse road traffic noise impacts are Cannington and Bridgwater.

11.8.15 In Bridgwater the scale of noise impacts arising from HPC traffic is materially lower in absolute terms than for Cannington and background traffic flows – in particular during the day – are much higher. Noise impacts arising from daytime HGV movements along one of the designated routes in Bridgwater (the Northern Distributor Route) are assessed as being of **moderate adverse** significance in 2016. Before the opening of the freight management facilities in 2013, and on the other designated HGV route in 2013 and 2016, these daytime impacts are assessed as no more than **minor adverse**. Where other **moderate** or **major adverse** impacts have been assessed in Bridgwater, these relate to the shorter periods of time associated with early morning and late evening bus movements which have as noted above, been modelled on a worse-case basis. These impacts are also limited to existing A-roads which are recognised as the main corridors for traffic through Bridgwater.

11.8.16 The scale of adverse road traffic noise impacts is greatest in Cannington prior to the construction of the Cannington bypass. Properties adjacent to the road in Cannington, on the HGV route to the HPC development site, will experience both daytime noise impacts from HGV movements which are assessed as **major adverse** and early morning/late evening noise impacts from bus movements which are also assessed as **major adverse**. The absolute change in noise levels arising from HPC related traffic is also significantly higher in Cannington prior to the construction of the bypass, than would be the case in Bridgwater.

11.8.17 In recognition of the scale of adverse noise impacts which have been assessed, and taking account of the relatively rural/village character of Cannington, EDF Energy will be providing an offer of noise insulation support to those properties in Cannington which are most affected by transport related noise arising from the HPC Project construction phase. Detailed eligibility will be based on a careful analysis of the findings of the noise assessment work, and further details and communication to eligible residents will take place following submission of the DCO application. The noise insulation scheme will be similar to the support already being offered to properties closest to the HPC development site and will be offered by EDF Energy on a voluntary basis.

11.8.18 Road traffic noise impacts in Cannington will of course also be of a temporary nature as the Cannington bypass will provide traffic relief for the village for the majority of the construction programme. It can be noted that there are long-term and permanent **moderate** to **minor beneficial** noise impacts predicted in Cannington in 2016 and 2021, respectively, arising from the operation of the Cannington bypass and this will persist as a permanent legacy benefit of the HPC Project.

c) In-Combination of Construction

11.8.19 The in-combination noise and vibration effects of on-site machinery and off-site vehicle movements during the construction phase have been assessed to be no more significant than those determined by the detailed individual assessments.

d) Highway Improvements

11.8.20 The most significant proposed highway improvement works with potential to cause adverse noise impact are associated with the construction of roundabouts at Sandford Corner, Cannington and Washford Cross, Williton. It is assessed that construction of the Sandford Corner roundabout will result in a residual short-term noise impact of **moderate adverse** significance at the nearest residential dwelling. These temporary works would be undertaken during standard working day periods only.

11.8.21 Construction of the Washford Cross roundabout will result in a short-term residual noise impact of **minor adverse** significance at the nearest residential dwelling, but **moderate adverse** significance at an adjacent public amenity location. Again, these temporary works would be undertaken during standard working day periods only.

11.8.22 The residual vibration impacts resulting from short-term roundabout construction activities at each location are assessed as being of **minor adverse** significance.

e) On-site Operation

11.8.23 The noise prediction modelling exercise has indicated that worst case, the proposed target criterion of 38dB $L_{Aeq,T}$ is unlikely to be exceeded. Therefore, the overall long-term operational noise impact of the proposed nuclear power station is assessed as being of **minor adverse** significance.

11.8.24 Vibration attenuation measures adopted to ensure no adverse operational impacts to ongoing nuclear power generation at Hinkley Point B, as well as the proposed Hinkley Point C power station itself, should provide sufficient protection to the nearest sensitive receptors. It is therefore assessed that vibration impacts once fully operational will be of **minor adverse** significance.

f) Off-site Operation Traffic

11.8.25 The predicted change in 18-hour daytime road traffic noise during early operation, and subsequent long-term operation, of the proposed nuclear power station in 2021 is assessed as being of **minor adverse** to **moderate beneficial** significance on all existing highways.

11.8.26 The residual impact of road traffic noise during the early morning and late evening periods is of **minor adverse** significance on all but one road link during early operation of HPC. On the A39 southern Cannington bypass, between 06:00-07:00, the residual road traffic noise impact is assessed as being of **moderate adverse** significance. In the permanent operation scenario, however, this is expected to reduce to a **minor adverse** impact.

11.8.27 During the daytime, peak traffic early operational movements in 2021, including construction of the ISFS building and deconstruction of the associated development sites, are predicted to result in road traffic noise impacts of **moderate adverse** significance on the A39 southern bypass of Cannington. Again, these impacts are expected to reduce to **minor adverse** significance in the permanent operation scenario. The impact on all other links is assessed as being of **minor adverse** significance.

11.8.28 During the early operation phase in 2021, hourly road traffic noise impacts of **minor beneficial** significance are predicted on many routes, particularly at night and most notably within Cannington.

11.9 Summary of Impacts

11.9.1 **Table 11.22** presents a summary of the impacts predicted with respect to noise and vibration during the construction, operation and post-operational phase of the proposed development, setting out impacts prior to mitigation, the mitigation proposed and the subsequent residual impacts.

Table 11.22: Summary of Impacts

Receptor	Potential Impact	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
On-site Construction Phase							
Residential dwellings south of the development site	Daytime noise during: • Construction of the emergency access road; • Early landscaping; and • Final landscaping.	High	Localised Direct Adverse Temporary Short-term Reversible	Medium	Major	EDFE to offer a voluntary Main Site Neighbourhood Support Scheme to these properties	Major adverse
	Daytime noise during final landscaping	High	Localised Direct Adverse Temporary Medium-term Reversible	Medium	Major	EDFE to offer a voluntary Main Site Neighbourhood Support Scheme to these properties	Major adverse
	Noise during all other concurrent construction works	Low/very low	Localised Direct Adverse Temporary Long-term Reversible	Medium	Minor	n/a	Minor adverse
	Night-time noise from Jetty construction	Low/very low	Localised Direct Adverse Temporary Long-term Reversible	Medium	Minor	n/a	Minor adverse

NOT PROTECTIVELY MARKED

Receptor	Potential Impact	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
	Vibration	Low/very low	Localised Direct Adverse Temporary Long-term Reversible	Medium	Minor	n/a	Minor adverse
	Noise from occupation of the accommodation campus	Low	Localised Direct Adverse Temporary Long-term Reversible	Medium	Minor	n/a	Minor adverse
Visitors to Pixies Mound	Noise during road upgrading works	High	Localised Direct Adverse Temporary Short-term Reversible	Low	Moderate	None proposed	Moderate adverse
	Noise during all other construction works	Medium to very low	Localised Direct Adverse Temporary Long-term Reversible	Low	Minor	n/a	Minor adverse

Receptor	Potential Impact	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Users of the public footpath along the western site boundary	Noise during final landscaping close to the site boundary	High	Localised Direct Adverse Temporary Medium-term Reversible	Low	Moderate	None proposed	Moderate adverse
Users of the coastal footpath	Noise during: • jetty construction; and • final landscaping close to the site boundary.	High	Localised Direct Adverse Temporary Medium-term Reversible	Low	Moderate	None proposed	Moderate adverse
Users of the public footpath along the western site boundary and coastal footpath	Noise during all other concurrent construction works	Medium/very low	Localised Direct Adverse Temporary Long-term Reversible	Low	Minor to negligible	n/a	Minor to negligible adverse
Off-site Highways Improvement Works							
Tropiquaria Zoo, children's playground	Noise from Washford Cross roundabout construction	High	Localised Direct Adverse Temporary Short-term Reversible	Low	Moderate	None proposed	Moderate adverse

Receptor	Potential Impact	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Nearest residential property to Washford Cross roundabout construction	Noise	Low	Localised Direct Adverse Temporary Short-term Reversible	Medium	Minor	n/a	Minor adverse
	Vibration	Low	Localised Direct Adverse Temporary Short-term Reversible	Medium	Minor	n/a	Minor adverse
Nearest residential property to Sandford Corner roundabout construction	Noise	Medium	Localised Direct Adverse Temporary Short-term Reversible	Medium	Moderate	None proposed	Moderate adverse
	Vibration	Low	Localised Direct Adverse Temporary Short-term Reversible	Medium	Minor	n/a	Minor adverse

Receptor	Potential Impact	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Off-site Construction Phase Road Traffic							
Residential properties in proximity to the proposed western bypass of Cannington	2016 Daily road traffic noise	High	Localised Direct Adverse Temporary Long-term Reversible	Medium	Major	EDFE to offer a voluntary Transport Noise Insulation Scheme	Major adverse
	2016 Road traffic noise at night	High	Localised Direct Adverse Temporary Long-term Reversible	Medium	Major	EDFE to offer a voluntary Transport Noise Insulation Scheme	Major adverse
	2016 Daily road traffic vibration	Low	Localised Direct Adverse Temporary Long-term Reversible	Medium	Minor	n/a	Minor adverse
Residential properties on designated bus and HGV routes in Bridgwater (between the M5 and the Quantock	Daily road traffic noise	Low/very low	Localised Direct Adverse Temporary Long-term Reversible	Medium	Minor	n/a	Minor adverse

Receptor	Potential Impact	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Roundabout)	Road traffic noise at night	High/medium	Localised Direct Adverse Temporary Long-term Reversible	Medium	Major to moderate	None proposed	Major to moderate adverse

Glossary

Term	Definition
dB	Sound levels from any source can be measured in frequency bands in order to provide detailed information about the spectral content of the noise i.e. whether is it high pitched, low pitched or with no distinct tonal character. These measurements are usually undertaken in octave or 1/3 octave frequency bands. If these values are logarithmically summed a single dB figure is obtained. This is usually not very helpful as it simply describes the total amount of acoustic energy measured and does not take any account of the ear's ability to hear certain frequencies more readily than others.
dB L_A	The dB L_A figure is used to relate better to the loudness of the sound heard. The dB L_A figure is obtained by subtracting an appropriate correction, which represents the variation in the ear's ability to hear different frequencies, from the individual octave or 1/3 octave band values, before logarithmically summing them. As a result, the single dB L_A value provides a good representation of how loud a sound is perceived.
L_{Aeq}	As almost all sounds vary or fluctuate with time it is helpful, instead of having an instantaneous value to describe the noise event, to have an average of the total acoustic energy experienced over its duration. The L_{Aeq}, 07:00-19:00 for example, describes the equivalent continuous noise level over the 12 hour period between 07:00 and 19:00. In the assessment of proposed industrial equipment or machinery noise, this is referred to as 'specific noise level'.
L_{Amax}	The L_{Amax} is the loudest instantaneous noise level. This is usually the loudest 125 milliseconds measured during any given period of time.
L_{An}	Method of describing with a single value a noise level which varies over a given time period, is to consider the average amount of acoustic energy and the length of time for which a particular noise level is exceeded. If a level of *x* dB L_A is exceed for 6 minutes within one hour, that level can be described as being exceeded for 10% of the measurement period. This is denoted as the $L_{A10\,(1\text{-hour})}$ = x dB. The L_{A10} index is often used to describe road traffic noise whilst the L_{A90}, the noise level exceeded for 90% of the time, is the usual descriptor of the underlying background noise. L_{A1} in addition to L_{Amax} are common descriptors of construction noise.
$L_{Ar,T}$	The rating level, $L_{Ar,T}$, is the specific noise level from proposed industrial plant or machinery plus any adjustment for the characteristic features of the noise.
Pascal (Pa)	Unit of pressure equal to 1 N/m2.
PPV	The Peak Particle Velocity (PPV) is the maximum velocity which is recorded during a particular event and can refer to a particular orientation (vertical or horizontal) or to the maximum (units: mm/s).
SWL or L_w	Sound Power Level (L_w) is the sound power measured on a decibel scale: Lp = 10 Log (*W/W0*), where W0 is the reference value of sound power, 10-12 Watts.
BNL	The basic noise level (BNL) is a parameter used in Guidance document 'Calculation of Road Traffic Noise'. It is the $L_{A10\,(18\text{-hour})}$ or $L_{A10\,(1\text{-hour})}$ at a reference distance of 10m away from the nearside carriageway edge. It is determined based upon the traffic flow, the speed of the traffic, the composition of the traffic, the gradient of the road and the road surface. On any given road the traffic flow, mean speed and composition are interdependent; for example, increasing the traffic flow may cause a reduction in the mean speed so that the net increase in noise level may be comparatively small. Similar effects are observed with changes in composition.
L_{AE} SEL	Sound Exposure Level. A parameter closely related to L_{Aeq} for assessment of events that have similar characteristics but are of different duration. The L_{AE} value contains the same amount of acoustic energy over a 'normalised' one second period as the actual noise event under consideration.

Appendix 12F: Input Parameters and Results of ADMS 4 Assessment of Marine Vessel Emissions

[This page is intentionally left blank]

12. AIR QUALITY

12.1 Introduction

12.1.1 This chapter of the Environmental Statement (ES) provides an assessment of the potential non-radiological air quality impacts associated with the construction and operation of the Hinkley Point C (HPC) development site (see **Volume 2**, **Chapters 2-4** for details). Radiological aspects are covered in **Volume 2**, **Chapter 21**.

12.1.2 Air quality effects arising from the construction and operation (including commissioning) of HPC relate to:

- Site preparation and ground terracing activities.
- Construction operations including the movement and operation of a wide range of construction plant and machinery.
- Off-site construction transport-related movements.
- HPC commissioning and operational processes.
- Off-site operational transport-related movements.

12.1.3 An introduction to air quality and the associated terminology used in this chapter is provided in **Appendix 12A.**

12.2 Scope and Objectives of Assessment

12.2.1 The scope of this assessment has been determined through a formal Environmental Impact Assessment (EIA) scoping process undertaken with the Infrastructure Planning Commission (IPC). It has also been informed by consultation with statutory consultees including West Somerset Council (WSC) and Sedgemoor District Council (SDC), as the relevant local authorities, and also by comments received from non-statutory consultees, including local residents and members of the general public, in response to the Stage 1, Stage 2, and Stage 2 Update consultations.

12.2.2 This chapter is complemented by an air quality monitoring report (Ref. 12.1), henceforth referred to as the "Air Quality Monitoring Report", and an air quality modelling report (Ref. 12.2), henceforth referred to as the "Air Quality Modelling Report". The Air Quality Monitoring Report includes details of the baseline air quality monitoring completed at locations in the vicinity of the HPC development site, whilst the Air Quality Modelling Report contains technical details of all the dispersion modelling studies undertaken to assist with the prediction of the potential air quality impacts as a result of the HPC development.

12.2.3 The assessment of air quality impacts has been undertaken adopting the methodologies described in **Volume 1**, **Chapter 7** and in section 12.4. The existing baseline conditions, against which the likely environmental impacts of the proposed development are assessed, have been determined through baseline air quality monitoring and modelling, and are described in sections 12.5 and 12.6.

12.2.4 Air quality impacts are presented in section 12.6, and appropriate mitigation measures aimed at preventing, reducing or off-setting any potential adverse impacts that are identified to be potentially significant are identified in section 12.7. An assessment of residual impacts following implementation of these mitigation measures is presented in section 12.8.

12.2.5 The potential site-specific cumulative air quality impacts from different aspects of the proposed HPC development during the construction and operational phases are assessed in this chapter. Cumulative air quality impacts arising from the proposed development in combination with other elements of the HPC Project and other relevant planned or reasonably foreseeable projects are identified and assessed in **Volume 11** of this ES.

12.2.6 The objectives underlying the air quality assessment are to:

- Identify potentially sensitive receptor locations that may be affected by the construction or operational phases of the proposed development.
- Characterise baseline air quality within the study area.
- Assess air quality impacts of the proposed development on sensitive receptors within the study area;
  - predict the potential air quality impacts during the site preparation works, construction of a temporary jetty, and construction of the two UK EPR Units (referred to herein as Units C1 and C2) and ancillary buildings;
  - predict the potential air quality impacts associated with road traffic at key stages of the construction phase and also during operation; and
  - predict the potential air quality impacts from the relevant components of the operational HPC power station.
- Recommend mitigation measures, if considered necessary, to prevent, reduce or off-set the air quality impacts on sensitive receptors.
- Assess the residual air quality impacts on sensitive receptors.

12.2.7 Air quality impacts resulting during decommissioning of the proposed HPC power station are not considered in this assessment. Decommissioning is outlined in **Volume 2**, **Chapter 5** of the ES, and prior to undertaking this phase, a full EIA will be submitted for approval to the relevant organisation(s) at the appropriate time.

12.3 Legislation, Policy and Guidance

12.3.1 This section identifies and describes legislation, policy and guidance of relevance to the assessment of potential air quality impacts associated with the construction and operation of the proposed development.

12.3.1 As stated in **Volume 1**, **Chapter 4**, the Overarching National Policy Statement (NPS) for Energy (EN-1) when combined with the NPS for Nuclear Power Generation (EN-6) provides the primary basis for decisions by the IPC on applications for nuclear power generation developments that fall within the scope of the NPSs.

12.3.2 Notwithstanding this, the IPC may consider other matters that are both important and relevant to its decision-making. This could include Planning Policy Statements (PPSs), Planning Policy Guidance Notes (PPGs), regional and local policy documents, although, if there is a conflict between these and the NPS, the NPS prevails for the purposes of IPC decision making.

12.3.1 Further, the Planning Act 2008 provides that the IPC must, in making its decision on an application, have regard to any Local Impact Report (LIR) prepared by relevant local authorities. It is anticipated that the LIRs will rely in part on PPSs, PPGs, regional and local policy to provide a context for their assessment. On this basis, regard has been given to these documents (where relevant to the technical assessment) since they are likely to inform the LIRs prepared by the relevant local authorities.

a) International Legislation

i. The World Health Organisation (WHO) Air Quality Guidelines (AQGs) (Ref. 12.3 and Ref. 12.4)

12.3.2 WHO AQGs (Ref. 12.3 and Ref. 12.4) offer global guidance to policy-makers on reducing the health impacts of air pollution. The guidelines, first produced in 1987 and updated in 1997, previously adopted a European scope, whilst the current 2005 guidelines are applied globally. They recommend revised limits for the concentration of selected air pollutants including particulate matter (PM), ozone (O_3), nitrogen dioxide (NO_2) and sulphur dioxide (SO_2) applicable across all WHO regions.

12.3.3 In addition to the guideline values, the AQGs give interim targets (ITs) related to outdoor air pollution, for each air pollutant, aimed at promoting a gradual shift to lower concentrations. If these ITs are achieved, reductions in risks for acute and chronic health impacts from air pollution would be expected, but the ultimate objective should be progress towards the guideline values.

12.3.4 Although these guidelines are neither standards nor legally binding criteria, they are designed to offer guidance in reducing the health impacts of air pollution based on expert evaluation of current scientific evidence. The WHO AQGs and ITs are summarised in **Appendix 12B**, **Table 1**.

b) European Legislation

i. Directive 2008/50/EC of the European Parliament and of the Council of 21 May 2008 on Ambient Air Quality and Cleaner Air for Europe (EU Directive 2008/50/EC) (Ref. 12.5)

12.3.5 European Union (EU) policy on air quality aims to develop and implement appropriate instruments to improve air quality within the EU member states. EU Directive 2008/50/EC (Ref. 12.5), which came into force in June 2008, merges most of the existing air quality legislation into a single directive (the exception is the fourth "Daughter Directive" under the 1996 Framework Directive (96/62/EC)) (Ref. 12.6). This reorganisation of the legislation did not include a change to the existing air quality Limit Values. It introduces a new framework for $PM_{2.5}$ (fine particles), including the limit value and exposure related targets with a period of two years provided to all EU Member States to transpose the new Directive. The introduction of this framework was based on increasing evidence that this size of particle can be more closely associated with observed adverse health impacts than PM_{10}. The EU air quality Limit Values are summarised in **Appendix 12B, Table 2**.

12.3.6 The air quality Limit Values relate to ambient pollutant concentrations in the air and the limits are set on the basis of medical and scientific evidence reviewed by the Expert Panel on Air Quality Standards (EPAQS) and the WHO as to how each pollutant affects human health. Above these limits, sensitive members of the public (e.g. children, the elderly and the infirm) may experience adverse health impacts.

12.3.7 Other European Directives relate to equipment standards such as the control of emissions of gaseous and particulate pollutants from internal combustion engines and on the quality of petrol and diesel fuels. These are discussed in greater detail in section 12.6.

c) UK Legislation and Guidance

i. The Environment Act 1995 (Ref. 12.7)

12.3.8 The Environment Act 1995 (Ref. 12.7) required the preparation of a national Air Quality Strategy to set air quality standards and objectives for specified pollutants. The Act also outlined measures to be taken by local authorities (LAs) in relation to meeting those standards and objectives (the Local Air Quality Management (LAQM) framework).

ii. The Air Quality Standards Regulations (Ref. 12.8)

12.3.9 The Air Quality Standards Regulations 2010 (Ref. 12.8) transpose into UK legislation the European Directives (Ref. 12.4), the Council's decision on exchange of information (Ref. 12.9), as well as replacing the Air Quality Standards Regulations 2007 (Ref. 12.10). The Air Quality Standards Regulations 2010 came into force in the UK on 11 June 2010. The Air Quality Limit Values are transposed into the updated Regulations as Air Quality Standards (AQS) with attainment dates in line with the European Directives.

iii. The Air Quality Regulations 2000 (Ref. 12.11), the Air Quality Regulations 2002 (Ref. 12.12) and the Air Quality Strategy for England, Scotland, Wales and Northern Ireland (Ref. 12.13)

12.3.10 In the UK, action on air quality is driven by the health-based objectives for key air pollutants, which have been made statutory through the Air Quality Regulations 2000 (Ref. 12.11), as amended in 2002 (Ref. 12.12), and set out in the 2007 Air Quality Strategy for England, Scotland, Wales and Northern Ireland (The Air Quality Strategy) (Ref. 12.13). The Air Quality Objectives (AQOs) are based on the Air Quality Standards/Air Quality Limit Values, with interim target dates to help the UK move toward the achievement of the EU Air Quality Limit Values. The AQOs in The Air Quality Strategy are a statement of policy intentions or policy targets and as such, there is no legal requirement to meet these objectives, except in so far as they mirror any equivalent legally binding Limit Values in EU legislation.

12.3.11 The AQOs incorporate dates by which each standard is to be achieved. These are policy based targets set by the Government which take into account economic efficiency, practicability and technical feasibility. Some objectives are equal to the EPAQS recommended standards or WHO guideline limits, whereas others involve a margin of tolerance (i.e. a limited number of permitted exceedences of the standard over a given period).

12.3.12 The AQOs for each pollutant in The Air Quality Strategy and the Air Quality Regulations set out above are summarised in **Appendix 12B, Table 3**. For some pollutants (e.g. NO_2), there is both a long-term (annual mean) and a short-term standard. In the case of NO_2, the short-term objective is for a 1-hour averaging period, whereas for fine particles (PM_{10}) it is for a 24-hour averaging period. These periods reflect the varying impacts on health of differing exposures to pollutants, for example temporary exposure of persons on the pavement adjacent to a busy road, compared with the exposure of occupiers of residential properties adjacent to a road.

12.3.13 The 2007 Air Quality Strategy replaced the previous Air Quality Strategy for England, Scotland, Wales and Northern Ireland (January 2000) and Addendum (February 2003). The majority of the AQOs set out in this previous version of The Air Quality Strategy were retained; however, the provisional objectives previously proposed for PM_{10} were replaced in England, Wales and Northern Ireland with a new framework for considering the impacts of $PM_{2.5}$. The Air Quality Standards Regulations 2010 (Ref. 12.8) incorporated into statute the annual mean $PM_{2.5}$ AQO limit value of 25µg/m^3 as previously set out in The Air Quality Strategy (to be achieved by 2015), and also defined exposure reduction targets for $PM_{2.5}$. However, these $PM_{2.5}$ objectives/reduction targets have not been incorporated into LAQM Regulations and local authorities have no statutory obligation to review and assess air quality against them.

12.3.14 Of the pollutants included in the Air Quality Strategy, NO_x/NO_2, PM_{10} and $PM_{2.5}$ are particularly relevant to this assessment, as road traffic is a major source of these pollutants. Where road traffic is the dominant source of air pollution, the objectives for these pollutants tend to be the most difficult to achieve according to the experience of local authorities undertaking review and assessments of air quality. Further, it is generally considered that where the AQOs for the concentrations of NO_2 and PM_{10} are achieved, and where there are no other significant local sources of air pollution, such as from industrial processes, the AQOs for the other pollutants included within the Air Quality Standards Regulations 2010 (Ref. 12.8) should also be achieved.

iv. Local Air Quality Management Technical Guidance LAQM.TG(09) (Ref. 12.14)

12.3.15 The Department for Environment, Food and Rural Affairs (Defra) has published technical guidance for use by local authorities in their review and assessment work. Local Air Quality Management Technical Guidance LAQM.TG(09) (Ref. 12.14) is designed to support local authorities in carrying out their duties under the Environment Act 1995 (Ref. 12.7) and subsequent Air Quality Regulations (Ref. 12.11 and Ref. 12.12).

12.3.16 LAQM.TG(09) provides guidance to local authorities on when to declare an Air Quality Management Area (AQMA) should exceedences of AQOs occur. In setting an AQMA, a local authority must then formulate an Air Quality Action Plan (AQAP) to seek to reduce pollutant concentrations to values below AQO levels. Progression towards this goal is managed through the on-going LAQM review and assessment process.

12.3.17 The guidance, referred to in this chapter as LAQM.TG(09), has been used where appropriate to inform the assessment presented herein.

v. The Environmental Protection Act 1990 (EPA) (Ref. 12.15)

12.3.18 The EPA 1990 (Ref. 12.15) makes provision within England, Wales and Scotland for the improved control of pollution arising from certain industrial and other processes. Part of the EPA applies to the control of dust and particulates associated with construction.

12.3.19 The EPA (Ref. 12.15) defines statutory nuisances. Definitions of statutory nuisance relevant to dust and particles are:

- *“Any dust, steam, smell or other effluvia arising from industrial, trade or business premises or smoke, fumes or gases emitted from premises so as to be prejudicial to health or a nuisance”; and*
- *“Any accumulation or deposit which is prejudicial to health or a nuisance”.*

12.3.20 Section 79 of the EPA states that where a statutory nuisance is shown to exist, the local authority must serve an abatement notice. Failure to comply with an abatement notice is an offence and, if necessary, the local authority may abate the nuisance and recover expenses.

12.3.21 There are no statutory limit values for dust deposition above which ‘nuisance’ or ‘annoyance’ is deemed to exist. Nuisance/annoyance is a subjective concept and its perception is highly dependent upon the existing conditions and the change to air quality conditions which has occurred (i.e. increases in pollutant concentrations or dust deposition rates relative to background levels).

12.3.22 However, research carried out on behalf of the former Department of the Environment (DoE) (Ref. 12.16) provides some guidance as to the determination of annoyance from dust and suggests that complaints are likely when the rate of dust deposition is 2 to 3 times the normal background level of dust deposition in the area. The report suggests that it is preferable that continuous sources with a high or medium dust emission potential are separated by a stand-off distance from sensitive uses, and goes on to recommend a distance of between 100-200m separation from a significant dust emitting source (with the qualification that these distances can be reduced if appropriate, and if effective mitigation measures are identified and implemented).

d) National Planning Policy

i. Planning Policy Statement 23: Planning and Pollution Control (PPS23) (2004) (Ref. 12.17)

12.3.23 National policy for local planning authorities in England regarding local air quality and new development is provided in PPS23 (Ref. 12.17). This statement provides advice on the policies and practices that should be taken into account by those involved in the planning of any development that has the potential to cause pollution.

12.3.24 With regard to emissions to air, and specifically LAQM, PPS23 states, in Paragraph 8, that:

- *"any consideration of the quality of air and potential impacts arising from development, possibly leading to an impact on health, is capable of being a material planning consideration, in so far as it arises or may arise from any land use."*

12.3.25 This is most likely to be the case in situations where the proposed development could produce an exceedence of the AQOs and result in an AQMA designation, where development is proposed in an AQMA, or where a proposed development renders a local authority's AQAP unworkable.

12.3.26 PPS23 also states that the presence of an AQMA should not result in the sterilisation of a site from development.

e) Regional Planning Policy

12.3.27 The Government's revocation of regional strategies was quashed in the High Court on 10 November 2010. However, on that same date the Government reiterated in a letter to Chief Planners its intention to revoke regional strategies through the Localism Bill. This letter was also challenged but, on 7 February 2011, the High Court held that the Government's advice to local authorities that the proposed revocation of regional strategies was to be regarded as a material consideration in their planning development control decisions should stand. The decision of the High Court was upheld by the Court of Appeal on 27 May 2011. Therefore, the regional strategies remain in place but in the case of development control decisions it is for planning decision makers to decide on the weight to be attached to the strategies (see **Volume 1**, **Chapter 4** for a full summary of the position regarding the status of regional planning policy).

i. Regional Planning Guidance 10 for the South West 2001-2016 (RPG10) (2001) (Ref. 12.18)

12.3.28 RPG 10 (Ref. 12.18) sets out the broad development strategy for the South West for the period to 2016 and beyond. Paragraph 4.9 explains that reducing the need to travel by concentrating development in and around urban areas and placing a greater emphasis on movement by foot, cycle and public transport will be important in helping to reduce air pollution overall. Policy EN2: Air Quality states:

"Local authorities should:

- *include in their development plans and proposals policies on the location of potentially polluting developments and of sensitive developments in the vicinity of existing polluting developments, in line with guidance in PPS23 (as and when it is updated) and in Air Quality and Land Use Planning LAGM.G3(00);*
- *designate air quality management areas where required as part of the local air quality management process; and*
- *ensure that air quality considerations are properly considered along with other material considerations in the planning process, particularly where any air quality management areas have been designated."*

ii. Draft Revised Regional Spatial Strategy (RSS) for the South West Incorporating the Secretary of State's Proposed Changes for Public Consultation (July 2008) (Ref. 12.19)

12.3.29 **Chapter 7** sets out the strategy's approach to environmental quality. Within this chapter, Policy RE9: Air Quality states:

- *"The impacts of development proposals on air quality must be taken into account and Local Authorities should ensure, through LDD's that new development will not exacerbate air quality problems in existing and potential AQMA's.*
- *This should include considerations of the potential impacts of new developments and increased traffic levels on internationally designated nature conservation sites, and adopt mitigation measures to address these impacts."*

iii. Somerset & Exmoor National Park Joint Structure Plan Review 1991-2001 (2000) (Policies 'saved' from 27 September 2007) (Ref. 12.20)

12.3.30 **Chapter 4** provides a framework for protection, conservation and management for the natural and built environment. There are no specific policies relating to air quality within the Structure Plan.

f) Local Planning Policy

i. West Somerset District Council. The West Somerset District Local Plan (2006) (Ref. 12.21)

12.3.31 The West Somerset District Local Plan forms part of the development plan for the site. The Local Plan was adopted in 2006 with relevant policies saved from April 2009.

12.3.32 There are no specific policies relating to air quality within the Local Plan and the HPC development site is not affected by any specific air quality designations.

ii. Sedgemoor District Local Plan 1991-2011 (Policies 'saved' from 27 September 2007) (Ref. 12.22)

12.3.33 The Sedgemoor District Local Plan (Ref. 12.22) forms part of the Development Plan for Sedgemoor. The Local Plan was adopted in September 2004 (with relevant policies 'saved' from 27 September 2007). The Proposals Map (Southern Sheet and Inset Map No. 20) indicates that the wider HPC Project area is not subject to any specific air quality designations. The site lies outside of the defined Development Boundary.

12.3.34 There are no specific policies relating to air quality within the Local Plan.

iii. Sedgemoor District Council Local Development Framework (LDF) Core Strategy (Proposed Submission) (September 2010) (Ref. 12.23)

12.3.35 The Sedgemoor LDF Core Strategy (Proposed Submission) was consulted on from September to November 2010. Changes prior to submission proposed as a result of the consultation process were reported and endorsed by the Council's Executive Committee on 9 February 2011. The Core Strategy (Proposed Submission) was submitted to the Secretary of State on 3 March 2011 and an Examination in Public (EiP) was held in May 2011. Once adopted, the Core Strategy will form part of the Development Plan for Sedgemoor.

12.3.36 EDF Energy submitted representations objecting to the Core Strategy (Proposed Submission), relating to chapter 4 ‘Major Infrastructure Projects’ (and policies MIP1, MIP2 and MIP3 contained in that chapter) and those sections relating to housing and Hinkley Point. EDF Energy also participated at the relevant EiP hearings. See **Volume 1**, **Chapter 4** for a full summary of the position regarding the status of the Core Strategy.

12.3.37 The following Core Strategy (Proposed Submission) policies are of potential relevance:

12.3.38 Policy S3 (Sustainable Development Principles) states that development proposals will be expected to, amongst other things, protect and enhance the quality of the natural, built and historic environment.

12.3.39 Policy D4 (Renewable and Low Carbon Energy Generation) states that the Council will support such proposals provided that such installations would not have significant adverse impact taking into account, amongst other things, any unreasonable adverse impact on users and residents of the local area including the generation of emissions.

12.3.40 Policy D9 (Sustainable Transport and Movement) states that proposals should contribute to the reduction of adverse environmental issues, including air pollution, through appropriate mitigation measures.

12.3.41 Policy D10 (Managing the Transport Impacts of Development) states that development proposals that will have a significant transport impact should be supported by an appropriate Air Quality Assessment.

12.3.42 Policy D16 (Pollution Impacts of Development and Protecting Residential Amenity) states:

> *“Development proposals that are likely to result in levels of air, noise, light or water pollution (including groundwater) vibration or soil contamination that would be harmful to other land uses, human health, tranquillity or the built and natural environment will not be supported.*
>
> *Where there are reasonable grounds to suggest that a development proposal may result in a significant adverse environmental impact, the Council will require planning applications to be supported by assessments relating to [amongst other things]:*
>
> - *air pollution; and*
> - *carbon emissions.*
>
> *Where it is demonstrated that it is possible to manage the potential adverse impacts of the development proposals through its design or mitigation measures, the Council will, by means of condition or legal agreement, seek to ensure such measures are effective, for example improving limitations on matters including hours of operation, emissions of fumes, noise and light, parking and servicing for both construction and operational stages.”*

g) Supplementary Planning Guidance

12.3.43 Sedgemoor District Council and West Somerset Council have jointly prepared draft supplementary planning guidance in relation to the HPC Project. Public consultation on the Consultation Draft version of the Hinkley Point C Project Supplementary Planning Document (the draft HPC SPD) commenced on 1 March 2011 and concluded on 12 April 2011. EDF Energy has submitted representations which object to the draft HPC SPD. See **Volume 1**, **Chapter 4** for a full summary of the position regarding the status of the draft HPC SPD.

12.3.44 The draft HPC SPD does not set out any specific guidance in relation to air quality impacts at the site. In relation to transport generally, Box 8 of the draft HPC SPD states that the County Council and District Councils will expect the HPC Project promoter to, amongst other things, provide necessary improvements to the transport network to mitigate against any adverse impacts on the community; including but not limited to congestion and air quality (page 19).

12.3.45 Further planning policy context is provided in the Legislative Planning Policy Context chapter (**Volume 1**, **Chapter 4**) and the Introduction chapter (**Volume 2**, **Chapter 1**).

i. Bridgwater Vision (Ref. 12.24)

12.3.46 Whilst not forming part of the statutory Development Plan for Sedgemoor, the Bridgwater Vision (Ref 12.24) sets out a regeneration framework for Bridgwater, comprising a 50 year vision and seven transformational themes for the town.

12.3.47 The document makes specific reference to Hinkley Point as a strategic project and acknowledges the opportunities and challenges such development will have on the area. It goes on to state that it will be essential to evaluate the environmental impact of the Hinkley Point proposals both pre and post construction but makes no specific reference to air quality issues.

ii. Air Quality Strategy for Somerset 2008 (Ref. 12.25)

12.3.48 The Air Quality Strategy for Somerset 2008 (Ref. 12.25) sets out strategic recommendations for working towards improved air quality and protecting existing air quality across Somerset. The Strategy represents the culmination of air quality management work over recent years, incorporating input from all six Councils that form the administrative region of Somerset (i.e. Somerset County Council (SCC) and the five local authorities of Mendip District Council, South Somerset District Council, Taunton Deane Borough Council, SDC and WSC).

12.3.49 The Strategy recognises the need to provide an integrated response to air quality management, and sets out a view to facilitating future improvements. The Strategy aims to complement the LAQM process, and the actions within the document provide a framework for how these improvements can be facilitated within Somerset.

iii. West Somerset Council Air Quality Progress Report 2011 (Ref. 12.26)

12.3.50 The 2011 Air Quality Progress Report (Ref. 12.26), prepared by WSC, forms part of the LAQM system introduced by the Environment Act 1995 (Ref. 12.7) and subsequent Air Quality Regulations (Ref. 12.11 and Ref. 12.12). This report follows on from the Council's Progress Report in 2010 (Ref. 12.27), which concluded that a

Detailed Assessment would not be required for any pollutant. There are currently no AQMAs declared within the authority area.

12.3.51 The report identifies that ambient NO_2 pollutant concentrations (the only pollutant monitored by the Council) at properties close to the main highway were found to be highest in Williton owing to relatively high traffic flows, reduced speed (congestion) and narrowing of the A39.

12.3.52 Recent monitoring data results suggest that annual mean NO_2 concentrations in Williton have increased in 2010 compared to the previous year (the observed temporal trend between 2007 and 2009 was for a general reduction in NO_2 concentrations in Williton), most notably at 'Williton County Stores' where an annual concentration increase of 4.3µg/m^3 was observed.

12.3.53 However, at the 'Williton County Stores' monitoring site, due to missing diffusion tubes during the monitoring period, data capture over 2010 was only 83%. This is below the 90% threshold that Defra suggest is preferred, as specified in LAQM.TG(09) (Ref. 12.14). Also, the two periods with missing diffusion tubes occur at times in the year (July 2010 onwards) when NO_2 concentrations at this location generally appear to be lower (Ref. 12.26). Furthermore, preliminary analysis of temporal trends from other national monitoring locations suggest that 2010 NO_2 annual mean concentrations at these locations were also higher than for previous years, indicating that these increases and the observed NO_2 concentration increases in Williton during 2010 are more likely to be due to regional or national factors, e.g. meteorological conditions resulting in poor dispersion, as opposed to factors local to Williton. The increased 2010 NO_2 annual mean concentrations in Williton, particularly at the 'Williton County Stores' monitoring location, should therefore be treated with caution, as opposed to a definitive indication that the trend of a general reduction in annual mean NO_2 concentrations in Williton (as observed between 2007 and 2009) has been reversed. Further local authority NO_2 monitoring results obtained at these locations for 2011 will help determine any definitive trends.

12.3.54 The 2011 Air Quality Progress Report concluded that no exceedences of either the annual mean or 1-hour mean NO_2 AQOs were identified within the authority area.

iv. Sedgemoor Air Quality Progress Report 2010 (Ref. 12.28)

12.3.55 The 2010 Air Quality Progress Report (Ref. 12.28), prepared by SDC, forms part of the LAQM system introduced by the Environment Act 1995 (Ref. 12.7) and subsequent Air Quality Regulations (Ref. 12.11 and Ref. 12.12). This report follows on from the Council's Updating and Screening Assessment Report in 2009 (Ref. 12.29), which concluded that a Detailed Assessment would not be required for any pollutant. There are currently no AQMAs declared within the authority area.

12.3.56 The report identifies that ambient NO_2 pollutant concentrations were highest in Bridgwater owing to high traffic flows, reduced speed (congestion) and narrowing of the A38, with properties close to the main highway.

12.3.57 The 2010 Air Quality Progress Report concluded that no exceedences of either the annual mean or 1-hour mean NO_2 objectives were identified within the authority area. Forward projection of the NO_2 monitoring results (the only pollutant monitored by the Council) to 2010 suggested that the NO_2 annual mean AQO would likely be met.

12.3.58 SDC plans to continue with existing NO_2 monitoring and to provide an Air Quality Progress Report in 2011.

12.4 Methodology

12.4.1 The assessment and all supporting surveys have been conducted in accordance with relevant best practice guidance and standard methodologies.

a) Study Area

12.4.2 The study area with respect to potential dust and particulate impacts and on-site construction plant and machinery exhaust emissions impacts is shown on **Figure 12.1** and **Figure 12.2**. **Figures 12.3, 12.4** and **12.5** show the study areas and road sources considered in the vehicle exhaust emissions impact assessment related to construction and early operational phase traffic. **Figures 12.6** and **12.7** show the study areas and sources considered in the assessment of marine vessel exhaust emissions, and the HPC commissioning and routine test impact assessment. The locations of the assessed sensitive receptors are also presented on each figure.

12.4.3 The geographical extent of the study area for this assessment includes:

- Human receptors located in proximity to the HPC development site boundary at residential dwellings in the villages of Burton and Shurton to the south, Wick to the south-east, and Stolford to the east of the site.
- Human receptors located adjacent to the highways potentially affected by the proposed development, in the villages of Williton and Cannington, and the town of Bridgwater.
- Ecological receptors located adjacent to either the HPC development site boundary or parts of the highway network where traffic flows may be affected by the proposed development.

12.4.4 The purpose of the assessment is to determine the potential worst-case impacts associated with the proposed development. Therefore, it is considered reasonable to assume that the nearest (unscreened, i.e. with no current barriers between the source and receptor which would reduce air quality impacts, e.g. dense woodland) receptor locations to the proposed HPC development site and road network are those likely to experience the greatest air quality impacts.

12.4.5 With regards to the inclusion of ecological receptors within the assessment of operational (non-vehicular) emissions from HPC, the screening criteria as defined in Environment Agency Horizontal Guidance Note H1 (Ref. 12.30) has been followed:

- Special Protection Areas (SPAs), Special Areas of Conservation (SACs) or Ramsar sites within 15km of the site.
- Sites of Special Scientific Interest (SSSIs) within 2km of the site.
- National Nature Reserves (NNRs), Local Nature Reserves (LNRs), local wildlife sites and ancient woodland within 2km of the site.

12.4.6 In the absence of specific guidance for the scoping of ecological receptors within air quality assessments of marine vessel emissions, a 200m distance from the emission source has been applied. This is consistent with Highways Agency guidance published in the Design Manual for Roads and Bridges (DMRB) (Ref. 12.31) for the scoping of ecological receptors for inclusion within air quality assessments of vehicular emissions. Designated ecological sites (SACs, SPAs, SSSIs or Ramsar sites) within 200m of the source location (temporary jetty head) were therefore included within the assessment of marine vessel emissions.

12.4.7 With regards to the air quality assessment of vehicular emissions, with the exception of the C182 and the private access road leading from the C182 to the Combwich site, there are no affected roads within 200m of the above designated ecological sites (SACs, SPAs, SSSIs or Ramsar sites). Therefore, designated ecological sites located within 200m of the C182 and the private access road were considered in the off-site vehicular emissions assessment (consistent with Highways Agency DMRB guidance (Ref. 12.31).

12.4.8 The ecological receptors (statutory and non-statutory designated ecological sites) within the study area are identified and considered within **Volume 2, Chapter 20** but are also discussed herein, and in the context of the air quality assessment study area are illustrated in **Figure 12.1**.

12.4.9 For assessed off-site highway improvements, the working areas together with an area of 200m around them were considered. As above, the purpose of the assessment was to determine the potential worst-case impacts associated with the proposed development. In general this was represented by assessments of potential air quality impacts at the nearest residential dwelling or other identified sensitive receptor.

12.4.10 Only the human receptors and ecological sites that are located within the study area (as defined in **Figures 12.1, 12.2, 12.3, 12.4, 12.5** and **12.6**) are included in the assessment.

b) Baseline Assessment

12.4.11 Baseline environmental characteristics for the HPC development site and surrounding areas with specific reference to air quality were identified through:

- a baseline air quality monitoring campaign;
- review of desk based information; and
- consultation with officers of WSC and SDC.

12.4.12 With respect to air quality, the nearest human receptor locations to the HPC development site comprise residential dwellings in the villages of Burton, Shurton to the south and Wick to the south-east, and Stolford to the east. Therefore, in order to determine the existing background air quality at Hinkley Point, a baseline air quality monitoring programme was undertaken at sites that are representative of these receptor locations, as well as a continuous background monitoring site located adjacent to the existing Hinkley Point B power station.

12.4.13 The monitoring programme was undertaken for the pollutants of primary concern (NO_x, NO_2, PM_{10} and SO_2), for a period of over six months, commencing on 25 February 2009 and finishing on 15 September 2009 (Ref. 12.32). Full details of the monitoring results are provided in the Air Quality Monitoring Report (Ref. 12.1).

12.4.14 Desk based studies carried out for the assessment included the identification and evaluation of:

- local industrial pollution emission sources within the districts of West Somerset and Sedgemoor; and
- existing air quality - an evaluation of estimated ambient background pollutant concentrations provided in Defra's UK Air Quality Information Resource (UK-AIR) (Ref. 12.33).

12.4.15 The annual mean pollutant concentrations obtained during the monitoring programme were compared with the pollutant background concentrations available in the desk based assessment literature. From this comparison, with the exception of the assessment of vehicular exhaust emissions within the Bridgwater ADMS Roads model, the decision was taken to use the background concentrations as determined from the baseline monitoring programme for assessment purposes (see section 12.6 and the Air Quality Modelling Report, Ref. 12.2), as this would provide a worst-case approach in terms of evaluation of total concentrations (i.e. background plus development related emissions contributions) against the AQOs. With regards to the assessment of vehicular emissions at receptors within the Bridgwater ADMS Roads model area, the decision was taken to use the highest UK-AIR background pollutant concentrations for those grid squares located within the entire ADMS-Roads 'Bridgwater model' area, as this would provide a worst-case approach in terms of evaluation of total concentrations against the AQOs (see the Air Quality Modelling Report, Ref. 12.2).

c) Consultation

12.4.16 In undertaking this assessment, consultations have been held with WSC and SDC.

12.4.17 At a scoping consultation meeting held with both parties on 9 December 2008, the specific requirements for the air quality assessment were discussed and agreements reached regarding the methodologies to be adopted.

12.4.18 The following advice and direction was provided by WSC and SDC and has been taken into account within this assessment:

- baseline monitoring of NO_2 along potential vehicular routes to/from HPC was not required;
- use of UK-AIR background pollutant concentrations (Ref. 12.31) would be acceptable; and
- use of Environmental Protection UK (EPUK) significance criteria (Ref. 12.34) would provide a robust assessment of potential air quality impacts.

12.4.19 A second consultation meeting was held with the above parties on 1 October 2009, where the main findings of the assessment work undertaken to date were presented. No significant deviations to the planned scope or assessment methodology were requested.

12.4.20 A third consultation meeting was held with on 22 February 2011. The purpose of this meeting was to present additional work undertaken since Stage 2 consultation, and to review consultation comments received at Stage 2 and how these were to be addressed. The following key points were agreed during the meeting:

- With regards to the vehicular emissions dispersion modelling studies, there was no need to consider varying queue lengths at junctions for each scenario modelled, but there was, however, a need to consider a varying vehicle average speed for junctions within each scenario modelled.
- Exclusion of car park area sources within the vehicular dispersion modelling study would probably be acceptable, depending upon the size and intended usage of the car parks (see section 10.4 d)vi).

12.4.21 Responses were also received from the following consultees during the formal consultation process:

- WSC and SDC.
- Somerset County Council (SCC).
- Environment Agency (EA).
- Highways Agency (HA).
- Natural England (NE).
- Countryside Council for Wales (CCW).
- Health Protection Agency (HPA).
- Stogursey Parish Council (SPC).
- Cannington Parish Council (CPC).
- Fairfield Estate.
- Vale of Glamorgan Council.
- Homes & Communities Agency.
- Cannington Women's Institute.
- NHS Somerset Primary Care Trust.

12.4.22 Comments received have been reviewed and, where appropriate, addressed or additional clarification has been provided within this chapter. Detailed responses to all comments are provided in the **Consultation Report**.

d) Assessment Methodology

i. Introduction

12.4.23 For this chapter of the ES, the generic descriptions used to define the impact and its likelihood of occurrence (probability) are those given in **Volume 1**, **Chapter 7**. However, specific assessment criteria that define the magnitude and significance of air quality impacts have been developed and are presented below.

12.4.24 Beneficial impacts are identified, but not quantitatively assessed.

12.4.25 It is only necessary to describe mitigation measures for significant adverse impacts with respect to air quality. Major and moderate impacts are assessed as being potentially significant and are deemed to require specific mitigation.

12.4.26 Given the difference in the potential air quality impacts and assessment methodologies applied to fugitive dust and particulates, and other pollutant emissions to air (off-site vehicular emissions, on-site plant and machinery exhaust emissions, marine vessel emissions associated with operation of the temporary jetty, and HPC commissioning/operational emissions), two separate assessment criteria have been developed and applied, based upon current published best practice guidance:

- *Fugitive dust and particulates* – best practice guidance issued by the Greater London Authority (GLA) and London Councils (Ref. 12.35), Building Research Establishment (BRE) (Ref. 12.36) and Quality of Urban Air Review Group (QUARG) (Ref. 12.37) provide guidelines that allow the evaluation of the risk of air quality impacts occurring during demolition and/or construction activities, and these have been adapted for consideration of fugitive dust and particulates.
- *Other pollutant emissions to air* – assessment criteria applied to off-site vehicular emissions, on-site plant and machinery exhaust emissions, marine vessel emissions associated with operation of the temporary jetty, and HPC commissioning/operational emissions, have been developed from guidance published in the EPUK document entitled 'Development Control: Planning for Air Quality (2010 Update)' (Ref. 12.34).

ii. Assessment Criteria Applied to Off-site Vehicular Emissions, On-site Construction Plant and Machinery Exhaust Emissions, Marine Vessel Emissions and HPC Commissioning/Operational Emissions to Air

12.4.27 Air quality impacts associated with development related off-site vehicular emissions, on-site plant and machinery exhaust emissions, marine vessel emissions associated with operation of the temporary jetty, and HPC commissioning/operational emissions, have been determined by comparing the magnitude of change between the air quality predicted for the future assessment year with the proposed HPC development (the 'with development' scenario) against the air quality predicted for the future assessment year in the absence of the proposed development (the 'without development' scenario). This information has been used in combination with an evaluation of the air quality predicted for the 'with development' scenario against the relevant UK AQOs in order to determine the significance of the potential air quality impacts.

12.4.28 The descriptors presented in **Table 12.1** for the magnitude of change in pollutant concentrations due to off-site vehicular emissions, on-site plant and machinery exhaust emissions, marine vessel emissions associated with operation of the temporary jetty, and HPC commissioning/operational emissions, have been either taken directly or developed from guidance published by EPUK (Ref. 12.34). For long-term pollutant emissions, the magnitude of change is determined based upon the magnitude of increase of the annual mean pollutant concentration relative to the AQO limit value. For short-term pollutant emissions from road traffic and on-site exhaust emissions to air from construction plant and machinery, the magnitude of change is determined based upon the number of predicted exceedences of the short-term AQO limit, derived from empirical relationships between the annual mean concentrations and the number of exceedences of the short-term mean AQOs provided within LAQM.TG(09) (Ref. 12.14) (see section 12.4d) for more information).

12.4.29 In the absence of equivalent empirical relationships between the annual mean concentrations and the number of exceedences of the short-term mean AQOs for pollutants from non-road traffic sources, the magnitude of change of short-term pollutant emissions from marine vessels and HPC commissioning/operational sources has not been determined as above, as to do so would require a full calendar year of background monitoring data (in order to identify the existing number of exceedences within this period). Consequently, the magnitude of change of short-term emissions from marine vessels and HPC commissioning/operational sources has been determined based upon the magnitude of increase of the model-predicted short-term pollutant percentile concentration relative to the short-term AQO limit value (e.g. for 1-hour mean SO_2, the magnitude of increase in the 99.73 percentile relative to the 1-hour SO_2 AQO limit value of 350µg/m^3). With regards to pollutant emissions from marine vessels and HPC commissioning/operational sources, the same percentage criteria as defined in **Table 12.1** for 'other pollutants' has been applied to the predicted pollutant annual mean and percentile concentration increases.

12.4.30 The specific magnitude criteria for the 'other pollutants' which are relevant to this assessment (including those applied to marine vessel and HPC commissioning/ operational pollutant emissions), in relation to their defined objective and limit value, are presented in **Appendix 12C**.

Table 12.1: Definition of Impact Magnitude Developed for Off-site Vehicular Emissions and On-Site Exhaust Emissions to Air from Construction Plant and Machinery

Magnitude of change [a]	Annual mean NO_2/PM_{10} [b]	Number of days with PM_{10} > 50µg/m^3 [b]	Other Pollutants [b]
Large	Increase >4µg/m^3	Increase >4 days	Increase >10%
Medium	Increase 2 to 4µg/m^3	Increase 2 to 4 days	Increase 5-10%
Small	Increase 0.4 to 2µg/m^3	Increase 1 to 2 days	Increase 1-5%
Imperceptible	Increase <0.4µg/m^3	Increase <1 day	Increase <1%

[a] *The magnitude of change descriptors as provided in the EPUK guidance have been retained for the Air Quality Impact Assessment. Comparing these descriptors to those presented in* ***Volume 1, Chapter 7****, 'imperceptible' equates to 'very low', 'small' equates to 'low', 'medium' equates to 'medium', and 'large' equates to 'high'.*

[b] *Taken from EPUK guidance.*

12.4.31 Once the magnitude of the potential impact is established, the actual pollutant concentration at the receptor is taken into account, in combination with the magnitude of change, using the approach set out below in **Table 12.2**.

Table 12.2: Air Quality Impact Descriptors for Off-site Vehicular Emissions and On-Site Exhaust Emissions to Air from Construction Plant and Machinery

Absolute Concentration in Relation to relevant Objective/Limit Value	Change in Concentration or Number of Exceedences [a, b, c]		
	Small	Medium	Large
Above Objective/Limit Value with Scheme			
Annual mean PM_{10}/NO_2 concentration >40µg/m^3	Slight Adverse	Moderate adverse	Substantial Adverse
24-hour PM_{10} objective >35 exceedences			
Other pollutants >100% objective/limit value			
Just Below Objective/Limit Value with Scheme			
Annual mean PM_{10}/NO_2 concentration 36 to 40µg/m^3	Slight Adverse	Moderate adverse	Moderate Adverse
24-hour PM_{10} objective 32 to 35 exceedences			
Other pollutants 90-100% objective/limit value			
Below Objective/Limit Value with Scheme			
Annual mean PM_{10}/NO_2 concentration 30 to 36µg/m^3	Negligible	Slight adverse	Slight Adverse
24-hour PM_{10} objective 26 to 32 exceedences			
Other pollutants 75-90% objective/limit value			
Well Below Objective/Limit Value with Scheme			
Annual mean PM_{10}/NO_2 concentration <30µg/m^3	Negligible	Negligible	Slight Adverse
24-hour PM_{10} objective <26 exceedences			
Other pollutants <75% objective/limit value			

[a] *The impact descriptors as provided in the EPUK guidance have been retained for the Air Quality Impact Assessment. Comparing these descriptors to those presented in* ***Volume 1, Chapter 7,*** *'negligible' equates to 'negligible', 'slight adverse' equates to 'minor', 'moderate adverse' equates to 'moderate', and 'substantial adverse' equates to 'major'. However, the above air quality impact descriptors are only used as a tool to describe predicted impacts; whether air quality impacts are rated as significant or not significant is based upon the professional judgement of the air quality expert performing the assessment (as is recommended in the EPUK guidance).*

[b] *See* ***Table 12.1****.*

[c] *An imperceptible change (see* ***Table 12.1****) would be described as '****negligible****'.*

12.4.32 With regards to pollutant emissions from marine vessels and HPC commissioning/operational sources, the same percentage criteria as defined in **Table 12.2** for 'other pollutants' has been applied to the predicted pollutant annual mean and short-term percentile concentrations.

12.4.33 The specific impact descriptor criteria for the 'other pollutants' which are relevant to this assessment (including those applied to marine vessel and HPC commissioning/operational pollutant emissions), in relation to their defined objective and limit values, are presented in **Appendix 12C**.

12.4.34 The criteria presented in **Table 12.1** and **Table 12.2** have been used for describing the impact at each specific receptor. This has then been used to inform the evaluation of the overall significance of impacts. The latest EPUK guidance (Ref. 12.34) allows for the greater application of professional judgement when assessing impact significance than was prescribed in earlier versions. Impacts are therefore rated in the current assessment as significant or not significant using the professional judgement of the air quality assessor. The EPUK guidance (Ref. 12.34) states that considerations in making these decisions should include:

- number of properties affected by slight, moderate or substantial air quality impacts;
- number of people exposed to poor air quality when a development introduces new exposure into an existing area of poor air quality;
- magnitude of the changes and descriptions of the impacts at receptors;
- exceedence of an objective or limit value predicted to arise where none existed before or size of an exceedence area is substantially increased as a result of the development;
- existing air quality in the study area exceeds an objective or limit value and this exceedence is removed or the exceedence area is reduced as a result of the development;
- development interferes significantly with or prevents the implementation of actions within an AQAP;
- development interferes significantly with the implementation of a local air quality strategy;
- uncertainty of the results; and
- extent to which an objective or limit value is exceeded.

iii. Assessment Criteria Applied to Fugitive Dust and Particulates

12.4.35 As previously noted, best practice guidance (Ref. 12.35, 12.36, 12.37) has been adapted for consideration of fugitive dust and particulates generated by construction works associated with the proposed development. The guidance consolidates existing best practice used in London, the UK and other countries in order to provide a consistent approach in reducing emissions from these activities. The evaluation criteria used to define risk are presented in **Table 12.3**.

Table 12.3: Best Practice Guidance on Fugitive Dust and Particulates Risk Classification

Risk Categories	Criteria
Low Risk Site	• development of up to 1,000m^2 of land; and • potential for emissions and dust to have an infrequent impact on sensitive receptors.
Medium Risk Site	• development between 1,000 and 15,000m^2 of land; and • potential for emissions and dust to have an intermittent or likely impact on sensitive receptors.
High Risk Site	• development of greater than 15,000m^2 of land; • major development as defined by the Local Planning Authority (LPA); and • potential for emissions and dust to have a significant or likely impact on sensitive receptors.

12.4.36 The above classifications are proposed in the absence of specific fugitive dust and particulates mitigation measures. They are used in combination with site specific conditions to inform the assessment of the significance of the potential impact of fugitive dust and particulates from the proposed development.

12.4.37 Once the risk category was established by following the above methodology, the degree of significance of an adverse impact was determined for each potential impact from the Impact Assessment Matrix (IAM) shown below in **Table 12.4**. The impact criteria in **Table 12.4** have been developed specifically for assessment of the construction impacts of fugitive dust and particulates based on best practice guidance issued by the GLA and London Councils (Ref. 12.35).

Table 12.4: Impact Significance Assessment Matrix for Fugitive Dust and Particulates

Distance to Human Receptors (m)	Distance to Ecological Receptors (m)	Risk from Development		
		Low	Medium	High
100-200	50-100	Negligible	Negligible	Minor
50-100	25-50	Minor	Moderate	Moderate
0-50	0-25	Minor	Moderate	Major

12.4.38 The 200m distance to receptor criterion is based on the distance beyond which no significant impacts are expected for road traffic emissions (Ref. 12.38). The 100m distance to receptor criterion is based on guidance which assumes that the majority of dust is deposited within 100m of the emissions sources (Ref. 12.39). The 50m criterion allows the identification of properties which are close to the source and therefore likely to experience a greater magnitude of impact during construction activities.

12.4.39 Given that vegetation is less sensitive to dust deposition than humans (Ref. 12.40), the distance to receptor criteria for ecological receptors has been considered to be half that applied to human receptors. These criteria are based upon professional judgement and discussions with practitioners in the field, together with consideration of published reports.

iv. Assessment of Impacts from Operational (Non-Vehicular) Emissions

12.4.40 The potential air quality impacts of operational (including commissioning) emissions to air (non-vehicular) were assessed following a two staged approach:

- Stage 1 - use of a screening tool to identify emissions which require more detailed assessment, and allow screening out of insignificant emissions.
- Stage 2 - for emissions identified by the screening tool as being potentially significant, further detailed dispersion modelling was undertaken.

12.4.41 The initial screening assessment was undertaken following the methodology provided in the Environment Agency's H1 Environmental Risk Assessment guidance (Ref. 12.30). Where the results of the H1 assessment suggested the need for detailed assessment of any of the emissions not screened out in the initial screening stage, ADMS 4.2 dispersion modelling software was used to assess the potential impact of these planned operational discharges to air.

12.4.42 The potential operational emissions to air (non-vehicular) arising from a single UK EPR unit and its associated infrastructure will primarily be from the following sources:

- SO_2, NO_x, CO and PM_{10} and $PM_{2.5}$ in the exhaust gases from engines of backup diesel generators during periodic testing:
  - For each UK EPR Unit there are four main backup electricity generators (Essential Diesel Generators or EDGs) each rated at around 7.5MWe, and two final emergency backup generator sets (Station Black Outs or SBOs) each rated at around 2.5MWe. This is safety equipment, providing backup power supply in the unlikely case of loss of the main off-site power supply when house load operation fails, so that the UK EPR Unit can be secured and the reactor cooled. These backup generators routinely operate during periodic tests, which represent an estimated 60 hours per year for each of the EDGs and SBO generators. Each EDG and SBO will also be operational for 245 hours per year during the initial commissioning of the plant. These emissions will be discharged via exhaust stacks (one per generator), approximately 30 metres in height, located on the roof of the diesel generator buildings. Each diesel generator building will house two EDGs and one SBO; thus there will be two diesel generator buildings per UK EPR Unit.

- Formaldehyde (H_2CO), that may in turn produce CO, emitted by the thermal decomposition of insulation material during reactor plant start-up at first-use (commissioning) or return to operation following maintenance (approximately every 18 months):
  - Part of the plant piping in the reactor building is insulated using material, which when first heated, during the first unit start-up (commissioning) or following renewal after maintenance, undergoes some thermal decomposition and releases steam containing H_2CO, which in turn may produce CO. It is estimated that for start-up at first-use (commissioning) it will take 10 hours to evacuate these gases at normal flow rates, and 52 hours at low flow rates. During return to operation following maintenance, the operating time required to evacuate these emissions is estimated at 8 hours at normal flow and 42 hours at low flow. These gases will be captured by the ventilation extraction system and discharged to atmosphere via the main stack, which would be in the order of 70 metres in height. Two installation restarts are assumed per year during routine operation.

- Ammonia (NH_3) discharged as the temperature rises in the steam generators during start-up:
  - Depending on the type of maintenance planned during shutdown, laying up the steam generators wet will prevent their fabric corroding and provides a biological barrier (a water shield) while carrying out work in the vicinity. In this case, the steam generators are filled with demineralised water, laid-up with hydrazine with added morpholine, ethanolamine or ammonia in the proportions defined in the chemical specifications for lay-up on shutdown. Once the outage is over, the rise in temperature in the steam generators generates gaseous ammonia partly from this wet lay-up solution, and partly from the steam generators emergency feedwater system. These emissions will be discharged via four exhaust stacks per UK EPR Unit, approximately 38 metres in height, located on the roofs of the safeguard electricity buildings. It has

been estimated that the NH_3 emissions (worst-case, assuming that all the hydrazine is broken down into NH_3 by heating) from an entire steam generator (there are four steam generators per UK EPR Unit) will be released during a period of 83 hours per restart. Two installation restarts are assumed per year.

- Auxiliary boilers, fire fighting and hydrant diesel pumps, domestic heating boilers, and small diesel engines associated with the Interim Storage Facility For Spent Fuel (SO_2, NO_x, CO, PM_{10} and $PM_{2.5}$):
  - Domestic heating and auxiliary boilers will be routinely used around the site (particularly during periods of cold weather). Fire fighting diesel pumps located around the site will only be used for short periods in the event of an emergency or during periodic tests. Small diesel engines will also be used to provide backup power supply to the Interim Spent Fuel Storage Facility (ISFS) building. Emissions from these sources will be discharged to air via their own flue gas vents.

12.4.43 The operational assessment considers emissions to air during two potential emission scenarios:

- Commissioning scenario:
  - This scenario assesses all potential releases to air from the EDGs and SBOs, and all non-diesel generator emissions during the commissioning of the plant.
  - It is not anticipated that more than one EDG or SBO will be in operation at any one time during plant commissioning. As such, maximum short-term concentrations have been determined assuming that one EDG is operational continuously throughout the year; this approach enables the particular meteorological conditions conducive to producing transient peaks in ground level concentrations to be appropriately considered. Emission rates from the EDGs are greater than those occurring from the SBOs, hence the decision to only consider EDG emissions for the short-term assessment. The maximum predicted concentration from any particular EDG is reported in the impact assessment section.
  - With respect to longer-term pollutant concentrations, the maximum modelled annual mean concentrations, assuming continuous operation of any particular generator, have been factored by taking into account the combined annual operational hours of all EDGs and SBOs, i.e. 2,940 combined hours per year.
  - Similar approaches are adopted with regards to emissions from the non-diesel generator sources.
- Routine test scenario:
  - The routine test scenario presents the likely potential impacts to be expected as a result of the standard EDG/SBO testing, which will be scheduled throughout the lifetime of the power station. It is understood that testing of the backup diesel generators will take place individually, with only a single generator running at any one time. Consequently, the approach with regards to predicting short-term and long-term concentrations during this scenario is consistent with that used for the commissioning scenario but with combined annual operational hours factored accordingly.

H1 Screening Assessment

12.4.44 The Environment Agency's H1 Environmental Risk Assessment guidance (Ref. 12.30) provides a methodology to assess the risks to the environment and human health from facilities that produce discharges to the environment. The point source emissions to air released from the proposed UK EPR Units during the operational phase (as outlined above) were initially screened following the H1 methodology.

12.4.45 H1 Annex F contains long and short-term Environmental Assessment Levels (EALs) for releases to air derived from a number of published UK and international sources. For most of the pollutants considered in this study, these EALs are equivalent to the AQS and AQOs described in section 12.3. **Appendix 12B, Table 4** provides EALs for those pollutants and averaging periods for which an equivalent AQS or AQO is not prescribed.

12.4.46 The following steps of the H1 methodology have been followed for screening the non-vehicular operational point source emissions to air from HPC:

- calculate the process contribution to air (PC_{air});
- screen out insignificant emissions; and
- identify the need for detailed modelling.

12.4.47 The methodology used to calculate the process contribution and screen out insignificant emissions is provided in detail in the Air Quality Modelling Report (Ref. 12.2).

Detailed Dispersion Modelling

12.4.48 Detailed dispersion modelling was undertaken for those operational (non-vehicular) emissions to air that were identified by the H1 screening methodology as requiring further detailed assessment. ADMS 4 Version 4.2 modelling software with Surfer Version 9 was used for this study.

12.4.49 The results of the initial H1 screening assessment undertaken (**Appendix 12D**) showed that detailed dispersion modelling was required for the majority of pollutant emissions discharged from all release points. Consequently, with the exception of those sources that, due to their size (e.g. auxiliary boilers and engines from the ISFS), are unlikely to contribute significantly to ground level concentrations outside the HPC development site boundary, a detailed assessment of all potential emissions to air from the plant are considered within the operational emissions (non-vehicular) detailed dispersion modelling sections.

12.4.50 The emission parameters used in this study are presented in the Air Quality Modelling Report (Ref. 12.2) for the commissioning and routine test scenarios, respectively. All release rates were either obtained from information made available from EDF or the equipment manufacturer, with the exception of release rates for PM_{10} and CO discharged from the backup diesel generators. These release rates were calculated from Environmental Benchmark values for emissions to air for a compression ignition engine running off liquid fuel, published in Annex 1 of the Environment Agency's Environmental Permitting Regulations sector guidance for Combustion Activities (Ref. 12.41).

12.4.51 Information on additional model treatments, including those relating to the treatment of buildings, terrain, surface roughness, formulation of the receptor grid and exposure groups can be found in the Air Quality Modelling Report (Ref. 12.2). **Figure 12.7** illustrates the buildings and emission sources within the ADMS model setup.

12.4.52 Prior to compiling the dispersion model, minor variations to some of the building dimensions were made; in most, cases these changes to the building length and/or width by a few metres. These changes are not sufficient to alter the dimensions of the single, effective building which ADMS generates from the constituent buildings included in the model. Furthermore, the height of the 'main' building specified in the model did not change. Consequently, these minor variations will not affect the model predictions.

12.4.53 Annual hourly sequential meteorological data used in the model was obtained for the Hinkley Point site from the United Kingdom Meteorological Office (UKMO) Numerical Weather Prediction Model. The meteorological data used for this assessment covers the period 1 January 2005 to 31 December 2009, and includes hourly values for wind speed (m/s), wind direction (°), cloud amount (oktas), temperature (°C), sensible heat flux ($J/s/m^2$), boundary layer depth (m), precipitation rate (mm/hour) and relative humidity (%). A wind-rose for 2005 to 2009 is shown in **Figure 12.8**.

12.4.54 The ADMS model was run independently for each year of meteorological data in order to identify the year which produced the highest predicted concentrations, i.e. the worst-case scenario. The meteorological data for this year, if considered to be representative of the typical meteorological conditions at the HPC development site, was then used for the study.

12.4.55 Long-term (annual mean) and short-term concentrations were predicted at local human and ecological receptors in order to assess compliance with the statutory air quality standards and non-statutory guideline environmental assessment levels. This has been achieved using the "long term" mode of ADMS; the "short term" mode does not allow for percentile values and objective limit exceedences to be calculated.

12.4.56 With respect to emissions of NO_x, these were modelled using guidance issued by the Environment Agency's Air Quality Modelling and Assessment Unit (AQMAU) (Ref. 12.42). The Air Quality Modelling Report (Ref. 12.2) contains a full description of this guidance but, in summary, emissions of NO_x were modelled as NO_x (as NO_2) with subsequent factors applied to the modelled predictions to calculate the resulting ambient concentration of NO_2. The 'Worst-Case' factors in the AQMAU guidance were applied for the purposes of predicting NO_2 concentrations.

12.4.57 The predominant route by which emissions will affect land in the vicinity of a process is by deposition of atmospheric emissions. Potential ecological receptors can be sensitive to the deposition of pollutants, particularly nitrogen and sulphur compounds, which can affect the character of the habitat through eutrophication and acidification.

12.4.58 Deposition processes in the form of dry and wet deposition remove material from a plume and alter the plume concentration. Dry deposition occurs when particles and gases are brought towards the ground by gravitational settling and turbulence. They are then removed from the atmosphere by deposition on the land surface. Wet deposition occurs due to rainout (within cloud) scavenging and washout (below cloud) scavenging of the material in the plume. These processes lead to a variation with downwind distance of the plume strength and may alter the shape of the vertical concentration profile as dry deposition only occurs at the surface.

12.4.59 Near to sources of pollutants, dry deposition is the predominant removal mechanism (Ref. 12.43). For the purposes of the quantitative prediction of air pollutant deposition, dry deposition rates of nitrogen and acidic equivalents have been calculated by applying the short vegetation deposition velocities detailed in Environment Agency (draft) technical guidance (Ref. 12.44) to the modelled annual mean concentrations of NO_x NH_3 and SO_2. Wet deposition has not been assessed since this is not a significant contributor to total deposition over shorter ranges (Ref. 12.43 and Ref. 12.44). Detailed descriptions of the algorithms used to quantify deposition rates are provided in the Air Quality Modelling Report (Ref. 12.2).

v. Assessment of Impacts from Marine Vessels

12.4.60 Given the low numbers of vessels that would be used during the construction of the temporary jetty, air quality impacts associated with jetty construction are not considered to be significant and therefore no further detailed assessment of these impacts has been undertaken.

12.4.61 During operation of the temporary jetty, however, there is the potential for emissions to have significant impacts to air from marine vessel movements. It is anticipated that vessels would include self-discharging dredgers and cement carriers used to supply the aggregate, sand and cement for concreting. There may also be periodic dredging to maintain the required berthing pocket depth, which will be dependent upon the rate of sediment accumulation.

12.4.62 A dispersion modelling exercise was thus undertaken in order to estimate the maximum long-term and short-term air pollutant concentrations (NO_x/NO_2, PM_{10}, $PM_{2.5}$ and SO_2) generated by marine vessel exhaust emissions. The quantitative assessment was undertaken using the same dispersion model as described for the operational (non-vehicular) assessment described above.

12.4.63 A single model scenario was considered; including long-term and short-term air pollutant concentrations generated by marine vessel exhaust emissions whilst manoeuvring and at berth during the operation of the temporary jetty. Marine vessel emissions were assumed to occur within the temporary jetty seaward harbour limits (see **Figure 12.6**). Emissions at sea were not calculated, on the basis that the location and magnitude of environmental impacts will be dependent on each vessel’s route, and environmental effects at berth are considered more significant than those at sea, since vessels are stationary and downwind receptors will be affected for a longer period.

12.4.64 To provide a worst-case assessment of potential air quality impacts, it was assumed that there would be one vessel berthing at the temporary jetty each day, as opposed to the likely 18 vessels per month. Furthermore, emissions have been calculated assuming a generic vessel of approximately 5,000dwt, the largest size of vessel likely to use the jetty; smaller vessels will have smaller engines and emissions would be lower.

12.4.65 Published pollutant emission factors for main and auxiliary engines of marine vessels (Ref. 12.45) were utilised for this study in order to calculate appropriate pollutant emission rates. Other emissions parameters were based on relevant studies (Ref. 12.46 and 12.47). Details of the potential releases, including the pollutant discharge rate, volumetric flux, and temperature are provided in the Air Quality Modelling Report (Ref. 12.2).

12.4.66 Information on additional model treatments, including those relating to the treatment of terrain, surface roughness, formulation of the receptor gird and exposure groups can be found in the Air Quality Modelling Report (Ref. 12.2). The approach with regards to selection of meteorological data, deposition and conversion of NO to NO_2 is consistent with that described for the operational (non-vehicular) assessment.

vi. Assessment of Impacts from Vehicle Emissions

12.4.67 Within the UK, assessments of air quality impacts related to emissions from road traffic focus only upon NO_2 and fine particulate matter (PM_{10} and $PM_{2.5}$) concentrations in the atmosphere. This is because exhaust emissions of the other pollutants associated with road traffic (SO_2, carbon monoxide (CO) and hydrocarbons, including benzene and 1,3-butadiene) are only released in relatively small quantities and urban roadside concentrations are all well within the relevant UK AQOs. It is only NO_2, PM_{10} and $PM_{2.5}$ that currently pose a human health concern where road traffic is the dominant source of air pollution, and which are close to and, in some traffic-congested urban areas, above AQOs. All the AQMAs in the UK that have been declared as a result of road traffic emissions have been declared either for NO_2 or for both NO_2 and PM_{10}. In this way, local authority review and assessment can be cost-effectively targeted at the pollutants of real concern and the insignificant pollutants can be scoped out of the assessment. This applies equally to the EIA process.

12.4.68 Consequently, detailed dispersion modelling and subsequent assessment of NO_x/NO_2, PM_{10} and $PM_{2.5}$ emissions to air arising from road traffic has been undertaken.

12.4.69 For the prediction of air quality impacts due to emissions arising from road traffic associated with the proposed development, the air pollutant dispersion model ADMS-Roads has been used. This model, developed by Cambridge Environmental Research Consultants (CERC), uses detailed information regarding traffic flows and composition on the local road network, combined with local meteorological conditions, to predict pollution concentrations at specific locations selected by the user. ADMS-Roads version 3.0 with Surfer version 9 was used for this study.

12.4.70 Full details of the ADMS-Roads dispersion modelling study which has been undertaken are presented in the Air Quality Modelling Report (Ref. 12.2). In summary, the traffic data used for the road traffic air quality impact assessment has been taken from the validated Paramics micro-simulation traffic model built to assess the effect of the HPC Project proposals (see **Volume 2**, **Chapter 10**). For each modelling scenario the output traffic data from the Paramics model were factored using Automatic Traffic Count data to provide 24-hour Annual Average Daily Traffic (AADT) data for Light Duty Vehicles (LDVs) and Heavy Duty Vehicles (HDVs). In line with LAQM.TG(09) (Ref. 12.14) HDVs represent all vehicles over 3.5 tonnes unladen weight, and therefore include all Heavy Goods Vehicles (HGVs) and Buses. The 24-

hour AADT traffic input data relevant to the assessment is presented in **Appendix 12E**.

12.4.71 Given the large spatial extent of the road network to be considered within the modelling domain (which includes all the associated development sites and HPC), three ADMS-Roads models were set-up and run, encompassing the three main geographical areas within the overall HPC Project study area; one for the road network around Cannington (the ‘Cannington model’), one for the road network around Bridgwater (the ‘Bridgwater model’), and one for the road network around Williton (the ‘Williton model’). The proposed HPC development site was included within the ‘Cannington model’ (see the Air Quality Modelling Report (Ref. 12.2) for further information), however the impacts of the HPC Project on all three model areas are considered in this chapter.

12.4.72 Annual mean pollutant concentrations (NO_x/NO_2, PM_{10} and $PM_{2.5}$) were predicted at human receptor locations, which include locations adjacent, or near, to the routes that are likely to experience a change in traffic flow or composition as a result of the proposed development. These human receptor locations have been selected to be representative of the likely worst-case impacts which may occur in the area surrounding the road network where traffic flows and/or composition may be affected by the proposed development.

12.4.73 Exceedences of the short-term relevant human health AQOs were predicted by utilising published relationships between the annual mean and short-term pollutant concentrations. LAQM.TG(09) (Ref. 12.14) advises that it is valid to assume that exceedences of the 1-hour mean AQO for NO_2 are only likely to occur where annual mean concentrations are 60µg/m^3 or greater.

12.4.74 An empirical relationship between the annual mean and the number of exceedences of the 24-hour mean AQO for PM_{10} is also provided within LAQM.TG(09) (Ref. 12.14):

$$\text{Number of 24-hour mean exceedences} = -18.5 + 0.00145 \times \text{annual mean}^3 + \frac{206}{\text{annual mean}}$$

12.4.75 This relationship was used to determine whether exceedences of the short-term PM_{10} AQO are likely, based upon the annual PM_{10} concentrations predicted by the model.

12.4.76 For impacts to ecological receptors, annual and 24-hour mean NO_x concentrations were predicted at selected specific receptor points, which are representative of worst-case ecological designated site exposure (i.e. given that pollutant concentrations drop off rapidly with increasing distance from the road source). The locations of these specific receptors relative to the ecological designated sites are illustrated in **Figure 12.4**.

12.4.77 The model-predicted pollutant concentrations were verified against available monitoring data, following the methodology published in LAQM.TG(09) (Ref. 12.14), in order to minimise modelling uncertainty and systematic error. This involved correcting modelled results by an adjustment factor to gain greater confidence in the final results. Full details of the verification procedure are presented in the Air Quality Modelling Report (Ref. 12.2), however, in summary, adjustment factors of 2.838, 6.589 and 9.413 were applied to the modelled road NO_x contributions predicted by the Bridgwater, Cannington and Williton models respectively. In the absence of roadside monitoring data for particulate matter and in line with the recommendations provided in LAQM.TG(09) (Ref. 12.18), the same verification factors were also applied to PM_{10} and $PM_{2.5}$ modelled road contributions. The impact assessment was undertaken using these verified results, and all discussion herein therefore refers to verified model outputs.

12.4.78 Quantitative assessment of the impacts on local air quality from vehicular emissions associated with traffic generated by the proposed HPC Project was then completed through a comparison of modelled pollutant concentrations with the current statutory standards and objectives set out in **Appendix 12B**. This chapter provides a summary of the overall air quality impacts predicted at all identified worst-case sensitive receptor group locations within the HPC Project study area as a whole.

12.4.79 For the assessment, seven scenarios have been modelled:

- 2009 'model verification/baseline'.
- 2013 'without development'.
- 2013 'with development'.
- 2016 'without development'.
- 2016 'with development'.
- 2021 'without development'.
- 2021 'with development'.

12.4.80 2009 was selected as the model verification/baseline year (model verification is discussed in further detail within the Air Quality Modelling Report (Ref. 12.2)), as this is the most recent year for which monitoring data, meteorological data, traffic data and emissions factors were all available at the time the assessment was undertaken.

12.4.81 2013 was selected as an assessment year as it represents the year with peak HDV movements relating to the proposed HPC Project, prior to operation of the majority of the associated development sites, which will reduce adverse impacts on the highway network during the construction of HPC. This assessment year therefore represents the time of construction of the majority of the associated development sites.

12.4.82 The 2013 'without development' scenario represents the future 2013 baseline scenario, and includes forecast traffic growth with committed development only (see **Volume 2**, **Chapter 10** for information on what committed development has been included).

12.4.83 The 2013 'with development' scenario includes:

- forecast traffic growth including committed development;
- construction of the proposed HPC nuclear power station; and
- construction of the majority of the associated development sites.

12.4.84 2016 was selected to represent the year with peak construction related traffic movements associated with the HPC Project (peak workforce on the HPC development site), following the commencement of operation of the associated development sites. This assessment year therefore includes the operation of the associated development sites.

12.4.85 The 2016 'without development' scenario represents the future 2016 baseline scenario, and includes forecast traffic growth with only committed development (see **Volume 2**, **Chapter 10**).

12.4.86 The 2016 'with development' scenario includes:

- forecast traffic growth including committed development;
- construction of the proposed HPC nuclear power station (peak workforce on the HPC development site); and
- operation of the associated development sites.

12.4.87 2021 was selected to represent the early operational phase traffic movements associated with the HPC Project, and the post-operational phase of the associated development sites where relevant.

12.4.88 The 2021 'without development' scenario represents the future 2021 baseline scenario, and includes forecast traffic growth with only committed development (see **Volume 2**, **Chapter 10**).

12.4.89 The 2021 'with development' scenario includes:

- forecast traffic growth including committed development;
- early operation of the proposed HPC nuclear power station;
- operation of the Cannington bypass; and
- post-operation of the associated development sites.

12.4.90 Car parks have not been included within the ADMS models on the basis of their size and intended usage. During HPC construction, 200 parking spaces will be provided at the HPC development site for use by EDF Energy staff and their contractors, with a further 100 on-site parking spaces to be provided for business visitors, VIP visitors, disabled visitors and bus parking for the Public Information Centre. Similarly, during HPC operation, total parking spaces on the HPC development site will be limited to 1,193 (plus six coach spaces). Similar parking restrictions have been also applied at the various associated development sites (see **Volumes 3** to **10**, **Chapter 10**) and, furthermore, parking spaces at the associated development sites will generally not be used in a similar manner to, for example, a supermarket car park, whereby multiple users will use the same space within one day. At the associated development sites occupancy of each space will be defined by the number of construction working shifts at the HPC development site, i.e. each space will be used by a maximum of three different vehicles per day and vehicle movements associated with the occupancy of these spaces will occur over a short time period.

12.4.91 A description of the traffic data scenarios used in the assessment is contained within **Volume 2**, **Chapter 10**. Whilst certain traffic mitigation measures (such as the highways improvements schemes) are proposed that will help to reduce congestion issues, they can encourage higher traffic flows in some locations as driver behaviour patterns change. Subsequently, changes (increases or decreases) in vehicular exhaust emissions may result from these measures. Consideration has also been given to non-work (i.e. leisure) vehicle movements of the HPC construction staff using the road network, and the impacts associated with such movements are included within the air quality assessment.

vii. Assessment of Impacts during On-Site Construction Activities

12.4.92 A qualitative assessment of the potential air quality impacts due to the generation and dispersion of fugitive dust and particulates from the HPC development site has been undertaken using information in guidance documents produced by the following organisations:

- Building Research Establishment (BRE) (Ref. 12.36).
- Quality of Urban Air Review Group (QUARG) (Ref. 12.37).
- GLA and London Councils (Ref. 12.35).

12.4.93 As there are no formal assessment criteria for fugitive dust and particulates generation and dispersion, the significance of impacts associated with this phase of the proposed development has been determined qualitatively by:

- identifying the site construction works activities that could generate fugitive dust and particulates and their likely duration;
- identifying sensitive receptors (e.g. schools, residential properties, statutory designated ecological sites) within 200m of the defined site boundary or closest area of site construction activity; and
- taking account of the prevailing wind direction and wind speed.

12.4.94 The potential impact of fugitive dust and particulates on the closest human and ecological receptors to the HPC development site has been considered. As described above, these receptors are illustrated in **Figures 12.1** and **12.2**.

12.4.95 Emissions to air from the exhausts of on-site construction plant and machinery were also assessed qualitatively, based upon the assumed number of items of equipment and plant expected on-site during the site construction works, and their likely duration of use. The significance of these emissions was then determined in accordance with the assessment methodology described herein.

viii. Assessment of Impacts from Highway Improvements

12.4.96 As part of the HPC Project, eleven improvement schemes are proposed to existing public highways (see **Volume 1**, **Chapter 2**).

12.4.97 With the exception of the construction of new roundabouts; at the junction of the A39 and B3190 at Washford Cross near the proposed Williton park and ride site, and at the junction of the A39 and B3339 at Sandford Corner south of Cannington, all proposed highways improvement schemes will require small-scale works lasting for very short periods, and will be completed within the existing highway boundaries.

12.4.98 Construction of the Washford Cross and Sandford Corner roundabouts, which will replace the existing priority junction(s), is expected to last a maximum of 6 months.

The closest receptor to the proposed works is Tropiquaria Zoo and a single residential dwelling, both approximately 25m from the proposed roundabouts. The nature of the construction works would mean that works at this separation distance may exist for only a matter of days, or even hours at a time. There would be regular periods, even during the course of a single day, when the assumed construction plant would not be in operation, for example during breaks or changes of working routine. Therefore, despite this proximity, given the nature of the proposed construction activities, the likelihood of fugitive dust and particulate matter impacts at these receptors is considered to be very low, as are any potential air quality impacts associated with emissions from construction plant and machinery.

12.4.99 As such, air quality impacts during the construction phases of the highway improvements are not considered to be significant and have therefore not been subject to detailed assessment. Air quality impacts from the resultant operation of the highway improvements are inherently considered in the assessment of vehicular exhaust emissions associated with the overall HPC Project, as the traffic input data assumes their operation.

ix. Cumulative Impacts

12.4.100 **Volume 1**, **Chapter 7** of this ES sets out the methodology used to assess cumulative impacts. Additive and interactive effects between site-specific impacts are considered within this chapter. The assessment of cumulative impacts with other elements of the HPC Project and other proposed and reasonably foreseeable projects are considered in **Volume 11** of this ES. The only exception is cumulative air quality impacts from off-site vehicle emissions, which are presented within this chapter as the traffic data used for the assessment includes both development related traffic associated with all aspects of the HPC Project and other committed development in the study area.

e) Limitations, Assumptions and Uncertainties

12.4.101 Whilst average speeds of queuing traffic specific to each link and scenario have been applied to each ADMS-Roads modelled scenario, queuing distances determined for the 2009 scenario were applied to all of the scenarios. However, sensitivity analysis which has been undertaken indicates that queuing distances do not significantly impact the model predicted pollutant concentration results obtained (see Air Quality Modelling Report (Ref. 12.2)).

12.4.102 The entire modelled road network was input within the ADMS-Roads models at an elevation of 0m without terrain elevation due to the study area being relatively flat. This is consistent with recommendations made by CERC, which state that terrain effects need only to be included where the gradient exceeds 1 in 10.

12.4.103 ADMS 4.2 cannot model dispersion for meteorological data lines (hourly data within the meteorological input file) with calm wind conditions, if either the puff, fluctuations, hills or coastlines model options are selected. Meteorological data lines with wind speed at a height of 10m which are less than 0.75m/s were therefore skipped in the modelling runs.

12.4.104 The coastline module option in ADMS 4.2 was not implemented for the purposes of this assessment. The module requires additional meteorological parameters which were not available, such as the difference in temperature between the sea surface temperature and the near surface temperature over land.

12.4.105 Pollutant emissions associated with the backup diesel generators only occur for a limited number of hours of the year. Despite the assessment focussing upon predicted pollutant concentrations against short-term air quality standards, such standards are based upon the number of exceedences of a threshold concentration over a full calendar year. Pollutant concentrations have therefore been calculated for each 1-hour line of meteorological data for a year, assuming pollutant release for each hour, and in the case of predicted annual mean concentrations have been multiplied by the fraction of number of hours per year of operation for each scenario to obtain the contribution of diesel generator emissions to the annual mean. It is not possible to apply such a procedure to the predicted short-term pollutant concentrations. Had the testing schedule of the diesel generators been known with greater precision, it would have been possible to use the "time-varying source" option of the ADMS 4.2 model to produce pollutant concentration data resembling the "real" likely exceedences expected for an operating scenario, for both long-term and short-term pollutant emissions.

12.4.106 Assumptions have been made about the type of equipment and machinery to be used during the construction works based upon likely methods to be adopted and previous development project experience, but contractors may adopt different working methods to reach the same goals. The assessment presented herein has adopted a worst-case approach.

12.4.107 Assumptions have been made about the type of marine vessel that will use the temporary jetty during its operation, based upon previous project experience, but contractors may adopt the use of different types of vessels to reach the same goals. The assessment presented herein has adopted a worst-case approach.

12.4.108 Despite the limitations, assumptions and uncertainties noted above, the approach and methodology adopted for this chapter is both transparent and consistent with the relevant UK EIA legislation and key guidance. The assessment approach is considered to be fit for purpose and an appropriate representation of the assessment scenarios; the approach has also been discussed and agreed with the relevant local authorities.

12.5 Baseline Environmental Characteristics

a) Introduction

12.5.1 This section describes the baseline environmental characteristics for the HPC development site and surrounding areas with specific reference to air quality.

b) Study Area Description

i. Environmental Setting

12.5.2 The HPC development site is located in a rural setting on the coastline of Bridgwater Bay. This location provides favourable conditions for pollutant dilution and dispersion, with an on-shore breeze dominating from the west-north-west (see **Figure 12.8**). The topography of the study area is also conducive to efficient pollutant dispersion, with the immediate area surrounding the HPC development site being predominantly undulating countryside. The Quantock Hills is the main topographical feature in a regional context, located approximately 6km to the west and south of the HPC development site with the main ridge rising to approximately 350m Above Ordnance Datum (AOD).

12.5.3 There are several statutory designated ecological sites within immediate proximity to the HPC development site and these are identified in **Figure 20.2**, **Volume 2, Chapter 20**. The sites include the Severn Estuary Ramsar site, SPA and SAC, the Bridgwater Bay NNR, and the Bridgwater Bay SSSI. There are also several non-statutory designated ecological sites within close proximity to the application site, including the Hinkley County Wildlife Site (CWS).

12.5.4 Residential dwelling ‘Doggetts’ to the south-east is the property closest to the HPC development site, whilst other residential dwellings nearby include those in the villages of Burton, Shurton to the south and Wick located to the south-east, and Stolford to the east of the HPC development site. **Figures 12.1**, **12.2** and **12.6** illustrate those residential dwellings that are located in close proximity to the HPC development site. The main residential areas located along the principal roads to the HPC development site include Cannington and Bridgwater.

12.5.5 The main arterial road in the study area is the A39 that lies approximately 6km south of Hinkley Point. It provides a route through the towns of Cannington and Bridgwater that lie to the south-east of the HPC development site, connecting to the M5 which runs approximately 11km east of Hinkley Point. Roads in closer proximity to the HPC development site comprise less heavily trafficked minor B and C class roads.

ii. Local Emission Sources

12.5.6 WSC and SDC have not identified any industrial sources of emissions which may significantly impact air quality (Ref. 12.27 and Ref. 12.26) within their districts. This was confirmed by an Environment Agency ‘What’s in your backyard?’ search undertaken in August 2011 (Ref. 12.48).

12.5.7 Within the district of West Somerset, industrial pollution sources are limited to two Part-A processes (Hinkley Point B power station and Wansbrough Paper Mill) and seven Part-B processes regulated under the Environmental Permitting Regulations 2010. The Wansbrough Paper Mill is located approximately 7km from the HPC development site and is thus not expected to significantly impact the air quality in the locality of the site. There are limited emissions to air arising from the operation of Hinkley Point B, although these will be principally limited to particulate, SO_2, NO_2 and CO emissions released during the periodic testing of backup diesel generators. Consequently, industrial pollutant sources to air in the locality of the HPC development site will not have substantive impact on local air quality.

12.5.8 WSC has identified the A39 as the most significant source of vehicle emissions to air in the district, and as a consequence, in 2007, they established a new roadside monitoring site in Williton, and also relocated a background NO_2 monitoring site to Washford, both situated along the A39. WSC currently undertakes air quality monitoring for NO_2 at two roadside locations within Williton along the A39. Their diffusion tube monitoring identified 2009 annual mean NO_2 concentrations at these two locations to be below the annual mean NO_2 AQO limit concentration of 40µg/m^3 (34.9µg/m^3 and 35.0µg/m^3 at “Williton County Stores” and “Williton P.O.” respectively (Ref. 12.26)).

12.5.9 Within the district of Sedgemoor, the main existing source of air pollutants is road traffic. The highest vehicle flows result from traffic on the M5, which has an AADT flow of approximately 80,000 vehicles per day. In addition to the M5 motorway, SDC has identified the A38 and A39 as the most significant sources of vehicle emissions to air in the district, however SDC has also indicated that the steady increase of traffic volume on the Northern Distributor Road since it opened in 2003 is of concern with regards to air quality. SDC currently undertakes air quality monitoring for NO_2 at ten roadside locations within Bridgwater. Their diffusion tube monitoring identified 2009 annual mean NO_2 concentrations at these locations to be below the annual mean NO_2 AQO limit concentration of 40µg/m^3.

12.5.10 Fugitive dust and particulates also arise in the locality of the HPC development site, both as a natural consequence (wind turbulence and subsequent suspension) and due to agricultural operations such as ploughing. The significance of these existing sources increases during periods of continuous dry weather and increased wind speeds. Furthermore, due to the coastal location of the HPC development site, the presence of marine aerosols may also constitute a significant natural local source of particulates.

iii. Existing Air Quality

UK Air Quality Information Resource

12.5.11 Estimated background pollutant concentrations are provided in Defra's UK-AIR (Ref. 12.33). Concentrations are provided for each 1km x 1km grid square for the entire UK. These background concentrations have been calculated from a base year of 2008 (or 2001 in the case of some pollutants, including SO_2), with projections provided for all years up to and including 2020, using the National Atmospheric Emissions Inventory (NAEI) and associated projections.

12.5.12 Estimated background concentrations from Defra's UK-AIR are available for PM_{10}, $PM_{2.5}$, NO_2, NO_x, SO_2, CO, benzene and 1,3-butadiene. **Table 12.5** below summarises the NO_x, NO_2, PM_{10}, $PM_{2.5}$, SO_2 and CO background concentrations obtained for 2009 from Defra's UK-AIR for the four grid-squares located closest to the HPC development site (for the purposes of this assessment, data are only required for these pollutants - see section 12.4).

Table 12.5: Summary of Annual Mean NO_x, NO_2, PM_{10}, $PM_{2.5}$, SO_2 and CO Background Concentrations at the Proposed Development Site Obtained for 2009 from Defra's UK Air Quality Information Resource

OS National Grid Reference	2009 Annual Mean Background Concentration (µg/m^3)					
	NO_2	NO_x	PM_{10}	$PM_{2.5}$	CO [a]	SO_2 [a]
320500,146000	5.8	7.5	12.2	7.7	-	-
321500,146000	6.1	8.0	12.3	7.7	-	-
320500,145000	6.0	7.9	13.1	7.9	78.5	2.4
321500,145000	9.3	12.6	13.6	8.3	79.1	2.7
Average	**6.8**	**9.0**	**12.8**	**7.9**	**78.8**	**2.6**

[a] *In the absence of annual adjustment factors for SO_2, the 2001 background concentrations for SO_2 obtained from Defra's UK Air Quality Information Resource have been taken to represent the 2009 background SO_2 concentration. 2001 SO_2 and CO concentrations are not available for 320500,146000 and 321500,146000 due to their falling just offshore.*

12.5.13 Averaging the concentrations for these four squares provides 2009 annual mean background concentrations for NO_x, NO_2, PM_{10} and $PM_{2.5}$ of 9.0µg/m^3, 6.8µg/m^3, 12.8µg/m^3 and 7.9µg/m^3 respectively. The 2009 annual mean background CO concentration was calculated as 78.8µg/m^3. In the absence of annual adjustment factors for SO_2, the background SO_2 annual mean concentration from 2001 has been taken to represent the 2009 background, with a value of 2.6µg/m^3. This value for SO_2 is likely to be an overestimate of the current background concentration, in light of tighter restrictions being imposed regarding the sulphur content of fuels since 2001, thus decreasing SO_2 emissions to air. The UK annual mean NO_2 and PM_{10} AQOs are both set at 40µg/m^3, whilst the annual mean $PM_{2.5}$ AQO is set at 25µg/m^3. There is no annual mean UK AQO for SO_2 or CO. The UK annual mean NO_x and SO_2 AQOs (for the protection of vegetation and ecosystems) are set at 30µg/m^3 and 20µg/m^3 respectively.

Council Air Quality Progress Reports

12.5.14 WSC's 2011 Air Quality Progress Report (Ref. 12.26) provides the latest published review and assessment of air quality in the West Somerset district. WSC currently undertakes passive diffusion tube monitoring for NO_2 at six locations within the settlements of Minehead, Washford and Williton. These represent roadside, urban centre and background locations. No other air pollutants are monitored.

12.5.15 The 2010 annual mean (bias adjusted) NO_2 concentrations for the six WSC monitoring sites ranged between 20.9µg/m^3 to 39.2µg/m^3. Study of the diffusion tube results has not identified any locations within the district that are expected to exceed the annual mean NO_2 AQO of 40µg/m^3. There are also therefore no potential exceedences of the 1-hour mean NO_2 AQO of 200µg/m^3.

12.5.16 The WSC NO_2 diffusion tube monitoring data from two roadside monitoring sites located in Williton was used for verification purposes for the Williton ADMS Roads model output (see the Air Quality Modelling Report - Ref. 12.2). Concentrations at these two roadside locations have been decreasing each year between 2007 and 2009.

12.5.17 SDC's 2010 Air Quality Progress Report (Ref. 12.28) provides the latest published review and assessment of air quality in the Sedgemoor district. SDC currently undertakes passive diffusion tube monitoring for NO_2 at 22 locations within the towns of Bridgwater, Highbridge, Cheddar, and at a number of bridges along the M5. These represent roadside, urban centre and background locations. No other air pollutants are monitored.

12.5.18 The 2009 annual mean (bias adjusted) NO_2 concentrations for the 22 SDC monitoring sites ranged between 9.2µg/m^3 and 39.2µg/m^3. Study of the diffusion tube results has not identified any locations within the district that are expected to exceed the annual mean NO_2 AQO of 40µg/m^3. There are also therefore no potential exceedences of the 1-hour mean NO_2 AQO of 200µg/m^3.

12.5.19 The SDC NO_2 diffusion tube monitoring data from three roadside monitoring sites located in Bridgwater was used for verification purposes for the Bridgwater ADMS Roads model output (see the Air Quality Modelling Report - Ref. 12.2).

c) Baseline Air Quality Monitoring Campaign

12.5.20 Full details and results of the air quality monitoring programme are presented in the Air Quality Monitoring Report (Ref. 12.1). In summary, following the methodology provided in LAQM.TG(09) (Ref. 12.14) in order to calculate annual background concentrations from monitoring data of less than a full year, background baseline pollutant concentrations of 11.5µg/m^3, 6.8µg/m^3, 18.2µg/m^3 and 1.8µg/m^3 were obtained for the year 2009 at Hinkley Point, for NO_x, NO_2, PM_{10} and SO_2 respectively.

12.5.21 Comparison of the 2009 pollutant background concentrations obtained from the monitoring results with the 2009 pollutant background concentrations obtained for the locality of the development site from Defra's UK-AIR, show that the NO_x monitoring derived 2009 background concentration is 27.8% higher, and the PM_{10} monitoring derived 2009 background concentration is 42.2% higher than Defra derived background pollutant levels. The NO_2 monitoring derived 2009 background concentration is the same as the UK-AIR background value. The monitoring derived SO_2 value confirms the earlier conclusion that actual 2009 values are less (30.8% lower) than those estimated for 2001.

12.5.22 This comparison confirms that use of the baseline pollutant concentrations, as determined from the baseline air quality monitoring programme, constitutes a worst-case approach for assessment purposes within the HPC commissioning/operational ADMS model (see the Air Quality Modelling Report) (Ref. 12.2). Given the similar characteristics of Hinkley Point and the ADMS Roads 'Williton model' and 'Cannington model' areas (i.e. comparable UK-AIR background concentrations and both being of a rural nature), background concentrations as derived from the baseline monitoring programme are also considered to be representative of the background air quality in these model areas and have thus been used for modelling and assessment purposes. As a worst-case approach, the highest UK-AIR background pollutant concentrations for those grid squares located within the entire ADMS-Roads 'Bridgwater model' area were used for modelling and assessment purposes (see the Air Quality Modelling Report (Ref. 12.2).

12.5.23 The baseline air quality monitoring programme confirmed that the ambient background air quality in the immediate vicinity to the HPC development site can be generally categorised as good, with both annual mean NO_2 and PM_{10} background concentrations well below the 40µg/m^3 annual mean UK AQO limits.

12.5.24 Monitoring data from a single roadside diffusion tube monitoring site located along the C182 near Hill Farm Cottage, as obtained during the baseline air quality monitoring programme, was used for verification purposes for the Cannington ADMS Roads model output (see the Air Quality Modelling Report - Ref. 12.2).

d) Receptors and Identified Value and Sensitivity

12.5.25 The human receptors considered in this assessment, i.e. both residents local to the HPC development site (as illustrated in **Figures 12.1**, **12.2** and **12.6**) and those located along the road network, as illustrated in **Figures 12.3**, **12.4** and **12.5**, are all of high value and high sensitivity in terms of local air quality impacts.

12.5.26 **Table 12.6** below provides a summary of the sensitivity of the assessed human receptors to potential air quality impacts from the proposed development. The value and sensitivity of ecological receptors is discussed in **Volume 2**, **Chapters 19** and **20**.

Table 12.6: Summary of Receptor Sensitivity

Receptor	Exposure	Sensitivity	Justification
Human receptors at residential locations near to the development site boundary (as illustrated in **Figures 12.1, 12.2** and **12.6**) and along the affected road network (as illustrated in **Figures 12.3, 12.4** and **12.5**)	Continuous long-term	High	Potential adverse health impacts may be possible as a result of continuous long-term exposure to potentially elevated air pollutant concentrations
Users of footpaths and Public Rights of Way (PRoW) (human receptors - casual walkers and hikers) (as illustrated in **Figure 12.6**)	Transient short-term	Low	Potential adverse health impacts are not expected as a result of transient short-term exposure to potentially elevated air pollutant concentrations

e) 'Without development' Scenario

12.5.27 Should the HPC Project not proceed, and HPC not be developed, future baseline conditions over the duration of the project (but without the development) would be expected to marginally improve year on year. While it is expected that the study area would continue with its current use minor improvements to baseline air quality conditions are anticipated with time as a result of technological improvements (to vehicle engines and industrial processes), legislative measures and government incentives to improve air quality.

12.6 Assessment of Impacts

a) Introduction

12.6.1 The impact assessment with respect to air quality on the existing environment covers the following issues:

- qualitative assessment of fugitive dust and particulate emissions during the HPC development site construction works;
- qualitative assessment of exhaust emissions of on-site plant and machinery, during the HPC development site construction works;
- quantitative assessment of off-site road traffic emissions during the construction and operation of HPC;
- quantitative assessment of marine vessel emissions during the operation of the temporary jetty; and
- quantitative assessment of potential air quality impacts during HPC on-site commissioning/operational activities.

12.6.2 Whilst this chapter also presents the additional air pollutant deposition flux (of both nitrogen and acidic equivalents) as a result of the construction and commissioning/operational phases of HPC, at both statutory and non-statutory designated ecological sites, the significance of associated impacts to the ecological receptors is discussed within **Volume 2**, **Chapter 20**.

12.6.3 EDF Energy is committed to implementing best practice to reduce dust impacts to acceptable levels. However, to make the impact assessment more transparent, impacts from dust are assessed prior to implementation of best practices for dust control. These dust control measures (best practices) have been listed under the mitigation section in this chapter.

b) Construction Impacts

12.6.4 Potential impacts will vary during the construction phase for the HPC development according to the activities being undertaken, which include:

- mobilisation;
- excavation, levelling and preparation of working platforms;
- construction of the temporary jetty;
- construction of temporary and permanent access roads and parking areas;
- construction of the sea wall;
- deep excavations and tunnelling;
- construction of a workers accommodation campus;
- building construction; and
- construction of the National Grid 400kV substation.

12.6.5 Whilst the potential impact may vary throughout these stages of the construction phase, the primary air pollution sources will be those typical of any industrial construction site that may cause dust and particulate matter to be emitted to the atmosphere. These sources relate to activities which will include (but not be limited to) earthworks; excavations, drilling and compacting; crushing and grinding and cement batching.

12.6.6 Dust comprises particulate matter typically in the size range 1-75µm in aerodynamic diameter and is mostly created through the action of crushing and abrasive forces on materials. The larger dust particles fall out of the atmosphere quickly after initial release and therefore tend to be deposited in close proximity (10 to 20m) to the source of emission. The smaller particles of dust (typically less than 10µm in aerodynamic diameter) are known as particulate matter (PM_{10}) and represent only a small proportion of total dust released. As these particles are at the smaller end of the size range of dust particles they remain suspended in the atmosphere for a longer period of time than the larger dust particles of greater than 10µm, and can be transported by wind over a wider area. It is the particles of greater than 10µm in size that generally fallout within 100m of the source, and this is what is known as the dust 'annoyance' component. If such dust is deposited on washing, window sills and cars, for example, it can cause 'soiling and discolouration', which may result in complaints of annoyance through amenity loss or perceived damage caused, which is usually temporary but can be episodic.

12.6.7 Dust and particulates generated by construction activities could theoretically also have an adverse impact on ecological receptors, smothering the leaves of plants and affecting photosynthesis, respiration and transpiration. The literature suggests that the most sensitive species appear to be affected by dust deposition at levels approximately five times greater than the level at which most dust deposition may start to cause a perceptible annoyance to humans, but most species appear to be unaffected until dust deposition rates are at levels considerably higher than this (Ref. 12.40).

12.6.8 In addition to fugitive dust and PM_{10}, there is also the potential for on-site emissions to air from the exhausts of associated on-site plant and machinery (known as Non-Road Mobile Machinery – NRMM), such as excavators and dozers, generators and compressors, plus exhaust emissions from the movements of marine vessels associated with the operation of the temporary jetty facility. These emissions would comprise airborne PM, and NO_X and SO_2.

12.6.9 Throughout the construction phase, the volume of construction traffic on local roads will vary considerably, with the potential to affect receptors sensitive to air quality along the roads connecting the development site with the M5 motorway to the south-east. The main pollutants of concern for road traffic are generally considered to be NO_2, PM_{10}, $PM_{2.5}$, CO and benzene. Based upon the baseline air quality environment and experience in undertaking air quality assessments, emissions of NO_x/NO_2, PM_{10} and $PM_{2.5}$ are most likely to result in exceedences of the relevant air quality standards or objectives in the study area.

12.6.10 During the construction phase there is also the potential for increased deposition of air pollutants to ecological receptors in proximity to the proposed HPC development. Emissions to air generated by on-site plant and machinery exhaust emissions, off-site road vehicle exhaust emissions, and marine vessel exhaust emissions associated with the operation of the temporary jetty during the HPC construction phase may all contribute towards annual nitrogen and acid deposition fluxes. Given that air pollutant deposition from on-site plant and machinery associated with the HPC construction phase are considered to be insignificant when compared to the likely deposition associated with off-site road vehicle exhaust emissions and marine vessel exhaust emissions, deposition from these construction sources has not been considered further. Deposition of air pollutants from off-site road vehicle exhaust emissions and marine vessel exhaust emissions associated with the operation of the temporary jetty during the HPC construction phase have therefore been considered, however the significance of associated impacts to the ecological receptors is discussed within **Volume 2**, **Chapter 20**.

i. Fugitive Dust and Particulate Matter Generated by Construction Activities

12.6.11 The extent to which dust and particulate matter generation, and possible annoyance, arising from construction activities might occur is difficult to assess quantitatively. Dust and particulate levels due to emissions directly from the development site and any roadways including haulage roads (if dry), would depend upon various factors at any one time, including:

- nature of work being undertaken;
- wind direction;
- wind speed;
- precipitation;
- type and quantity of material being handled;
- particle size distribution of the material being handled; and
- moisture content of the material being handled.

12.6.12 Although dust levels will be greatest when there is a plentiful supply of fine, dry particles, the majority of these influencing factors are dependent upon both site working methods and weather conditions. As a consequence, the uncertainties associated with estimated emission factors and therefore any numerical predictions are too great for such estimates to be useful. A qualitative approach has therefore been taken to assessing the impact of dust emissions from the construction works as a whole.

12.6.13 The assessment presented within this chapter considers the potential impact of fugitive dust and particulate matter. Assessment of the potential implications of contaminated dust arising from any contaminated soils during the construction activities is presented within **Volume 2**, **Chapter 14**.

Assumed Construction Plant

12.6.14 In order to evaluate fugitive dust and particulate generation during the construction phase, it is necessary to define the various activities that will be undertaken. It is possible to undertake a generic assessment of air quality impacts based on expected methods of working gained from experience with previous similar developments. In undertaking this assessment, a worst-case approach has been taken by considering the upper range estimates for required plant numbers, which therefore provides a conservative basis for assessment of potential air quality impacts. This assessment also considers all combined elements of construction at the development site, as opposed to each in isolation, i.e. consideration has been given to any potential overlap as a result of multiple activities being undertaken at the same time.

12.6.15 Typical construction plant and equipment that is likely to be used on-site includes the following:

- excavators;
- cranes;
- earthmoving plant;
- batching plant;
- compressors;
- diesel generators;
- road-going HGVs moving spoil and delivering material (to be minimised by the construction of a jetty to be used for aggregates and cement delivery);
- hand held tools such as disc cutters, grinders and nut runners;

- piling plant;
- concrete pumping plant and trucks;
- rock breakers and crushing plant;
- dewatering pumps; and
- tunnel boring plant.

12.6.16 In addition to the above, blasting of fresh rock may be required during excavation. Whilst these operations might generate increased fugitive emissions of dust and PM_{10}, they will be infrequent and of an extremely short-term duration.

Local Climate Conditions

12.6.17 Meteorological data covering the period 1 January 2005 to 31 December 2009 were obtained for the Hinkley Point site from the United Kingdom Meteorological Office (UKMO) Numerical Weather Prediction model to provide an indication of prevailing wind directions and the frequency of moderate to strong winds. These wind data and accompanying precipitation rate data were used to assess the likelihood of receptors located in the vicinity of the development site being affected by fugitive dust and particulate emissions.

12.6.18 Wind sectors have been assigned for the hourly meteorological data for Hinkley Point (covering the period 2005 to 2009), based upon the reported wind direction (degrees). Each wind sector category represents the mid-point of each wind sector ±11.25°, e.g. the mid-point of north-north-west (NNW) is 326.25°, and therefore any winds with a bearing ranging from 337.50° to 348.75° have been classified as NNW. Each of the 16 wind sectors thus represents 22.5°.

12.6.19 The wind-rose for 2005 to 2009 (see **Figure 12.8**) illustrates a predominant wind direction from the west-north-west (WNW) at 18.0% of the time, with winds from the west also occurring frequently at 10.5% of the time. These are followed by southerly and west-south-westerly (WSW) winds, both at a frequency of 7.2%. Wind directions from the north and NNW occur relatively infrequently (2.4% and 2.6% of the time, respectively).

12.6.20 **Table 12.7** presents the frequency of winds as a percentage of all winds at Hinkley Point between 2005 and 2009, for each wind direction within specified wind speed categories. Calm conditions (<0.5m/s) occur for only 0.4% of the time. Wind speeds between 0.5 and 5.0m/s occur for approximately 45.7% of the time, whilst winds of above 5m/s occur for around 53.9% of the time.

12.6.21 Although the critical wind speed for raising particles into the air will be dependent upon the physical condition of the surface and the size range of particles present, the potential for the generation of airborne dust will increase with elevated wind speed.

12.6.22 A wind-rose showing the frequency of winds of a speed greater than 5m/s is presented in **Figure 12.9** (wind-blown dust arising, for example as a result of erosion of stockpiled material, typically occurs with winds in excess of 5.4m/s (Ref. 12.35). Wind directions from the WNW and westerly sectors occur most frequently for the higher wind speeds, accounting for 23.3% and 15.0% of winds above 5m/s, respectively.

Table 12.7: Frequency of Winds as a Percent
+age of all Winds at Hinkley Point between 2005 and 2009

Wind Speed (m/s)	Wind direction (°)																TOTAL (%)

TOTAL %	**2.40**	**3.75**	**5.28**	**5.17**	**3.56**	**3.80**	**4.72**	**5.38**	**7.24**	**6.87**	**6.54**	**7.20**	**10.49**	**17.96**	**7.04**	**2.59**	**100.00**

12.6.23 Airborne dust levels are also more likely to be elevated during periods of prolonged warm, dry weather. During periods of wetter weather, precipitation not only minimises the amount of fugitive dust and PM_{10} that becomes airborne, but also enhances the removal of airborne dust and PM_{10} from the atmosphere via washout and rainout. Analysis of precipitation rate data between 2005 and 2009 for Hinkley Point indicates that dry conditions are prevalent for 67.0% of time. Thus, for the remaining 33.0% of the time, airborne fugitive dust and PM_{10} levels are not likely to be significant.

Construction Scenarios

12.6.24 Three construction phase scenarios were considered, each representing a point in time during the HPC construction phase:

- Scenario A – 2011/2012 Preliminary Site Preparation Works. During this phase, the following key construction activities will take place:
  - removal of vegetation;
  - stripping of topsoil and subsoil;
  - soil and rock stockpiling in the Southern Construction Phase Area (SCPA) (north of latitude 144750mN) and at the western boundary of the SCPA;
  - establishment of platform areas in the northern part of the development site;
  - preparation works for construction of the northern roundabout close to Pixies Mound and the southern roundabout; and
  - construction of the temporary jetty.
- Scenario B – 2013. During this phase, the following key construction activities will take place:
  - deep (rock) excavation at UK EPR Units 1 and 2;
  - excavated materials transported to the stockpiles within the SCPA;
  - vehicles using circular haul route between northern and southern areas of the development site;
  - construction of sea wall;
  - construction of on-site workers accommodation campus;
  - early landscaping in the land to the south of latitude 144750mN within the SCPA;
  - construction of bridge over Bum Brook; and
  - construction of emergency access road in south of the HPC site.
- Scenario C – Late 2014. During this phase, the following construction activities will take place:
  - construction of buildings for UK EPR Unit 1 and shared (UK EPR Units 1 and 2) buildings and excavations back-filled;
  - on-going construction of roads and networks; and
  - construction of the National Grid 400kV substation.

Receptor Location Relative to Source

12.6.25 The distance from the dust source to the sensitive receptor location is also critical. Both airborne dust and particulate concentrations, and dust deposition rates, decrease rapidly with distance from the source.

12.6.26 The worst-case (i.e. closest) human receptors to the HPC construction site areas were identified for the three construction phase scenarios as described above. Distance and bearing from potential dust generating construction activities, direction and frequency of winds carrying airborne particles from construction activities to the receptor, and the frequency of dry days were calculated. Distance has been calculated from the receptor to the closest point of on-site construction activity for each of the scenarios. **Table 12.8** presents a summary of these results.

12.6.27 It can be seen from **Table 12.8** that the lowest frequency of occurrence of meteorological conditions that may carry airborne fugitive dust and PM_{10} from on-site construction activities towards sensitive receptors (unfavourable wind directions, wind speed greater than 5m/s and no precipitation) is for receptors affected by predominantly northerly winds, namely Shurton Village and Bishops Farm House (2.4%). These two receptors are therefore the least likely to experience meteorological conditions that may carry airborne dust and PM_{10} from the development site, with “unfavourable” conditions occurring only 2.4% of the time.

12.6.28 In contrast, “unfavourable” conditions are most frequent for the receptors affected by predominantly NW winds, namely Point west of Wick, Gunter’s Grove and Wick Village. This is evidenced by a frequency of wind with speed greater than 5m/s and no precipitation of 13.1%, which suggests that meteorological conditions that may lead to fugitive dust and PM_{10} at this location are prevalent 13.1% of the time. However, the closest receptors (Point west of Wick) is almost 500m away from the closest construction activities. Given that the majority of fugitive dust and PM_{10} is deposited within 200m of the source, these receptors are therefore at sufficient distance from the development site for substantial dispersion, dilution and deposition of dust and PM_{10} to occur between the development site and the receptor locations. It is therefore unlikely that fugitive dust and particulates will be significant at these receptors.

Scenario A – 2011/2012 Preliminary Site Preparation Works

12.6.29 The potential for fugitive dust and PM_{10} generation will be greatest during this phase of the construction works whilst the main earthworks are undertaken. This will involve an initial site strip of vegetation and removal of topsoil and subsoil, followed by site levelling and terracing. Soils will be transported to temporary storage areas located in the SCPA. Some of the soils will be used to construct a bund along the development site’s western boundary south of Green Lane.

12.6.30 During site levelling/terracing, there may be a limited requirement for blasting of the bedrock. If required, this is likely to involve drilling of a number of holes within a rock face, into which are placed the necessary explosive charges. Blast events would be localised and, therefore, a minimum explosive charge would be used to achieve the required rock extraction rate. However, blasting and the other methods used for the removal of rock deposits (principally ripping and breaking) may lead to increased levels of airborne dust and PM_{10}. Given the large area to undergo stripping and the considerable volume of soil and rock material to be moved around site during the earthworks, there is the potential that elevated levels of airborne dust and PM_{10} will be generated by mechanical disturbance of the soil and rock materials during this period.

12.6.31 However, during this period, land to the south of latitude 144750mN and within the development site boundary of the proposed on-site workers accommodation campus will remain undisturbed.

12.6.32 There are 15 identified human receptor locations that are within 1km from the proposed construction activities during this phase of the works. With the exception of Doggetts, all of the human receptor locations are greater than 200m from the closest point of site activity. Following the methodology presented in section 12.4, the development site is classified as high risk site with respect to fugitive dust and PM_{10} generation (the proposed development covers greater than 15,000m^2 of land and there is the potential for emissions and dust to have a significant or likely impact on sensitive receptors). Therefore, excluding Doggetts, the significance of this impact is predicted to be **negligible** at all assessed human receptor locations during this phase of the construction works. The impact from dust at these receptors would be local, direct, unlikely and medium-term.

12.6.33 Doggetts is situated approximately 128m from the closest point of site activity. Following the methodology presented in section 12.4, the significance of fugitive dust and PM_{10} impacts at Doggetts are predicted to be **minor** during this phase of the construction works, in the absence of mitigation. Meteorological conditions that may lead to elevated levels of fugitive dust and PM_{10} at this location are prevalent for only 4.2% of the time (see **Table 12.8**). The potential frequency that fugitive dust and PM_{10} may be experienced at this receptor is therefore limited by the reduced occurrence of meteorological conditions that are conducive to elevated dust levels. The impact from dust at this receptor would be local, direct, possible and medium-term.

12.6.34 **Figure 12.1** illustrates the area of potential fugitive dust and PM_{10} impacts based on the extent of site construction activities that would be undertaken during Scenario A.

Table 12.8: Human Receptor Locations that may Experience Elevated Fugitive Dust and PM_{10} Emissions during HPC Construction

[1] *'Bearing from construction site' calculated based upon the angle from the approximate centre of the proposed HPC development site to the receptor.*

[2] *'Distance to receptor from closest point of site activity' calculated by measuring the minimum distance from the receptor to the extent of proposed HPC development site activity, and therefore represents a worst-case approach.*

[3] *'Dominant wind sector affecting each receptor' derived assuming that the wind originating from opposite each receptor (i.e. 'Bearing from construction site' ±180°) is most likely to affect that particular receptor.*

[4] *'Frequency of occurrence' values calculated based upon the sum of the frequency of particular weather conditions within the hourly meteorological dataset, for the 'Dominant wind sector affecting each receptor' plus the two adjacent wind sectors, e.g. if the dominant wind sector affecting a receptor is NNW, then 'frequency of occurrence' represents the total frequency of the particular weather condition occurring within the hourly meteorological dataset, for the wind sectors NW, NNW, and N, calculated as a percentage of all 43,848 hourly meteorological data values).*

Scenario B – 2013

12.6.35 The potential for fugitive dust and PM_{10} impacts will be greatest during this phase at the time when the early landscaping works are being undertaken to the south of latitude 144750mN. The early landscaping will provide screening of the construction works from the south and it is proposed that these works including the reprofiling will be undertaken at the earliest opportunity. This will involve the use of excavated soils to produce a landform with levels up to a finished level of 35m Above Ordnance Datum (AOD). Final landscaping and planting of this area will then have time to develop and mature during the construction works.

12.6.36 During the period whilst the bund is being constructed, fugitive dust and PM_{10} may be more of an potential concern at the closest human receptors. However, once the bund and early landscaping land profiling are completed, these works will result in an increase in the separation distance between potential dust and PM_{10} generating construction activities and the human receptors during later construction phase works, thus having an overall effect of reducing potential long-term construction phase impacts.

12.6.37 Similarly, the on-site accommodation campus located in the south-east of the SCPA would also be under construction using this phase, there is therefore the potential for elevated airborne dust and PM_{10} levels to be experienced, particularly at the nearby residential receptor Doggetts. Once completed, however, the early landscaping will provide separation between potential fugitive dust and PM_{10} generating construction activities and the receptors, and will also provide some screening. There will therefore be an overall effect of reducing the potential for long-term fugitive dust and PM_{10} impacts at Doggetts post construction of the on-site accommodation campus.

12.6.38 Construction of the emergency access road and the bridge over Bum Brook during this phase of works could also lead to the generation of limited amounts of airborne fugitive dust and PM_{10}.

12.6.39 The majority of the identified human receptors, however, will be located over 200m from the closest point of site activity during this period of construction. Only Bishops Farm House, Doggetts and Shurton village will be closer than 200m, located at a minimum distance of 10m, 26m and 105m, respectively, from the closest point of site activity. Therefore, with the exception of these three receptors, following the methodology presented in section 12.4, the significance of fugitive dust and PM_{10} impacts at human receptors is predicted to be **negligible** during this phase of the construction works. The impact from dust at these receptors would be local, direct, unlikely and medium-term.

12.6.40 Following the methodology presented in section 12.4, the significance of fugitive dust and PM_{10} impacts at Shurton Village are considered to be of **minor** significance during this phase of the construction works. Potential impacts at Bishops Farm House and Doggetts would be considered to be of **major** significance during this phase of the construction works without mitigation. Meteorological conditions that may lead to elevated dust and PM_{10} at Doggetts and Bishops Farm House from on-site construction activities are prevalent for only 4.2% and 2.4% of the time, respectively. The impact from dust at these three human receptors would be local, direct, likely and medium-term.

12.6.41 **Figure 12.2** illustrates the area of potential fugitive dust and PM_{10} impacts based on the extent of site construction activities that would be undertaken during Scenario B.

Scenario C – Late 2014

12.6.42 Similar to the Scenario A construction phase scenario assessed above, activities during this phase of the HPC construction works will be limited to the north of latitude 144750mN and to the north of the completed on-site workers accommodation campus. Impacts during this period would therefore be expected to be similar as those predicted during Scenario A.

12.6.43 Doggetts is the only human receptor location which is closer than 200m from the closest point of site activity at this time (located at a distance of approximately 128m). Following the methodology presented in section 12.4, fugitive dust and PM_{10} impacts at Doggetts would be considered to be of **minor** significance during this phase of the construction works, in the absence of mitigation, and **negligible** at other assessed human receptor locations. There will, however, be a screening effect from the on-site workers accommodation campus that will reduce the potential for dust impacts by acting as a separation barrier between the receptor and source of dust generation. After 2014, no substantive construction activities will take place any closer to the human receptors than during this phase. This therefore represents the long-term potential fugitive dust and PM_{10} impacts. The impact from dust at these receptors would be local, direct, unlikely and long-term but temporary.

12.6.44 **Figure 12.1** also illustrates the area of potential fugitive dust and PM_{10} impacts based on the extent of site construction activities that would be undertaken during Scenario C.

Ecological Receptors

12.6.45 The assessment process presented above was repeated for ecological receptors, i.e. the distance and bearing from the development site boundary, direction and frequency of winds carrying airborne particles from activities to the receptor, and the frequency of dry days were calculated. **Table 12.9** presents a summary of these calculations.

12.6.46 Given the geographical distribution of the ecological receptors (i.e. non-point receptors), there is the potential for a range of wind directions to carry fugitive dust and PM_{10} generated by the construction works to the receptors. Any winds with a prevailing direction between south-easterly to west north-westerly could potentially transport dust to the ecological receptors.

12.6.47 It can be seen from **Table 12.9** that the frequency of occurrence of meteorological conditions that may carry airborne fugitive dust and PM_{10} from the development site towards ecological receptors ("unfavourable" wind directions, wind speed greater than 5m/s and no precipitation), is less than 28% of the time. Therefore, for the majority of the duration of the construction works, meteorological conditions would not be conducive to transporting airborne dust from the development site to these ecological receptors. Furthermore, there is only a small likelihood of dust generating activities occurring during these worst-case meteorological conditions and, typically, even the most sensitive of plant species are only likely to be affected by dust deposition at levels approximately five times greater than the level at which most dust deposition may start to cause a perceptible annoyance to humans (Ref. 12.40).

Table 12.9: Ecological Receptor Locations that may Experience Elevated Fugitive Dust and PM_{10} Emissions during HPC Construction

Receptor	Bearing from Construction Site (°) [1]	Distance to Receptor from Construction Site (m) [2]	Dominant Wind Sector Affecting each Receptor [3]	Frequency of Occurrence (% of Hourly Values) [4]		
				All Weather Conditions	Wind with Speed >5 m/s	Wind with Speed >5 m/s, No Precipitation
Bridgwater Bay NNR & Severn Estuary SAC	311-67	0	SE-WSW	52.2	27.6	13.7
Bridgwater Bay SSSI and Severn Estuary SPA/Ramsar	311-113	0	SE-WNW	82.2	45.7	27.4
Hinkley CWS	64-85	0	W-SW	42.7	29.3	19.4

[1] *'Bearing from construction site' calculated based upon the angle from the approximate centre of the proposed HPC development site to the receptor. Bearing is provided as a range (assuming a clockwise rotation) due to the geographical spread of the ecological receptors.*

[2] *'Distance to receptor from construction site' calculated by measuring the minimum distance from the receptor to the proposed HPC development site boundary, and therefore represents a worst-case approach.*

[3] *'Dominant wind sector affecting each receptor' derived assuming that the wind originating from opposite each receptor (i.e. 'Bearing from construction site' ±180°) is most likely to affect that particular receptor. Dominant wind sector is provided as a range (assuming a clockwise rotation) due to the geographical spread of the ecological receptors.*

[4] *'Frequency of occurrence' values calculated based upon the sum of the frequency of particular weather conditions within the hourly meteorological dataset, for the 'Dominant wind sector affecting each receptor' plus the two adjacent wind sectors, e.g. if the dominant wind sector affecting a receptor is NNW, then 'frequency of occurrence' represents the total frequency of the particular weather condition occurring within the hourly meteorological dataset, for the wind sectors NW, NNW, and N, calculated as a percentage of all 43,848 hourly meteorological data values).*

12.6.48 Following the methodology presented in section 12.4, as the development site has been classified, for the purposes of this assessment, as high risk with respect to fugitive dust and PM_{10} generation, the significance of potential fugitive dust and PM_{10} impacts at the ecological receptors 'Bridgwater Bay SSSI/NNR', 'Severn Estuary SPA/SAC/Ramsar' and 'Hinkley CWS' is predicted to be **major**. Meteorological conditions that may lead to elevated fugitive dust and PM_{10} at these locations from on-site construction activities are prevalent for up to 27.4% of the time. The potential frequency that fugitive dust and PM_{10} may be experienced at these receptors is therefore limited by the limited occurrence of meteorological conditions that are conducive to elevated dust levels. Furthermore, the impact would also be limited to the proportion of the ecological receptor sites which are within 25m from the closest point of site activity (the majority of the ecological sites will not be impacted by fugitive dust at all). The impact from dust at these receptors would be local, direct, adverse, possible and long-term during the construction works, but temporary.

12.6.49 Further discussion of the potential fugitive dust and PM_{10} impacts upon biodiversity receptors, is presented in **Volume 2**, **Chapter 20**.

Summary

12.6.50 During the early HPC construction phase Scenario A, activities will be restricted to the north of latitude 144750mN and also outside of the footprint of the proposed on-site workers accommodation campus, and therefore fugitive dust and PM_{10} impacts are predicted to be of either **negligible** or **minor** significance at all human receptors during this period. During Scenario B when the bulk of the earthworks and construction of the on-site workers accommodation campus are taking place in the SCPA, in the absence of any mitigation, fugitive dust and PM_{10} impacts are predicted to be of **major** significance at Doggetts and Bishops Farm House. However, following the completion of these activities and the conclusion of works with substantive dust generating potential in the SCPA by late 2014, given the resultant effective separation distance increase between potential dust and PM_{10} generating construction activities and the receptors, the fugitive dust and PM_{10} impacts are predicted to be of either **negligible** or **minor** significance at all human receptors. Therefore post 2014, the long-term potential fugitive dust and PM_{10} impacts from the HPC construction works are considered to be no more than **minor** significance at human receptors, prior to the implementation of any mitigation. The potential for major fugitive dust and PM_{10} impacts at human receptor locations, in the absence of mitigation, will therefore be limited to the period between Scenario A and Scenario C, i.e. between 2011/2012 and late 2014.

12.6.51 Given the immediate proximity of the ecological receptors to the HPC development site boundary, the significance of fugitive dust and PM_{10} impacts at the ecological receptors 'Bridgwater Bay SSSI/NNR', 'Severn Estuary SPA/SAC/Ramsar' and 'Hinkley CWS' are predicted to be **major**. However, this level of impact would be limited to the proportion of the ecological sites which are within 25m from the closest point of site activity, with the potential impact significance reducing to no more than **minor** at distances greater than 50m from the development site (i.e. most of the ecological site areas will not be impacted by fugitive dust at all). **Volume 2, Chapter 20** discusses this issue further in the context of specific sensitive species within the designated ecological sites.

12.6.52 Measures will be taken to minimise fugitive dust and PM_{10} generation at source, and to monitor the fugitive dust and PM_{10} impacts at the most sensitive receptor location(s). Details of these management measures and associated monitoring will be provided in the **Air Quality Management Plan (AQMP)**. The application of best practice guidance and control measures employed on construction sites would minimise dust generation and mitigation measures would ensure that any potential impacts would be at an acceptable level at the identified human and ecological receptor locations (see section 12.7).

ii. Exhaust Emissions from On-site Plant and Machinery Utilised during Construction

12.6.53 Diesel powered off-road construction plant and machinery (NRMM) are not currently subject to the same stringent controls as normal road vehicles. It is therefore appropriate to assess the potential air quality impacts associated with exhaust emissions from NRMM used during construction. However, there are various European Directives which have been implemented to control NRMM emissions and progressively reduce their potential impact.

12.6.54 European Directive 2002/88/EC (Ref. 12.49) relates to measures to control the emission of gaseous and particulate pollutants from internal combustion engines to be installed in NRMM, and implements two stages of emission limit values for compression ignition engines. The two stages of emissions limits for new diesel engines set the maximum allowable emissions of NO_X, particulate matter, hydrocarbons and carbon monoxide. Stage I is already in force for all engine categories and Stage II has now been implemented for almost all engines.

12.6.55 Directive 2004/26/EC9 (Ref. 12.50) of the European Parliament and of the Council (amending Directive 97/68/EC (NRMM Directive) and Directive 2002/88/EC), implements three stages of future emissions limits (Stage IIIA, IIIB & IV) that apply to equipment already within the scope of Directive 97/68/EC (Ref. 12.51).

12.6.56 All engines installed that are not already available in the market will have to comply with the emission limits before 2015 (with the exception of Stage IV for engines other than constant speed engines with a production date prior to 31 December 2013 and 30 September 2014, where the compliance date may be postponed by two years).

12.6.57 Directive 98/70/EC (Ref. 12.52) (as amended by Directive 2003/17/EC (Ref. 12.53)) relating to the quality of petrol and diesel fuels establishes minimum specifications for petrol and diesel to be placed on the market in the EU, including gas oils intended for use by NRMM. These are required to contain less than 2,000mg/kg of sulphur decreasing to 1,000mg/kg by 1 January 2008 at the latest.

12.6.58 For small engines (37-75kW), the predicted technology required to meet Stage IIIA controls includes engine modifications, adoption of electronic engine control, improved fuel pumps and limited, un-cooled Exhaust Gas Recirculation (EGR). For larger engines which already utilise electronic engine control, the predicted technologies required are engine modifications, common rail injection, air-air charge cooling and limited, un-cooled EGR. Further reductions for small engines (i.e. 18 - 37kW) are considered impractical (Ref. 12.54).

12.6.59 For engines to meet Stage IIIB controls it is expected that Diesel Particulate Filters (DPFs) will be fitted. To ensure reliable operation of DPFs, the use of low sulphur content fuels will be needed (approximately 10mg/kg sulphur, whilst gas oil has 2,000mg/kg sulphur, decreasing to 1,000mg/kg from 2008) (Ref. 12.54).

12.6.60 Stage IV controls are expected to force the adoption of Selective Catalytic Reduction (SCR) de-NO_X after-treatment systems in addition to DPFs.

12.6.61 A summary of the implementation dates for the emission standards is presented in **Table 12.10**.

Table 12.10: Summary of the Implementation Dates for NRMM Emission Standards

Net Power, kW	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
130 – 560											
75 – 130											
56 – 75											
37 – 56											
18/19 – 37											

Stage I (1999)

Stage II (2001-2004)

Stage IIIA (2006-2008)

Stage IIIB (2011-2013)

Stage IV (2014)

12.6.62 For the purposes of this assessment, given the indicative plant and machinery required on site, a qualitative assessment approach of NRMM emissions to air of principal concern (NO_x, PM_{10} and SO_2) is considered appropriate. The adopted qualitative approach considers the likely quantities and type of NRMM to be used during the construction works, combined with the locations of sensitive receptor groups.

12.6.63 Given the likely numbers of plant items working on-site, their frequency and anticipated duration of operation, the magnitude of increase in pollutant concentrations associated with exhaust emissions from the numbers of NRMM operating would likely be either imperceptible or small, even at Bishops House Farm and Doggetts located approximately 10m and 26m from the development site boundary respectively (works at this separation distance to the receptors would be infrequent and of an intermittent nature). Therefore, there are no human receptors that have the potential to be significantly impacted by NRMM emissions generated by the HPC construction works.

12.6.64 Background pollutant concentrations in the development site locality are well below the relevant AQOs; there is therefore a significant amount of 'headroom' before any of the relevant short-term and long-term AQOs would potentially be exceeded (see section 12.5 and **Appendix 12B**). Given the above, on-site exhaust emissions to air as a result of NRMM associated with construction are predicted to be of small magnitude, and thus **negligible** in terms of impact at the assessed human receptors. This impact is therefore considered to be **not significant**. Impacts from on-site exhaust emissions from NRMM would be local, adverse, direct, unlikely and long-term but temporary in nature.

Ecological Receptors

12.6.65 With respect to ecological receptors, background air quality pollutant concentrations in the development site locality are well below the relevant AQOs for the protection of vegetation and ecosystems (see section 12.5 and **Appendix 12B**). Given the above and the numbers of plant and machinery likely to be required, on-site exhaust emissions to air as a result of NRMM associated with the construction works are also considered to be of either imperceptible or small magnitude, and therefore **negligible**, in terms of their potential impact on the assessed ecological receptors. Impacts from on-site exhaust emissions from NRMM would be local, adverse, direct, unlikely and long-term but temporary. Impact would also be limited only to the proportion of the ecological receptor which is within 200m from the development site boundary (i.e. the majority of the ecological sites would not be impacted by exhaust emissions from NRMM at all).

12.6.66 Further discussion of the potential impacts from on-site NRMM exhaust emissions upon biodiversity receptors, is presented in **Volume 2**, **Chapter 20**.

iii. Emissions from Marine Vessels Associated with Temporary Jetty Operation

12.6.67 This section presents the assessment of marine vessel emissions to air associated with the operation of the temporary jetty. The jetty will be a temporary structure, utilised during the construction of HPC to supply aggregate and cement for concreting.

12.6.68 It is forecast that up to 18 self-discharging vessels (13 aggregate dredgers and up to 5 cement carriers) would berth at the jetty head per month, to meet a peak concrete demand of 30,000m^3 per month (6 month period) during the construction of the proposed power station. During low concrete demand periods, other freight goods and materials may be delivered to the development site via the jetty once the second phase (larger) jetty is constructed, although the precise quantity of these additional movements is yet to be quantified.

12.6.69 Whilst the selection of operational vessels would be made by the works contractor, it is estimated that the jetty would accommodate vessels of up to 5,000 deadweight tonnes (dwt), using marine diesel oil, taking approximately one hour to berth, 30 minutes for departure and six hours moored alongside the jetty.

12.6.70 Based upon these assumptions, the potential impacts on human and ecological receptors from exhaust emissions to air resulting from marine vessel movements during operation of the jetty were predicted using the air pollutant dispersion model ADMS 4.2. The input data and further information used in the modelling study is presented in **Appendix 12F**.

12.6.71 The results of the dispersion modelling and an assessment of the significance of the potential impacts on ground level concentrations in relation to ambient air quality standards are presented in this section. The pollutant concentrations resulting from emissions from marine vessels have been combined with background concentrations and the percentage contribution that the total predicted air concentrations will make towards the relevant AQO calculated. Full results of the dispersion modelling exercise are presented in **Appendix 12F**.

12.6.72 Results are presented for the meteorological year resulting in the highest ground level concentrations, as a worst-case assumption. 2005 was identified to be the worst-case meteorological year for pollutant dispersion from the marine vessel source (i.e. it led to the highest pollutant concentrations at receptor locations) and therefore meteorological data for this year were used in this study. Results and associated impacts using meteorological data for 2005 are reported in the following sections.

Human Receptors

12.6.73 The pollutant concentration results and associated impacts predicted at the 31 human receptor locations as illustrated in **Figure 12.6**.

12.6.74 In addition to these 31 human receptors locations that represent residential locations in proximity to the HPC development site boundary, potential impacts at four additional transient human receptor locations have been assessed. These represent locations of recreation and amenity activity (i.e. Public Rights of Way and sites of archaeological interest) where humans would be present relatively infrequently and for only short periods of time. Exposure at these locations is therefore only considered over short-term averaging periods. These transient human receptor locations are also illustrated in **Figure 12.6**.

12.6.75 **Table 12.11** summarises the pollutant concentration results and associated impacts predicted at the 31 human receptor locations and the 4 transient human receptor locations. The table provides a summary of the maximum Process Contributions (PCs) and the maximum Predicted Environmental Concentrations (PECs) (i.e. the sum of the PC and the background concentration) from the marine vessels. A full set of results for all human receptor locations is presented in **Appendix 12F**.

12.6.76 The PCs of long-term NO_2, PM_{10} and $PM_{2.5}$ and short-term NO_2, PM_{10} and SO_2 marine vessel exhaust emissions (as detailed in **Appendix 12F**, **Tables 3**, **4**, **5** and **6**) are of imperceptible magnitude. The PEC values of long-term NO_2, PM_{10} and $PM_{2.5}$ and short-term NO_2, PM_{10} and SO_2 are all well below the objective/limit value and so are predicted to be **negligible**. Their impact on the human receptor locations is therefore **not significant**.

Table 12.11: Maximum Predicted Marine Vessel Exhaust Pollutant Concentrations and Impacts at Human Receptor Locations

Pollutant and Averaging Period	AQO/EAL Limit Value ($\mu g/m^3$)	Maximum Concentration Increase due to Development (PC) ($\mu g/m^3$) and as Percentage of AQO/EAL (%)	Maximum Concentration with Development (PEC) ($\mu g/m^3$) and as Percentage of AQO/EAL (%)	Magnitude of Change	Impact Descriptor
Human Receptors					
NO_2 annual mean	40	0.03 (0.1%)	6.83 (17.1%)	Imperceptible	Negligible
NO_2 1-hour mean	200	0.47 (0.2%)	14.07(7.0%)	Imperceptible	Negligible
PM_{10} annual mean	40	0.02 (0.1%)	18.22 (45.6%)	Imperceptible	Negligible
PM_{10} 24-hour mean	50	0.08 (0.2%)	36.48 (73.0%)	Imperceptible	Negligible
$PM_{2.5}$ annual mean	25	0.02 (0.1%)	7.92 (31.7%)	Imperceptible	Negligible
SO_2 15-minute mean	266	0.90 (0.3%)	4.50 (1.7%)	Imperceptible	Negligible
SO_2 1-hour mean	350	0.62 (0.2%)	4.22 (1.2%)	Imperceptible	Negligible
SO_2 24-hour mean	125	0.27 (0.2%)	3.87 (3.1%)	Imperceptible	Negligible
Transient Human Receptors					
NO_2 1-hour mean	200	2.59 (1.3%)	16.19 (8.1%)	Small	Negligible
SO_2 15-minute mean	266	4.30 (1.6%)	7.90 (3.0%)	Small	Negligible
SO_2 1-hour mean	350	3.55 (1.0%)	7.15 (2.0%)	Small	Negligible

iv. Transient Human Receptors

12.6.77 The PCs of short-term NO_2 and SO_2 marine vessel exhaust emissions (as detailed in **Appendix 12F**, **Tables 3** and **6**) are of no more than small magnitude. The PEC values of short-term NO_2 and SO_2 are all well below the objective/limit value and so are predicted to be **negligible**. Their impact on the transient human receptor locations is therefore **not significant**.

Summary

12.6.78 For all assessed pollutants, the potential impact of exhaust emissions from the commissioning of HPC on the identified human receptors is local, adverse, direct, likely and long-term but temporary. The impact on the human receptor (including transient human receptor) locations for all assessed pollutants is determined to be **not significant**.

Ecological Receptors

12.6.79 This section presents the pollutant concentrations results and associated impacts predicted at the following ecological receptor locations (see **Figure 12.6**):

- Bridgwater Bay SSSI/NNR.
- Severn Estuary SPA/SAC/Ramsar.

12.6.80 Given that the separation distance between the closest non-statutory designated ecological site (Hinkley CWS) and the location of potential marine vessel exhaust emissions is approximately 1.6km, marine vessel exhaust emissions at these locations have not been subject to a detailed assessment as potential impacts are considered to be insignificant.

12.6.81 **Table 12.12** summarises the pollutant concentrations results and associated impacts predicted at the statutory designated ecological receptor locations. The table provides a summary of the maximum PC and PEC concentrations from the marine vessels. A full set of results for all ecological receptor locations is presented in the **Appendix 12F**.

12.6.82 The PCs of long-term NO_x and SO_2 marine vessel exhaust emissions (as detailed in **Appendix 12F**, **Tables 7** and **8**) are of no more than small magnitude. The PEC values of long-term NO_x and SO_2 are all well below the objective/limit value and so are predicted to be **negligible**.

12.6.83 The PCs of 24-hour mean NO_x marine vessel exhaust emissions (as detailed in **Appendix 12F**, **Table 7**) are of up to medium magnitude. The PEC values of 24-hour mean NO_x are all well below the objective/limit value and so are predicted to be **negligible**.

Table 12.12: Maximum Predicted Marine Vessel Exhaust Pollutant Concentrations and Impacts at Ecological Receptor Locations

Pollutant and Averaging Period	AQO/EAL Limit Value ($\mu g/m^3$)	Maximum Concentration Increase due to Development (PC) ($\mu g/m^3$) and as Percentage of AQO/EAL (%)	Maximum Concentration with Development (PEC) ($\mu g/m^3$) and as Percentage of AQO/EAL (%)	Magnitude of Change	Impact Descriptor
Statutory Designated Ecological Receptors					
NO_x annual mean	30	1.06 (3.5%)	12.56 (41.9%)	Small	Negligible
NO_x 24-hour mean	75	7.48 (9.9%)	30.48 (30.5%)	Medium	Negligible
SO_2 annual mean	20	0.51 (2.6%)	2.31 (11.6%)	Small	Negligible

Summary

12.6.84 For all assessed pollutants, the potential impact of exhaust emissions from marine vessels associated with the temporary jetty operation on statutory ecological receptors is local, adverse, direct, likely and long-term but temporary.

12.6.85 The significance of these predictions of NO_x and SO_2 emissions, from marine vessels associated with the operation of the temporary jetty during HPC construction, upon biodiversity receptors is presented **Volume 2**, **Chapter 20**.

Deposition of Nutrifying and Acidifying Pollutants

12.6.86 The maximum additional deposition rates of nutrifying and acidifying pollutants at the statutory designated ecological receptor sites, due to the exhaust emissions from marine vessels associated with jetty operation during the proposed HPC development construction phase, are summarised in **Table 12.13** below.

Table 12.13: Maximum Deposition Rates at Statutory Designated Ecological Receptors from Marine Vessel Emissions

Site Designation	Nitrogen Deposition Rate – Commissioning (kg N/ha/y)	Acid Deposition Rate – Commissioning (keq/ha/y)
Statutory (Severn Estuary SPA/SAC/Ramsar and Bridgwater Bay SSSI)	0.15	0.07

12.6.87 Assessment of potential impacts, taking into account the relevant critical loads and existing background deposition rates, is provided in **Volume 2, Chapter 20**.

c) Operational Impacts (Non-Vehicular)

i. H1 Screening Assessment

12.6.88 The direct impacts on human and ecological receptor locations of point source emissions to air released from the proposed UK EPR reactor units during the operational (including commissioning) phase were initially screened following the methodology of the Environment Agency's H1 Environmental Risk Assessment guidance (Ref. 12.30).

12.6.89 The results of the H1 assessments are presented in **Appendix 12D**. The short-term and long-term Process Contributions to Air (PC_{air}) calculated for both the commissioning scenario and the routine test scenario are provided in this **Appendix 12D**.

12.6.90 The outcome of the H1 assessment is summarised below.

Human Receptors

12.6.91 When assessing the results from the H1 assessment, the following criteria, as defined in the H1 guidance note (Ref 12.30), have been applied:

- For long-term PCs less than 1% of the AQS/AQO/EAL, and short-term PCs less than 10% of the AQS/AQO/EAL, the PC is defined as **insignificant**.

- For those PCs that do not meet the above significance criteria, but where long-term PECs are less than 70% of the AQS/AQO/EAL, and where short-term PECs are less than 20% of the model headroom (i.e., the AQS/AQO/EAL concentration minus twice the annual mean background concentration), the PECs is defined as **not significant**.
- For those PCs or PECs that do not meet either of the above criteria, the predicted result is potentially significant and requires further assessment using detailed dispersion modelling of emissions.

12.6.92 Following the H1 methodology, the PC_{air} values calculated for the commissioning scenario were compared with the relevant human health AQS/AQOs//EALs in order to determine their potential significance and screen out insignificant emissions. This showed that, with the exception of long-term H_2CO emissions (which are defined as **insignificant**), emissions of all pollutants could not be screened out as being insignificant. Further consideration of the other air emissions associated with the commissioning scenario was required in order to determine if detailed air modelling was necessary. From those emissions identified above that could not be screened as insignificant, detailed air modelling was required for all remaining pollutants.

12.6.93 For the routine test scenario, only long-term H_2CO emissions could be screened out as being **insignificant**. Further consideration of the other emissions associated with the routine test scenario was therefore required with regards to human receptors, in order to determine if detailed air modelling was necessary. From those emissions identified that could not be screened out as being insignificant (all emissions except long-term H_2CO), detailed air modelling was then found to be required for all remaining pollutants with the exception of long-term NH_3, PM_{10} and $PM_{2.5}$ emissions. Long-term emissions of H_2CO associated with the routine test scenario are therefore considered to be **insignificant**, whilst long-term NH_3, PM_{10} and $PM_{2.5}$ emissions associated with the routine test scenario are considered to be **not significant**.

Ecological Receptors

12.6.94 Comparison of the relevant ecological EALs with the calculated PC_{air} values showed that long-term emissions of SO_2 and NO_x from the commissioning of the UK EPR Units and ancillary buildings could not be screened out as being insignificant. These emissions therefore required further consideration in order to determine if detailed modelling was necessary. For these emissions, detailed air modelling was required for all pollutants.

12.6.95 Considering the routine test operation scenario, comparison of the relevant ecological EALs with the calculated PC_{air} values showed that no emissions could be defined as insignificant. These emissions therefore required further consideration in order to determine if detailed air modelling was necessary. From those emissions identified above that could not be defined as insignificant, detailed air modelling was required for all pollutants.

H1 Assessment Summary

12.6.96 The H1 assessments undertaken did not screen out the majority of operational emissions from requiring detailed dispersion modelling. As a result, the detailed operational dispersion modelling considered all potential emissions that may occur during the commissioning and routine test scenarios.

ii. Detailed Dispersion Modelling

12.6.97 This section sets out the results of the dispersion modelling exercise and compares predicted ground level concentrations to ambient air quality standards. The predicted concentrations resulting from the modelling process are presented with background concentrations and the percentage contribution that the predicted environmental concentrations would make towards the relevant AQS/AQO/EAL.

12.6.98 Results and associated impacts are presented for the meteorological year resulting in the highest ground level concentrations, as a worst-case assumption. The worst-case was determined separately for long-term and short-term concentrations, based on NO_x process contributions at the human receptor experiencing the maximum process contribution during the commissioning scenario (**Table 12.14**).

Table 12.14: Identification of Worst-Case Meteorological Year for Pollutant Dispersion

Year	Predicted Ground Level Concentration due to Process Emissions (µg/m³) [a]	
	NO_x Annual Mean	NO_x 1-hour Mean
2005	2.41	77.83
2006	2.24	71.19
2007	2.38	74.15
2008	2.25	**79.00**
2009	**2.50**	78.74

[a] Determination based on maximum predicted NO_x process contribution at any human receptor during commissioning and without consideration of annual operational hours.

12.6.99 From **Table 12.14** it can be seen that 2009 meteorological data results in the highest predicted concentrations for long-term means, whilst the 2008 meteorological data results in the highest predicted concentrations for short-term means. Therefore, as a worst-case assumption, results using 2009 and 2008 data for long-term and short-term means, respectively, are presented below.

12.6.100 Results from all dispersion modelling undertaken, along with detailed discussion of the outputs, are presented in the Air Quality Modelling Report (Ref. 12.2).

12.6.101 It is important to note that the model-predicted number of exceedences of the short-term air quality objective limit values represents an extreme worst-case, as concentrations have been calculated by the model for each line of 1-hour meteorological data over a full year (i.e. 8,760 hours), assuming emissions are being discharged continuously throughout the year. Although the precise operating schedule for the UK EPR Units and ancillary buildings is not yet known and it is acknowledged that routine testing of the backup diesel generators could occur at any time during the year, it is known that testing will take place for approximately 60 hours per year per generator, with testing limited to one generator at any time. Therefore, the number of exceedences predicted by the model does not represent a likely scenario. It is extremely unlikely that backup diesel generators will be tested at exactly those times during which meteorological conditions are unfavourable and lead to pollutant concentrations above the short-term air quality objective limits at sensitive receptors. Thus, even if the potential impact is predicted to be significant, mitigation is unlikely to be required due to the very small likelihood of occurrence.

Human Receptors

12.6.102 This section presents the pollutant concentration results and associated impacts predicted at the 31 human receptor locations as illustrated in **Figure 12.6**.

12.6.103 In addition to these 31 human receptor locations that represent residential locations in proximity to the HPC development site boundary, potential impacts at four additional transient human receptor locations have been assessed. These represent locations of recreation and amenity activity (i.e. Public Rights of Way and sites of archaeological interest) where people would be present relatively infrequently and for only short periods of time. Exposure at these locations is therefore only considered over short-term averaging periods. These transient human receptor locations are also illustrated in **Figure 12.6**.

iii. Commissioning Impacts on Human Receptors

12.6.104 **Table 12.15** summarises the pollutant concentration results and associated impacts predicted at the 31 human receptor locations and the four transient human receptor locations for the HPC commissioning scenario. A summary of the maximum predicted PC and PEC concentrations for this scenario is presented. A full set of results for all human receptor locations is presented in **Appendix 12D**.

12.6.105 The PCs of long-term PM_{10}, $PM_{2.5}$ and H_2CO, and short-term PM_{10}, H_2CO and CO emissions from HPC commissioning (as detailed in **Appendix 12D, Tables 12, 13, 14 and 16**) are of imperceptible magnitude. Maximum PC values are observed at 'Trighern Farm' for long-term PM_{10} and $PM_{2.5}$, and short-term PM_{10}, and at 'Doggetts' for long-term H_2CO and short-term H_2CO and CO. The PEC values of long-term PM_{10}, $PM_{2.5}$ and H_2CO and short-term PM_{10}, H_2CO and CO are all well below the AQS/AQO/EAL and so are predicted to be **negligible**. Their impact on the human receptor locations is therefore **not significant**.

12.6.106 The PCs of long-term NO_2 and short-term SO_2 emissions from HPC commissioning (as detailed in **Appendix 12D, Tables 11 and 15**) are of no greater than small magnitude. Maximum PC values are observed at 'Trighern Farm' for long-term NO_2, and at 'Doggetts' for short-term SO_2. The PEC values of long-term NO_2 and short-term SO_2 are all well below the AQS/AQO/EAL and so are predicted to be **negligible**. Their impact on the human receptor locations is therefore **not significant**.

12.6.107 The PCs of short-term NO_2 emissions from HPC commissioning (as detailed in **Appendix 12D, Table 11**) are of no greater than medium magnitude. Maximum PC values are observed at 'Doggetts' for short-term NO_2. The PEC values of short-term NO_2 are all well below the AQS/AQO/EAL and so are predicted to be **negligible**. Their impact on the human receptor locations is therefore **not significant**.

Table 12.15: Maximum Predicted Pollutant Concentrations and Impacts at Human Receptor Locations from HPC Commissioning (Commissioning Scenario)

Pollutant and Averaging Period	AQO/EAL Limit Value ($\mu g/m^3$)	Maximum Concentration Increase due to Development (PC) ($\mu g/m^3$) and as Percentage of AQO/EAL (%)	Maximum Concentration with Development (PEC) ($\mu g/m^3$) and as Percentage of AQO/EAL (%)	Magnitude of Change	Impact Descriptor
Human Receptors					
NO_2 annual mean	40	0.59 (1.5%)	7.39 (18.5%)	Small	Negligible
NO_2 1-hour mean	200	18.37 (9.2%)	31.97 (16.0%)	Medium	Negligible
PM_{10} annual mean	40	0.02 (0.1%)	18.22 (45.6%)	Imperceptible	Negligible
PM_{10} 24-hour mean	50	0.18 (0.4%)	36.58 (73.2%)	Imperceptible	Negligible
$PM_{2.5}$ annual mean	25	0.02 (0.1%)	7.92 (31.7%)	Imperceptible	Negligible
CO 1-hour mean	30,000	6.33 (<0.1%)	163.33 (0.5%)	Imperceptible	Negligible
CO rolling 8-hour mean	10,000	4.99 (<0.1%)	161.99 (1.6%)	Imperceptible	Negligible
SO_2 15-minute mean	266	6.73 (2.5%)	10.33 (3.9%)	Small	Negligible
SO_2 1-hour mean	350	4.92 (1.4%)	8.52 (2.4%)	Small	Negligible
SO_2 24-hour mean	125	2.51 (2.0%)	6.11 (4.9%)	Small	Negligible
H_2CO annual mean	5	<0.01 (<0.01%)	<0.01 (<0.01%)	Imperceptible	Negligible
H_2CO 1-hour mean	100	0.71 (0.7%)	0.71 (0.7%)	Imperceptible	Negligible
Transient Human Receptors					
NO_2 1-hour mean	200	102.71 (51.4%)	116.31 (58.2%)	Large	Slight Adverse
CO 1-hour mean	30,000	25.89 (<0.1%)	182.89 (0.6%)	Imperceptible	Negligible
SO_2 15-minute mean	266	32.23 (12.1%)	35.83 (13.5%)	Large	Slight Adverse
SO_2 1-hour mean	350	27.82 (7.9%)	31.42 (9.0%)	Medium	Negligible
H_2CO 1-hour mean	100	1.04 (1.0%)	1.04 (1.0%)	Small	Negligible

Transient Human Receptors

12.6.108 The PCs of short-term CO (1-hour mean) emissions from HPC commissioning (as detailed in **Appendix 12D, Table 14**) are of imperceptible magnitude. Maximum PC values are observed at 'Footpath - Coastal' for short-term CO (1-hour mean). The PEC values of short-term CO (1-hour mean) are all well below the EAL and so are predicted to be **negligible**. Their impact on the transient human receptor locations is therefore **not significant**.

12.6.109 The PCs of short-term H_2CO emissions from HPC commissioning (as detailed in **Appendix 12D, Table 16**) are of no greater than small magnitude. Maximum PC values are observed at 'Footpath - Coastal' for short-term H_2CO. The PEC values of short-term CO are all well below the EAL and so are predicted to be **negligible**. Their impact on the transient human receptor locations is therefore **not significant**.

12.6.110 The PCs of short-term SO_2 (1-hour mean) emissions from HPC commissioning (as detailed in **Appendix 12D, Table 15**) are of no greater than medium magnitude. Maximum PC values are observed at 'Footpath - Coastal' for short-term SO_2 (1-hour mean). The PEC values of short-term SO_2 (1-hour mean) are all well below the AQS/AQO and so are predicted to be **negligible**. Their impact on the transient human receptor locations is therefore **not significant**.

12.6.111 The PCs of short-term NO_2 and SO_2 (15-minute mean) emissions from HPC commissioning (as detailed in **Appendix 12D, Tables 11 and 15**) are of up to large magnitude. Maximum PC values are observed at 'Footpath - Coastal' for short-term NO_2 and SO_2 (15-minute mean). The PEC values of short-term NO_2 and SO_2 (15-minute mean) are all well below the AQS/AQO/EAL and so are predicted to be **slight adverse**. Their impact on the transient human receptor locations is therefore **not significant**.

Summary

12.6.112 For all assessed pollutants, the potential impact of emissions from HPC commissioning on the identified human receptors is local, adverse, direct, likely and short-term but temporary. The impact on the human receptor (including transient human receptor) locations for all assessed pollutants is determined to be **not significant**.

iv. Routine Test Scenario Impacts on Human Receptors

12.6.113 **Table 12.16** summarises the pollutant concentration results and associated impacts predicted at the 31 human receptor locations and the 4 transient human receptor locations for the routine test scenario. A summary of the maximum predicted PC and PEC concentrations for this scenario is presented. A full set of results for all human receptor locations is presented in **Appendix 12D**.

Table 12.16: Maximum Predicted Pollutant Concentrations and Impacts at Human Receptor Locations from HPC Routine Operation (Routine Test Scenario)

Pollutant and Averaging Period	AQS/AQO/EAL ($\mu g/m^3$)	Maximum Concentration Increase due to Development (PC) ($\mu g/m^3$) and as Percentage of AQS/AQO/EAL (%)	Maximum Concentration with Development (PEC) ($\mu g/m^3$) and as Percentage of AQS/AQO/EAL (%)	Magnitude of Change	Impact Descriptor
Human Receptors					
NO_2 annual mean	40	0.14 (0.4%)	6.94 (17.4%)	Imperceptible	Negligible
NO_2 1-hour mean	200	18.37 (9.2%)	31.97 (16.0%)	Medium	Negligible
PM_{10} annual mean	40	0.01 (<0.1%)	18.21 (45.5%)	Imperceptible	Negligible
PM_{10} 24-hour mean	50	0.18 (0.4%)	36.58 (73.2%)	Imperceptible	Negligible
$PM_{2.5}$ annual mean	25	0.01 (<0.1%)	7.91 (31.6%)	Imperceptible	Negligible
CO 1-hour mean	30,000	6.33 (<0.1%)	163.33 (0.5%)	Imperceptible	Negligible
CO rolling 8-hour mean	10,000	4.95 (<0.1%)	161.95 (1.6%)	Imperceptible	Negligible
SO_2 15-minute mean	266	6.73 (2.5%)	10.33 (3.9%)	Small	Negligible
SO_2 1-hour mean	350	4.92 (1.4%)	8.52 (2.4%)	Small	Negligible
SO_2 24-hour mean	125	2.51 (2.0%)	6.11 (4.9%)	Small	Negligible
H_2CO annual mean	5	<0.01 (<0.1%)	<0.01 (<0.1%)	Imperceptible	Negligible
H_2CO 1-hour mean	100	0.51 (0.5%)	0.51 (0.5%)	Imperceptible	Negligible
NH_3 annual mean	180	0.05 (<0.1%)	1.15 (0.6%)	Imperceptible	Negligible
NH_3 1-hour mean	2,500	167.97 (6.7%)	170.17 (6.8%)	Medium	Negligible

Pollutant and Averaging Period	AQS/AQO/EAL (μg/m^3)	Maximum Concentration Increase due to Development (PC) (μg/m^3) and as Percentage of AQS/AQO/EAL (%)	Maximum Concentration with Development (PEC) (μg/m^3) and as Percentage of AQS/AQO/EAL (%)	Magnitude of Change	Impact Descriptor
Transient Human Receptors					
NO_2 1-hour mean	200	102.71 (51.4%)	116.31 (58.2%)	Large	Slight adverse
CO 1-hour mean	30,000	25.89 (<0.1%)	182.89 (0.6%)	Imperceptible	Negligible
SO_2 15-minute mean	266	32.23 (12.1%)	35.83 (13.5%)	Large	Slight adverse
SO_2 1-hour mean	350	27.82 (7.9%)	31.42 (9.0%)	Medium	Negligible
H_2CO 1-hour mean	100	0.74 (0.7%)	0.74 (0.7%)	Imperceptible	Negligible
NH_3 1-hour mean	2,500	498.60 (19.9%)	500.80 (20.0%)	Large	Slight adverse

12.6.114 The PCs of long-term NO_2, PM_{10}, $PM_{2.5}$, H_2CO and NH_3, and short-term PM_{10}, H_2CO and CO emissions from HPC routine operation (as detailed in **Appendix 12D**, **Tables 17**, **18**, **19**, **20**, **22** and **23**) are of imperceptible magnitude. Maximum PC values are observed at 'Trighern Farm' for long-term NO_2, PM_{10} $PM_{2.5}$ and NH_3, and short-term PM_{10}, and at 'Doggetts' for long-term H_2CO and short-term H_2CO and CO. The PEC values of long-term NO_2, PM_{10}, $PM_{2.5}$ H_2CO and NH_3, and short-term PM_{10}, H_2CO and CO are all well below the AQS/AQO/EAL and so are predicted to be **negligible**. Their impact on the human receptor locations is therefore **not significant**.

12.6.115 The PCs of short-term SO_2 emissions from HPC routine operation (as detailed in **Appendix 12D**, **Table 21**) are of no greater than small magnitude. Maximum PC values are observed at 'Doggetts' for short-term SO_2. The PEC values of short-term SO_2 are well below the AQS/AQO/EAL and so are predicted to be **negligible**. Their impact on the human receptor locations is therefore **not significant**.

12.6.116 The PCs of short-term NO_2 and NH_3 emissions from HPC routine operation (as detailed in **Appendix 12D**, **Tables 17** and **23**) are of no greater than medium magnitude. Maximum PC values are observed at 'Doggetts' for short-term NO_2 and NH_3. The PEC values of short-term NO_2 and NH_3 are well below the AQS/AQO/EAL and so are predicted to be **negligible**. Their impact on the human receptor locations is therefore **not significant**.

Transient Human Receptors

12.6.117 The PCs of short-term CO (1-hour mean) and H_2CO emissions from HPC routine operation (as detailed in **Appendix 12D**, **Tables 20** and **22**) are of imperceptible magnitude. Maximum PC values are observed at 'Footpath - Coastal' for short-term CO (1-hour mean) and H_2CO. The PEC values of CO (1-hour mean) and H_2CO are all well below the EAL and so are predicted to be **negligible**. Their impact on the transient human receptor locations is therefore **not significant**.

12.6.118 The PCs of short-term SO_2 (1-hour mean) emissions from HPC routine operation (as detailed in **Appendix 12D**, **Table 21**) are of no greater than medium magnitude. Maximum PC values are observed at 'Footpath - Coastal' for short-term SO_2 (1-hour mean). The PEC values of short-term SO_2 (1-hour mean) are all well below the AQS/AQO value and so are predicted to be **negligible**. Their impact on the transient human receptor locations is therefore **not significant**.

12.6.119 The PCs of short-term NO_2, NH_3 and SO_2 (15-minute mean) emissions from HPC routine operation (as detailed in **Appendix 12D**, **Table 17**, **21** and **23**) are of up to large magnitude. Maximum PC values are observed at 'Footpath - Coastal' for short-term NO_2, NH_3 and SO_2 (15-minute mean). The PEC values of short-term NO_2, NH_3 and SO_2 (15-minute mean) are all well below the AQS/AQO/EAL and so are predicted to be **slight adverse**. Their impact on the transient human receptor locations is therefore **not significant**.

Summary

12.6.120 For all assessed pollutants, the potential impact of emissions from HPC routine operation (Routine Test Scenario) on the identified human receptors is local, adverse, direct, likely and long-term. The impact on the human receptor (including transient human receptor) locations for all assessed pollutants is determined to be **not significant**.

Ecological Receptors

12.6.121 This section presents the pollutant concentration results and associated impacts predicted at the following ecological receptor locations (see **Figure 12.6**):

- Bridgwater Bay SSSI/NNR.
- Severn Estuary SPA/SAC/Ramsar.
- Hinkley CWS.

v. Commissioning Impacts on Ecological Receptors

12.6.122 **Table 12.17** summarises the pollutant concentration results and associated impacts predicted at the statutory and non-statutory designated ecological receptor locations for the commissioning scenario. A summary of the maximum predicted PC and PEC concentrations for this scenario is presented. A full set of results for all ecological receptor locations is presented in **Appendix 12D**.

Statutory Designated Ecological Receptors

12.6.123 The PCs of long-term SO_2 emissions from HPC commissioning (as detailed in **Appendix 12D**, **Table 25**) are of no greater than small magnitude. Maximum PC values are observed at 'Bridgwater Bay SSSI/Severn Estuary SPA/SAC/Ramsar' for long-term SO_2. The PEC values for long-term SO_2 are well below the AQS/EAL and so are predicted to be **negligible**.

12.6.124 The PCs of long-term NO_x emissions from HPC commissioning (as detailed in **Appendix 12D**, **Table 24**) are of up to large magnitude. Maximum PC values are observed at 'Bridgwater Bay SSSI/Severn Estuary SPA/SAC/Ramsar' for long-term NO_x. The PEC values for long-term NO_x are well below the AQS/EAL and so are predicted to be **slight adverse**.

12.6.125 The PCs of short-term NO_x emissions from HPC commissioning (as detailed in **Appendix 12D**, **Table 24**) are also of up to large magnitude. Maximum PC values are observed at 'Bridgwater Bay SSSI/Severn Estuary SPA/SAC/Ramsar' for short-term NO_x. The PEC values for short-term NO_x are above the EAL and so are predicted to be **moderate adverse**. However, the 24-hour mean values are derived based on continuous operation of an EDG over an entire 24-hour period, which is very unlikely to represent the actual operational profile. Furthermore, the 75µg/m^3 daily mean EAL is derived from the 2000 WHO Air Quality Guidelines for Europe (Ref. 12.55). The WHO state in this document that, with reference to the daily mean NO_x guideline level:

> *"There is insufficient data to provide these levels with confidence at present."*

12.6.126 Consequently, it is considered that greater emphasis should be placed on achievement of the more established annual mean NO_x AQS/EAL, which in this case is not exceeded.

Table 12.17: Maximum Predicted Pollutant Concentrations and Impacts at Ecological Receptor Locations from HPC Commissioning (Commissioning Scenario)

Pollutant and Averaging Period	AQS/EAL (µg/m^3)	Maximum Concentration Increase due to Development (PC) (µg/m^3) and as Percentage of AQS/AQO/EAL (%)	Maximum Concentration with Development (PEC) (µg/m^3) and as Percentage of AQS/AQO/EAL (%)	Magnitude of Change	Impact Descriptor
Statutory Designated Ecological Receptors					
NO_x annual mean	30	7.30 (24.3%)	18.80 (62.7%)	Large	Slight Adverse
NO_x 24-hour mean	75	189 (252%)	212 (282.7%)	Large	Substantial Adverse
SO_2 annual mean	20	0.70 (3.5%)	2.50 (12.5%)	Small	Negligible
Non-statutory Designated Ecological Receptors					
NO_x annual mean	30	16.57 (55.2%)	28.07 (93.6%)	Large	Moderate Adverse
NO_x 24-hour mean	75	251 (334.7%)	274 (365.3%)	Large	Substantial Adverse
SO_2 annual mean	20	1.71 (8.6%)	3.51 (17.6%)	Medium	Negligible

Non-statutory Designated Ecological Receptors

12.6.127 The PCs of long-term SO_2 emissions from HPC commissioning (as detailed in **Appendix 12D**, **Table 25**) are of no greater than medium magnitude. Maximum PC values are observed at 'Hinkley CWS' for long-term SO_2. The PEC values for long-term SO_2 are well below the AQS/EAL and so are predicted to be **negligible**.

12.6.128 The PCs of long-term NO_x emissions from HPC commissioning (as detailed in **Appendix 12D**, **Table 24**) are of up to large magnitude. Maximum PC values are observed at 'Hinkley CWS' for long-term NO_x. The PEC values for long-term NO_x are just below the AQS/EAL and so are predicted to be **moderate adverse**.

12.6.129 The PCs of short-term NO_x emissions from HPC commissioning (as detailed in **Appendix 12D**, **Table 24**) are of up to large magnitude. Maximum PC values are observed at 'Hinkley CWS' for short-term NO_x. The PEC values for short-term NO_x are above the EAL and so are predicted to be **substantial adverse**. However, as for statutory designated ecological receptors, it is considered that greater emphasis should be placed on achievement with the more established annual mean NO_x AQS/EAL, which in this case is not exceeded.

Summary

12.6.130 For all assessed pollutants, the potential impact of emissions from HPC commissioning (Commissioning Scenario) on the statutory and non-statutory designated ecological receptors for the commissioning scenario is local, adverse, direct, likely and short-term but temporary.

12.6.131 The significance of these predictions of NO_x and SO_2 emissions from HPC commissioning upon biodiversity receptors is assessed in **Volume 2**, **Chapter 20**.

vi. Routine Test Scenario Impacts on Ecological Receptors

12.6.132 **Table 12.18** summarises the pollutant concentration results and associated impacts predicted at the statutory and non-statutory designated ecological receptor locations for the routine test scenario. A summary of the maximum predicted PC and PEC concentrations for this scenario is presented. A full set of results for all ecological receptor locations is presented in **Appendix 12D**.

Statutory Designated Ecological Receptors

12.6.133 The PCs of long-term SO_2 emissions from HPC routine operation (as detailed in **Appendix 12D**, **Table 27**) are of imperceptible magnitude. Maximum PC values are observed at 'Bridgwater Bay SSSI/Severn Estuary SPA/SAC/Ramsar' for long-term SO_2. The PEC values for long-term SO_2 are well below the AQS/EAL and so are predicted to be **negligible**.

12.6.134 The PCs of long-term NO_x emissions from HPC routine operation (as detailed in **Appendix 12D**, **Table 26**) are of up to medium magnitude. Maximum PC values are observed at 'Bridgwater Bay SSSI/Severn Estuary SPA/SAC/Ramsar' for long-term NO_x. The PEC values for long-term NO_x are well below the AQS/EAL and so are predicted to be **negligible**.

Table 12.18: Maximum Predicted Pollutant Concentrations and Impacts at Ecological Receptor Locations from HPC Routine Operation (Routine Test Scenario)

Pollutant and Averaging Period	AQS/EAL Limit Value ($\mu g/m^3$)	Maximum Concentration Increase due to Development (PC) ($\mu g/m^3$) and as Percentage of AQO/EAL (%)	Maximum Concentration with Development (PEC) ($\mu g/m^3$) and as Percentage of AQO/EAL (%)	Magnitude of Change	Impact Descriptor
Statutory Designated Ecological Receptors					
NO_x annual mean	30	1.79 (6.0%)	13.29 (44.3%)	Medium	Negligible
NO_x 24-hour mean	75	189 (252%)	212 (282.7%)	Large	Substantial Adverse
SO_2 annual mean	20	0.17 (0.9%)	1.97 (9.9%)	Imperceptible	Negligible
NH_3 annual mean	3	0.73 (24.3%)	1.83 (61.0%)	Large	Slight Adverse
Non-statutory Designated Ecological Receptors					
NO_x annual mean	30	4.06 (13.5%)	15.56 (51.9%)	Large	Slight Adverse
NO_x 24-hour mean	75	251 (334.7%)	274 (365.3%)	Large	Substantial Adverse
SO_2 annual mean	20	0.42 (2.1%)	2.22 (11.1%)	Small	Negligible
NH_3 annual mean	3	0.55 (18.3%)	1.65 (55.0%)	Large	Slight Adverse

12.6.135 The PCs of long-term NH_3 emissions from HPC routine operation (as detailed in **Appendix 12D**, **Table 28**) are of up to large magnitude. Maximum PC values are observed at 'Bridgwater Bay SSSI/Severn Estuary SPA/SAC/Ramsar' for long-term NH_3. The PEC values for long-term NH_3 are well below the EAL and so are predicted to be **slight adverse**.

12.6.136 The PCs of short-term NO_x emissions from HPC routine operation (as detailed in **Appendix 12D**, **Table 26**) are of up to large magnitude. Maximum PC values are observed at 'Bridgwater Bay SSSI/Severn Estuary SPA/SAC/Ramsar' for short-term NO_x. The PEC values for short-term NO_x are above the EAL and so are predicted to be **substantial adverse**. However, as for the commissioning scenario, it is considered that greater emphasis should be placed on achievement of the more established annual mean NO_x AQS/EAL, which in this case is not exceeded.

Non-statutory Designated Ecological Receptors

12.6.137 The PCs of long-term SO_2 emissions from HPC routine operation (as detailed in **Appendix 12D**, **Table 27**) are of no greater than small magnitude. Maximum PC values are observed at 'Hinkley CWS' for long-term SO_2. The PEC values for long-term SO_2 are well below the AQS/EAL and so are predicted to be **negligible**.

12.6.138 The PCs of long-term NO_x and NH_3 emissions from HPC routine operation (as detailed in **Appendix 12D**, **Tables 26** and **28**) are of up to large magnitude. Maximum PC values are observed at 'Hinkley CWS' for long-term NO_x and NH_3. The PEC values for long-term NO_x and NH_3 are well below the AQS/EAL and so are predicted to be **slight adverse**.

12.6.139 The PCs of short-term NO_x emissions from HPC routine operation (as detailed in **Appendix 12D**, **Table 26**) are of up to large magnitude. Maximum PC values are observed at 'Hinkley CWS' for short-term NO_x. The PEC values for short-term NO_x are above the EAL and so are predicted to be **substantial adverse.** However, as for the commissioning scenario, it is considered that greater emphasis should be placed on achievement of the more established NO_x annual mean AQS/EAL, which in this case is not exceeded.

Summary

12.6.140 For all assessed pollutants, the potential impact of emissions from HPC routine operation (Routine Test Scenario) on the statutory and non-statutory designated ecological receptors for the routine test scenario is local, adverse, direct, likely and long-term but temporary.

12.6.141 The significance of these predictions of NO_x, SO_2 and NH_3 emissions from HPC routine operation upon biodiversity receptors is assessed in **Volume 2**, **Chapter 20**.

vii. Deposition of Nutrifying and Acidifying Pollutants

12.6.142 The maximum additional deposition rates of nutrifying and acidifying pollutants at the statutory and non-statutory designated sites, due to the commissioning (Commissioning Scenario) and routine operation (Routine Test Scenario) of HPC, are summarised in **Table 12.19** below.

Table 12.19: Maximum Deposition Rates at Statutory and Non-statutory Designated Ecological Receptors from the Commissioning and Operation of HPC

Site Designation	Nitrogen Deposition Rate – Commissioning (kg N/ha/y)	Nitrogen Deposition Rate – Routine Test (kg N/ha/y)	Acid Deposition Rate – Commissioning (keq/ha/y)	Acid Deposition Rate – Routine Test (keq/ha/y)
Statutory (Severn Estuary SPA/SAC/ Ramsar and Bridgwater Bay SSSI)	1.05	3.99	0.16	0.30
Non-statutory (Hinkley CWS)	2.13	3.14	0.36	0.29

12.6.143 Assessment of potential impacts, taking into account the relevant critical loads and existing background deposition rates, is provided in **Volume 2**, **Chapter 20**.

d) Vehicular Exhaust Emissions Impacts

12.6.144 The impacts on both human and ecological receptors of exhaust emissions to air resulting from vehicle movements associated with the HPC Project (including baseline traffic and traffic associated with committed development) during the 2013 (construction), 2016 (construction with peak workforce on the HPC development site) and 2021 (early operation) scenarios were predicted using the air pollutant dispersion model ADMS Roads. The traffic input data and further information used in the ADMS Roads assessment is presented in **Appendix 12E**. Additional details of the modelling methodology are provided in the Air Quality Modelling Report (Ref. 12.2).

12.6.145 Estimates of vehicle pollutant concentrations (NO_x/NO_2, PM_{10} and $PM_{2.5}$) were predicted and assessed for the 2013, 2016 and 2021 scenarios identified in section 12.4, for ‘with development’ (i.e. with all road traffic associated with the HPC Project) and ‘without development’ (i.e. future baseline without HPC) scenarios. Pollutant concentrations were also predicted for the 2009 model verification/baseline scenario. Comparison of these modelled scenarios allowed the specific impacts of exhaust emissions to air generated by vehicle movements associated with the combined HPC Project to be assessed, and also evaluated against the existing and future baseline air quality in the study area.

12.6.146 For the HPC accommodation campus, pollutant concentrations at four receptors (‘HPC Accommodation 1’, ‘HPC Accommodation 2’, ‘HPC Accommodation 3’ and ‘HPC Accommodation 4’) have been predicted for the 2016 scenario (i.e. during the operation of the HPC accommodation campus). These locations are considered to be representative of worst-case air pollutant concentrations likely to be experienced by the on-site residential workforce.

12.6.147 A full set of results from all vehicular emissions dispersion modelling undertaken, along with detailed discussion of the outputs, is presented in the Air Quality Modelling Report (Ref. 12.2).

i. Human Receptors

12.6.148 This section presents the pollutant concentrations results and associated impacts predicted at the 104 human receptor locations as illustrated in **Figures 12.3**, **12.4** and **12.5**.

12.6.149 A summary of the main results relating to these human receptors located adjacent to the affected roads are provided below in **Table 12.20**, whilst pollutant concentrations predicted at all the assessed human receptor locations are presented in **Appendix 12E**.

2013 Scenario – Construction of HPC and the Associated Development Sites

12.6.150 **Table 12.21** summarises the pollutant concentration results and associated impacts predicted at the 104 human receptor locations for the 2013 'with development' scenario. The table provides a summary of the maximum vehicular pollutant contributions from road traffic movements associated with the HPC Project and the maximum ambient pollutant concentrations (i.e. the sum of the vehicular contribution and the background concentration) for the 2013 'with development' scenario. A full set of results for all human receptor locations is presented in **Appendix 12E**.

12.6.151 The annual mean PM_{10} and $PM_{2.5}$ vehicular contributions in both the Bridgwater and Williton models (as detailed in **Appendix 12E**, **Tables 32**, **35**, **56** and **59**) are of imperceptible magnitude. Maximum vehicular contributions are observed at '131 The Drove' in the Bridgwater model and 'Williton County Stores' in the Williton Model for annual mean PM_{10} and $PM_{2.5}$. The 'with development' ambient concentration values for annual mean PM_{10} and $PM_{2.5}$ in both the Bridgwater and Williton models are all well below the objective/limit value and so are predicted to be **negligible**. Their impact on the human receptor locations is therefore **not significant**.

12.6.152 The annual mean NO_2 vehicular contributions in the Williton model, and PM_{10} and $PM_{2.5}$ vehicular contributions in the Cannington model (as detailed in **Appendix 12E, Tables 44**, **47** and **50**) are of no greater than small magnitude. Maximum vehicular contributions are observed at 'Williton County Stores' for annual mean NO_2 in the Williton model and at 'The Lodge, Withycombe' for annual mean PM_{10} and $PM_{2.5}$ in the Cannington Model. The 'with development' ambient concentration values for annual mean NO_2 in the Williton model, and annual mean PM_{10} and $PM_{2.5}$ in the Cannington model, are all below the objective/limit value. Annual mean NO_2 in the Williton model, and PM_{10} and $PM_{2.5}$ in the Cannington model, are therefore predicted to be **negligible**. Their impact on the human receptor locations is therefore **not significant**.

12.6.153 The annual mean NO_2 vehicular contributions in the Bridgwater model (as detailed in **Appendix 12E**, **Table 26**) are of no greater than medium magnitude. Maximum vehicular contributions are observed at '131 The Drove' for annual mean NO_2 in the Bridgwater model. The 'with development' ambient concentration values for annual mean NO_2 in the Bridgwater model are all well below the objective/limit value and so are predicted to be **negligible**. Their impact on the human receptor locations is therefore **not significant**.

Table 12.20: Maximum Predicted Annual Mean Pollutant Concentrations at Human Receptor Locations for all Modelled ADMS Roads Scenarios.

	2009 'Model Verification/ Baseline'	2013 'Without Development'	2013 'With Development'	2016 'Without Development'	2016 'With Development'	2021 'Without Development'	2021 'With Development'
Bridgwater Model							
Maximum annual mean NO_2 concentration (µg/m^3)	32.05	29.05	29.73	23.48	25.01	19.82	20.64
Maximum annual mean PM_{10} concentration (µg/m^3)	19.89	19.27	19.28	18.30	18.56	18.12	18.38
Maximum annual mean $PM_{2.5}$ concentration (µg/m^3)	12.39	11.72	11.73	10.96	11.12	10.68	10.83
Cannington Model							
Maximum annual mean NO_2 concentration (µg/m^3)	22.22	18.27	23.78	15.27	19.54	11.35	12.50
Maximum annual mean PM_{10} concentration (µg/m^3)	20.78	19.50	19.95	18.84	19.35	18.19	18.39
Maximum annual mean $PM_{2.5}$ concentration (µg/m^3)	9.88	8.90	9.22	8.37	8.72	7.87	7.99
Williton Model							
Maximum annual mean NO_2 concentration (µg/m^3)	39.46	34.27	35.37	27.67	28.46	18.84	19.49
Maximum annual mean PM_{10} concentration (µg/m^3)	23.56	21.98	22.30	20.98	21.18	19.94	20.11
Maximum annual mean $PM_{2.5}$ concentration (µg/m^3)	12.01	10.67	10.90	9.81	9.95	8.94	9.05

Table 12.21: Maximum Predicted Pollutant Concentrations and Impacts At Human Receptor Locations During the 2013 'With Development' Scenario

Pollutant and Averaging Period	AQO Limit Value ($\mu g/m^3$)	Maximum Vehicular Contribution due to Development ($\mu g/m^3$) and as Percentage of AQO (%)	Maximum Ambient Concentration 'with development' ($\mu g/m^3$) and as Percentage of AQO (%)	Magnitude of Change	Impact Descriptor
Bridgwater Model					
NO_2 annual mean	40	3.15 (7.9%)	29.73 (74.3%)	Medium	Negligible
PM_{10} annual mean	40	0.22 (0.6%)	19.28 (48.2%)	Imperceptible	Negligible
$PM_{2.5}$ annual mean	25	0.17 (0.7%)	11.73 (46.9%)	Imperceptible	Negligible
Cannington Model					
NO_2 annual mean	40	7.85 (19.6%)	23.78 (59.5%)	Large	Slight Adverse
PM_{10} annual mean	40	0.57 (1.4%)	19.95 (49.9%)	Small	Negligible
$PM_{2.5}$ annual mean	25	0.41 (1.7%)	9.22 (36.9%)	Small	Negligible
Williton Model					
NO_2 annual mean	40	1.10 (2.8%)	35.37 (88.4%)	Small	Negligible
PM_{10} annual mean	40	0.32 (0.8%)	22.30 (55.8%)	Imperceptible	Negligible
$PM_{2.5}$ annual mean	25	0.23 (0.9%)	10.90 (43.6%)	Imperceptible	Negligible

12.6.154 The annual mean NO_2 vehicular contributions in the Cannington model (as detailed in **Appendix 12E**, **Table 38**) are of up to large magnitude. Maximum vehicular contributions are observed at '41 High Street' for annual mean NO_2 in the Cannington model. The 'with development' concentration values for annual mean NO_2 in the Cannington model are all well below the objective/limit value and so are predicted to be **slight adverse**. Their impact on the human receptor locations is therefore **not significant**.

Summary

12.6.155 For all assessed pollutants, the potential impact of vehicular emissions from road traffic movements associated with the HPC Project on human receptors for the 2013 'with development' scenario is local, adverse, direct, likely and medium-term but temporary. The impact on the human receptor locations for all assessed pollutants is determined to be **not significant**.

2016 Scenario – Construction of HPC with Peak Workforce On-site

12.6.156 **Table 12.22** summarises the pollutant concentration results and associated impacts predicted at the 104 human receptor locations for the 2016 'with development' scenario. The table provides a summary of the maximum vehicular pollutant contributions from road traffic movements associated with the HPC Project and the maximum ambient pollutant concentrations (i.e. the sum of the vehicular contribution and the background concentration) for the 2016 'with development' scenario. A full set of results for all human receptor locations is presented in **Appendix 12E**.

12.6.157 The annual mean PM_{10} and $PM_{2.5}$ vehicular contributions in both the Bridgwater and Williton models (as detailed in **Appendix 12E**, **Tables 33**, **36**, **57** and **60**) are of imperceptible magnitude. Maximum vehicular contributions are observed at '86 Bath Road' in the Bridgwater model and 'Williton County Stores' in the Williton Model for annual mean PM_{10} and $PM_{2.5}$. The 'with development' ambient concentration values for annual mean PM_{10} and $PM_{2.5}$ in both the Bridgwater and Williton models are all well below the AQS/AQO/EAL and so are predicted to be **negligible**. Their impact on the human receptor locations is therefore **not significant**.

12.6.158 The annual mean NO_2 vehicular contributions in the Bridgwater and Williton models, and PM_{10} and $PM_{2.5}$ vehicular contributions in the Cannington model (as detailed in **Appendix 12E**, **Tables 28**, **45**, **48** and **52**) are of no greater than small magnitude. Maximum vehicular contributions are observed for annual mean NO_2 at 'Williton County Stores' and '131 The Drove' in the Williton and Bridgwater models respectively, and at 'Grange Lodge' for annual mean PM_{10} and $PM_{2.5}$ in the Cannington Model. The 'with development' ambient concentration values for annual mean NO_2 in the Williton and Bridgwater models, and annual mean PM_{10} and $PM_{2.5}$ in the Cannington model, are all well below the AQS/AQO/EAL. Annual mean NO_2 in the Williton and Bridgwater models, and PM_{10} and $PM_{2.5}$ in the Cannington model, are therefore predicted to be **negligible**. Their impact on the human receptor locations is therefore **not significant**.

Table 12.22: Maximum Predicted Pollutant Concentrations and Impacts at Human Receptor Locations during the 2016 'With Development' Scenario

Pollutant and Averaging Period	AQS/AQO/EAL ($\mu g/m^3$)	Maximum Vehicular Contribution due to Development ($\mu g/m^3$) and as Percentage of AQS/AQO/EAL (%)	Maximum Ambient Concentration 'with development' ($\mu g/m^3$) and as Percentage of AQS/AQO/EAL (%)	Magnitude of Change	Impact Descriptor
Bridgwater Model					
NO_2 annual mean	40	1.79 (4.5%)	25.01 (62.5%)	Small	Negligible
PM_{10} annual mean	40	0.26 (0.7%)	18.56 (46.4%)	Imperceptible	Negligible
$PM_{2.5}$ annual mean	25	0.16 (0.6%)	11.12 (44.5%)	Imperceptible	Negligible
Cannington Model					
NO_2 annual mean	40	4.27 (10.7%)	19.54 (48.9%)	Large	Slight Adverse
PM_{10} annual mean	40	0.51 (1.3%)	19.35 (48.4%)	Small	Negligible
$PM_{2.5}$ annual mean	25	0.35 (1.4%)	8.72 (34.9%)	Small	Negligible
Williton Model					
NO_2 annual mean	40	0.79 (2.0%)	28.46 (71.2%)	Small	Negligible
PM_{10} annual mean	40	0.20 (0.5%)	21.18 (53.0%)	Imperceptible	Negligible
$PM_{2.5}$ annual mean	25	0.14 (0.5%)	9.95 (39.8%)	Imperceptible	Negligible
HPC Accommodation Campus On-site Receptors					
NO_2 annual mean	40	0.74 (1.9%)	6.76 (16.9%)	Small	Negligible
PM_{10} annual mean	40	0.07 (0.2%)	17.40 (43.5%)	Imperceptible	Negligible
$PM_{2.5}$ annual mean	25	0.04 (0.2%)	7.37 (29.5%)	Imperceptible	Negligible

12.6.159 The annual mean NO_2 vehicular contributions in the Cannington model (as detailed in **Appendix 12E**, **Table 40**) are of up to large magnitude. Maximum vehicular contributions are observed at ‘Grange Lodge’ for annual mean NO_2 in the Cannington model. This large magnitude increase is due to traffic using the proposed Cannington bypass to the west of Cannington village, in an area that is otherwise predominantly of an agricultural nature. The purpose of the proposed Cannington bypass is to minimise adverse effects on the local highway network, particularly through the centre of the village, during the HPC construction phase. There will be a benefit with respect to air quality associated with the operation of the Cannington bypass within the village, as HPC development traffic will be routed away from the centre of Cannington. In addition some of the non-HPC traffic that would have previously used the existing roads through Cannington will in preference travel along the bypass. The ‘with development’ concentration values for annual mean NO_2 in the Cannington model are all well below the AQS/AQO/EAL and so are predicted to be **slight adverse**. Their impact on the human receptor locations is therefore **not significant**.

HPC Accommodation Campus On-site Receptors

12.6.160 **Table 12.22** summarises the pollutant concentration results and associated impacts predicted at the four HPC accommodation campus on-site human receptor locations for the 2016 ‘with development’ scenario. The table provides a summary of the maximum vehicular pollutant contributions from road traffic movements associated with the HPC Project and the maximum ambient pollutant concentrations (i.e. the sum of the vehicular contribution and the background concentration) for the 2016 ‘with development’ scenario. A full set of results for all human receptor locations is presented in **Appendix 12E**.

12.6.161 The annual mean PM_{10} and $PM_{2.5}$ vehicular contributions at the on-site HPC accommodation campus receptor locations (as detailed in **Appendix 12E**, **Tables 45** and **48**) are of imperceptible magnitude. Maximum vehicular contributions are observed at ‘HPC Accommodation 2’ for annual mean PM_{10} and $PM_{2.5}$. The ‘with development’ ambient concentration values for annual mean PM_{10} and $PM_{2.5}$ for on-site HPC accommodation campus receptor locations are all well below the AQS/AQO/EAL and so are predicted to be **negligible**. Their impact on the on-site HPC accommodation campus receptor locations is therefore **not significant**.

12.6.162 The annual mean NO_2 vehicular contributions at the on-site HPC accommodation campus receptor locations (as detailed in **Appendix 12E**, **Table 40**) are of no greater than small magnitude. Maximum vehicular contributions values are observed at ‘HPC Accommodation 2’ for annual mean NO_2. The ‘with development’ ambient concentration values for annual mean NO_2 for on-site HPC accommodation campus receptor locations all well below the AQS/AQO/EAL and so are predicted to be **negligible**. Their impact on the on-site HPC accommodation campus receptor locations is therefore **not significant**.

Summary

12.6.163 For all assessed pollutants, the potential impact of vehicular emissions from road traffic movements associated with the HPC Project on human receptors and on-site HPC accommodation campus receptors for the 2016 ‘with development’ scenario is local, adverse, direct, likely and long-term but temporary. The impact on human receptors at the on-site HPC accommodation campus, for all assessed pollutants, is determined to be **not significant**.

2021 Scenario – Early Operation of HPC

12.6.164 **Table 12.23** summarises the pollutant concentration results and associated impacts predicted at the 104 human receptor locations for the 2021 'with development' scenario. The table provides a summary of the maximum vehicular pollutant contributions from road traffic movements associated with the HPC Project and the maximum ambient pollutant concentrations (i.e. the sum of the vehicular contribution and the background concentration) for the 2016 'with development' scenario. A full set of results for all human receptor locations is presented in **Appendix 12E**.

12.6.165 The annual mean PM_{10} and $PM_{2.5}$ vehicular contributions in the Bridgwater, Cannington and Williton models (as detailed in **Appendix 12E**, **Tables 34**, **37**, **46**, **49**, **58** and **61**) are of imperceptible magnitude. Maximum vehicular contributions are observed at '86 Bath Road' in the Bridgwater model, 'Withiel Farm, Withiel Drive' in the Cannington model and 'Williton County Stores' in the Williton model for annual mean PM_{10} and $PM_{2.5}$. The 'with development' ambient concentration values for annual mean PM_{10} and $PM_{2.5}$ in the Bridgwater, Cannington and Williton models are all well below the AQS/AQO/EAL and so are predicted to be **negligible**. Their impact on the human receptor locations is therefore **not significant**.

12.6.166 The annual mean NO_2 vehicular contributions in the Bridgwater, Cannington and Williton models (as detailed in **Appendix 12E**, **Tables 30**, **42** and **54**) are of no greater than small magnitude. Maximum vehicular contributions are observed at '86 Bath Road' in the Bridgwater model, 'Grange Lodge' in the Cannington model and 'Williton County Stores' in the Williton Model for annual mean NO_2. The 'with development' ambient concentration values for annual mean NO_2 in the Bridgwater, Cannington and Williton models are all well below the AQS/AQO/EAL and so are predicted to be **negligible**. Their impact on the human receptor locations is therefore **not significant**.

Summary

12.6.167 For all assessed pollutants, the potential impact of vehicular emissions from road traffic movements associated with the HPC Project on human receptors for the 2021 'with development' scenario is local, adverse, direct, likely, long-term and permanent. The impact on human receptor locations for all assessed pollutants is determined to be **not significant**.

NO_2 1-hour Mean Concentrations

12.6.168 The empirical relationship given in LAQM.TG(09) (Ref. 12.14) states that exceedences of the 1-hour mean NO_2 AQO are only likely to occur where annual mean concentrations are 60µg/m^3 or above. Although it is not possible to determine with precision the number of potential exceedences of the short-term AQO concentration, it is evident that annual mean NO_2 concentrations at all of the identified human receptor locations in proximity to roads affected by the HPC Project are well below this value, for the assessed 2013, 2016 and 2021 'with development' scenarios.

Table 12.23: Maximum Predicted Pollutant Concentrations and Impacts at Human Receptor Locations during the 2021 'With Development' Scenario

Pollutant and Averaging Period	AQS/AQO/EAL ($\mu g/m^3$)	Maximum Vehicular Contribution due to Development ($\mu g/m^3$) and as Percentage of AQS/AQO/EAL (%)	Maximum Ambient Concentration 'with Development' ($\mu g/m^3$) and as Percentage of AQS/AQO/EAL (%)	Magnitude of Change	Impact Descriptor
Bridgwater Model					
NO_2 annual mean	40	0.82 (2.1%)	20.64 (51.6%)	Small	Negligible
PM_{10} annual mean	40	0.26 (0.7%)	18.38 (46.0%)	Imperceptible	Negligible
$PM_{2.5}$ annual mean	25	0.15 (0.6%)	10.83 (43.3%)	Imperceptible	Negligible
Cannington Model					
NO_2 annual mean	40	1.15 (2.9%)	12.50 (31.3%)	Small	Negligible
PM_{10} annual mean	40	0.22 (0.6%)	18.39 (46.0%)	Imperceptible	Negligible
$PM_{2.5}$ annual mean	25	0.14 (0.6%)	7.99 (32.0%)	Imperceptible	Negligible
Williton Model					
NO_2 annual mean	40	0.65 (1.6%)	19.49 (48.7%)	Small	Negligible
PM_{10} annual mean	40	0.17 (0.4%)	20.11 (50.3%)	Imperceptible	Negligible
$PM_{2.5}$ annual mean	25	0.11 (0.4%)	9.05 (36.2%)	Imperceptible	Negligible

12.6.169 Therefore, with regard to potential impact on the 104 human receptor locations along the affected road network, short-term vehicle emissions of NO_2 associated with traffic generated by the combined HPC Project during the 2013 (construction of both HPC and the majority of the associated development sites), 2016 (construction of HPC with peak workforce on-site) and 2021 (early HPC operation) scenarios are of imperceptible magnitude. The potential impact of these emissions on the identified human receptors is local, adverse, direct and likely. Potential impacts will be medium-term but temporary during the 2013 scenario, long-term but temporary during the 2016 scenario, and long-term but permanent during the 2021 scenario. The potential impact is rated as **negligible** and is therefore determined to be **not significant**.

PM_{10} 24-hour Mean Concentrations

12.6.170 The empirical relationship between the annual mean and the predicted number of exceedences of the PM_{10} 24-hour mean AQO given in LAQM.TG(09) (Ref. 12.14), was used to estimate the increase in the number of days exceeding the 24-hour mean PM_{10} AQS/AQO/EAL, at receptor locations located in proximity to the road network.

12.6.171 In all three model areas, there was a maximum of six predicted days exceeding the 50µg/m^3 AQS/AQO/EAL concentration metric for the 2013 'without development' scenario, and seven predicted days exceeding for the 2013 'with development' scenario. A maximum of five days was predicted to exceed the 50µg/m^3 AQS/AQO/EAL concentration metric for both the 2016 'without development' and 2016 'with development' scenarios. A maximum of three days exceeding the 50µg/m^3 AQS/AQO/EAL concentration metric was predicted for the 2021 'without development' scenario, whilst four days were predicted to exceed the 50µg/m^3 AQS/AQO/EAL concentration metric for the 2021 'with development' scenario. Thus, at the 104 human receptor locations located in proximity to the road network, there was a maximum increase of only one day exceeding the short-term PM_{10} AQS/AQO/EAL concentration metric as a result of traffic generated by the HPC Project during the assessed 2013, 2016 and 2021 scenarios.

12.6.172 Therefore, with regard to potential impact on the 104 human receptor locations along the affected road network, short-term vehicle emissions of PM_{10} associated with traffic generated by the HPC Project during the 2013 (construction of both HPC and the majority of the associated development sites), 2016 (construction of HPC with peak workforce on-site) and 2021 (early HPC operation) scenarios are of no more than small magnitude. The potential impact of these emissions on the human receptors is local, adverse, direct, and likely. Potential impacts will be medium-term but temporary during the 2013 scenario, long-term but temporary during the 2016 scenario, and long-term but permanent during the 2021 scenario. The potential impact is rated as **negligible** and is therefore determined to be **not significant**.

Uncertainty in Future Year NO_2 Predictions

12.6.173 The Defra LAQM helpdesk (Ref. 12.56) has identified analyses of historical monitoring data within the UK that show a disparity between measured concentration data and the projected decline in concentrations associated with emission forecasts for future years. Trends in ambient concentrations of NO_x and NO_2 in many urban areas of the UK have generally shown two characteristics; a decrease in concentration from about 1996 to 2002-2004, followed by a period of more stable concentrations from 2002-2004 up until 2009. The main areas showing evidence of a consistent downward trend in either NO_x or NO_2 concentrations that would be supported by UK-AIR and emission inventory estimates, are more rural, less densely trafficked, parts of the UK.

12.6.174 The reason for this disparity is currently not fully understood, but it is thought to be related to the actual on-road performance of diesel road vehicles when compared with calculations based on the Euro emission standards. Preliminary studies suggest the following:

- NO_x emissions from petrol vehicles appear to be in line with current projections and have decreased by 96% since the introduction of 3-way catalysts in 1993.
- NO_x emissions from diesel cars, under urban driving conditions, do not appear to have declined substantially, up to and including Euro 5. There is limited evidence that the same pattern may occur for motorway driving conditions.
- NO_x emissions from HDVs equipped with Selective Catalytic Reduction (SCR) which are much higher than expected when driving at low speeds.

12.6.175 This disparity in the historical national data highlights the uncertainty of future year projections of both NO_x and NO_2. At this stage however, there is no robust evidence upon which to base any revised road traffic emissions projections.

12.6.176 Defra and the devolved administrations are currently investigating these issues, and once the reasons are fully understood updated guidance will be published.

12.6.177 To take account of this uncertainty, for the purposes of this assessment, a worst-case approach was taken through the application of emission factors and background concentrations for 2009 (i.e. base year levels) for all future years. This is in addition to the above assessment approach, for which the currently published guidelines have been followed (i.e. emission factors and background concentrations reduce in future years). This approach provides a means by which to assess the extreme worst-case concentrations that may occur in future years.

Worst-case NO_2 Annual Mean Concentrations

12.6.178 **Table 12.24** summarises the worst-case pollutant concentration results and associated impacts predicted at the 104 human receptor locations for the 2013, 2016 and 2021 ‘with development’ scenarios, assuming emission factors and background concentrations at 2009 levels. The table provides a summary of the maximum worst-case vehicular pollutant contributions from road traffic movements associated with the HPC Project and the maximum ambient pollutant concentrations (i.e. the sum of the vehicular contribution and the background concentration) for the 2013, 2016 and 2021 ‘with development’ scenarios. A full set of results for all human receptor locations is presented in **Appendix 12E**.

Table 12.24: Maximum Predicted Worst-Case Pollutant Concentrations and Impacts at Human Receptor Locations during the 2013, 2016 and 2021 'With Development' Scenarios

Pollutant and Averaging Period	AQS/AQO/EAL ($\mu g/m^3$)	Maximum Vehicular Contribution due to Development ($\mu g/m^3$) and as Percentage of AQS/AQO/EAL (%) (worst-case)	Maximum Ambient Concentration 'with development' ($\mu g/m^3$) and as Percentage of AQS/AQO/EAL (%) (worst-case)	Magnitude of Change (worst-case)	Impact Descriptor (worst-case)
Bridgwater Model					
2013 NO_2 annual mean	40	3.88 (9.7%)	35.70 (89.3%)	Medium	Slight Adverse
2016 NO_2 annual mean	40	3.39 (8.5%)	35.55 (88.9%)	Medium	Slight Adverse
2021 NO_2 annual mean	40	2.80 (7.0%)	36.99 (92.5%)	Medium	Moderate Adverse
Cannington Model					
2013 NO_2 annual mean	40	10.91 (23.7%)	29.79 (74.5%)	Large	Slight Adverse
2016 NO_2 annual mean	40	8.16 (20.4%)	30.48 (76.2%)	Large	Slight Adverse
2021 NO_2 annual mean	40	4.43 (11.1%)	27.49 (68.7%)	Large	Slight Adverse
Williton Model					
2013 NO_2 annual mean	40	1.08 (2.7%)	42.74 (106.9%)	Small	Slight Adverse
2016 NO_2 annual mean	40	0.79 (2.0%)	42.74 (106.9%)	Small	Slight Adverse
2021 NO_2 annual mean	40	0.80 (2.0%)	42.75 (106.9%)	Small	Slight Adverse
HPC Accommodation Campus On-site Receptors					
2016 NO_2 annual mean	40	1.68 (4.2%)	9.97 (20.3%)	Small	Negligible

12.6.179 The worst-case annual mean NO_2 vehicular contributions in the Williton model for the 2013, 2016 and 2021 'with development' scenarios (as detailed in **Appendix 12E**, **Tables 51**, **53** and **55**) are of no greater than small magnitude. Maximum worst-case vehicular contributions are observed at 'Williton County Stores' for the 2013, 2016 and 2021 'with development' scenarios for annual mean NO_2. The worst-case ambient concentration values for annual mean NO_2 for the 2013, 2016 and 2021 'with development' scenarios are all above the AQS/AQO/EAL. However, worst-case ambient concentration values for annual mean NO_2 for the 2013, 2016 and 2021 'without development' scenarios are all also above the AQS/AQO/EAL. This indicates that the 40μg/m^3 annual mean NO_2 AQS/AQO/EAL would be exceeded without HPC Project traffic, and so would thus not be caused by either the construction or operation of the combined HPC Project. The increase in traffic volume when comparing the 2013 'without development' and 'with development' scenarios represents only construction traffic for the Williton park and ride site, hence the extremely small NO_2 concentration increase associated with the HPC development in this assessment year. When comparing 2016 and 2021 'without development' and 'with development' scenarios, the increase in traffic volume represents only operational traffic associated with the Williton park and ride site, which is entirely composed of LDVs, hence the small NO_2 concentration increase. Therefore the impacts of 'with development' NO_2 ambient concentration values are predicted to be **slight adverse**. The worst-case potential impact on the human receptor locations is therefore **not significant**. This does not, therefore, affect the judgement of significance as presented earlier in this section.

12.6.180 The worst-case annual mean NO_2 vehicular contributions in the Bridgwater model for the 2013 and 2016 'with development' scenarios (as detailed in **Appendix 12E**, **Tables 27** and **29**) are of no greater than medium magnitude. Maximum worst-case vehicular contributions are observed at '131 The Drove' for the 2013 and 2016 'with development' scenarios for annual mean NO_2. The worst-case ambient concentration values for annual mean NO_2 for the 2013 and 2016 'with development' scenarios are below the AQS/AQO/EAL and so are predicted to be **slight adverse**. The worst-case potential impact on the human receptor locations is therefore **not significant**. This does not, therefore, affect the judgement of significance as presented earlier in this section

12.6.181 The worst-case annual mean NO_2 vehicular contributions in the Bridgwater model for the 2021 'with development' scenario (as detailed in **Appendix 12E**, **Table 31**) are of no greater than medium magnitude. Maximum worst-case vehicular contributions are observed at '86 Bath Road' for the 2021 'with development' scenario for annual mean NO_2. The worst-case ambient concentration value at '86 Bath Road' for annual mean NO_2 for the 2021 'with development' is just below the AQS/AQO/EAL and so is predicted to be **moderate adverse**. However, concentration values at the other 43 human receptors are below the AQS/AQO/EAL and so are predicted to be either **slight adverse** or **negligible**. Therefore, on the basis of professional judgment and taking into account the factors presented in section 12.4, the worst-case modelling approach taken, that only a single sensitive receptor '86 Bath Road' falls in the 'just below objective/limit value' category and that there are no predicted exceedences of the annual mean NO_2 AQS/AQO/EAL, the worst-case potential impacts are determined to be **not significant**. This does not, therefore, affect the judgement of significance as presented earlier in this section.

12.6.182 The worst-case annual mean NO_2 vehicular contributions in the Cannington model the 2013, 2016 and 2021 'with development' scenarios (as detailed in **Appendix 12E**, **Tables 39**, **41** and **43**) are of up to large magnitude. Maximum worst-case vehicular contributions are observed at '41 High Street' for the 2013 'with development' scenario, and at 'The Lodge, Withycombe' for the 2016 and 2021 'with development' scenarios for annual mean NO_2. The worst-case ambient concentration values for annual mean NO_2 for the 2013, 2016 and 2021 'with development' scenarios are all below the AQS/AQO/EAL and so are predicted to be **slight adverse**. Their worst-case potential impact on the human receptor locations is therefore **not significant**. This does not, therefore, affect the judgement of significance as presented earlier in this section.

HPC Accommodation Campus On-site Receptors

12.6.183 The worst-case annual mean NO_2 vehicular contributions at the on-site HPC accommodation campus receptor locations (as detailed in **Appendix 12E**, **Table 41**) are of no greater than small magnitude. Maximum worst-case vehicular contributions are observed at 'HPC Accommodation 2' for annual mean NO_2. The 'with development' ambient concentration values for annual mean NO_2 for on-site HPC accommodation campus receptor locations all well below the AQS/AQO/EAL and so are predicted to be **negligible**. The worst-case potential impact on the on-site HPC accommodation campus receptor locations is therefore **not significant**. This does not, therefore, affect the judgement of significance as presented earlier in this section.

Worst-case NO_2 1-hour Mean Concentrations

12.6.184 The empirical relationship given in LAQM.TG(09) (Ref. 12.14) states that exceedences of the 1-hour mean objective for NO_2 are only likely to occur where annual mean concentrations are 60µg/m^3 or above. Although it is not possible to determine with precision the worst-case number of potential exceedences of the short-term AQS/AQO/EAL concentration, it is evident that worst-case annual mean NO_2 concentrations at all of the identified human receptor locations in the proximity to roads affected HPC Project traffic are well below this limit, for the assessed worst-case 2013, 2016 and 2021 'with development' scenarios.

12.6.185 Therefore, adopting the worst-case approach (i.e. assuming 2009 emission factors and background pollutant concentrations for future assessment years), with regard to potential impact on the 104 human receptor locations along the affected road network, worst-case short-term vehicle emissions of NO_2 associated with traffic generated by the HPC Project during the 2013 (construction of both HPC and the majority of the associated development sites), 2016 (construction of HPC with peak workforce on-site) and 2021 (early HPC operation) scenarios are of imperceptible magnitude. The potential impact of these emissions on the identified human receptors is local, adverse, direct and likely. Potential impacts will be medium-term but temporary during the 2013 scenario, long-term but temporary during the 2016 scenario, and long-term but permanent during the 2021 scenario. The potential worst-case impact is rated as **negligible** and is therefore determined to be **not significant**.

Summary

12.6.186 Therefore, regardless of which of the two modelling methodologies are adopted for both annual mean and 1-hour mean future year NO_2 concentration predictions, with regard to potential impact on the 104 human receptor locations along those routes associated with traffic generated by the combined HPC Project, vehicular emissions during the construction and operational periods of the combined HPC Project (i.e. 2013, 2016 and 2021 scenarios), are **not significant**.

12.6.187 All predicted pollutant concentrations at the four HPC accommodation campus on-site receptors locations are below the relevant AQOs for the 2016 'with development' scenario, and potential air quality impacts at these locations have been assessed to be **not significant**. The HPC accommodation campus is therefore considered appropriate, in air quality terms, for residential use by the on-site residential workforce.

ii. Ecological Receptors

12.6.188 The Bridgwater Bay SSSI is located immediately to the east of the C182 (Wick Moor Drove), which will be used during the construction and operational phases of the HPC Project to access the HPC development site. The Hinkley CWS also adjoins the C182 close to the HPC development site. There is therefore the potential for vehicular exhaust emissions associated with the HPC Project development traffic to affect these ecological receptor locations.

12.6.189 This section presents the pollutant concentration results and associated impacts predicted at nine selected ecological receptor points, which are representative of worst-case exposure at the Bridgwater Bay SSSI and the Hinkley CWS ecological receptor locations (see **Figure 12.4**). In order to understand how vehicular pollutant concentrations decrease from the C182 roadside within the designated ecological sites, receptor points were selected at distances of approximately 10m, 15m and 20m from the road within the SSSI boundary (the SSSI boundary is approximately 10m from the C182 at its closest point). Pollutant concentrations from vehicular exhausts generally decrease rapidly as a function of increased distance from the road source. Whilst the receptor points themselves are situated within the Bridgwater Bay SSSI, the traffic volume along the C182 will be identical at both locations (i.e. within the SSSI and CWS), and thus pollutant concentrations and potential impacts will be directly comparable.

12.6.190 Pollutant concentrations from vehicular exhaust emissions and associated impacts at the ecological receptor points in proximity to the Combwich associated development site, which are representative of worst-case exposure at the ecological receptors Bridgwater Bay SSSI/NNR and Severn Estuary SPA/SAC/Ramsar, are significantly lower than those presented here, and are described in **Volume 7**, **Chapter 10** and **Volume 7**, **Chapter 14**.

12.6.191 **Table 12.25** summarises the pollutant concentrations and associated impacts at the ecological receptor locations adjacent to the C182 for the 2013, 2016 and 2021 'with development' scenarios. Pollutant concentrations predicted at all of the identified ecological receptors located in proximity to the road network with the potential to be affected by the HPC Project, including those in proximity to the Combwich associated development site, are presented in **Appendix 12E**.

Table 12.25: Maximum Predicted Pollutant Concentrations and Impacts at Ecological Receptor Locations Adjacent to the C182 near the HPC Development Site during the 2013, 2016 and 2021 'With Development' Scenarios

Pollutant and Averaging Period	AQS/AQO/EAL ($\mu g/m^3$)	Maximum Vehicular Contribution due to Development ($\mu g/m^3$) and as Percentage of AQS/AQO/EAL (%)	Maximum Ambient Concentration 'with Development' ($\mu g/m^3$) and as Percentage of AQS/AQO/EAL (%)	Magnitude of Change	Impact Descriptor
2013 Scenario					
NO_x annual mean	30	10.65 (35.5%)	28.66 (95.5%)	Large	Moderate Adverse
NO_x 24-hour mean	75	37.30 (49.7%)	86.48 (115.3%)	Large	Substantial Adverse
2016 Scenario					
NO_x annual mean	30	5.16 (17.2%)	20.24 (67.5%)	Large	Slight Adverse
NO_x 24-hour mean	75	18.00 (24.0%)	58.49 (78.0%)	Large	Slight Adverse
2021 Scenario					
NO_x annual mean	30	1.13 (3.8%)	12.8 (42.7%)	Small	Negligible
NO_x 24-hour mean	75	3.92 (5.2%)	34.28 (45.7%)	Medium	Negligible

12.6.192 The annual mean NO_x vehicular contributions for the 2021 'with development' scenario (as detailed in **Appendix 12E**, **Table 66**) are of no greater than small magnitude. The ambient concentration values for annual mean NO_x in the 2021 'with development' scenario are well below the AQS/AQO/EAL and so are predicted to be **negligible**.

12.6.193 The 24-hour mean NO_x vehicular contributions in the 2021 'with development' scenario (as detailed in **Appendix 12E**, **Table 66**) are of no greater than medium magnitude. The ambient concentration values for 24-hour mean NO_x in the 2021 'with development' scenario are well below the AQS/AQO/EAL and so are predicted to be **negligible**.

12.6.194 The annual mean and 24-hour mean NO_x vehicular contributions in the 2016 'with development' scenario (as detailed in **Appendix 12E**, **Table 64**) are of up to large magnitude. The ambient concentration values for annual mean and 24-hour mean NO_x in the 2016 'with development' scenario are all below the AQS/AQO/EAL and so are predicted to be **slight adverse**.

12.6.195 The annual mean NO_x vehicular contributions in the 2013 'with development' scenario (as detailed in **Appendix 12E**, **Table 62**) are of up to large magnitude. The ambient concentration values for annual mean NO_x in the 2013 'with development' scenario are just below the AQS/AQO/EAL and so are predicted to be **moderate adverse**. However, annual mean NO_x concentrations reduce rapidly with increased distance from the road source, and therefore with an additional 5m separation distance from the roadside, the potential impact is rated as being no more than **slight adverse** ('Main Eco Receptor 3b'). There is therefore only a very small proportion of the designated ecological sites, on the boundary closest to the C182, which will have the potential to be impacted by the long-term NO_x emissions.

12.6.196 The 24-hour mean NO_x vehicular contributions in the 2013 'with development' scenario (as detailed in **Appendix 12E**, **Table 62**) are of up to large magnitude. The ambient concentration values for 24-hour mean NO_x in the 2013 'with development' scenario are above the objective/limit value and so are predicted to be **substantial adverse**. However, 24-hour mean NO_x concentrations also reduce rapidly with increased distance from the road source, and therefore with an additional 10m separation distance from the roadside the potential impact is rated as being no more than **slight adverse** ('Main Eco Receptor 3c'). There is therefore only a very small proportion of the designated ecological sites, on the boundary closest to the C182, which will have the potential to be impacted by the short-term NO_x emissions. For the same reasons as discussed previously, it is also considered that greater emphasis should be placed on achievement of the more established annual mean NO_x AQS/AQO/EAL, which in this case is not exceeded.

Summary

12.6.197 For annual mean and 24-hour mean NO_x concentrations, the potential impact of vehicular emissions from road traffic movements associated with the HPC Project on ecological receptor locations for the 2013, 2016 and 2021 'with development' scenarios is local, adverse, direct and likely. Potential impacts will be medium-term but temporary during the 2013 scenario, long-term but temporary during the 2016 scenario, and long-term but permanent during the 2021 scenario.

12.6.198 The significance of these predictions of short-term and long-term NO_x emissions from vehicles associated with the construction and operational phases of the HPC Project, upon biodiversity receptors, is assessed in **Volume 2**, **Chapter 20**.

Uncertainty in Future Year NO_x Predictions

12.6.199 As for the approach taken to dealing with the uncertainty of future year NO_2 concentration predictions at human receptor locations, a worst-case approach was taken to the prediction of NO_x concentrations at the ecological receptor locations, i.e. through the application of emission factors and background concentrations for 2009 (i.e. base year levels) for all future years. This approach provides a means by which to assess the extreme worst-case upper NO_x concentrations that may prevail in future years. These worst-case results are discussed below.

12.6.200 **Table 12.26** summarises the worst-case NO_x concentration results and associated impacts predicted at the ecological receptor locations for the 2013, 2016 and 2021 ‘with development’ scenarios, assuming emission factors and background concentrations at 2009 levels.

12.6.201 The worst-case annual mean NO_x vehicular contributions in the 2013, 2016 and 2021 ‘with development’ scenarios (as detailed in **Appendix 12E, Tables 63, 65 and 67**) are of up to large magnitude. The worst-case ambient concentration values for annual mean NO_x in the 2013, 2016 and 2021 ‘with development’ scenarios are all above the AQS/AQO/EAL and so are predicted to be **substantial adverse**. However, the worst-case annual mean NO_x concentrations would reduce rapidly with increased distance from the road source; at approximately 10m from the C182, the worst-case annual mean NO_x concentration at ‘Main Eco Receptor 3a’ is 39.30µg/m^3, whilst at 15m the worst-case NO_x concentration reduces to 34.10µg/m^3 (‘Main Eco Receptor 3b’). Concentrations reduce further at 20m from the roadside, with a worst-case concentration of 30.54µg/m^3 predicted at ‘Main Eco Receptor 3c’. The worst-case annual mean NO_x concentration at ‘Main Eco Receptor 3b’ is only marginally above the 30µg/m^3 NO_x annual mean AQS/AQO/EAL. Therefore, at ecological receptor locations at distances of marginally greater than 20m between the road source and receptor, worst-case annual mean NO_x concentrations would be below the 30µg/m^3 AQS/AQO/EAL. There is therefore only a very small proportion of the ecological sites adjacent to the C182, where there will be the potential for exceedence of the annual mean NO_x AQO. Potential impacts will decrease rapidly with increased distance from the road, and thus sensitive biodiversity receptors may not necessarily be present in the locations experiencing the highest worst-case annual mean NO_x concentrations.

12.6.202 The worst-case 24-hour mean NO_x vehicular contributions in the 2013, 2016 and 2021 ‘with development’ scenarios (as detailed in **Appendix 12E, Tables 63, 65 and 67**) are also of up to large magnitude. The worst-case ambient concentration values for 24-hour mean NO_x in the 2013, 2016 and 2021 ‘with development’ scenarios are all above the EAL and so are predicted to be **substantial adverse**. However, for the same reasons as previously discussed, given the lack of confidence in the 75µg/m^3 NO_x 24-hour mean EAL (derived from the 2000 WHO Air Quality Guidelines for Europe) (Ref. 12.55) it is considered that greater emphasis should be placed on achievement of the more established NO_x annual mean AQS/AQO/EAL.

Table 12.26: Maximum Predicted Worst-Case Pollutant Concentrations and Impacts at Ecological Receptor Locations during the 2013, 2016 and 2021 'With Development' Scenarios

Pollutant and Averaging Period	AQS/AQO/EAL ($\mu g/m^3$)	Maximum Vehicular Contribution due to Development ($\mu g/m^3$) and as Percentage of AQS/AQO/EAL (%) (worst-case)	Maximum Ambient Concentration 'with development' ($\mu g/m^3$) and as Percentage of AQS/AQO/EAL (%) (worst-case)	Magnitude of Change (worst-case)	Impact Descriptor (worst-case)
2013 Scenario					
NO_x annual mean	30	16.29 (54.3%)	39.30 (131.0%)	Large	Substantial Adverse
NO_x 24-hour mean	75	57.10 (76.1%)	121.06 (161.4%)	Large	Substantial Adverse
2016 Scenario					
NO_x annual mean	30	12.92 (43.1%)	35.90 (119.7%)	Large	Substantial Adverse
NO_x 24-hour mean	75	45.26 (60.3%)	109.13 (145.5%)	Large	Substantial Adverse
2021 Scenario					
NO_x annual mean	30	6.89 (23.0%)	30.55 (101.8%)	Large	Substantial Adverse
NO_x 24-hour mean	75	24.12 (32.2%)	90.37 (120.5%)	Large	Substantial Adverse

Summary

12.6.203 Adopting the worst-case modelling approach, there may be very small proportions of the ecological sites close to their boundaries to the C182, which could have the potential to exceed the annual mean and 24-hour mean NO_x AQS/AQO/EAL. However, NO_x concentrations and associated potential worst-case impacts decrease rapidly with increased distance from the road, and thus sensitive biodiversity receptors are unlikely to be present in the locations experiencing the highest (and worst-case) NO_x concentrations.

12.6.204 The significance of these worst-case predictions of annual mean and 1-hour NO_x emissions, from vehicular exhaust emissions associated with the HPC Project, upon biodiversity is presented in **Volume 2, Chapter 20**.

Deposition of Nutrifying and Acidifying Pollutants

12.6.205 The maximum additional deposition rates of nutrifying and acidifying pollutants at the statutory and non-statutory designated sites, due to vehicle exhaust emissions associated with the construction and operational phases of the HPC Project, are summarised in **Table 12.27** below.

Table 12.27: Maximum Deposition Rates at Statutory and Non-statutory Designated Ecological Receptors from Vehicular Emissions Associated with the HPC Development

	Nitrogen Deposition Rate – (kg N/ha/y)			Acid Deposition Rate – (keq/ha/y)		
	2013	2016	2021	2013	2016	2021
Maximum predicted rate at ecological receptors	1.53	0.74	0.16	0.11	0.05	0.01
Worst-case maximum predicted rate at ecological receptors	2.35	1.86	0.99	0.17	0.13	0.07

12.6.206 Assessment of potential impacts, taking into account the relevant critical loads and existing background deposition rates, is provided in **Volume 2, Chapter 20.**

e) Cumulative Air Quality Impacts from the HPC Development

12.6.207 There is the potential for site-specific cumulative air quality impacts from different aspects of the proposed HPC development to act additively on a receptor, during both the construction and operational phases.

12.6.208 Due to the inherit uncertainty of short-term events and the small likelihood of worst-case short-term emissions from multiple sources occurring simultaneously, and potentially causing an additive impact on any receptor location, only long-term site-specific cumulative air quality impacts have been considered.

i. Cumulative Impacts during HPC Construction

12.6.209 Potential additive cumulative impacts during the HPC development construction phase may occur on both human and ecological receptor locations.

Human Receptors

12.6.210 During the HPC construction phase, there is the potential for site-specific additive impacts at human receptor locations from the following sources:

- dust and particulate emissions generated during on-site activities;
- exhaust emissions from road vehicles associated with HPC construction;
- exhaust emissions from on-site plant and machinery (NRMM); and
- exhaust emissions from marine vessels associated with the operation of the temporary jetty.

12.6.211 The potential human receptors that may be susceptible to such additive air quality impacts would be limited to a small number of residential locations, sited primarily in close proximity to the HPC development site boundary. The receptor 'Doggetts' has therefore been taken as a representative worst-case location where such cumulative construction impacts may occur.

12.6.212 Annual mean pollutant concentrations from vehicular exhausts at 'Doggetts' were found to be greatest during the 2013 'with development' construction scenario, where process contributions from development-related road traffic were predicted to be 0.41µg/m^3, 0.02µg/m^3 and 0.02µg/m^3 for NO_2, PM_{10} and $PM_{2.5}$ respectively. NO_2 vehicular emissions were found to be of no more than small magnitude, whilst both PM_{10} and $PM_{2.5}$ emissions were found to be of imperceptible magnitude, and thus of negligible potential impact at 'Doggetts'.

12.6.213 Marine vessel pollutant emissions associated with the operation of the temporary jetty were predicted to lead to an increase of no more than 0.02µg/m^3 for the pollutants NO_2, PM_{10} and $PM_{2.5}$. At 'Doggetts', these emissions were identified to be of imperceptible magnitude and their potential impact rated as negligible. Exhaust emissions from NRMM were qualitatively determined to be of small magnitude and of negligible potential impact.

12.6.214 With regard to NO_2 emissions from the above sources, there is therefore no potential for significant additive air quality impacts at 'Doggetts'. Combined NO_2 emissions during the HPC construction phase are considered to be of no more than small magnitude at Doggetts, with the potential cumulative impact rated as **negligible** and therefore **not significant**.

12.6.215 In the context of particulate (PM_{10} and $PM_{2.5}$) emissions during the HPC construction phase, the most significant source of these pollutants at 'Doggetts' will arise from sources on-site during particularly dust-generating construction activities. Dust and particulate impacts at 'Doggetts' during the assessed 2013 construction scenario (Scenario A) were qualitatively rated as being of **major adverse** significance, in the absence of standard good practice and mitigation measures. This source will therefore dominate the overall particulate concentrations at this receptor, with the contribution from the other sources being comparatively insignificant.

12.6.216 Suitable best practice measures to minimise the generation and dispersion of dust and particulates, and to monitor dust and particulate concentrations at this receptor location, as detailed in the **Air Quality Management Plan (AQMP)**, would ensure that any potential cumulative impacts would be minimised.

Ecological Receptors

12.6.217 During the HPC construction phase, there is the potential for additive cumulative air quality impacts at ecological receptor locations from the same sources as outlined above for human receptors. The main potential for additive impacts at ecological receptor locations arises due to combined NO_x emissions from various sources. Consideration has therefore specifically been given to this issue below.

12.6.218 The maximum annual mean NO_x contribution from vehicular exhaust emissions, associated with HPC development-related road traffic during the 2013 ‘with development’ construction scenario at an ecological receptor location, was determined to be 10.65µg/m^3, occurring at both the Bridgwater Bay SSSI and Hinkley CWS site areas which are adjacent to the C182. This increase was considered to be of large magnitude and the potential impact rated as being moderate adverse.

12.6.219 Marine vessel NO_x emissions associated with the operation of the temporary jetty were predicted to lead to a maximum increase of only 1.06µg/m^3, at an ecological receptor location north of the HPC development site, adjacent to the jetty head. These emissions were identified to be of imperceptible magnitude and their potential impact rated as negligible. Exhaust emissions from NRMM were qualitatively determined to be of small magnitude and also of negligible potential impact.

12.6.220 Given the above, and that the locations of the maximum annual mean NO_X process contributions from the above sources do not spatially overlap, the potential for additive cumulative air quality impacts at ecological receptor locations during the HPC construction phase is considered to be low. The worst-case potential NO_x additive cumulative impacts at an ecological receptor location are thus considered to be no worse than the predicted impacts from vehicular exhaust emissions associated with development related road traffic during the 2013 construction scenario.

12.6.221 The maximum annual mean NO_x concentration from all sources is therefore likely to occur at the Bridgwater Bay SSSI and Hinkley CWS immediately adjacent to the C182, where a concentration of 28.66µg/m^3 was predicted as a result of the HPC development-related vehicular exhaust emissions (i.e. just below the 30µg/m^3 NO_x annual mean AQS/AQO/EAL). The potential additive cumulative impact is therefore rated as being **moderate adverse**. However, annual mean NO_x concentrations reduce rapidly with increased distance from the road source, and therefore the potential additive impact is rated as being no more than **slight adverse** within an additional 5m separation distance from the roadside.

ii. Cumulative Impacts during HPC Operation

12.6.222 Potential additive cumulative impacts during the operational phase of the HPC development may occur on both human and ecological receptor locations.

Human Receptors

12.6.223 During the HPC operational phase, there is the potential for additive impacts at human receptor locations from the following sources:

- exhaust emissions from road vehicles associated with HPC operation; and
- emissions from on-site HPC operational activities.

12.6.224 As with the potential cumulative air quality impacts during the HPC construction phase, the human receptors that may potentially be impacted would be limited to a small number of residential locations in close proximity to the HPC development site boundary. The receptor 'Doggetts' has therefore again been taken as a representative worst-case location where such additive cumulative operational impacts may occur.

12.6.225 The additional contribution to annual mean pollutant concentrations from vehicular exhaust emissions at 'Doggetts' from the development-related road traffic during the 2021 'with development' operational scenario, were predicted to be 0.05µg/m^3 for NO_2, and 0.01µg/m^3 for PM_{10} and $PM_{2.5}$. These emissions were found to be of imperceptible magnitude and thus of negligible potential impact at 'Doggetts'.

12.6.226 The routine testing of the backup diesel generators associated with the UK EPR Units and their ancillary buildings during the operation of HPC would lead to additional process contributions at 'Doggetts' of 0.04µg/m^3 for NO_2, and <0.01µg/m^3, for both PM_{10} and $PM_{2.5}$.

12.6.227 Given the above, there is no potential for significant additive cumulative air quality impacts at Doggetts during HPC operation. Combined pollutant emissions during the HPC operational phase are considered to be of no more than imperceptible magnitude at 'Doggetts', with the potential cumulative impact rated as **negligible** and therefore **not significant**.

Ecological Receptors

12.6.228 During the HPC operational phase, there is also the potential for additive cumulative air quality impacts at ecological receptor locations from the same sources as described above for human receptors. Similar to the construction phase, specific focus has been given to additive HPC operational NO_x emissions at ecological receptor locations.

12.6.229 The maximum additional contribution to annual mean NO_x concentrations from HPC development-related vehicular exhaust emissions at an ecological receptor location during the 2021 'with development' operational scenario, was predicted to be 1.13µg/m^3. This was assessed to be of small magnitude and thus of negligible potential impact at ecological receptor locations.

12.6.230 The routine testing of the backup diesel generators associated with the UK EPR Units and their ancillary buildings during the operation of HPC would lead to a maximum additional NO_x process contribution at an ecological receptor location of 4.06µg/m^3, occurring at Hinkley CWS. These emissions were found to be of large magnitude and thus of slight adverse potential impact at ecological receptor locations.

12.6.231 Given the above, the greatest potential additive cumulative impact from NO_x emissions at an ecological receptor location during HPC operation, is rated as no greater than **slight adverse**, with combined NO_x PEC concentrations (i.e. combined process contributions plus background) still well below the 30µg/m^3 NO_x annual mean AQS/AQO/EAL.

12.7 Mitigation of Impacts

12.7.1 For the purpose of this assessment, mitigation measures have been proposed where there is an adverse impact of greater than minor significance and the impact magnitude, spatial scope and temporal nature make it appropriate to do so.

12.7.2 With the exception of dust and particulate impacts at Bishops Farm House and Doggetts in the assessed 2013 scenario, all potential air quality impacts have been rated as negligible, minor or not significant before any best practice or mitigation has been applied. Dust and particulate impacts at Bishops Farm House and Doggetts during the above scenario were considered to be major prior to the implementation of any standard good practice measures or mitigation relating to dust.

12.7.3 Impacts from the on-site NRMM exhaust emissions and marine vessel exhaust emissions during the HPC construction phase have been rated as **not significant** for all pollutants.

12.7.4 Impacts from the commissioning and operation of the HPC nuclear power station have been rated as **not significant** for all pollutants.

12.7.5 Impacts from traffic during the construction and operational phases have also been rated as **not significant** for all pollutants and scenarios.

12.7.6 The following section provides best practice methods and mitigation measures that would be implemented to minimise the predicted air quality impacts, with specific focus given to measures that could be implemented to minimise the dust and particulate matter impacts that may potentially be generated by construction activities.

a) Construction Mitigation

12.7.7 Environmental impacts and disturbance arising from construction activities will be managed through a range of control measures and monitoring procedures the principles of which are outlined in the **Environmental Management and Monitoring Plan (EMMP)** with further information in associated Subject-Specific Management Plans. The control measures for the management of the air quality, including minimisation of dust and particulate generation and dispersion from the HPC development site, are outlined in the **AQMP**.

i. Dust and PM_{10} Generated from Construction Activities

12.7.8 Best practice guidance control methods and mitigation measures that will be implemented to manage dust and PM_{10} emissions during the construction works, and to ensure associated impacts are prevented in areas in proximity to the site, are presented within the **AQMP**.

12.7.9 The **AQMP** makes reference to current best practice guidance and other supporting documentation, including:

- BRE publication 'Control of dust from construction and demolition activities' (2003) (Ref. 12.36).
- QUARG publication 'Airborne Particulate Matter in the UK – Third report of the Quality of Urban Air Review Group' (1996) (Ref. 12.37).
- Office of the Deputy Prime Minister 'Minerals Policy Statement 2: Controlling and Mitigating the Effects of Mineral Extraction in England – Annex 1: Dust' (Ref. 12.39).
- Greater London Authority and London Councils publication 'The control of dust and emissions from construction and demolition - Best Practice Guidance' (2006) (Ref. 12.35).
- CIRIA 'Environmental good practice on site guide' (third edition) (Ref. 12.57).
- Defra Secretary of State's Guidance for Mobile Crushing and Screening - Process Guidance Note 3/16(04) (Ref. 12.58).

12.7.10 The **AQMP** will be implemented throughout the duration of the HPC construction phase, ensuring that dust and particulate emissions are kept to a minimum. Typical good construction practice methods and dust mitigation that will be implemented where appropriate to control dust and PM_{10} generation during the construction works include:

- Vehicles carrying loose materials to be sheeted during periods of dry and windy weather, or if dust emissions become a problem.
- Implementation of design controls for construction equipment and vehicles and use of appropriately designed vehicles for materials handling.
- Completed stockpiles to be covered or seeded as soon as is practicable in order to stabilise surfaces (finished platforms would be covered, external slopes would be seeded and therefore eventually vegetated).
- Use of mobile or fixed spray units to dampen surfaces as dictated by weather conditions.
- Provision and use of wheel washing facilities at all exits as well as procedures for effective cleaning and inspection of vehicles, which should include total vehicle washing and ticketing of vehicles.
- Regular inspection and, if necessary, cleaning of local highways and site boundaries to check for dust deposits (and removal if necessary).
- Use of dust-suppressed tools for all operations, and use of dust extraction techniques where available.
- Ensuring that all construction plant and equipment are maintained in good working order and not left running when not in use.
- Regulating on-site movements to keep dust generating activities to a minimum.

12.7.11 A formal system would need to be put in place during the works which identifies the roles and responsibilities of site staff regarding the procedures to be applied to respond to any complaints or observations which may be made relating to air quality. Site logs will be maintained, detailing all complaints or observations received and the corresponding action taken including the response made to each complainant.

12.7.12 The extent to which dust mitigation measures will be implemented on site during the construction works will be flexible and responsive, with additional recommendations and measures introduced when required during particular activities which have significant dust generating potential, sensitive periods, or upon receipt of valid complaints relating to dust. Working practices will be systematically audited and revised where necessary in order to ensure dust impacts are mitigated to an acceptable level at the identified sensitive receptor locations.

ii. Exhaust Emissions from On-site Plant and Machinery

12.7.13 Best practice guidance control methods and mitigation measures that will be implemented to control on-site exhaust emissions from plant and machinery (NRMM) during the construction phase include:

- minimising idling times of plant and machinery;
- ensuring all equipment is in good working order and working efficiently;
- use of ultra low sulphur diesel (ULSD) in all equipment and plant, where practicable;
- ensuring that all equipment is fitted with appropriate particulate filters or any other appropriate exhaust after-treatments, where practicable; and
- use of equipment that meets the latest emission standards.

iii. Exhaust Emissions from Marine Vessels

12.7.14 Best practice guidance measures that will be implemented where appropriate to control emissions from marine vessels during the operation of the temporary jetty include:

- marine vessels to use fuels with low sulphur content (<1%), where practicable;
- all vessel engines (main and auxiliary) to be maintained in good working order; and
- minimise idling times of all vessel engines (main and auxiliary).

b) Operational Mitigation

12.7.15 The operation of backup diesel generators (EDGs and SBOs) will lead to the discharge of air pollutants, mostly formed by oxidation (fixation) of nitrogen in the combustion air. Many of the Best Available Technique (BAT) options, relative to management of the burner arrangements, are not applicable in compression ignition engines such as those proposed for the plant at HPC.

12.7.16 Optimisation of the diesel generator management with regards to NO_X control will be considered at the engine procurement phase, as reflected in the design specification.

However, these considerations will be considered against equipment reliability which is the priority for diesel generators.

12.7.17 In addition to optimisation at the design and procurement stages, NO_X control will also be addressed by the maintenance programme applied to the backup diesel generators to ensure optimum performance. The maintenance of the EDGs and SBOs will be addressed in the Operator's Maintenance Policy, which will specify the work programme required to maintain the backup diesel generators in the best possible standby state to ensure optimum engine availability. This work programme will be based on engine running hours and manufacturer's recommendations. It should be noted that following maintenance activities, which can significantly affect the engine performance, specific tests, such as stack testing, could be performed following completion of the work if deemed necessary.

12.7.18 Emissions of sulphur (as SO_2) are directly related to the sulphur content of the fuel (i.e. there is no sulphur in the air therefore it is only the sulphur in the fuel that contributes to the SO_2). Combustion management cannot be used to reduce SO_2 releases. The backup diesel generators will use a low sulphur fuel oil, which will ensure low emissions of SO_2. Fuel oil must contain a maximum of 0.1% sulphur by weight, as required under the Sulphur Content of Liquid Fuels (SCOLF) Regulations 2007 (Ref. 12.59) (or the requirements of future legislation).

12.7.19 During the routine testing schedule of the backup diesel generators (approximately 60 hours per year for each of the generators), where possible, effort would be made to ensure that their testing occurred during meteorological conditions that are conducive to good pollutant dispersion, i.e. moderate to strong winds with a northerly component that would disperse the plume in the opposite direction to the majority of the air quality receptor locations. This would minimise the pollutant concentrations occurring at such locations.

c) Vehicular Emissions Mitigation

12.7.20 The **Framework Travel Plan** and the **Freight Management Strategy** are included as an annex to this ES. The plan and strategy will be implemented to minimise traffic volumes during the construction and operational phases of the HPC Project, hence reducing the associated impacts from vehicle exhaust emissions to air relative to the worst-case assessment detailed in section 10.6. Full details of the proposed traffic mitigation measures are provided within the above documents. As relevant air quality criteria for the protection of human health are not predicted to be exceeded for locations in proximity to the highway network, specific air quality mitigation measures are not deemed to be necessary.

12.8 Residual Impacts

12.8.1 With the exception of fugitive dust and particulate impacts at both Bishops Farm House and Doggetts in the assessed 2013 scenario, all potential air quality impacts have been rated as **negligible**, **minor** or **not significant** before any best practice or mitigation has been applied.

12.8.2 Construction activities at the HPC development site will require management to minimise the potential for dust and particulate matter impacts to the nearest neighbouring residential properties. The implementation of the mitigation and best practice measures described above would result in a residual impact from dust and particulate matter impacts at Bishops Farm House and Doggetts, of no more than **minor** significance.

12.8.3 The residual additive impact from combined dust and particulate emissions during the HPC construction phase would also be rated as **minor**, following the implementation of the measures outlined in the **AQMP**.

12.8.4 All residual air quality impacts have, therefore, been determined to be of an acceptable level of significance.

12.9 Summary of Impacts

12.9.1 **Table 12.28** presents a summary of the air quality impacts. Note that the assessment methodology applied to the assessment of impacts from dust and PM_{10} is different to the methodology applied to the assessment of other air quality impacts. Therefore, the descriptors given in the “magnitude/risk and method of determination”, “impact descriptor”, “impact significance” and “residual impact significance” columns for dust/PM_{10} impacts and other air quality impacts are not directly comparable. section 12.4 provides full details of the assessment methodologies employed for the air quality impact assessment.

Table 12.28: Summary of Impacts

Receptor	Potential Impact	Magnitude/Risk and Method of Determination	Description	Impact Descriptor	Significance	Proposed Mitigation/ Best Practices	Residual Impact
Construction Phase							
Local air quality and amenity at assessed human receptor location - Doggetts	Fugitive dust and PM_{10} originating from construction activities during Scenario A (2011/2012 Preliminary Site Preparation Works)	High Risk (qualitative fugitive dust and PM_{10} assessment)	• Local • Adverse • Direct • Possible • Medium-term • Temporary	N/A	Minor	Measures to minimise fugitive dust and PM_{10} generation are provided in the **AQMP**, and follow best practice guidance and measures typically employed on construction sites	Minor
Local air quality and amenity at assessed human receptor locations – all locations excluding Doggetts	Fugitive dust and PM_{10} originating from construction activities during Scenario A (2011/2012 Preliminary Site Preparation Works)	High Risk (qualitative fugitive dust and PM_{10} assessment)	• Local • Adverse • Direct • Unlikely • Medium-term • Temporary	N/A	Negligible	Measures to minimise fugitive dust and PM_{10} generation are provided in the **AQMP**, and follow best practice guidance and measures typically employed on construction sites	Negligible
Local air quality and amenity at assessed human receptor locations – Bishops Farm House and Doggetts	Fugitive dust and PM_{10} originating from construction activities during Scenario B (2013)	High Risk (qualitative fugitive dust and PM_{10} assessment)	• Local • Adverse • Direct • Likely • Medium-term • Temporary	N/A	Major	Measures to minimise fugitive dust and PM_{10} generation are provided in the **AQMP**, and follow best practice guidance and measures typically employed on construction sites	Minor
Local air quality and amenity at assessed human receptor location - Shurton Village	Fugitive dust and PM_{10} originating from construction activities during Scenario B (2013)	High Risk (qualitative fugitive dust and PM_{10} assessment)	• Local • Adverse • Direct • Possible • Medium-term • Temporary	N/A	Minor	Measures to minimise fugitive dust and PM_{10} generation are provided in the **AQMP**, and follow best practice guidance and measures typically employed on construction sites	Minor

Receptor	Potential Impact	Magnitude/Risk and Method of Determination	Description	Impact Descriptor	Significance	Proposed Mitigation/ Best Practices	Residual Impact
Local air quality and amenity at assessed human receptor locations – all locations excluding Bishops Farm House, Doggetts and Shurton Village	Fugitive dust and PM_{10} originating from construction activities during Scenario B (2013)	High Risk (qualitative fugitive dust and PM_{10} assessment)	• Local • Adverse • Direct • Unlikely • Medium-term • Temporary	N/A	Negligible	Measures to minimise fugitive dust and PM_{10} generation are provided in the **AQMP**, and follow best practice guidance and measures typically employed on construction sites	Negligible
Local air quality and amenity at assessed human receptor location - Doggetts	Fugitive dust and PM_{10} originating from construction activities during Scenario C (Late 2014)	High Risk (qualitative fugitive dust and PM_{10} assessment)	• Local • Adverse • Direct • Possible • Medium-term • Temporary	N/A	Minor	Measures to minimise fugitive dust and PM_{10} generation are provided in the **AQMP**, and follow best practice guidance and measures typically employed on construction sites	Minor
Local air quality and amenity at assessed human receptor locations – all locations excluding Doggetts	Fugitive dust and PM_{10} originating from construction activities during Scenario C (Late 2014)	High Risk (qualitative fugitive dust and PM_{10} assessment)	• Local • Adverse • Direct • Unlikely • Long-term • Temporary	N/A	Negligible	Measures to minimise fugitive dust and PM_{10} generation are provided in the **AQMP**, and follow best practice guidance and measures typically employed on construction sites	Negligible
Local air quality and amenity at assessed ecological receptors - 'Bridgwater Bay SSSI/NNR', 'Severn Estuary SPA/SAC/ Ramsar' and 'Hinkley CWS'	Fugitive dust and PM_{10} originating from construction activities	High Risk (qualitative dust and PM_{10} assessment)	• Local • Adverse • Direct • Possible • Long-term • Temporary	N/A	Major	Measures to minimise dust and PM_{10} generation are provided in the **AQMP**, and follow best practice guidance and measures typically employed on construction sites	Minor

Receptor	Potential Impact	Magnitude/Risk and Method of Determination	Description	Impact Descriptor	Significance	Proposed Mitigation/ Best Practices	Residual Impact
Local air quality at assessed human and ecological receptors	Exhaust emissions (PM_{10}, NO_x and SO_2) from on-site plant and machinery (NRMM) associated with construction activities	Imperceptible/Small Magnitude (qualitative on-site exhaust emissions assessment)	• Local • Adverse • Direct • Unlikely • Long-term • Temporary	Negligible	Not significant	Measures to minimise dust and PM_{10} generation are provided in the **AQMP**, and follow best practice guidance and measures typically employed on construction sites, construction traffic management, phasing of construction activities, and use of plant and vehicles compliant with current emissions standards.	Not significant
Local air quality at all assessed human receptor locations	Long-term NO_2, PM_{10} and $PM_{2.5}$, and short-term NO_2, PM_{10}, and SO_2 emissions associated with marine vessels during the construction of HPC	Imperceptible Magnitude (quantitative assessment of marine vessel emissions)	• Local • Adverse • Direct • Likely • Long-term • Temporary	Negligible	Not significant	Measures to minimise dust and PM_{10} generation are provided in the **AQMP**, and follow best practice guidance.	Not significant
Local air quality at all assessed transient human receptor locations	Short-term NO_2 and SO_2 emissions associated with marine vessels during the construction of HPC	Small Magnitude (quantitative assessment of marine vessel emissions)	• Local • Adverse • Direct • Likely • Long-term • Temporary	Negligible	Not significant	Measures to minimise dust and PM_{10} generation are provided in the **AQMP**, and follow best practice guidance.	Not significant

NOT PROTECTIVELY MARKED

Receptor	Potential Impact	Magnitude/Risk and Method of Determination	Description	Impact Descriptor	Significance	Proposed Mitigation/ Best Practices	Residual Impact

Local air quality at assessed human receptor locations in the Williton model	Short-term PM_{10} emissions associated with traffic during HPC construction (peak workforce on-site) (2016)	Small Magnitude (quantitative assessment of vehicular emissions)	• Local • Adverse • Direct • Likely • Long-term • Temporary	Negligible	Not significant	The **Freight Management Strategy** and the **Framework Travel Plan** would be implemented to minimise vehicular movements, and use of vehicles compliant with emissions standards	Not significant
Local air quality at assessed human receptor locations in the Williton model	Short-term NO_2 emissions, and long-term PM_{10} and $PM_{2.5}$ emissions associated with traffic during HPC construction (peak workforce on-site) (2016)	Imperceptible Magnitude (quantitative assessment of vehicular emissions)	• Local • Adverse • Direct • Likely • Long-term • Temporary	Negligible	Not significant	The **Freight Management Strategy** and the **Framework Travel Plan** would be implemented to minimise vehicular movements, and use of vehicles compliant with emissions standards	Not significant
Local air quality at assessed ecological receptor locations	Long-term NO_x emissions associated with traffic during HPC construction (peak workforce on-site) (2016)	Large Magnitude (quantitative assessment of vehicular emissions)	• Local • Adverse • Direct • Likely • Long-term • Temporary	Slight Adverse/Substantial Adverse	Impact significance presented in **Volume 2, Chapter 20**	The **Freight Management Strategy** and the **Framework Travel Plan** would be implemented to minimise vehicular movements, and use of vehicles compliant with emissions standards	Impact significance presented in **Volume 2, Chapter 20**
Local air quality at assessed ecological receptor locations	Short-term NO_x emissions associated with traffic during HPC construction (peak workforce on-site) (2016)	Large Magnitude (quantitative assessment of vehicular emissions)	• Local • Adverse • Direct • Likely • Long-term • Temporary	Slight Adverse/Substantial Adverse	Impact significance presented in **Volume 2, Chapter 20**	The **Freight Management Strategy** and the **Framework Travel Plan** would be implemented to minimise vehicular movements, and use of vehicles compliant with emissions standards	Impact significance presented in **Volume 2, Chapter 20**

Receptor	Potential Impact	Magnitude/Risk and Method of Determination	Description	Impact Descriptor	Significance	Proposed Mitigation/ Best Practices	Residual Impact
Operational Phase							
Local air quality at assessed human receptor locations	Long-term PM_{10}, $PM_{2.5}$ and H_2CO and short-term PM_{10}, H_2CO and CO emissions from HPC commissioning (commissioning scenario)	Imperceptible Magnitude (quantitative assessment of operational emissions)	• Local • Adverse • Direct • Likely • Short-term • Temporary	Negligible	Not significant	Measures will include regular inspection, maintenance and optimisation of the backup diesel generator combustion, and the use of fuels with a <0.1% sulphur content.	Not significant
Local air quality at assessed human receptor locations	Long-term NO_2 and short-term SO_2 emissions from HPC commissioning (commissioning scenario)	Small Magnitude (quantitative assessment of operational emissions)	• Local • Adverse • Direct • Likely • Short-term • Temporary	Negligible	Not significant	Measures will include regular inspection, maintenance and optimisation of the backup diesel generator combustion, and the use of fuels with a <0.1% sulphur content.	Not significant
Local air quality at assessed human receptor locations	Short-term NO_2 emissions from HPC commissioning (commissioning scenario)	Medium Magnitude (quantitative assessment of operational emissions)	• Local • Adverse • Direct • Likely • Short-term • Temporary	Negligible	Not significant	Measures will include regular inspection, maintenance and optimisation of the backup diesel generator combustion, and the use of fuels with a <0.1% sulphur content.	Not significant
Local air quality at assessed transient human receptor locations	Short-term CO emissions from HPC commissioning (commissioning scenario)	Imperceptible Magnitude (quantitative assessment of operational emissions)	• Local • Adverse • Direct • Likely • Short-term • Temporary	Negligible	Not significant	Measures will include regular inspection, maintenance and optimisation of the backup diesel generator combustion, and the use of fuels with a <0.1% sulphur content.	Not significant

Receptor	Potential Impact	Magnitude/Risk and Method of Determination	Description	Impact Descriptor	Significance	Proposed Mitigation/ Best Practices	Residual Impact
Local air quality at assessed transient human receptor locations	Short-term H_2CO emissions from HPC commissioning (commissioning scenario)	Small Magnitude (quantitative assessment of operational emissions)	• Local • Adverse • Direct • Likely • Short-term • Temporary	Negligible	Not significant	Measures will include regular inspection, maintenance and optimisation of the backup diesel generator combustion, and the use of fuels with a <0.1% sulphur content.	Not significant
Local air quality at assessed transient human receptor locations	Short-term SO_2 (1-hour) emissions from HPC commissioning (commissioning scenario)	Medium Magnitude (quantitative assessment of operational emissions)	• Local • Adverse • Direct • Likely • Short-term • Temporary	Negligible	Not significant	Measures will include regular inspection, maintenance and optimisation of the backup diesel generator combustion, and the use of fuels with a <0.1% sulphur content.	Not significant
Local air quality at assessed transient human receptor locations	Short-term NO_2 and SO_2 (15-minute) emissions from HPC commissioning (commissioning scenario)	Large Magnitude (quantitative assessment of operational emissions)	• Local • Adverse • Direct • Likely • Short-term • Temporary	Slight Adverse	Not significant	Measures will include regular inspection, maintenance and optimisation of the backup diesel generator combustion, and the use of fuels with a <0.1% sulphur content.	Not significant
Local air quality at assessed statutory designated ecological receptor locations	Long-term SO_2 emissions from HPC commissioning (commissioning scenario)	Small Magnitude (quantitative assessment of operational emissions)	• Local • Adverse • Direct • Likely • Short-term • Temporary	Negligible	Impact significance presented in **Volume 2, Chapter 20**	Measures will include regular inspection, maintenance and optimisation of the backup diesel generator combustion, and the use of fuels with a <0.1% sulphur content.	Residual impact significance presented in **Volume 2, Chapter 20**

Receptor	Potential Impact	Magnitude/Risk and Method of Determination	Description	Impact Descriptor	Significance	Proposed Mitigation/ Best Practices	Residual Impact
Local air quality at assessed statutory designated ecological receptor locations	Long-term NO_x emissions from HPC commissioning (commissioning scenario)	Large Magnitude (quantitative assessment of operational emissions)	• Local • Adverse • Direct • Likely • Short-term • Temporary	Slight Adverse	Impact significance presented in **Volume 2, Chapter 20**	Measures will include regular inspection, maintenance and optimisation of the backup diesel generator combustion, and the use of fuels with a <0.1% sulphur content.	Residual impact significance presented in **Volume 2, Chapter 20**
Local air quality at assessed statutory designated ecological receptor locations	Short-term NO_x emissions from HPC commissioning (commissioning scenario)	Large Magnitude (quantitative assessment of operational emissions)	• Local • Adverse • Direct • Likely • Short-term • Temporary	Substantial Adverse	Impact significance presented in **Volume 2, Chapter 20**	Measures will include regular inspection, maintenance and optimisation of the backup diesel generator combustion, and the use of fuels with a <0.1% sulphur content.	Residual impact significance presented in **Volume 2, Chapter 20**
Local air quality at assessed non-statutory designated ecological receptor locations	Long-term SO_2 emissions from HPC commissioning (commissioning scenario)	Medium Magnitude (quantitative assessment of operational emissions)	• Local • Adverse • Direct • Likely • Short-term • Temporary	Negligible	Impact significance presented in **Volume 2, Chapter 20**	Measures will include regular inspection, maintenance and optimisation of the backup diesel generator combustion, and the use of fuels with a <0.1% sulphur content.	Residual impact significance presented in **Volume 2, Chapter 20**
Local air quality at assessed non-statutory designated ecological receptor locations	Long-term NO_x emissions from HPC commissioning (commissioning scenario)	Large Magnitude (quantitative assessment of operational emissions)	• Local • Adverse • Direct • Likely • Short-term • Temporary	Moderate Adverse	Impact significance presented in **Volume 2, Chapter 20**	Measures will include regular inspection, maintenance and optimisation of the backup diesel generator combustion, and the use of fuels with a <0.1% sulphur content.	Residual impact significance presented in **Volume 2, Chapter 20**

Receptor	Potential Impact	Magnitude/Risk and Method of Determination	Description	Impact Descriptor	Significance	Proposed Mitigation/ Best Practices	Residual Impact
Local air quality at assessed non-statutory designated ecological receptor locations	Short-term NO_x emissions from HPC commissioning (commissioning scenario)	Large Magnitude (quantitative assessment of operational emissions)	• Local • Adverse • Direct • Likely • Short-term • Temporary	Substantial Adverse	Impact significance presented in **Volume 2, Chapter 20**	Measures will include regular inspection, maintenance and optimisation of the backup diesel generator combustion, and the use of fuels with a <0.1% sulphur content.	Residual impact significance presented in **Volume 2, Chapter 20**
Local air quality at assessed human receptor locations	Long-term NO_2, PM_{10} $PM_{2.5}$, H_2CO and NH_3, and short-term PM_{10}, CO and H_2CO emissions from HPC operation (routine test scenario)	Imperceptible Magnitude (quantitative assessment of operational emissions)	• Local • Adverse • Direct • Likely • Long-term • Permanent	Negligible	Not significant	Measures will include regular inspection, maintenance and optimisation of the diesel generator combustion, and the use of fuels with a <0.1% sulphur content. During the routine testing of the backup diesel generators, where possible, effort would be made to ensure that their testing occurred during meteorological conditions that are conducive to good pollutant dilution	Not significant

13. SOILS AND LAND USE

13.1 Introduction

13.1.1 This chapter provides an assessment of the potential impacts on soils, land use and agriculture during the construction, operation and the restoration of land after the construction of the Hinkley Point C (HPC) development. Where required, mitigation measures are identified to prevent, reduce and, where possible off-set any potential adverse impacts that are identified to be of significance.

13.1.2 A glossary of terminology is provided in **Volume 1** of this ES**.**

13.2 Scope and Objectives of Assessment

13.2.1 The scope of the assessment has been determined through the formal EIA scoping process with the Infrastructure Planning Commission (IPC) and the pre-application consultations. The assessment of impacts on soil, land use and agriculture arising from the proposed development has been undertaken adopting the methodologies described in **Volume 1**, **Chapter 7** and Section 13.4 below. The existing baseline conditions, against which the likely environmental effects of the HPC development are assessed, have been determined through soil and land condition surveys which are described in Section 13.5; this section also identifies existing and future receptors. The study area for this assessment, as described in Section 13.4 and illustrated in **Figure 13.1**, comprises the site itself and land within a distance of 100m from the perimeter of the site. The extent of this zone of land adjacent to the site boundary is based on consideration of the scale of development earthworks, the nature of site boundaries, and the type of adjacent land uses. Also included within the study area are any contiguous agricultural drainage ditches and field drainage systems.

13.2.2 Section 13.6 assesses the potential impacts on soils, land use and agricultural receptors.

13.2.3 Appropriate mitigation measures aimed at preventing, reducing or off-setting any potential adverse impacts that are identified to be of significance are presented in Section 13.7. Section 13.8 provides details on residual impacts following implementation of the mitigation measures. The assessment of cumulative impacts of the HPC development with other elements of the HPC C Project and other planned or reasonably foreseeable projects is provided in **Volume 11** of the ES.

13.2.4 The objectives of the assessment are to:

- identify all soils, land use and agricultural receptors within and adjacent to the development site that may be affected by the works;
- characterise the baseline environmental conditions for soils, land use and agriculture within the site;
- assess the impacts of the construction works, and their removal and site restoration, on soil, land use and agriculture;

- recommend mitigation measures, if determined necessary, to reduce the impacts on soil, land use and agriculture; and
- assess the residual impacts of the construction, operation and post operational phases of the proposed development on soil, land use and agriculture.

13.2.5 Due to the fact that many environmental aspects are interrelated there may be a degree of overlap with other chapters in this volume, particularly that concerning geology and land contamination (**Volume 2**, **Chapter 14**), surface water (**Volume 2**, **Chapter 16**) and terrestrial ecology and ornithology (**Volume 2**, **Chapter 20**). Where impacts are identified in the assessment that are addressed in greater depth in relation to other environmental aspects (e.g. potential impacts from contaminated land, alterations to drainage regimes and impacts on biodiversity) these impacts will be considered in this chapter but only in so far as how they may result from changes to soils, land use and agriculture.

13.2.6 Issues relating to changes to farming practices, such as severance of farm holdings or routes, interruption to the operation of current land management units and other effects on farm practices with the potential to affect farm economics, are addressed in **Chapter 9** of this volume.

13.3 Legislation, Policy and Guidance

13.3.1 This section identifies and describes legislation, policy and guidance relevant to the assessment of impacts on soil, land use and agriculture associated with the construction, operational and landscape restoration phases of the proposed development.

13.3.2 The Overarching National Policy Statement (NPS) for Energy (EN-1) when combined with the NPS for Nuclear Power Generation (EN-6) provides the primary basis for decisions by the IPC on applications for nuclear power generation developments that fall within the scope of the NPSs.

13.3.3 Notwithstanding this, the IPC may consider other matters that are both important and relevant to its decision-making. This could include Planning Policy Statements (PPSs), Planning Policy Guidance Notes (PPGs), regional and local policy documents, although, if there is a conflict between these and the NPS, the NPS prevails for the purposes of IPC decision making.

13.3.4 Further, the Planning Act 2008 provides that the IPC must, in making its decision on an application, have regard to any Local Impact Report (LIR) prepared by relevant local authorities. It is anticipated that the LIRs will rely in part on PPSs, PPGs, regional and local policy to provide a context for their assessment. On this basis, regard has been given to these documents (where relevant to the technical assessment) since they are likely to inform the LIRs prepared by the relevant local authorities.

a) International Legislation

13.3.5 The European Commission adopted a Thematic Strategy for Soil Protection (COM (2006) 231)) on September 22, 2006, in order to provide a comprehensive common framework for protecting soils across the European Union (Ref. 13.1). The EU Strategy includes: a proposed legislative framework for the protection and sustainable use of soil, in order to integrate soil protection into national and EU policies; measures to improve knowledge of soil functions; and measures to increase public awareness. It seeks to establish rational land use planning practices at all levels of government to ensure the sustainability of soils, consistent with a "precautionary principle" used by the EU in establishing environmental policy.

13.3.6 The Thematic Strategy includes proposals for an EU Soil Framework Directive requiring Member States to adopt a systematic approach to identifying and combating soil degradation and integrate soil protection into other policies, especially with respect to agriculture, regional development, transport, and research. This proposed Directive has not yet been passed by the European Parliament and Council of Ministers.

b) UK Legislation

i. The Wildlife and Countryside Act 1981 (as amended) (Ref. 13.2)

13.3.7 This Act restricts the introduction of certain animals and plants, for example Japanese knotweed *(Reynoutria japonica)* and giant hogweed *(Heracleum mantegazzianum)* are listed under Schedule 9 and are subject to Section 14 of the Act which makes it an offence to plant, or cause these species to grow in the wild.

ii. The Environmental Protection Act 1990 (Ref. 13.3)

13.3.8 Japanese knotweed and giant hogweed are regarded as a controlled waste under the Environmental Protection Act 1990 and must be disposed at licensed sites or by burning on site.

iii. The Environmental Stewardship (England) Regulations 2005 and the Countryside Stewardship Regulations 2000 (Ref. 13.4)

13.3.9 Countryside Stewardship was introduced as a pilot scheme in 1991 to encourage farmers and land managers to enhance and conserve English landscapes, their wildlife and history. That scheme is now closed to new applicants and has been superseded by the Environmental Stewardship Scheme, which was introduced by the 2005 Regulations. The Environmental Stewardship Scheme is an agri-environment scheme that provides funding to farmers and other land managers in England who deliver effective environmental management on their land.

13.3.10 The Environmental Stewardship Scheme comprises three elements: Entry Level Stewardship (ELS), Organic Entry Level Stewardship (OELS) and Higher Level Stewardship (HLS). The ELS Scheme is open to all farmers and land managers who want to deliver a basic level of environmental management. ELS, requires a basic level of environmental management and participants can choose from a wide range of management options. These cover all farming types and include matters such as hedgerow management, stone wall maintenance, low nutrient input grassland, buffer strips, and arable options. OELS is the strand of ELS that applies to organic farming and is open to farmers who manage all or part of their land organically. HLS aims to deliver significant environmental benefits in high priority situations and areas. It involves more complex environmental management and the preparation of a Farm Environmental Plan.

iv. Commons Act 2006 (Ref. 13.5)

13.3.11 Section 38 of the Commons Act 2006 prohibits the carrying out of certain works on land which is registered as common land, including works that prevent or impede access to or over that land and works for resurfacing that land, without the consent of the Secretary of State. Landowners can apply to the Secretary of State under Section 16 of the Commons Act 2006 for the common to be de-registered. In such cases, the landowner must offer an alternative piece of land to the commoners. An area of common land lies adjacent to the site.

c) National Planning Policy

i. Planning Policy Statement 7 'Sustainable Development in Rural Areas' (PPS7) (2004) (Ref. 13.6)

13.3.12 PPS7 sets out the Government policy on development within the countryside. It sets out policy for promoting development in rural areas whilst conserving the character of the countryside and protecting the best and most versatile agricultural land, defined as Grade 1, 2 and 3a of the Agricultural Land Classification (ALC) (paragraph 28).

13.3.13 Paragraph 28 of PPS7 states:

> *"The presence of best and most versatile agricultural land (defined as land in grades 1, 2 and 3a of the ALC), should be taken into account alongside other sustainability considerations (e.g. biodiversity... including soil quality) when determining planning applications."*

13.3.14 The loss of best and most versatile land (BMVL) is no longer considered to be of *national* importance (as was set out in the precursor to PPS7, Planning Policy Guidance 7 (PPG7)). The loss of BMVL is now a matter to be taken into account at a local level rather than at a national level (via the former Ministry of Agriculture Fisheries and Food (MAFF)) as was the case previously.

ii. Consultation Paper on a New Planning Policy Statement: Planning for a Natural and Healthy Environment (March 2010) (Ref. 13.7)

13.3.15 In March 2010, the Government published a Consultation Paper for a new Planning Policy Statement: Planning for a Natural and Healthy Environment. The document was published in March 2010 and the consultation period expired in June 2010.

13.3.16 At the outset, the document makes clear that in its final form, the PPS will replace PPS7 in so far as it relates to, amongst others, soils and agricultural quality (paragraphs 28 and 29).

13.3.17 With specific reference to agricultural land, proposed Policy NE8.9 states:

> *"When considering applications involving significant areas of agricultural land, local planning authorities should take account of the presence of best and most versatile agricultural land (defined as land in grades 1, 2 and 3a of the ALC) alongside other sustainability considerations. Where significant development of agricultural land is unavoidable, local planning authorities should seek to develop areas of poorer quality land (grades 3b, 4 and 5) in preference to that of a higher quality, except where this would be inconsistent with other sustainability considerations. Little weight should be*

given to the loss of agricultural land in grades 3b, 4 and 5, except in areas (such as uplands) where particular agricultural practices may themselves contribute to the quality and character of the environment or the local economy."

iii. Safeguarding our Soils. A Strategy for England (2009) (Ref. 13.8)

13.3.18 The first Soils Action Plan for England 2004-2006 was published by the Department for Environment, Food and Rural Affairs (Defra) in 2004. This has been developed into "Safeguarding Our Soils. A Strategy for England" which was published by Defra in 2009 (Ref. 13.8). The strategy outlines the Government's approach to safeguarding England's soils for the long-term. It provides a guide to future policy development across a range of areas and sets out the practical steps that need to be taken to prevent further degradation of soils, to enhance, restore and ensure soils resilience, and to improve understanding of the threats to soil and best practice in responding to those threats.

13.3.19 The purpose of the strategy is to support the Thematic Strategy and to achieve Defra's goals of a thriving farming sector and a sustainable, healthy food supply. A supplementary purpose is to increase the value placed on soil and to set a framework for safeguarding the amount and quality of England's soil resource for the future.

iv. Design Manual for Roads and Bridges (DMRB) – Volume 11 Section 3, Part II: Geology and Soils (1993) (Ref. 13.9)

13.3.20 The Highway Agency's 'Design Manual for Roads and Bridges' Volume 11 Section 3 Part II, published in 1993, provided very basic guidance on impact assessment on geology and soils. Since then understanding of the role and importance of soil in the environment has improved greatly and key policy and guidance has been published, including the European Commission's Thematic Strategy for Soil Protection and soil strategies in both England and Scotland.

13.3.21 DMRB Volume 11, Section 3 Part II states:

'...where soils are excavated and stored for reuse the level of damage and deterioration in soil quality will depend upon the types of earthmoving machinery employed, method of handling, weather conditions and provision of storage. In addition to any deterioration in soil quality there may be a loss of valuable seed banks, for example, when soil is taken from a site of nature conservation interest...'.

13.3.22 DMRB Volume 11, Section 3 Part II is currently being updated.

d) Regional Planning Policy

13.3.23 The Government's revocation of regional strategies was quashed in the High Court on 10 November 2010. However, on that same date the Government reiterated in a letter to Chief Planners its intention to revoke regional strategies through the Localism Bill. This letter was also challenged but, on 7 February 2011, the High Court held that the Government's advice to local authorities that the proposed revocation of regional strategies was to be regarded as a material consideration in their planning development control decisions should stand. The decision of the High

Court was upheld by the Court of Appeal on 27 May 2011. Therefore, the regional strategies remain in place but in the case of development control decisions it is for planning decision makers to decide on the weight to attach to the strategies (see **Volume 1, Chapter 4** for a full summary of the position regarding the status of regional planning policy).

i. Regional Planning Guidance 10 for the South West 2001 – 2016 (RPG10) (2001) (Ref. 13.10)

13.3.24 RPG10 sets out the broad development strategy for the period to 2016 and beyond. With specific reference to soil and agricultural land use, paragraph 3.76 explains that land quality is considered in various ways including its value for agricultural production. It goes on to refer to the ALC system which is used to grade agricultural land which forms the basis for classifying best and most versatile agricultural land. It also refers to further guidance contained within PPG7, which as explained above, has now been replaced by more recent guidance contained within PPS7.

13.3.25 Policy SS20 relates to Rural Land (including Urban Fringe) Uses. It states that local authorities and other agencies, in their plans, policies and proposals should, amongst others:

> *"Conserve the region's best and most versatile agricultural land and associated soils in accordance with the guidance in PPG7; land of a poorer quality should be used in preference to higher quality except where other sustainability criteria suggest otherwise.*
>
> *Development Plans should set out policies on the level of protection from development, to be afforded to the best and most versatile agricultural land and associated soils in relation to other considerations such as landscape character, biodiversity and sustainability."*

ii. Draft Revised Regional Spatial Strategy (RSS) for the South West Incorporating the Secretary of State's Proposed Changes for Public Consultation (July 2008) (Ref. 13.11)

13.3.26 Chapter 7 deals with Enhancing Distinctive Environments and Cultural Life. Paragraph 7.13.17 relates to Best and Most Versatile (BMV) land and states:

> *"Best and Most Versatile (BMV) land needs to be taken into account alongside other sustainability considerations when deciding between sites. The BMV agricultural soils need to be protected from development because these are the most flexible in terms of the range of crops or produce that can be grown, and therefore the most valuable for current and future agricultural production. Given changes to Common Agricultural Policies (CAP) and the fact that this is driving businesses to become more economically efficient, it is important that the best land is protected, for possible future agricultural needs. In some circumstances, BMV land may be subject to development pressures, particularly in areas identified for growth in Sections 3 and 4."*

iii. Somerset and Exmoor National Park Joint Structure Plan Review 1991-2011 (2000) (Ref. 13.12) (Policies 'saved' from 27 September 2007)

13.3.27 The Somerset and Exmoor National Park Joint Structure Plan was adopted in 2000 with saved policies from 27 September 2007. All policies have been saved with the exception of Policy 53 which is unrelated to soil, land use and agriculture. The Plan provides a strategic base for all land use planning within the plan area for the period up to 2011.

13.3.28 Policy 7 relates to Agricultural Land and states:

> *“Subject to the overall aims of the strategy, provision should not be made for permanent development, excluding forestry and agriculture, involving the best and most versatile agricultural land (Grades 1, 2 and 3a) unless there are no alternative sites on lower quality agricultural land and there is an overriding need for development in that location. Where land in Grades 1, 2 and 3a does need to be developed and there is a choice between different grades, development should be diverted towards land of the lowest grade.”*

13.3.29 The supporting text to Policy 7 explains that better quality agricultural land can be significantly more productive than other land, whatever the intensity of production, and that its protection from development is a material consideration in assessing proposals. Paragraph 4.31 goes on to state:

> *“Where provision has to be made for permanent development, it should preferably involve land falling into one of the lower grades of the ALC (Grades 3b, 4 or 5), as defined by the Ministry of Agriculture, Fisheries and Food. It must be recognised that this lower quality land can often be the richest in terms of biodiversity, archaeology and its contribution to the quality of the landscape. Where land in Grades 1, 2 and 3a has to be developed, the development should be directed towards land of the lowest grade. Provision for permanent development involving the best and most versatile agricultural land should only be made where there are no alternative sites available on lower quality land and where there is an overriding need for development in that location. Consideration may also need to be given to the ecological value and nature conservation issues, particularly habitat and species protection, which affects lower grade agricultural land. This could inhibit or restrict its development potential and thus increase pressure for development on agricultural land of a higher grade. Where this occurs, a balance will need to be sought between the requirements of this policy and those of Policy 1: Nature Conservation, where the lower grade agricultural land has had a nature conservation designation applied to it.”*

a) Local Planning Policy

i. West Somerset Local Plan (2006-2009) (2004) (Ref. 13.13)

13.3.30 The West Somerset Local Plan forms part of the development plan for West Somerset. The Local Plan was adopted in April 2006 (with relevant policies ‘saved’ from 17 April 2009). The site lies outside of the defined Development Boundary.

13.3.31 The following saved policy is considered to be potentially relevant:

13.3.32 The Local Plan was adopted in April 2006 with relevant policies saved from 17 April 2009. Policy A/2 (Best and Most Versatile Agricultural Land) states:

> *"The best and most versatile agricultural land (grades 1, 2 and 3a) will be protected from development. Planning permission for development affecting such land will only be granted exceptionally if there is an overriding need for the development and either*
>
> *i) sufficient land of a lower grade (grades 3b, 4 and 5) is unavailable; or*
>
> *ii) available lower grade land has an environmental value recognised by a statutory or non-statutory wildlife, historic or archaeological designation and outweighs the agricultural considerations.*
>
> *If best and most versatile land needs to be developed and there is a choice between sites in different grades, land of the lowest grade available should be used."*

ii. West Somerset District Local Development Framework (LDF) Core Strategy (Options Paper) (January 2010) (Ref. 13.14)

13.3.33 The Core Strategy is at a preliminary stage of preparation and the Options Paper does not include any specific policies relating to soils and land use impacts.

iii. Supplementary Planning Guidance

13.3.34 Sedgemoor District Council and West Somerset Council have jointly prepared draft supplementary planning guidance in relation to the HPC Project. Public consultation on the Consultation Draft version of the Hinkley Point C Project Supplementary Planning Document (the draft HPC SPD) commenced on 1 March 2011 and concluded on 12 April 2011. EDF Energy has submitted representations which object to the draft HPC SPD. See **Volume 1**, **Chapter 4** for a full summary of the position regarding the status of the draft HPC SPD.

13.3.35 The draft HPC SPD provides advice in relation to the HPC proposals, expanding upon the policy context for the proposals. This includes associated development.

13.3.36 Box 19 in the draft HPC SPD sets out the approach to masterplanning and design of the Main Site, and sets out a number of requirements that the County Council and Councils will expect of the HPC project promoter. In relation to soils and land use, Box 19 states that the HPC project promoter is expected to, where development is temporary, to reinstate and/ or create, amongst other things, agricultural land (Page 36-37).

13.3.37 Further planning policy context is provided in the Legislative Planning Policy Context chapter (**Volume 1**, **Chapter 4**) and the Introduction chapter (**Volume 2**, **Chapter 1**).

13.4 Methodology

13.4.1 The assessment and all supporting soil and land use surveys, have been conducted in accordance with standard guidance for England and Wales and detailed below.

This chapter addresses the likely impacts of the development during the construction, operation and final restoration of the development site..

a) Study Area

13.4.2 The geographical extent of the study area for this assessment includes:

- all land within the HPC development site boundary, comprising three areas of land defined as: Built Development Area West (BDAW); Built Development Area East (BDAE) and Southern Construction Phase Area (SCPA) (see **Figure 13.1**);
- surrounding land within 100m of the site, as, given the scale of proposed earthworks, surrounding land use and boundary hedgerows and trees, it is within this radius that any potential impacts associated with soil erosion or dust emissions on soil, land use or agricultural receptors are considered likely to occur; and
- the agricultural drainage ditches and field drainage systems which are contiguous with drainage ditches and drainage systems within the site.

13.4.3 The study area described above is illustrated in **Figure 13.1**.

b) Baseline Assessment

13.4.4 Characterisation of the existing soil, land use and agricultural conditions was identified through:

- desk-based studies of web-based resources, published maps and documents;
- field surveys of soils and land use commissioned specifically for this assessment; and
- consultation with appropriate statutory and non-statutory bodies (particularly Natural England, Defra and the site freeholder).

13.4.5 Desk-based studies and field surveys were carried out in accordance with best practice and standard methodologies where applicable.

i. Desk based Review

13.4.6 The following published literature and web-based information was reviewed to characterise baseline environmental conditions:

- Soil types (information obtained from the Soil Survey of England and Wales (1984) Soils and Their Use in South West England. SSEW Bulletin No 14, and associated Map Sheet No 5 (Ref. 13.15).
- Preliminary Agricultural Land Classification (ALC) grades (information obtained from mapping provided on the Multi-Agency Geographic Information for the Countryside (MAGIC) website (www.magic.defra.gov.uk) and accessed on 8 November 2010 (Ref. 13.16).
- Agri-environment schemes (Environmental Stewardship Agreements and Countryside Stewardship schemes). Information obtained from mapping provided on the MAGIC website (www.magic.defra.gov.uk) and accessed on 8 November 2010 (Ref. 13.16).

- Relevant previously published environmental studies and assessments, including West Hinkley Wind Farm ES (2006) (Ref. 13.17), Hinkley A ES (2000) (Ref. 13.18) and Hinkley Point C ES (1987) (Ref. 13.19).
- Defra – June National Census of Agriculture and Horticulture (Land Use and Livestock on Agricultural Holdings at 1 June 2010), England – Final Results. Website accessed on 6 June 2011 at: http://www.defra.gov.uk/statistics/foodfarm/landuselivestock/junesurvey/junesurveyresults. (Ref. 13.20).
- Defra – Regional Results and Datasets 2007-2009. Website accessed 6 June 2011 at: http://www.defra.gov.uk/statistics/foodfarm/landuselivestock/junesurvey/junesurveyresults. (Ref. 13.21).

ii. Field Soil Survey

13.4.7 A preliminary soil survey of the site was conducted in 1988 and further field surveys, commissioned specifically for this assessment, were carried out in 2009 and 2010 (**Appendix 13A**) to provide data on soil type, distribution and ALC across the site. A series of observations were made across the site using both hand dug soil pits, supplemented by hand augering to examine and record soil profiles. At each observation point, the following characteristics (Ref. 13.22) were assessed for each soil horizon up to a maximum depth of 120cm or to the depths of any impenetrable layer:

- soil texture;
- significant stoniness;
- colour (including local grey and mottle colours);
- consistency;
- structural condition;
- free carbonate; and
- depth.

13.4.8 Soil Wetness Class (WC) (definitions of soil wetness, described in **Appendix 13B**) was inferred from the matrix colour, presence or absence of, and depth to, greyish and ochreous gley mottling and/or poorly permeable subsoil layers at least 15cm thick. Soil droughtiness was investigated by the calculation of moisture balance equations. Crop-adjusted Available Profile Water (AP) is estimated from texture, stoniness and depth, and then compared to a calculated moisture deficit (MD) for the standard crops: wheat and potatoes. Eight soil samples were subject to laboratory determination of particle size analysis, pH and total soil nutrients: phosphorous, potassium and magnesium. The samples, collected in 2009 and 2010 (**Appendix 13A**) were also analysed for organic matter content using the Walkley-Black method. Four soil samples were taken north of Holford Stream valley within the BDAW and four samples were taken south of Holford Stream valley within the SCPA.

iii. Agricultural Land Classification (ALC)

13.4.9 The ALC system classifies land into five main categories (Grade 1 to 5) and two subdivisions within Grade 3, i.e. Classes 3a, and 3b. Grade 1 is the highest quality land with no or very limited restriction to agricultural use. Grade 5 is of least agricultural value, usually only of limited grazing use. Under PPS 7, Grades 1, 2 and 3a are defined as the 'best and most versatile' land (BMVL) and are a national resource to be protected. A description of ALC Grades is provided in **Appendix 13C**. To establish the ALC, results from the soil surveys were combined with data on the topography and climate of the area (taken from the Meteorological Office (1989) (Ref. 13.23)) to provide an assessment of the land classification. Land grade is determined by a combination of soils types, drainage status, climatic factors and topography (land gradient) according to the methodology provided in MAFF (1988) (Ref. 13.24).

iv. Land Use Crops and Stock

13.4.10 Land use, including agricultural cropping and stocking, was determined from published data (**Appendix 13A**), photographic evidence and site observations made during initial walkover surveys in 2008 and in subsequent site investigation work in 2009 and 2010.

c) Consultation

13.4.11 There has been ongoing consultation throughout the EIA process (further information may be found in the **Consultation Report).** Consultation on soils, land use and agriculture formed part of the overall consultation process, particularly as there is an interaction with (a) terrestrial ecology, (b) surface water and (c) landscape issues. The following organisations were contacted for available information on soil types, soil and land quality and agricultural land use:

- Department for Environment, Food and Rural Affairs (Defra) (animal burial pits);
- Natural England (agri-environment schemes and ALC data);
- West Somerset Council;
- Somerset County Council; and
- The site freeholder.

13.4.12 Meetings were held with the site freeholder throughout the assessment process to discuss specific aspects of the development such as existing soil conditions and proposed site restoration.

13.4.13 Responses from consultees during both formal and informal consultation have been taken into account.

d) Assessment Methodology

13.4.14 **Volume 1**, **Chapter 7** of this ES describes the assessment methodology for this EIA. Whilst soil loss and land degradation can have adverse consequences, for example in relation to agricultural production, water quality and biodiversity, there are no established or published methods for assessing the impacts of development upon soils, land use and agricultural receptors.

13.4.15 The criteria used in this assessment are the ALC Grades as set out by the former Ministry of Agriculture, Fisheries and Food (MAFF) (1988) (Ref. 13.24), together with professional knowledge of soil conditions and quality.

13.4.16 The assessment follows the approach set out in **Volume 1**, **Chapter 7** involving three key steps: impact assessment (including assessment of cumulative impacts), provision of mitigation measures and assessment of residual impacts. The magnitude of impacts and receptor value/sensitivity are assessed using criteria that are specific for soil, land use and agriculture (set out below); then the significance of impacts is assessed using the impact assessment matrix (IAM) provided in **Volume 1**, **Chapter 7** which combines the magnitude of impact and receptor value/sensitivity assessments specific for soil, land use and agriculture as well as professional judgment. Impacts rated as negligible or minor are considered to be acceptable without requiring further mitigation.

13.4.17 This assessment addresses likely impacts of the HPC development during the construction, operational and landscaping phases. The assessment of impacts on land use and soils relates to the following:

- the soil types and agricultural land classification likely to be affected by the HPC development, evaluated via field soil surveys carried out especially for this assessment;
- the type of farms and farming practices present, including any agri-environment schemes, based on information from field observation and the MAGIC website; and
- the possible presence of crop/soil/animal diseases or noxious weeds, using information on the presence/absence of animal burial pits obtained from the Animal Health Division of Defra and from data on invasive weeds collected during ecological field survey work (see **Volume 2**, **Chapter 20**).

13.4.18 The assessment considers the potential for impacts during commissioning tests, start-up and continued operation of HPC. Based on professional judgement of both engineers and environmental scientists. The operational phase of the development is not expected to have any further impact on land use and soils beyond those caused during construction.

i. Receptor Value and Sensitivity

13.4.19 All of the soil, land and agricultural receptors that have the potential to be impacted by the HPC development have been assigned a level of importance in accordance with the quality of the soil and the ALC grade of land. These are described in **Table 13.1**. Where a receptor can reasonably be placed within more than one value and sensitivity rating, professional judgement has been used to determine which rating would be applicable.

Table 13.1: Guidelines for the Assessment of Value and/or Sensitivity

Value and Sensitivity	Guidelines
High	**ALC and agricultural productivity:** Grade 1 agricultural land and specialised agricultural activity such as horticultural crops, soft fruit, etc. Irrigated agriculture. Higher level Agri-environment scheme lands. **Soil Conditions:** **(i) Value for Agriculture** Soils with low or no wetness limitation affecting workability (wetness class I or II), where drought is not also a limitation. **(ii) Vulnerability to damage** Soils with a high susceptibility to structural damage and soil erosion throughout the year, including heavy textured, poorly structured soils,
Medium	**ALC and agricultural productivity:** Grades 2 and 3a agricultural land. Annual horticultural cropping (non-irrigated). Entry level Agri-environment scheme lands. **Soil Conditions:** **(i) Value for Agriculture** Soils with low wetness limitation affecting workability (wetness class II), where drought is not a limitation. **(ii) Vulnerability to damage** Soils with some seasonal susceptibility to structural damage and soil erosion.
Low	**ALC and agricultural productivity:** Grades 3b and lower agricultural land. Arable or grassland areas. **Soil Conditions:** **(i) Value for Agriculture** Soils with moderate wetness limitation affecting workability (wetness class III or IV); or **(ii) Vulnerability to damage** Soils with medium to course textures and some resistance to soil structural damage for most of the year.
Very low	**ALC and agricultural productivity:** Agricultural land of Grades 4 or 5 Arable or grassland areas. **Soil Conditions:** **(i) Value for Agriculture** Soils with high wetness limitation affecting workability (wetness class V or VI); Soils in which droughtiness is a limitation to crop growth; or **(ii) Vulnerability to damage** Coarse textured and stony soils with little potential for soil structural damage.

13.4.20 In addition to the receptors described in **Table 13.1**, agricultural stock (off-site grazing animals) and pets have been identified as possible receptors in relation to the very specific issue of potential (unrecorded) animal burial pits within the site and the risk of exposure to disease from these pits, if present and accidentally disturbed.

This is also addressed in **Volume 10, Chapter 12**, with regard to human receptors. Stock animals and pets are considered to be high value/sensitivity receptors.

ii. Impact Magnitude

13.4.21 The magnitude of impact is based on the consequences that the HPC development would have upon soils, land and agricultural receptors, and has been considered in terms of high, medium, low and very low (see **Table 13.2**). Where an impact could reasonably be placed within more than one magnitude rating, professional judgement has been used to determine which rating would be applicable. There is no published guidance on thresholds for assessing what scale of loss is a significant loss of agricultural land, but the presence of best and most versatile land (BMVL) is a factor in the consideration of the sustainability of development proposals as set out in Paragraph 28 of PPS7. PPS7 promotes the creation of a sustainable countryside framework, and places the loss of best and most versatile land within the context of meeting wider sustainability objectives. The assessment of magnitude of change provided in **Table 13.2** is based on (a) generic guidelines used throughout this EIA (**Volume 1, Chapter 7,**), (b) timescales of permanent or temporary (both long and short term) loss of agricultural land and (c) land area loss thresholds previously adopted by MAFF (Ref. 13.24) when considering proposals involving more than 20ha of BMVL, and also land not classified as BMVL, but still given over to agricultural use.

Table 13.2: Guidelines for the Assessment of Magnitude

Magnitude	Guidelines
High	Permanent or long–term (over ten years) loss of over 50ha of BMVL, or entire regional resource of BMVL (ALC Grades 1, 2, 3a). (50ha being the size of a moderate to large sized land holding according to Defra statistics for Somerset)*. Existing land use would not be able to continue.
Medium	Medium to long term (5-10 years) loss of 20 – 50ha of BMVL, or large proportion of local resource of BMVL. (20-50ha being the size of a moderate sized land holding according to Defra statistics for Somerset)*. Existing land use would be able to continue but noticeable changes (such as a measureable loss of yield, additional land management or increased fertilising would occur.
Low	Temporary (<5 years) loss of 10 – 20ha of BMVL, or large proportion of local resource of BMVL. (10-20ha being the size of a small to moderate sized land holding according to Defra statistics for Somerset)*. Existing land use would be able to continue but noticeable changes (such as the need for additional land management, increased fertilising, or reduced cropping choices) would occur.
Very low	Temporary short term (<two years) loss of <10ha of BMVL. 0-10ha being the size of a small sized land holding according to Defra statistics for Somerset)*. Short term adverse changes to the value of the receptor but recovery is expected in the short term (0 – one years), and there would be no impact on its integrity. No material change to existing land use. Loss or degradation of area of BMVL but a small proportion of local resources. No impact on overall agricultural land availability for wider area/region.

**Data taken from the Defra website (Ref. 13.21) at: http://www.defra.gov.uk/statistics/foodfarm/landuselivestock/junesurvey/junesurveyresults/*

13.4.22 Potential impacts have been considered in terms of whether they are: direct or indirect, permanent or temporary, adverse (negative) or beneficial (positive) and cumulative.

iii. Significance of Impacts

13.4.23 The significance of the impact is judged on the relationship of the magnitude of impact to the assessed receptor sensitivity and/or importance. The method for determining significance of the impacts, without mitigation, is outlined in **Volume 1, Chapter 7**. The assessment of impact significance is the most important step in the EIA process, since it is this which is used to determine whether mitigation is required and also to determine whether mitigation measures have reduced the impact to an acceptable residual level. Only impacts assessed as being moderate or major significance are considered to require mitigation.

iv. Residual impacts

13.4.24 The final step in the EIA process is the assessment of the residual impacts after the implementation (where necessary) of the proposed mitigation measures. In this assessment, residual impacts assessed as minor or negligible are considered to be acceptable for the project.

v. Cumulative Effects

13.4.25 **Volume 1, Chapter 7** of this ES refers to the methodology used to assess cumulative impacts. Additive and interactive effects between impacts generated within the site boundary and study area are considered within this chapter. Cumulative impacts that consider activities and impacts generated at distance from the site and study area are considered in **Volume 11** of this ES; this assesses the project-wide cumulative impacts and in-combination impacts with other proposed or reasonably foreseeable projects.

e) Limitations, Assumptions and Uncertainties

13.4.26 Agricultural Land Classification (ALC) and soil survey fieldwork was carried out across the site, but did not include the BDAE as it is classified as ‘made ground’ rather than agricultural land. However, there is grazing in the BDAE, including the area of made ground, as part of the management of the Hinkley Point County Wildlife Site (CWS) (see **Volume 2, Chapter 20**, Terrestrial Ecology and Ornithology) and hence this area of land is included in this assessment.

13.4.27 ALC and soil survey fieldwork was carried out on land within the HPC development site boundary. ALC grades and soil types within the study area but beyond the site boundary (**Figure 13.1**) have been interpreted from the following published sources:

- Soil Survey of England and Wales (1984) Soils and Their Use in South West England. SSEW Bulletin No 14, and associated Map Sheet No 5 (Ref. 13.15);
- Findlay, D.C. 1965. The Soils of the Mendip District of Somerset (Sheets 279 and 280). Memoir of the Soil Survey of Great Britain, Harpenden, and Map Sheet entitled: ‘Soil Survey of England and Wales, Weston-super-Mare, Sheet 279’. (Ref. 13.25) ;
- Groundsure Environmental Data Report 2008 (Ref. 13.26) ; and

- MAGIC (Multi-Agency Geographic Information for the Countryside) website (www.magic.defra.gov.uk)) (Ref. 13.16).

13.4.28 Defra has no records of animal burial pits within the site; however, this does not eliminate the possibility that unrecorded pits may be present.

13.5 Baseline Environmental Characteristics

a) Introduction

13.5.1 This section presents the baseline environmental characteristics for the site and the rest of the study area with specific reference to soil, land use and agriculture.

b) Study Area Description

13.5.2 **Figure 13.1** illustrates the study area which includes the HPC development site, comprising the three land parcels described in Section 13.4. Collectively, the three parcels of land are referred to hereafter as the development site. The areas of 11 off-site highway improvements schemes have also been considered in this assessment, but these are not included in Figure 13.1.

13.5.3 The development site comprises land required for the permanent HPC development, and also land required during the construction phase, to accommodate contractor compounds; the on-site accommodation campus; access and haulage roads, and storage areas for excavated materials.

13.5.4 The development site is generally open rolling countryside, primarily in agricultural use (mixed pasture and arable) with some areas of woodland/scrub. The site is bisected by Holford Stream (which flows from west to east) and its associated shallow valley.

13.5.5 Land immediately adjacent to and within 100m of the site is also primarily in agricultural use, comprising a mosaic of pasture, arable land and small tracts of woodland. Two small areas of Common Land adjacent to the site's eastern boundary, small areas of Shurton village to the south of the site, a short section of the C182 road and a small section of Hinkley Point A (HPA) to the north-east are also included within the study area.

13.5.6 The proximity of the site to Sites of Special Scientific Interest (SSSI), National Nature Reserve (NNR), Special Protection Area (SPA), Special Area for Conservation (SAC), a Ramsar Site and a locally designated County Wildlife Site (CWS) highlights the ecological interest and value of the area, to which soils and land use may have some relationship (see **Chapter 20**).

c) Soil Types

i. Soil Parent Materials

13.5.7 The development site lies in an area of weathered Blue Lias formation deposits comprising mudstones and limestones of Jurassic Age. These rocks are overlain by previously deposited fill material (in the BDAE) and the weathered products of in-situ rocks and transported materials. Transported materials include "head deposits" formed by the mass movements of soils down slope and periglacial disturbance, both of which result from the effect of freezing and thawing of the ground during the

Quaternary Ice Age. Other soil parent materials include marine estuarine deposits and fluvial glacial sands. The underlying geology of the site is described in detail in **Volume 2**, **Chapter 14**.

ii. Description of Soil Types

13.5.8 The more generalised distribution of soil types (Soil Survey of England and Wales, 1984) (Ref. 13.15) indicates that the majority of the study area consists of soils of the Evesham Association which are described as being slowly permeable, calcareous clayey brown earths.

13.5.9 Findlay (1965) (Ref 13.25), the primary source of information used in this section, provides more detailed descriptions and distributions of soils and maps them at the Soil Series level, compared to the more generalised Soil Association level and mapping which is provided in the SSEW Bulletin 14 (Ref. 13.15). The following soil descriptions are taken from both scales of mapping.

13.5.10 Five soil types (identified as Soil Series) are mapped for the area within the site (Refs. 13.15 and 13.25):

- **Evesham Series:** Slowly permeable, calcareous, clayey soils with some loamy soils over clayey subsoils. Some seasonal waterlogging. Developed over Jurassic and Cretaceous clay. Wetness Class II or III.
- **Worcester Series:** Reddish, slowly permeable clayey soils developed over Permo-Triassic Mercia mudstone and clay shales (previously described as Keuper Marls by Findlay (1965) (Ref 13.25). Some seasonal gleying. Wetness Class III.
- **Butleigh Series**: Calcareous, slowly permeable clay soils developed over fine-textured alluvium and colluvium derived from calcareous Lower Lias shales and clays. Wetness Class IV.
- **Compton Series**: Reddish brown clay soil developed over fine-textured alluvium and colluvium derived from Permo-Triassic Mercia mudstone and clay shales (described as Keuper Marls by Findlay 1965 (Ref 13.25)). Wetness Class IV.
- **Huntworth Series:** Reddish brown, freely draining and non-calcareous, sandy loam and sandy clay loam soils developed over Permo-Triassic Mercia mudstone and clay shales (described as Keuper Marls by Findlay 1965 (Ref 13.25)). Wetness Class I or II.

iii. Geographical Distribution of Soil Types

13.5.11 The geographical distribution of these soil types is provided in **Figure 13.2**.

13.5.12 The northern and southern parts of the site, including the BDAW and the BDAE, and the major part of the SCPA consist of soils of the Evesham Soil Series. These slowly permeable soils require artificial drainage to enable cultivation. They can be subject to seasonal waterlogging which can result in poaching if livestock are grazed on the land in early spring or late autumn.

13.5.13 The Holford Stream valley in the SCPA consists of alluvial and colluvial gley soils of the Butleigh Series. In this location, these soils have high groundwater levels, seasonal flood risk and, in places, are intensely gleyed. Cultivation is dependent on artificial drainage and soil damage and poaching can result from use of equipment or stocking in early spring or late autumn when the soil is wet.

13.5.14 There are two small areas of silty clay Worcester Soil Series in the western part of the site, picking out an area of easily weathered and eroded Mercia mudstones.

13.5.15 The northern part of Bum Brook valley in the southern part of the SCPA consists of re-deposited soils of the Compton Series which, in this location, are seasonally waterlogged and, in places, intensely gleyed, requiring artificial drainage to enable cultivation.

13.5.16 Huntworth soils only occur in the location of the proposed emergency access route, on the southern boundary of the site at Shurton village.

iv. Drainage, Moisture Status and Soil Wetness Class

13.5.17 The drainage and wetness characteristics of soils and their ability to retain soil moisture during the growing season are described in terms of their Wetness Class (WC). The range of WC grades used in soils in England and Wales is provided in **Appendix 13B**.

13.5.18 The Soil Survey of England and Wales describe soils of the Evesham 2 Association (described as Evesham Soil Series, Ref. 13.15) as:

> *"…slowly permeable soils which are subject to winter waterlogging. Evesham 2 soils are well-structured and respond well to artificial drainage (Wetness Class II or III). Evesham 2 topsoils are difficult to cultivate and can only be satisfactorily worked over a narrow range of moisture content, so timeliness is essential. There are few opportunities for landwork in spring, especially in wet years, and the soils are best cultivated in autumn and sown to winter crops. Winter cereals, particularly wheat, and grass are the main crops. Some oilseed rape is grown as a break crop. Grass yields are limited by droughtiness and the appreciable poaching risk reduces the safe grazing period".*

13.5.19 Described as WC II-III (see **Appendix 13B**), Evesham 2 soils can be waterlogged within 70cm of the surface for up to 180 days per year, thus limiting the season of soil workability.

13.5.20 The Soil Survey of England and Wales (Ref 13.15) describes the Worcester Association (described as the Worcester Soil Series by Findlay (1965) (Ref. 13.25)) as:

> *"….normally seasonally waterlogged (Wetness Class III) but on slopes greater than 11 degrees this may be reduced to Wetness Class II. The slowly permeable subsoils cause rapid winter run-off. These soils benefit from drainage measures but they compact easily so careful management is needed if improvements in soil water regime are to be maintained"*

13.5.21 The Butleigh Soil Series is described by Findlay (1965) (Ref. 13.25) as:

"…found on flat or gently sloping land which receives drainage waters from adjoining high ground in winter but is rarely flooded. The internal drainage is slow and a zone of permanent waterlogging may be present below 3ft (approx 900mm)".

13.5.22 The Compton Soil Series is described by Findlay (1965) (Ref. 13.25) as:

> *"…occurring at the foot of steep slopes where downwash rests on estuarine clay or peat at depths normally in excess of 3ft (approximately 900mm). Where peat is shallower, surface mineral soils become more intensely gleyed."*

13.5.23 The soil Wetness Classification was not in use at the time of the Findlay study (1965) (Ref. 13.25). However, the location of both Butleigh and Compton soils in the lower parts of the Holford Stream and Bum Brook valleys contributes to their seasonal wetness and both soils are gleyed in subsoil and often in topsoil horizons. Both poorly drained soils would be classified as WC IV under today's classification (**Appendix 13B**).

13.5.24 The Huntworth Soil Series is described by Findlay (1965) (Ref. 13.25) as:

> *"Gravelly deposits...are found around the Quantock Hills....and on the north side of the hills between Holford and Stogursey. (Huntworth soils are)...coarse textured…free draining and do not appear to include much clay.... The gravels occur on flat land or on gentler slopes at various levels between 50 and 150ft".*

13.5.25 As explained above, soil Wetness Classification was not in use at the time of the Findlay study (1965) (Ref. 13.25). The coarse texture and freely draining status of Huntworth soils would cause them to be classified as WC I or II under today's classification (**Appendix 13B**).

13.5.26 The four main soil types within the site (Evesham, Worcester, Butleigh and Compton) are vulnerable to damage at certain times of the year because they are workable only within a narrow moisture range, hence winter working under wet conditions is likely to cause compaction and damage to soil structure.

13.5.27 The distribution of Compton soils within the site is limited to the very southern boundary of the site. These soils north of Shurton have been identified as being 'teart' soils, showing higher than normal concentrations of molybdenum, which can lead to toxicity in cattle grazed on herbage from these soils. No local evidence of this effect has been identified for the study area.

d) Land Use

i. Land Use Description

13.5.28 The site is generally open countryside, primarily in agricultural use (mixed pasture and arable) with some areas of woodland. Adjacent land use to the south and west is also primarily agricultural. Within the BDAW, there are three derelict barn buildings, indicating the past agricultural use of the site (see **Volume 2**, **Chapter 23** on Historic Environment).

13.5.29 The topography of the site consists of undulating countryside, terminating at the Severn Estuary to the north at a natural cliff line which descends to a shingle beach and wave cut platform. The topography is generally typical of that in the wider locality, with the exception of the BDAE where the topography has been influenced by a number of man-made features.

13.5.30 Within the BDAW and the SCPA are a series of east-west trending ridges and depressions. The lowest terrain within the site is formed by an east-west trending linear depression which runs along the boundary between the BDAW and the SCPA. The base of the depression is occupied by Holford Stream. North of this depression, within the BDAW, the ground rises sharply towards the Green Lane ridge. An agricultural access track runs east to west along the ridge.

13.5.31 There are a series of agricultural drainage ditches present within the site, running along field boundaries. Two surface drainage features are present within and adjacent to the BDAW. Site reconnaissance has confirmed these water features serve as agricultural drainage ditches which are typically ephemeral (i.e. seasonally dry) (see **Chapter 16 of this volume**). Agricultural land drains are in place at two locations within the BDAW. The indicative locations of these are shown in **Appendix 13D**. There is no connectivity shown between these drains and land drains within adjoining agricultural land outside the site.

ii. Historic Land Use

13.5.32 A review of historical maps and plans included within the reports described above has identified that both the BDAW and SCPA have remained as greenfield agricultural land since the earliest available map was published in 1886. Agricultural buildings are likely to have been associated with this historic agricultural land use. Within the SCPA, Corner Farm was on-site from 1886 but had been removed by 2002. Within the BDAW, Benhole Farm was located on the north-western corner of this land parcel until around 1976 when it was demolished to leave a single remnant outbuilding which is still present on-site, along with two other derelict farm buildings.

13.5.33 The BDAE comprised greenfield, predominantly agricultural, land until 1957 - 1958 when sewage works, a hostel and a fabrication and construction area was constructed in the north eastern part of the area, during the construction of Hinkley Point A. Further development and changes of land use continued thereafter including construction of a small sewage works at the western boundary in 1968. Also, during the construction of the Hinkley Point B nuclear power station an accommodation/construction camp and fabrication area with associated electrical substations were developed on the southern section of the area, and surplus spoil from the construction was deposited in the centre of the area. A former licensed waste management facility (NDA temporary spoil storage area) was also present. Other non-agricultural land use included vehicle storage areas and the creation of a visitor's centre. As a result of these land use activities, this area is categorised as Non-Agricultural land. Infilled ponds potentially present within the BDAE and elsewhere across the site are discussed **Chapter 14 of this volume.**

13.5.34 The improved grassland areas within the BDAE area are grazed annually. Other areas are maintained in Good Agricultural and Environmental Condition (GAEC).

13.5.35 Land use surrounding the site has remained predominantly agricultural with the exception of the existing Hinkley Point Power Station Complex to the east.

e) Agricultural Land Classification (ALC)

13.5.36 In order to assess the impacts of the development on soils and land use, the baseline soil conditions and land use on and around the site have been assessed. The ALC was assessed through site survey (ALC Survey Reports by Reading Agricultural Consultants (RAC) Ltd. 2009 and 2010 (**Appendix 13A**).

13.5.37 The methodology for determining ALC, combines the results from the soil surveys (see **Appendix 13A**) with topographic data and long-term averaged climate data of the study area, obtained from the Meteorological Office (1989) (Ref. 13.23).

13.5.38 The 2010 ALC report (**Appendix 13A**) assesses both the potential of the land for agricultural use and its soil quality. In summary, most of the land forms an undulating plain with an overall fall to the north. There is a series of parallel east-west ridges with a south-facing scarp face forming the northern side of the Holford Stream valley. Soils in the northern part of the site have generally good drainage (wetness class WC I), with some areas of imperfect drainage (WC III) where there is underlying clay. Soils in the southern part of the site mainly lie on the valley interfluve and exhibit variable wetness characteristics ranging from moderately well to imperfectly drained (WC II-III). The valley bottom soils are affected by a high water table and act as a receiving site for local rainfall. These soils are poorly drained (WC IV). These WC findings differ from those described in the SSEW 1:250,000 mapping (Ref. 13.15) due to the much greater degree of detail provided by the ALC fieldwork.

13.5.39 Published broad scale mapping of agricultural land quality (ALC status), at a scale of 1:250,000, taken from the MAGIC website (Ref. 13.16), indicates the entire site and most of the surrounding land as being of Grade 3, but this is not subdivided into Grades 3a and 3b. This grade split is the divide between what Government policy defines as best and most versatile (Grades 1, 2 and 3a) and agricultural land of only moderate quality (Grade 3b). There is a small area of Grade 4 land to the south and east of the Hinkley Point B nuclear power station. Field survey results of ALC conditions (see **Appendix 13A**) indicate that the principal constraints to agriculture within the site are:

- seasonal soil wetness, from soil profile impermeability and the presence of heavy textured impermeable layers in soil profiles, exacerbated by the slightly longer than average field capacity period of 167 days in an average year, which combine to limit soil workability and the opportunity days for land works;
- superficial stoniness, often associated with shallow soil depth, which makes cultivation, seed-bed preparation and seed sowing difficult;
- locally steep gradient, often associated with an uneven land form in some fields and occasional rock outcrops, which hinder cultivation;
- cumulative wetness in the Holford Stream valley, which is a receiving site, causing prolonged wetness which seriously limits soil workability and the opportunity days for landworks; and
- exposure to strong winds, sometimes salt-laden, which may damage crops.

13.5.40 The distribution of surveyed ALC grades across the site is illustrated in **Figure 13.3**.

13.5.41 The range of arable cropping is considered to be restricted to autumn-sown cereal and oilseed rape crops, or grass. The steep south-facing scarp to the north of the

Holford Stream valley has gradients in excess of 7°, which limit the land quality to Subgrade 3b, and gradients in excess of 11°, but less than 18°, limit the land quality to Grade 4. The downgrading is based on the hazardous nature of operating agricultural equipment on steep slopes.

13.5.42 The areas occupied by the various ALC grades for the site are given in **Table 13.3** below (adapted from the RAC ALC Report 2010 (**Appendix 13A**)).

Table 13.3: Agricultural Land Classifications (ALC) for the Study Area

Grade	Description	Area (ha)	Area (% of agricultural land)
Subgrade 3a (Best and most versatile)	Good quality	19.8	14
Subgrade 3b	Moderate quality	102.6	73
Grade 4	Poor quality	18.8	13
Total Agricultural		141.2	100
Non-agricultural land		30.2	
Total Land		171.4	

Note: The total land excludes the foreshore over required for the construction of the seawall.

13.5.43 Approximately 73% of the surveyed land is classified as Moderate Quality Agricultural Land (ALC Subgrade 3b). 14% of the surveyed agricultural land on-site is ALC Subgrade 3a which falls within the category of BMVL (ALC Grades 1, 2, and 3a). This band of Subgrade 3a, good quality agricultural land, crosses the southern part of the BDAW. The remaining 13% is Poor Quality (ALC Grade 4) land.

13.5.44 In the wider context, **Figure 13.4** illustrates the distribution of ALC Grades across Somerset and **Table 13.4** provides approximate total areas of ALC Grades across Somerset, based on ALC data provided by Natural England from their Geographical Information System (GIS).

Table 13.4: Agricultural Land Classifications (ALC) for Somerset

ALC Grade	Approximate Area (ha)
Grade 1	9,342
Grade 2	33,365
Grade 3 (undifferentiated)	204,108
Grade 4	61,706
Grade 5	22,712
Non-Agricultural	6,572
Urban	6,653

f) Agricultural Activity and Crops

13.5.45 With the exception of the BDAE, historic and current land use within the site is primarily agricultural, comprising arable (including oil seed rape and wheat) or grazing use. Some areas of land are non-farmed woodland and scrub habitat. There are small areas of non-farmed grassland alongside ditches and along cliff tops. Hedgerows and fences form field boundaries.

13.5.46 Incidental field observations made during 2008 noted fields within the site planted with oil seed rape and wheat, with smaller areas used for hay production and grazing. Plates which illustrate the agricultural activity taking place across the site are provided in **Appendix 13E**.

i. Built Development Area West (BDAW)

13.5.47 Approximately a fifth of the BDAW, amounting to approximately 15ha, consists of permanent pasture and the rest (approximately 60ha) is arable, primarily cereals (wheat). There are three fields in this part of the site which are permanent grassland, with only the two inland fields being used for cattle grazing (see **Plates 13.E1** and **13.E3**, **Appendix 13E**). Permanent grassland in the field along the cliff top (**Plate 13.E2, Appendix 13E**) appears to have been re-sown with a grass and wildflower seed mixture approximating National Vegetation Classification (NVC) MG6c.

13.5.48 Between Green Lane and the topographic ridge which runs west to east through this part of the site, the arable fields were planted with oil seed rape in 2008 and wheat in 2009. The western area of this part of the site was planted with wheat in 2008 (**Plates 13.E4** and **13.E7, Appendix 13E**) and oil seed rape in 2009.

ii. Built Development Area East (BDAE)

13.5.49 The whole of the BDAE, excluding the existing car park, is included in the Hinkley Point CWS and consists of areas of pasture for cattle grazing, mixed deciduous woodland and overgrown, scrubby hedgerows.

iii. Southern Construction Phase Area (SCPA)

13.5.50 As for the BDAW, the SCPA, south of Green Lane, consists of a mosaic of land used for oil seed rape or wheat (approximately 40ha), with permanent grassland (approximately 15ha) in Holford Stream valley which is used for cattle grazing and grass conservation (hay or silage) (**Plates 13.E5** and **13.E6, Appendix 13E**).

iv. Land Use in Somerset

13.5.51 This section provides a comparison of the areas of agricultural land uses within the site with the areas of those land uses recorded across the whole of Somerset in the 2010 Defra census which was carried out in June, 2010 (Ref. 13.21).

13.5.52 The total area of permanent pasture within the site is approximately 30ha. The total area of permanent pasture in Somerset recorded in the 2010 Defra census was 153, 593ha. Permanent pasture within the development constitutes approximately 0.02% of the pasture land in Somerset.

13.5.53 The total area of arable land (primarily wheat or oil seed rape) within the site is approximately 100ha. The total area of wheat in Somerset recorded in the 2010 Defra census was 24,277ha. If it is assumed that all of the arable land within the site is wheat, it would constitute approximately 0.4% of the area of wheat in Somerset.

13.5.54 The total area of oil seed rape in Somerset recorded in the 2010 Defra census was 4,340ha. If it is assumed that all of the arable land within the site is oil seed rape, it would constitute approximately 2.3% of the area of oil seed rape in Somerset.

13.5.55 The total area of farm woodlands within the site is approximately 3.6ha. The total area of farm woodland in Somerset recorded in the 2010 Defra census was 7,994ha. The area of farm woodland within the site constitutes approximately 0.05% of the area of farm woodlands in Somerset.

g) Agri-environment Schemes

13.5.56 Land that is part of an agri-environment scheme is shown indicatively in **Figure 13.5**.

i. Built Development Area West

13.5.57 The majority of the land in the northern part of the BDAW, (approximately 37ha) is part of a Countryside Stewardship Agreement with the site freeholder. There is also a strip of land, consisting of four fields, running along the northern part of the Holford Stream valley which belongs to an existing Countryside Stewardship Agreement (approximately 17.9ha). There is a total of approximately 54.9ha of land within Countryside Stewardship Agreements in the BDAW. These agreements would end prior to any construction activities commencing.

ii. Built Development Area East

13.5.58 Land immediately west of HPA nuclear power station in the BDAE (approximately 13.8ha) is the subject of an entry level Environmental Stewardship Agreement (see **Figure 13.5)**.

13.5.59 This agreement would end prior to any construction activities commencing.

iii. Southern Construction Phase Area

13.5.60 All but one of the fields within the SCPA, which includes the southern part of Holford Stream valley (approximately 61.5ha), is the subject of an entry level Environmental Stewardship Agreement. This will end prior to commencement of any construction activities on site.

iv. Agri-Environment Schemes in Somerset.

13.5.61 According to Natural England, the total number of agreements and the total area of land in Countryside Stewardship Schemes or entry level Environmental Stewardship Schemes in Somerset (as July 2011) is as follows:

- Total Entry Level Environmental Stewardship Schemes – 1,128 agreements, amounting to 88,406.8ha of land.
- Total Countryside Stewardship Scheme – 211 agreements, amounting to 6,113.2ha of land.

13.5.62 The amount of land under Entry Level Environmental Stewardship Agreements within the site is approximately 0.09% of the land under such agreements in the whole of Somerset. The amount of land under Countryside Stewardship Agreements within the site is approximately 0.9% of the land under these types of agreements in the whole of Somerset.

h) Agricultural Field Drainage

13.5.63 Two areas within the site are known to have existing agricultural field drainage systems. These areas are illustrated in **Appendix 13D**. The date and type of drainage is unknown.

i) Common Land

13.5.64 There are two small areas of Common Land which lie adjacent to the SCPA (**Table 13.6**). Both of these fields are permanent pasture land. Both are excluded from the HPC site. Since they are within 100m of the site boundary, and hence within the study area for this chapter, they are included in this impact assessment.

j) Invasive and Alien Weed Species

13.5.65 Invasive weed species such as Japanese knotweed *Reynoutria japonica* and ragwort *Senecio jacobea* are not currently considered to be widespread or invasive within the site. The baseline habitat surveys for the site (see **Volume 2, Chapter 20** on Terrestrial Ecology and Ornithology) have not recorded any presence of Japanese knotweed for example and, although these surveys were not primarily concerned with identifying invasive species, the presence of such species would be recorded if observed in the course of survey.

k) Animal Health and Animal Burial Pits

13.5.66 The Animal Health Division of Defra has been consulted about the potential presence of any animal burial pits relating to foot and mouth or other disease outbreaks (**Appendix 13F**). No such pits are recorded within the site.

13.5.67 It should be noted that burial pits were not registered before 1972, and individual animals could still be buried without registration up to the early 1990s. However the potential for unrecorded burials being present within the site is unlikely.

l) Summary

13.5.68 With the exception of the BDAE, historic and current land use within the site is primarily agricultural, comprising arable (including oil seed rape and wheat) or grazing use. Some areas of land are non-farmed grassland, hedgerow, and woodland and scrub habitat.

13.5.69 The majority of the surveyed agricultural land within the site (86%) is classified as Moderate or Poor quality land. A smaller proportion (14%) of the land is classified as BMVL (ALC Grad 3a). Much of the land within the site is under agri-environment schemes.

13.5.70 Approximately two thirds of the land within the site is part of an agri-environment scheme which will end prior to commencement of any construction activities on site.

13.5.71 The value/importance of the agricultural land within the site is considered to be low/medium overall, due to the presence of agri-environment schemes, but with the agricultural land classification being predominantly Subgrade 3b.

13.5.72 The land immediately adjacent to and within 100m of the site is also predominantly agricultural, but also includes two small areas of Common Land, a very small part of the Hinkley Point A power station site, a small section of the C182 road and a small part of Shurton village.

m) Receptor Value and Sensitivity

13.5.73 The baseline section has identified six types of soil, land use and agriculture receptors which could potentially be impacted by the proposed development. This section summarises the value and sensitivity of these site-specific receptors.

13.5.74 The approach to determining the sensitivity or value of the soil, land use and agricultural receptors is described in Section 13.3. The sensitivity or value of soil, land use and agricultural receptors at the site is summarised here (**Table 13.5**) in order that impact magnitude and, hence, significance can be assessed in a consistent way.

Table 13.5: Summary of Receptor Sensitivity/Value

Receptor	Sensitivity/Value	Comment
Agricultural potential (via ALC) On-site and off-site land	Medium	Determined in relation to the potential of the land, in terms of its ALC, for productive farming activity.
Soil quality (i.e. vulnerability to damage) On-site and off-site soils	High	Determined in relation to identified soil type and wetness class and vulnerability to being damaged through physical disturbance during ground preparation activities. Soils on site are considered to be vulnerable to structural damage as a result of trafficking, stripping, and handling.
Agricultural crops Off-site crops and grassland	Medium	Determined in relation to the ALC grade of the land and the crops/grassland generally present.
Agricultural stock, and pets (dogs etc.) Off-site grazing animals	High	Determined in relation to the sensitivity of stock and (potentially) household pets to diseases from disturbed animal burial pits.
Agricultural field drainage and drainage ditches	High	Determined in relation to the need to maintain continuity and efficacy of drainage systems in adjacent (off-site) agricultural fields.
Common Land off-site*	Medium	Determined in relation to the ALC grade of the land and the grassland present.

** Value of Common Land in relation to amenity and recreation is assessed in Chapter 25*

13.6 Assessment of Impacts

a) Introduction

i. Development Description Relevant for Soil Impact Assessment

13.6.1 A description of the HPC development is provided in **Volume 2**, **Chapter 2**.

13.6.2 Earthworks are required to prepare the site for the construction of the proposed new power station and will primarily involve the creation of a series of level platforms for the built development and for construction activities (e.g. materials, plant and equipment lay down and contractor's compounds). A description of the site preparation works is provided in **Appendix 1** of **Annex 2.**

13.6.3 It is estimated that during the site preparation earthworks, which are required principally to form the construction and development platform, approximately 2.3 million m^3 of material (un-bulked) will be excavated, of which (according to current best estimates), approximately 234,000m^3 would be topsoil and an equivalent volume of subsoil. Volumes of excavated soils are slightly higher than the estimates presented in the Site Preparation Works Planning Application and supporting Environmental Statement submitted to WSC in November 2010. The soil volumes in this document are the result of more detailed site knowledge of soil depths and conditions while soil volumes provided in the ES for the Site Preparation Works were based on calculations to inform the overall bulk earthworks appraisal of materials cut and fill balancing.

13.6.4 The topsoil and subsoil volumes provided above represent the scenario in which subsoil and topsoil would not be stripped from beneath materials stockpiling areas in the SCPA or under the western bund. Volumes for this scenario have beens calculated to ensure that sufficient space is reserved for appropriate stockpiling of topsoil and subsoil materials which are destined for re-use in landscape restoration post-construction. A significant area of land would be required in order to stockpile excavated soil and rock materials and land south of Green Lane (the Southern Construction Phase Area (SCPA)) has been proposed for this purpose. This enables the earthworks balance to be maintained within the HPC development site and ensure that materials are retained on site. As part of the site preparation works, it is proposed that Holford Stream would be culverted and suitable fill material used to infill Holford Stream valley. The resulting platform would be used for materials stockpiling as illustrated in the phasing plans presented in the **Construction Method Statement** (see **Annex 2**).

13.6.5 The HPC development site is approximately 175ha, of which approximately 105ha would be required only temporarily during the construction and hence would be restored to agriculture, woodland or ecological habitat post-construction. Topsoil and subsoil stripped and stockpiled during site preparation works will be re-used in the early and final landscaping, details of which are presented in the **Landscape Restoration Plan (see Chapter 2 of this volume)**.

13.6.6 Key considerations relating to soil stripping and stockpiling are listed below (see **Appendix 1** of **Annex 2** of the ES**):**

- an assessment of the thickness of soils has been derived from extensive site investigation works and for the calculation of topsoil volumes to be stripped and stockpiled, an average depth of 250mm has been assumed;
- topsoil will be stripped and stockpiled separately from subsoil;
- subsoil, where it is assessed as being suitable quality for reuse in restoration post-construction, will stripped and stockpiled separately from unsuitable 'overburden'; and
- soils beneath materials stockpiles in the SCPA will not be stripped. Post construction, when the final topographic surfaces are prepared for landscape restoration, a rigorous programme of soil restoration will be implemented which

will include deep ripping of areas where overburden or subsoil is compacted, prior to soil profile reconstruction.

13.6.7 This impact assessment acknowledges that given the large volumes of soil materials that will be moved and stored during the construction phase of the development, a robust plan is required to manage and conserve these soil resources in a suitable condition for re-use in restoration of the non-developed parts of the site post-construction.

13.6.8 Accordingly, a **Soil Management Plan** (**SMP**) (see **Annex 3**) has been prepared for the HPC development to address both standard good working practices and site-specific mitigation measures.

Soil Stripping and Stockpiling

13.6.9 Stockpiling of stripped soil will take place in the SCPA, south of Green Lane; some soil being used to create a bund along the western. Stockpiling will be restricted to land to the north of the southern main construction fenceline. The volumes of topsoil and subsoil to be stripped and stockpiled are described above and in **Appendix 1** of **Annex 2** of the ES. Earthworks associated with the site preparation works are projected to commence in early in 2012, with soil stripping being undertaken during the earthworks.

13.6.10 Topsoils and subsoils will be segregated during stripping and stockpiling into the following three soil resources:

- topsoil (comprising agricultural grassland and woodland);
- subsoil (comprising agricultural, grassland and woodland); and
- alluvium (wet grassland topsoil and subsoil mixed, where available).

13.6.11 Land in the BDAE will be used for construction of HPC. Accordingly there will be no land in this part of the site to restore after construction. Soils stripped from the BDAE will be stored separately in the stockpile area reserved for overburden.

13.6.12 The plan to select the above three soil types for segregated stripping and storage is designed to ensure that sufficient appropriately stored soils is available for agricultural land and ecological habitat creation during land restoration after the construction of the HPC development has ended.

13.6.13 Since larger areas of semi-natural and calcareous grasslands, and woodland habitats are proposed post construction (as detailed in the **Landscape Restoration Plan**) than currently exist on site, nutrient-poor subsoils will also be used to create future topsoils for calcareous and neutral grasslands.

ii. Introduction to Impact Assessment

13.6.14 This chapter assesses those aspects of the HPC development which have the potential to cause adverse impacts upon soil, land use and agricultural receptors within the study area, including:

- temporary and permanent loss of agricultural land;

- damage to in-situ soils (impacts on soil quality and profiles) due to trafficking, handling and storage associated with vegetation removal, soil stripping and landscape restoration activities;
- damage to soils and agricultural land within the study area which are adjacent to the site, but are off-site, due to soil erosion, surface runoff or dust deposition;
- loss of land currently managed under Countryside Stewardship Agreements and Environmental Stewardship schemes;
- disruption of agricultural field drainage systems; and
- spreading of noxious weeds and/or diseases.

13.6.15 Potential soil, land use and agricultural receptors have been identified in accordance **Table 13.5** as follows:

- medium quality agricultural land both on and off-site;
- good quality soil both on and off-site;
- agricultural crops and pasture off site;
- common land adjacent to the site;
- agri-environment schemes;
- agricultural field drainage systems both onsite and adjacent to the site; and
- health of agricultural stock and domestic pets.

13.6.16 The proposed works and potential soil, land use and agricultural impacts are discussed below. As a precautionary approach to the impact assessment, where more than one receptor value or sensitivity is considered relevant, the higher or more sensitive score is used in the significance assessment to ensure that the 'worst case' is assessed.

13.6.17 Impacts are assessed in relation to the construction, operational and landscape restoration phases of the HPC development, identified soil, land use and agricultural receptors and relevant legislation and policy as described in section 13.2. Hence, for example, impacts affecting BMVL (Grades 1, 2 and 3a), soil quality, agri-environment schemes and animal health are considered in line with PPS7, the West Somerset Local Plan (2006) 'saved' Policy A/2, the Environmental Stewardship (England) Regulations (2005) and the Countryside Stewardship (Amendment) Regulations (2000). The potential for construction activities, particularly the ground preparation works, to cause a breach of the Wildlife and Countryside Act 1981 (as amended) in relation to the spread of noxious and invasive weeds is also assessed.

13.6.18 The following impact assessment has been undertaken assuming legislative compliance and the adoption of standard good working practices.

b) Off-site Highway Improvements

13.6.19 An assessment has been undertaken for all 11 proposed schemes in relation to soils and land use. None of the highway improvements would result in the loss of any agricultural land, however a number of the highway improvements have the potential for loss of a very small area of urban green space and urban trees. These are as follows:

- Wylds Road/The Drove: Two very small areas of green space with trees would be lost – one area of trees screening a warehouse and one screening a car park.
- Bristol Road/Wylds Road: It is possible that two very small areas of urban trees would be lost – one screening a car park and one screening a car park and series of warehouses.
- Huntworth Roundabout: A very small area of existing roadside verge with semi-mature trees would be lost as a result of proposed road widening. This amounts to an extremely small part of an existing block of roadside woodland.

13.6.20 The implications of these changes in land use are considered in terms of (a) ecology and (b) recreation and amenity in **Volume 2**, **Chapters 20** and **25** respectively.

13.6.21 As the highway improvements do not affect either agricultural land or agricultural soils, they are scoped out of further assessment in this chapter.

c) Construction Impacts

13.6.22 Activities during the construction phase with the potential to cause adverse impacts on soils and land use primarily occur during the early site preparation works and include: the vehicle and plant activities associated with removal of trees and hedgerows, and erection of perimeter fencing; and soil stripping and soil stockpiling. Other activities, during the construction phase include bulk earthworks, deeper excavations, construction of haul roads, site compounds, site access road and roundabouts, sea wall and main HPC construction; these will take place after vegetation clearance and topsoil stripping. Therefore, there would be no adverse impacts on soils and land use related to these activities in addition to those arising during the early site preparation works.

i. Temporary and Permanent Loss of Agricultural Land within the Site

13.6.23 Land take during construction will involve both permanent and temporary loss of agricultural land and changes in cropping and farming activity.

13.6.24 The majority of construction related land use impacts will involve direct land take and loss of agricultural land within the site. The majority of the changes to current land use and agricultural activity within the site arising as a result of construction are likely to be permanent or at least long-term over the lifetime of the facility, as a large proportion of the area will be occupied by the permanent HPC development. Some land take impact will be medium term during the construction period, with land required on a temporary basis to accommodate the construction activities and then restored post-construction. Of the total site area (approximately 175ha), 67.5ha of land will be permanently lost as a result of the development. Post-construction, approximately 105ha of land will be restored (as described in the **Landscape Restoration Plan**) to arable agricultural land, grassland, woodland and scrub, hedgerow and wetland habitats.

13.6.25 Vegetation clearance and ground preparation works will result in the loss of and changes to existing agricultural land use. The impact will be site-specific, adverse, largely long-term or permanent, and direct. The spatial extent is likely to cover all, or a significant proportion of, the site. The likelihood of this occurring is certain.

13.6.26 Soil (topsoil and subsoil) stripping and storage will cause a loss of soils and loss of land with potential for agricultural use. The stripping of topsoil directly affects some land areas defined as BMVL (Grade 3a) within the BDAW and is a material consideration of the sustainability of development proposals (paragraph 28 of PPS 7) (Ref. 13.6). This is in line with the Government's expectation that a "high level of protection" is to be afforded to all natural resources (guidance contained in PPS1 (2005) (Ref. 13.27) on sustainable development). The HPC development directly or indirectly affects 19.8ha of land defined as best and most versatile land (Grade 3a) (**Table 13.3**), based on ALC survey **Appendix 13A**). The 19.8ha of Grade 3a land equates to 14% of the total area of surveyed agricultural land affected within the site.

13.6.27 Of the 19.8ha of BMVL, only 9.7ha would be permanently lost as part of the footprint of HPC development. The remaining 10.1ha would be taken out of agricultural use temporarily during the construction phase and restored to agricultural land of the same ALC Grade post-construction.

13.6.28 ALC data made available from Natural England does not differentiate between Grades 3a and 3b, hence the total area of Grade 3a land across Somerset cannot be determined. However, from **Table 13.3** and **Table 13.4**, and **Figure 13.4**, it can be seen that the amount of Grade 3a and Grade 3b land directly impacted by the development, both temporarily and permanently (122.4ha), is an extremely small proportion of the overall available Grade 3 (undifferentiated) agricultural land in Somerset – that is as a worst-case less than 0.06% of Grade 3 land in Somerset. However, it should be noted that PPS7 promotes the creation of a sustainable countryside framework, and places less emphasis on the loss of BMVL than the preceding PPG7.

13.6.29 Using the criteria set out in Section 13.3, the agricultural land quality within the site is assessed as medium value/sensitivity due to its grade and extent (**Table 13.5**). The impact of direct land take and removal/storage of soils on agricultural land use and quality is certain to occur, and will be medium/long-term to permanent in duration. The magnitude of impact is assessed as low given the overall area of BMVL affected within the site, and as a proportion of Grade 3 (undifferentiated) land across Somerset as a whole (**Table 13.3** and **Table 13.4** and **Figure 13.4**).

13.6.30 Given that the sensitivity/importance of the receptor is medium, and the magnitude of change is low, the significance of unmitigated land take impact on agricultural soils within the site is assessed as **minor adverse**.

13.6.31 There will be no soil stripping or stockpiling of soil beyond the development site boundary, hence there will be no impact (direct off-site) on agricultural land quality.

ii. Damage to Soil Quality within the Site due to Vegetation Removal

13.6.32 Vehicle and plant trafficking associated with the removal of trees and hedgerows and the erection of perimeter fencing has the potential to damage topsoils through compaction and puddling/smearing if the activities take place when the soil is wet. The heavy clay soils and soil profiles within the site are considered to be a receptor of high sensitivity (**Table 13.5**) because their structure is particularly vulnerable to damage when the soils are wet. Since the vegetation clearance activities will take place around field boundaries, areas of woodland and the entire perimeter of the site, there is potential for soils and soil profiles across the site to be impacted. The impact will be adverse, direct and limited to areas within the site. The likelihood of the impact occurring is considered to be likely. Since trafficking in relation to vegetation clearance activities could occur across the whole site, the magnitude of the impact is assessed as being medium. The significance of the impact is therefore assessed as being **major adverse** without mitigation measures in place.

iii. Damage to Soil Quality and Profiles within the Site due to Soil Stripping

13.6.33 Soil stripping will impact upon soils and soil profiles which are, as indicated above, a receptor of high sensitivity (**Table 13.5**). The impact will arise from damage to soil structure, integrity and profiles during stripping and storage. Since the *in situ* soils are predominantly heavy clays with relatively poor structure, adverse impacts such as soil compaction, loss of soil structure and creation of impermeable soil conditions could occur as soils are excavated, handled and stored for later re-use. As described above, soils of the Evesham 2 Association are vulnerable to damage at certain times of the year because they are workable only within a narrow moisture range.

13.6.34 The impact on soil quality and soil profiles will be limited to land within the site and will be adverse and direct due to the scale of soil stripping, movement and storage that will be required. The spatial extent of the impact is likely to cover all, or a significant proportion of the BDAE and BDAW and will include much of the SCPA where stockpiling will take place. There will be no soil strip or stockpiling or other soil disturbance outside the site, and, hence, there will be no (direct off-site) impact from these activities on soil quality.

13.6.35 The impact on soil quality and soil profiles on site will be site specific, adverse and direct due to the scale of soil stripping, movement and length of storage time that will be required. The spatial extent of the impact is likely to cover all, or a significant proportion of, the site at various times during the construction phase, and will include parts of the SCPA where temporary stockpiling and potentially permanent placement of spoil will occur. These works will disturb soil profiles and, without suitable site specific mitigation, may adversely affect soil quality and its future value as both topsoil and subsoil for re-use. The impact would be both permanent (i.e. topsoil will be removed from areas of the site used for buildings, hardstanding and certain permanent works such as roads) and temporary (i.e. some topsoil will be replaced and re-used over time). The probability of this impact occurring is certain.

13.6.36 The magnitude of impact is assessed as medium given the extent of soils affected. The significance of impact is therefore assessed as **major adverse** without mitigation measures in place via a **SMP**, but this would be at a local geographic scale, i.e. the impact would be on soils within the development site itself.

13.6.37 There will be no vegetation removal, soil stripping or stockpiling or other soil disturbance outside the site, and hence there will be no off-site impacts on soil quality as a result of these ground preparation activities.

iv. Disturbance to Agricultural Crops and Grazed Grassland Off-site, including Common Land

13.6.38 All plants, trees, crops and other vegetation within areas which may be directly affected by the construction works will be removed during the early vegetation clearance activities. As a result there will not be any plants, trees, crops and other vegetation present on the areas directly impacted by the main construction phase.

However, plants, trees, crops and other vegetation will be retained where practicable within areas which are not directly affected by the construction activities.

13.6.39 Farming activity (including crops and other vegetation, and livestock) and Common Land beyond the boundaries of the site could potentially be indirectly affected by disturbance during ground preparation activities, which have the potential to cause dust generation/deposition during earthworks and soil erosion, surface run-off and sediment deposition. Dust can be generated from machinery movements on exposed, dry soils, soil stockpiles and excavation activities. If dust becomes airborne it could be transported and then deposited on nearby agricultural land and potentially taint or adversely affect stock pasture or crops. It should be noted that, due to the relatively short distance that dust will travel before it is deposited, this impact is only a risk to land immediately adjacent to active working locations within the site. These issues are discussed in greater detail in **Chapter 12** of this volume on Air Quality. Such impacts are considered to be unlikely and would be highly localised and restricted to agricultural land and Common Land immediately adjacent to construction areas. Any impacts would also be short-term and reversible.

13.6.40 The proposed site drainage works include the re-routing of existing surface drainage systems, installation of a temporary de-watering system and installation of a deep underground drainage system. Surface water from the working areas will be captured and discharged as part of the temporary drainage of the construction site. During the re-grading of land and bulk earthworks activities there is potential for localised changes to surface water runoff. Within the site, there will be no direct impact on soils and land use as a result of the drainage works, over and above that identified for vegetation and topsoil removal. Temporary construction phase drainage facilities will help to maintain soil contained in stockpiles in a viable condition for re-use.

13.6.41 Off-site farming activity (including crops and other vegetation, and livestock) and Common Land adjacent to the boundaries of the site could potentially be indirectly affected by localised changes to surface run-off (e.g. from terraced areas, haul roads and soils/materials stockpiles). Such impacts would be of very low magnitude and unlikely, since a temporary surface water drainage system, and a **Water Management Plan**, will be put in place (see **Chapter 16** of this volume on Surface Water). If any impact did occur, it would be highly localised and restricted to land immediately adjacent to working areas. These indirect impacts would also be short term and reversible. The value/sensitivity of the receptor (trees, crops and stock off-site) is considered to be a localised receptor of medium sensitivity and hence impact significance is assessed as being **minor adverse** in relation to land off-site adjacent to the site.

v. Disturbance to Adjoining Land from Invasive and Noxious Weed Species

13.6.42 The areas of bare ground created during construction works provide opportunities for colonisation by a variety of plant species, including potentially noxious and invasive weeds. If left uncontrolled, these could potentially spread beyond the site onto adjacent land areas, and cause an offence under the Wildlife and Countryside Act 1981 (Ref. 13.2) (see Section 13.3). It is both a legal requirement and standard construction good practice to implement prevention and control measures to avoid the establishment and spread of invasive and noxious weed species and hence these measures would be implemented as a matter of course. Accordingly, the likelihood of such an impact is unlikely, and due to the pattern of weed dispersal, would affect only very small area of land in close proximity to the site. Such an impact is readily reversible and short-term.

13.6.43 As a result, the potential magnitude of impact of weed colonisation of or spread from stripped areas is assessed as low, affecting the ALC or agricultural land quality of adjacent land. The value and sensitivity of adjacent off-site agricultural land is assessed as medium. The significance of impact on agricultural land quality or potential is therefore assessed, pre-mitigation, as **minor adverse** given the lack of evidence of any existing weed problem within the site.

13.6.44 The movement of plant and machinery on and off-site has the potential to spread or introduce noxious weeds or invasive alien plant species, if carried on tyre treads for example. However, site surveys to date have identified little or no occurrence of invasive weeds, and therefore it is considered unlikely to occur unless through the accidental transport of weed species in association with vehicles and equipment. This impact on agricultural land quality would be applicable only to off-site land adjoining the site (land within the site itself would no longer part of agricultural production) and is assessed as low, but possible without appropriate preventative or control measures in place. The impact significance is assessed as **minor**.

vi. Loss of Land in Agri-environment Schemes

13.6.45 The HPC development will affect land currently managed under agri-environment schemes (comprising Entry Level Environmental Stewardship and Countryside Stewardship Agreements). Land within the site has been acquired for the HPC development and schemes within the site will cease prior to commencement of the HPC construction phase.

13.6.46 This change is not assessed as an impact in this chapter according to the methodology described in Section 13.3, because the land required for the HPC development will already have been taken out of agricultural production prior to the start of the works. The impact on farm economics through loss of grant is assessed in **Chapter 9** of this volume of the ES. Ecological/biodiversity issues associated with changes to agri-environment schemes are addressed in **Chapter 20** of this volume of the ES

vii. Disturbance to Agricultural Field Drainage due to Soil Stripping and Earthworks

13.6.47 During soil stripping and earthworks activities, existing agricultural field drainage systems or drainage ditches within the proposed development area would be disrupted or lost either temporarily, or within the permanent area of construction, permanently. The temporary drainage system for the HPC development will ensure that there is no flooding or waterlogging on site. However, disruption of any agricultural drainage systems which are contiguous with field drainage systems off-site could result in temporary flooding or at least waterlogging of adjacent (off-site) agricultural land. This impact would be direct, localised and reversible, through reinstatement of artificial drainage. The magnitude of the impact is assessed to be low on an agricultural field drainage receptor of high value (**Table 13.5**). The significance of damage to agricultural field drainage systems is assessed as being **moderate adverse** without mitigation measures in place.

viii. Animal Health from Exposed Animal Burial Sites

13.6.48 No records of animal burials are recorded within the site and the potential impact magnitude is assessed as very low. The likelihood of encountering or accidentally disturbing unrecorded old burial pits is considered to be unlikely. The potential impacts on humans should previously unrecorded burial pits be discovered are addressed in **Volume 2, Chapter 14**. With regard to non-human receptors (including livestock, pets and working dogs), the value/sensitivity is considered to be high. Livestock and other animals would not be present within construction working areas, but may be present on public paths and on adjacent farmland, hence there is the possibility (albeit unlikely) of exposure to disease from burial pits should an unrecorded pit be accidentally disturbed during works. The significance of impact is therefore assessed as **minor adverse**.

d) Cumulative Construction Impacts

13.6.49 There will be no site-specific cumulative construction impacts on soil, land use and agricultural receptors.

e) Operational Impacts

13.6.50 HPC will be operational for 60 years. In the early post-construction phase, land restoration will take place on the non-developed footprint. This section addresses the activities during the restoration works which have the potential to cause adverse impacts on soils and land use including: the vehicle and plant activities associated with removal of stored soils from stockpiles and re-placement ahead of land restoration.

13.6.51 On completion of the construction of HPC, the land outside of the permanent development site would be restored as proposed in the **Landscape Restoration Plan**. This would involve the re-use of stored topsoil, subsoil and possibly ‘overburden’ as part of the restoration of land to agricultural use and ecological habitat creation. It is intended that areas of arable agricultural land, calcareous grassland, neutral grassland, scrub, woodland, wetland and hedgerow habitat will be created. Subsoil and topsoil will be replaced in sequence (i.e. subsoil before topsoil) to re-establish natural soil profiles. This will generally involve similar machinery and plant to the earthworks component of the construction phase.

i. Damage to Soil Quality and Soil Profiles within the Site

13.6.52 On-site impacts due to landscape restoration will arise due to the handling and removal of soils from stockpiles, soil transport, deposition and grading on previously stripped areas. Without mitigation in place, the structure and integrity of stored soil and its future value as both reinstated topsoil and subsoil may be adversely impacted due to this handling and movement. Impacts will also arise as a result of tracking of machinery over stockpiles and re-deposited soils, causing localised compaction. The magnitude of impact is assessed as low because soils are being replaced on-site from temporary and artificially created stockpiles and have therefore already experienced a degree of disruption to natural profiles and structure. For the purposes of this assessment the value/sensitivity of the soils is considered to remain as high, despite having been stripped and stored, to reflect the relative sensitivity and vulnerability of these soils to handling and movement. The significance of impact is therefore assessed as **moderate adverse** without mitigation.

ii. Disturbance to Agricultural Land, Crops and Grazed Grassland Off-site, including Common Land

13.6.53 Farming activity (including crops and other vegetation, and livestock), Common Land and soils beyond the boundaries of the site could potentially be indirectly affected by disturbance during restoration works in a similar way to that previously described for the construction phase, with the potential for dust generation/deposition during earthworks and soil erosion, surface run-off and sediment deposition. The impacts would also be short term and reversible. The value/sensitivity of the agricultural receptor plants, including crops and grazed grassland and Common Land off-site is considered to be medium. Indirect dust deposition and runoff impacts are considered to be very low magnitude adverse impacts on a localised receptor and are assessed as being of **minor** significance in relation to land or soils adjacent to the site.

iii. Changes to Off-site Agricultural Field Drainage Systems

13.6.54 Soil handling and restoration of soils and final landscaping works could result in impacts on the field drainage of adjacent (off-site) agricultural land. This impact would be localised and reversible, through reinstatement of artificial or field drainage systems and connections. The magnitude impact assessed to be low on a receptor of high value/sensitivity, and the impact significance is assessed as being **moderate adverse**.

f) Cumulative Operational Impacts

13.6.55 There will be no site-specific cumulative impacts during the landscape restoration and operational phase on soil, land use and agricultural receptors.

13.7 Mitigation of Impacts

a) Introduction

13.7.1 This section describes the proposed mitigation measures to manage and reduce, wherever possible, any impacts on the soil resources and current land uses on-site during the construction operation and post-construction land restoration of the HPC development.

13.7.2 For the purpose of this assessment, mitigation measures have been proposed where there is an adverse impact of greater than minor significance and the impact magnitude, spatial scope and temporal nature make it appropriate to do so.

b) Mitigation of Impacts during Ground Preparation Activities

13.7.3 To protect the physical condition of and reduce disturbance to on-site soils during vegetation removal and fencing activities, an access plan showing permitted routes and working areas will be clearly delimited. This will ensure that compaction by vehicles and equipment of *in-situ* soils is reduced as far as practicable.

13.7.4 The proposed mitigation in relation to impacts on soils, land use and agriculture during the HPC development (particularly in relation to vegetation clearance and soil stripping and stockpiling activities) includes development of a **Soil Management Plan** (**SMP**) (see **Annex 3**). The measures therein and the implementation of the **SMP** are site-specific and area designed to conserve surface soils, both topsoil and subsoil, in a viable condition suitable for re-use during landscape restoration for the creation of a variety of semi-natural habitats and agricultural land uses.

13.7.5 As part of general good working practice, procedures will be implemented as part of the **SMP** for the HPC development to ensure appropriate biosecurity (disease and pest control) and weed control to protect both on-site soils and adjacent land holdings. Standard procedures will be developed in line with Environment Agency guidance to control the spread of invasive/alien plants or disease for example the inspection and cleaning of vehicle and plant wheels and tread, and inspection of any planting material brought in for landscape restoration. In addition, the design includes a wide buffer zone created by a soil bund on the western part of the site (**Chapter 22** of this volume of the ES) which will provide a physical barrier to the dispersal of weeds between the site and adjacent agricultural land to the west.

13.7.6 The restoration of land within the site has been designed for the sustainable re-use of soil. Stripped and stored soil materials will not be wasted and different soil materials will be used to fulfil different functions in landscape restoration.

13.7.7 Measures to manage and treat site runoff, and prevent erosion and dust generation will also be set in place through a series of specific control measures in the **Water Management Plan** (**WMP**) and **Air Quality Management Plan** (AQMP). These are more fully described in **Chapter 16** on Surface Water, and **Chapter 12** on Air Quality.

13.7.8 An outline of the measures that would protect land drainage and underpin the mitigation provided by the **SMP** is set out below.

i. Mitigation for Disrupted or Damaged Agricultural Field Drainage

13.7.9 Ahead of ground preparation works and soil stripping, inspections will be made of agricultural field drainage systems, both on site and adjacent to the site boundary. Inspections will assess whether any connections to adjacent drainage systems exist. If so, plans will be put in place to reconnect and subsequently reinstate (as practical and appropriate) adjacent drainage systems so as to prevent any damage or flooding to off-site receptors from the development's landscape restoration works.

13.7.10 Measures to manage and treat site drainage and run-off and prevent erosion are set out in the **WMP**. This will include any necessary measures to maintain agricultural field drainage function on adjoining land if affected by changes within the HPC development site.

ii. Soil Quality Protection Measures

13.7.11 A number of site-specific measures are required to protect soil quality during soil stripping, handling, transporting, storing, and restoration, including re-use of soils, so as to maintain as far as practicable, soil viability and biological activity.

13.7.12 A **SMP** has been prepared to manage impacts on soil quality as a result of carrying out construction activities on the development site. It includes a number of measures that are set out below:

- measures of *in situ* soil protection ahead of and during soil stripping;
- measures for segregation and separate storage of different soil types, separately from other excavated materials;

- methods of topsoil stockpiling;
- quality control and auditing measures;
- criteria for cessation of works; and
- use of Tool Box Talks.

13.7.13 The detailed implementation of these measures would be developed before, and as, the construction works proceed.

13.7.14 The **SMP** follows Defra's Code of Practice on Sustainable Soils (2009) (Ref. 13.28) and complies with the MAFF Good Practice Guide for Handling Soils by Machine (2000) (Ref. 13.29). The term Soil Management Plan is synonymous with the term 'Soil Resource Plan' which is described in the Defra Code of Practice.

Measures of In-Situ Soil Protection Ahead of During Soil Stripping

13.7.15 Designated routes of access and egress will be put in place during vegetation removal and fencing activities. This will prevent and reduce to an absolute minimum the amount of vehicle and plant trafficking across areas of topsoil ahead of stripping.

13.7.16 Before any soil stripping activities take place, a soil stripping phasing plan will be prepared by the earthworks contractor. The plan will provide timescales and sequencing of topsoil and subsoil stripping for a series of coded compartments and will permit identification and tracking of topsoil and subsoil resources from stripping, through handling and transport to stockpiling and to landscape restoration. It will also ensure that (a) topsoil is stripped ahead of subsoil, (b) soils are stripped in each part of the site ahead of bulk earthworks activities, and (c) access routes and working areas are clearly delimited to ensure that soil compaction on areas not directly involved in the works is avoided. This will minimise the total area impacted and will, as far as possible, protect soil structure so that stripped soils can be used in later landscape restoration.

Measures for Segregation and Separate Storage of Different Soil Types

13.7.17 The soil survey and Site Investigation trial pit logs (see **Volume 2, Chapter 14**) indicate that topsoil depths vary across the different parts of the site. To ensure that the correct depths of topsoils and subsoils are stripped and stockpiled according to the conditions laid out below, guidance for soil stripping would be provided for each section of the site and will be supervised by the EDF Energy Site Environmental Engineer. The sources of all soil stockpiled will be logged as part of the **SMP** auditing process.

13.7.18 There will be separate stockpiling for each of the three soil resources described in Section 13.6. Documentation and control measures will be set in place to prevent accidental mixing and to ensure that soils are segregated according to source location and eventual planned re-use, as required in the **Landscape Restoration Plan**.

Methods of Soil Stockpiling

13.7.19 The viability of soil re-use after storage depends on how appropriately the soil has been stored. Topsoil and subsoil stripping methodologies will be based upon that recommended by Defra (2009) (Ref 13.28). Antecedent weather conditions are critical for this and soil stripping and handling will not take place if there are heavy rainfall conditions which exceed those agreed for cessation of works (see below). Accordingly the **SMP** provides guidance on soil storage, including regular monitoring of stockpile conditions.

13.7.20 Key issues for soil handling and storage are soil moisture and soil consistency (plastic or non-plastic). These characteristics are used to determine appropriate size and height of stockpiles and their method of formation. During the soil stripping activities, this will be determined *in-situ* at the weekly work planning stage, in relation to each geographical part of the site and reviewed daily with adjustments provided by the EDF Energy Site Environmental Engineer.

13.7.21 There will be two principal methods for forming soil stockpiles, based on the soil moisture and consistency of stripped soil:

- **Method 1** will be applied to soil that is in a dry and non-plastic state when stripped. The aim would be to create a large core of dry soil, and to restrict the amount of water that can get into the stockpile during the storage period. Dry soil that is stored in this manner can remain so for a period of years and it is re-useable within days of re-spreading.
- **Method 2** will be applied if the programme or prevailing weather conditions result in soil having to be stockpiled when wet and/or plastic in consistency. This method minimises the amount of compaction, while at the same time maximising the surface area, through the use of windrows, to enable the soil to dry out further. It also allows the soil to be heaped up into a ‘Method 1’ type stockpile, once it has dried out.

13.7.22 Good methods of topsoil stockpiling are required to prevent loss of soil structure and the development of anaerobic conditions. Particular care is required to maintain their viability for future use in restoration. Space has been designated to (a) allow segregation of three different soil materials, (b) allow for sufficient and appropriate soil stockpiling and, should this be necessary, (c) include areas for drying very wet topsoils in windrows before stockpiling to minimise damage to soil structure and viability.

13.7.23 In relation to stockpiling, the Defra (2009) Code of Practice acknowledges that:

13.7.24 “*Stockpile heights of 3-4m are commonly used for topsoil that can be stripped and stockpiled in a dry state but heights may need to be greater where space is limited.*”

13.7.25 Because of limitations on space within the HPC development site it may be necessary for soil stockpile heights in the SCPA to exceed 4m but heights will be minimised as far as is reasonably practicable. The methodology outlined above for soil stockpiling will ensure that an additional height of 1m, for example, would be no more detrimental to soil structure than stockpiling to 4m. Should stockpiling to 5m, for example, be required, a preliminary assessment of visual impact has indicated that there would be no change to views of the site from Shurton.

13.7.26 The general principles in relation to stockpile location and stability are as follows:

- stockpiles will not be positioned within the root or crown spread of trees, or adjacent to ditches, watercourses or existing or future excavations;

- topsoil and subsoil stockpiles will be seeded with a neutral grassland seed mix to maintain slope stability and to prevent erosion or dust generation;
- grass seeded and maintained stockpiles will have a maximum side slope of 1 in 2 (25°); and
- topsoil and subsoil stockpiles will be managed and inspected throughout their lifetime to ensure maintenance of stockpile stability and integrity.

Quality Control and Auditing Measures

13.7.27 The **SMP** will describe the management and documentation for the topsoil stripping and stockpiling process. There will be an associated written procedure and paper trail for each stripped earthworks area/soil type and associated stockpile which would address:

- soil type, depth stripped and source area identifier/location code;
- stockpile location, identifier code and stockpile height;
- stripping and handling method employed (noting any special conditions or measures used in stripping or stockpiling, such as preliminary windrowing to dry the soil or under-drainage); and
- planned and actual restoration or re-use, including proposed location identifier code.

13.7.28 Locations and quality of *in-situ* soils (both topsoils and subsoils), methods of stripping, stockpiling and spreading, location, size and content of stockpiles together with schedules of volumes of each material, expected after-use of each material and identification of the person responsible for supervising soil management during the works will form part of the audit process). It will also include drawings showing areas to be protected from soil stripping activities and showing locations of haul roads, compounds etc.

13.7.29 Stripped and stored topsoil and subsoil will be categorised according to the three separate soil types described in Section 13.6.

13.7.30 In addition, subsoil (described as 'overburden') will be excavated and stockpiled separately. Some of this subsoil material is likely to be required for the recreation of the subsurface parts of soil profiles in certain parts of the site where deeper soil is required. Topsoil and subsoil from the BDAE will be excavated and stockpiled separately.

13.7.31 The **SMP** includes measures to be implemented in the post-construction land restoration phase to ensure soil quality and integrity is maintained during the process of handling and transporting soils and their replacement across the previously stripped areas. This would include matching documented stockpiles to appropriate areas of restoration, defined movement routes for vehicles and machinery to minimise tracking over replaced soils and specific measures for grading and restoration of soils across the site.

Criteria for Cessation of Works

13.7.32 To ensure that soil structure (both topsoil and subsoil) is protected, appropriate weather and soil moisture criteria will be used to provide thresholds beyond which soil stripping, handling and stockpiling activities would cease. These criteria would be agreed with relevant stakeholders by the contractor in advance of any site operations.

Use of Tool Box Talks

13.7.33 Regular Tool Box talks will be used to ensure all site staff are aware of the **SMP** and applicable procures. The Tool Box Talks would be based on guidance provided by Defra:(http://www.defra.gov.uk/environment/quality/land/soil/builtenviron/documents/toolbox-talks.pdf).

c) Mitigation of Impacts during Later Phases of Construction

13.7.34 Once the vegetation clearance and soil stripping activities have been completed across the site, it is not anticipated that further bulk earthworks, terracing, haul road construction, site compound and sea wall construction, drainage, deep excavation or construction of HPC could have any effects on stockpiled soils. Mitigation for stored soils during these activities will include regular inspections of stockpile conditions to check that surfaces are appropriately shedding water, that no soil erosion has occurred and that soils are being maintained in a suitable condition.

13.7.35 Once the soil stripping has been completed across the site, a programme of topographic shaping and landscape planting will take place south of the line of latitude 144750. As part of the topographic re-shaping activities, subsoil and topsoil material from the stockpiles in the SCPA will be moved south of latitude 144750 and used to create the necessary planting conditions for the semi-natural grasslands, scrub and native woodland which will be created in this area.

d) Mitigation of Impacts during Land Restoration of the Non-Developed Footprint

13.7.36 The proposed **Landscape Restoration Plan** will be implemented when the construction phase of works for the HPC development has been completed. This will include the re-use of stockpiled soils and subsoils to create suitable conditions for agricultural land, woodland, calcareous and neutral grassland, scrub, hedgerows and wetland habitats. Good practice regarding soil restoration requires that soils should be returned as closely as possible to their original state after disturbance. Appropriate restoration techniques and the use of well-managed and viable soil materials will mean that site restoration planting establishes more quickly and is sustained.

13.7.37 The origin of stripped soils will be tracked and documented in the **SMP** as part of stripping, handling and stockpiling activities, such that they can be returned to their original locations during the restoration programme. Several areas of agricultural land will be reinstated in the north-west and west of the site (see Landscape Restoration Strategy, **Appendix 13G**). Within these areas the reinstated ALC grades would be the same as those existing prior to the commencement of ground preparation and soil stripping activities.

13.7.38 Excavated subsoil material will be re-used where it is of suitable quality. The methodology for moving soils from stockpiles and re-using topsoil, subsoils and other suitable materials across the site would be set out in the **SMP**.

13.7.39 **Table 13.6** below provides an indication of how soil would be restored in each of the proposed restored land use types in the **Landscape Restoration Strategy**.

Table 13.6: Soil Types and Indicative Depths to be used in the Landscape Restoration Strategy

Restored Land Use	Proposed Restored Topsoil Soil Type and Depth (cm)	Proposed Restored Subsoil Soil Type and Depth (cm)
Agricultural land	20-25 (stockpiled topsoil)	25-35 (stockpiled subsoil and/or ripped subsoil)
Woodland	20-25 (stockpiled topsoil)	25-35 (stockpiled subsoil and/or ripped subsoil)
Calcareous grassland (low nutrient conditions required)	20-25 (stockpiled subsoil)	10-20 (stockpiled topsoil)
Neutral grassland (low nutrient conditions required)	20-25 (stockpiled subsoil)	10-20 (stockpiled topsoil)
Wet meadow	20-25 (stockpiled valley alluvium, where available)	10-20 (stockpiled valley alluvium, where available and/or ripped subsoil)

i. Restoration of Different Land Types

13.7.40 Restoration of agricultural land uses, both arable and grassland, will be achieved using topsoil and subsoil stripped from agricultural and grassland areas of the site prior to construction and replaced to achieve the same soil profile depths and the same ALC Grade as prior to construction.

13.7.41 Creation of woodland, scrub and hedgerows will be achieved in the same manner, using stored topsoil and subsoil as indicated in **Table 13.6** above.

13.7.42 Successful creation of neutral and calcareous grassland habitats requires nutrient poor topsoil conditions to prevent weed competition. This will be achieved by creating the soil profile in these locations using topsoil first and placing stockpiled subsoil on top to create the seedbed.

13.7.43 The creation of wetland grassland will be achieved using stockpiled mixed (alluvial) topsoil and subsoil where available, stripped from areas of wet meadow grasslands in the Holford Stream valley section of the SCPA during the construction phase.

ii. Restoration of Land where Soil is not Stripped

13.7.44 Since areas beneath stockpiles in the SCPA would not have topsoil and subsoil stripped ahead of stockpiling, these areas will be inspected after stockpile removal and any necessary topographic regrading works, to determine what post-removal *in situ* treatment is required to reinstate appropriate soil conditions for agriculture, woodland or ecological habitat creation. Measures available for overburden on subsoil restoration, depending on their state, include:

- removal of any rock, overburden or aggregate residue from stockpiling;
- deep ripping to loosen soil, alleviate compaction and aerate the soil;
- cross ripping to ensure adequate coverage and connectivity between lines of ripping; and
- artificial drainage, should it be necessary to replace any agricultural field drainage and to connect with any adjacent drainage ditches or field drainage systems.

13.7.45 Best results from deep ripping are obtained during dry soil conditions. Accordingly, the ripping activities which precede restoration works will take place during dry Summer months to ensure that restoration is successful.

13.7.46 During the restoration works mitigation is required to reduce damage to soils due to the handling and removal of topsoils from stockpiles, soil transport, deposition, placement and grading on treated and ripped soil areas. Mitigation measures during this phase of work would closely follow those to be used during the initial topsoil and subsoil strip and stockpiling, including the implementation of the **SMP**.

13.7.47 Measures to manage and treat site run-off, and prevent erosion and dust generation during restoration works will also be set in place through a series of specific control measures described in **Chapters 12, 14 and 16** of this volume of the ES and the relevant SSMPs for the restoration works. Procedures will be implemented as part of the **SMP** for the restoration works to ensure appropriate biosecurity (disease and pest control) and weed control to protect both on-site soils and adjacent land holdings during restoration.

13.7.48 Despite deep ripping of *in situ* overburden and/or subsoil prior to site restoration and implementation of methods stated in the **SMP** to ensure correct handing and placement of topsoils, there will remain the potential for soils to be in poorer condition once restored compared to the condition of agricultural soils prior to construction. To ensure that the original soil conditions are correctly achieved, the site will be sown with a hay seed mix and both soil and herbage will be monitored over three growing season to ensure that specified soil and herbage criteria are achieved and that the initial agricultural soil conditions are correctly restored. The monitoring scheme and acceptability criteria are specified in the **SMP**. Should either restored subsoil or topsoil conditions fail to meet acceptability criteria during these three growing seasons, a suitably qualified agronomist will advise on appropriate remedial treatment and further monitoring will be prescribed, until required soil criteria are met and soil conditions are signed off.

iii. Methods and Timescales of Soil Restoration

13.7.49 During land and soil restoration works mitigation is required to ensure that there is minimal damage to soils due to the handling and removal of soils from stockpiles, soil transport, deposition and grading on previously stripped areas. Mitigation measures during this phase of work would closely follow those to be used during the initial topsoil strip and stockpiling, including the implementation of a **SMP**.

13.7.50 The primary objective of agricultural soil restoration is to restore to the same ALC grade in all parts of the site designated for restoration to agricultural land.

13.7.51 The primary objective of soil restoration for ecological areas is to create soil profile conditions suitable for the establishment and long-term sustenance of a functional semi-natural habitat for the following land uses: woodland, wet meadow grassland, calcareous grassland and neutral grassland, as indicated in the **Landscape Restoration Strategy**.

13.7.52 For each restored land use compartment, prescriptions for topsoil and subsoil replacement will be provided in the **SMP**. The soil restoration process will involve a number of stages and activities to recreate the soil profile in each restored compartment of the site. Since the soil types present within the site are heavy clays, soil handling and placement during restoration should be carried out while the soil and weather is dry. These activities will be scheduled to take place during summer and early autumn conditions.

13.7.53 As for the construction works, measures to manage and treat site runoff, and prevent erosion and dust generation during restoration works would also be set in place through implementation of a series of control measures which are described in the **WMP** and **AQMP**.

iv. Soil Monitoring

13.7.54 The SMP includes a soil monitoring programme. The programme of soil monitoring will include the following:

- **Baseline Soil Characterisation**. Testing of soil physical and chemical characteristics on in situ soils ahead of construction commencing to provide a baseline against which restored soil conditions post-construction can be compared.
- **Soil Moisture Testing**. At various stages throughout soil stripping and soil stockpiling, soil moisture testing will be used to inform the methods of stockpiling used.
- **Soil Stockpile Testing**. Testing of soil physical and chemical characteristics in topsoil and subsoil stockpiles immediately before their deployment for restoration activities, to ensure, after prolonged stockpiling, they are still fit for purpose.
- **Testing of in situ Soil Conditions after Restoration**. Testing of soil physical and chemical characteristics on *in situ* restored to determine whether set acceptability criteria have been achieved. Acceptability criteria are based on soil conditions prior to construction.

13.7.55 After restoration, should soil acceptability criteria not be met, methods will be provided in the **SMP** for treating a range of soil physical and chemical conditions, including alleviation of soil compaction, aeration, nutrient additions through fertilizing or nutrient depletion to achieve conditions for ecological habitat creation.

13.7.56 Sufficient time has been allocated for the restoration phase of work to permit *in situ* monitoring of soil conditions within restored areas over a minimum of three growing seasons post-restoration (i.e. during the landscape planting establishment phase). This is considered to be sufficient to ensure that appropriate soil conditions have been achieved and soil restoration criteria have been met.

13.7.57 Procedures would be implemented as part of the **SMP** for the restoration works to ensure appropriate biosecurity (disease and pest control) and weed control to protect both on-site soils and adjacent land holdings during the restoration phase of works.

13.8 Residual Impacts

a) Construction Impacts

13.8.1 Residual impacts, after mitigation measures have been taken into account, relating to soil, land use and agriculture during the construction phase of the HPC development, are summarised in **Table 13.7**. No mitigation is considered to be required for impacts that were assessed as negligible or of minor significance in Section 13.6. In relation to such impacts, where relevant, **Table 13.7** refers to standard good practice measures that would be set in place for the HPC development.

13.8.2 Residual impacts during the construction phase of the HPC development are predicted to be of no greater significance than minor adverse with mitigation measures in place. The identified mitigation mainly relates to potential impacts on soils during soil stripping, movement and storage. Mitigation in relation to these activities, as described in the **SMP**, is considered sufficient to reduce assessed significance from major adverse to minor adverse. The **SMP** as part of the **EMMP** for the HPC development will be a crucial element in ensuring that any residual impacts during vegetation clearance and soil stripping and stockpiling are reduced to an acceptable level.

13.8.3 Plans will be put in place to ensure that connectivity to adjacent drainage systems are appropriately treated so that there would be no on-site or off-site waterlogging or flooding. The design of the proposed development includes provision for temporary (construction phase) drainage management facilities. These will include provision to maintain the field drainage of adjoining land to ensure they are not adversely affected. Together, these measures are sufficient to ensure that there will be no significant residual impacts on field drainage conditions either within or outside the development during the construction phase.

b) Operational Impacts

13.8.4 Residual impacts, after mitigation measures have been taken into account, relating to soil, land use and agriculture during the operational phase of the HPC development, are summarised in **Table 13.7**. No mitigation is considered to be required for impacts that were assessed as negligible or of minor significance in Section 13.6. In relation to such impacts, where relevant, **Table 13.7** refers to standard good practice measures that will be set in place as part of the **EMMP** for the HPC development.

13.8.5 Residual impacts during the operational phase of the HPC development are predicted to be of no greater significance than minor adverse with mitigation measures in place. The identified mitigation mainly relates to potential impacts on soils and agricultural land adjacent to the site. Standard good practice measures are assessed to be sufficient to ensure that there will be no significant residual impacts on soils and land use during the operation of the HPC development.

c) Restoration Impacts

13.8.6 Residual impacts, after mitigation measures have been taken into account, relating to soil, land use and agriculture during the post-construction land restoration works associated with the HPC development, are summarised in **Table 13.7**. No mitigation is considered to be required for impacts that were assessed as negligible or of minor significance in Section 13.6. In relation to such impacts, where relevant, **Table 13.7** refers to standard good practice measures that would be set in place for the HPC development.

13.8.7 Residual impacts during the post-construction restoration phase of the HPC development are predicted to be of no greater significance than minor adverse with mitigation measures in place. The identified mitigation mainly relates to potential impacts on soils during their movement and handling from stockpiles and their replacement during restoration. Mitigation in relation to these activities, as laid out in the **SMP**, is considered sufficient to reduce assessed significance from moderate adverse to minor adverse. The **SMP** for the HPC development will be a crucial element in ensuring that any residual impacts during restoration activities are reduced to an acceptable level.

13.8.8 Post-operation, as part of the restoration of the site to agriculture, field drains will be reinstated within the restored land area as required to ensure adequate land drainage. These will connect with field drains present on adjoining land as necessary to maintain a properly functioning system. As a result of these design features and mitigation measures, there will be no significant residual impacts on field drainage condition within the site or in agricultural fields adjacent to it during the restoration phase.

d) Cumulative Restoration Impacts

13.8.9 Cumulative site-specific impacts have been considered in relation to the effects of restoration activities on soils and land use receptors. As no additional land take is required for the restoration process, and the long-term outcome is considered to be positive in that it will restore land over time to at least the same ALC Grade of agricultural land as prior to construction, no adverse cumulative impacts on soil, land use and agriculture are predicted to occur.

13.9 Summary of Impacts

13.9.1 A summary of identified residual impacts and mitigation measures is provided in **Table 13.7.** This addresses the construction, operation and restoration phases.

Table 13.7: Summary of Impacts

Receptor	Potential Impact	Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation/ Best Practices	Residual Impact
Construction							
Soil quality and profiles – within site	Vegetation removal.	Medium	Site Specific Direct Adverse Temporary	High	Major	Designated routes of access Soil Management Plan.	Minor
Soil quality and profiles – within site.	Ground preparation including topsoil stripping and stockpiling.	Medium	Site Specific Direct Adverse Temporary	High	Major	Designated routes of access Soil Management Plan. Reuse and restoration of soils in line with Landscape Restoration Strategy.	Minor
Temporary or permanent loss of agricultural land quality (ALC Grade and agricultural land use potential)	Vegetation removal and ground preparation including topsoil stripping and stockpiling.	Low	Site Specific Direct Adverse Temporary	Medium	Minor	None proposed.	Minor
Agricultural crops and grazed grassland and Common Land off-site	Indirect disturbance/dust/run-off impact on adjoining land.	Very low	Indirect Adverse Temporary	Medium	Minor	No specific mitigation required. As part of standard good working practice – controls on working.	Minor
Agricultural land – on and off-site	Accidental introduction or spread of noxious or invasive weeds and diseases.	Low	Direct & Indirect Adverse Temporary	Medium	Minor	No specific mitigation required. As part of standard good working practice – implement MAFF procedures for the control of soil transfer.	Minor

Receptor	Potential Impact	Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation/ Best Practices	Residual Impact
Construction							
Field drainage	Disruption to or loss of drainage infrastructure and any connections to adjacent agricultural drainage systems	Low	Site Specific Direct Adverse Temporary	High	Moderate	Mitigation measures to protect adjacent agricultural field drainage systems will be included in the SMP	Minor
Animal health – off-site	Disturbance of old animal burial pits	Very low	Site Specific Direct Adverse Temporary	High	Minor	No specific mitigation required. As standard good practice, include contingency measure to contact Defra Animal Health Division if previously undiscovered pit encountered.	Minor
Operation – Restoration of the Non-developed Footprint							
Soil quality and profiles	Earthworks – topsoil restoration.	Low	Site Specific Direct Adverse Temporary	High	Moderate	Soil Management Plan.	Minor
Agricultural land, crops and grazed grassland and Common Land off-site	Indirect disturbance/dust/run-off impact on adjoining land.	Very low	Indirect Adverse Temporary	Medium	Minor	No specific mitigation required. Soil Management Plan.	Minor
Field Drainage	Disruption to drainage infrastructure and connection to off-site agricultural drainage systems	Low	Site Specific Direct Adverse Temporary	High	Moderate	Mitigation measures to protect adjacent agricultural field drainage systems will be included in the SMP	Minor

APPENDICES

14. GEOLOGY AND LAND CONTAMINATION

14.1 Introduction

14.1.1 This chapter of the Environmental Statement (ES) provides an assessment of the potential impacts in relation to geology and land contamination during the construction, operation and the restoration of the Hinkley Point C (HPC) development and associated off-site highway improvements.

14.2 Scope and Objectives of Assessment

14.2.1 The scope of this assessment has been determined through a formal Environmental Impact Assessment (EIA) scoping process undertaken with the Infrastructure Planning Commission (IPC). It has also been informed by consultation with statutory consultees including the Environment Agency, Sedgemoor District Council (SDC), West Somerset Council (WSC) and Somerset County Council (SCC), as the relevant authorities, and also by comments received from non-statutory consultees including local residents and members of the general public in response to EDF Energy's Stage 1, Stage 2, and Stage 2 Update consultations (see the **Consultation Report**).

14.2.2 The assessment of geological and land contamination impacts on sensitive receptors arising from the proposed development has been undertaken adopting the methodologies described in Section 14.4. The existing baseline conditions, against which the likely environmental effects of the development are assessed, have been determined through a review of desk based and intrusive site investigation reports. These are described in Section 14.5, which also identifies the receptors of relevance to the assessment. The study area for this assessment, as illustrated in **Figure 14.1**, focuses on the HPC Development Site and also includes the associated off-site highway improvements.

14.2.3 Within this chapter, the assessment of land contamination includes both chemical and radiological contamination. In the context of land contamination, the scope of the assessment has been broadened to include the potential for 'contaminated land' and 'land affected by contamination' within the understanding and definition of these terms in the UK (i.e. in line with the definitions contained with Part 2A of the Environmental Protection Act 1990 (Ref. 14.1) and Planning Policy Statement 23 (Ref. 14.2)). The assessment includes the potential for groundwater contamination with respect to the presence of contaminated soils and assesses the potential risk/impacts using the 'source-pathway-receptor' approach.

14.2.4 Impacts associated with geology and land contamination are assessed in Section 14.6 of this chapter. Many environmental aspects are interrelated; as such impacts from land contamination have the potential to impact a number of other environmental components (e.g. land contamination may impact upon groundwater, surface waters and/or ecology). For the purpose of this chapter, the impact assessment related to land contamination is considered with respect to the following receptors: on-site and off-site human health, on-site and off-site terrestrial ecology (including plants, trees, and other vegetation but excluding crops), on-site and off-site crops and livestock, the on-site and off-site built environment, the on-site and off-site soil[1] environment and on-site and off-site controlled waters. Impacts to controlled waters are only considered with respect to assessment of impact to on-site groundwater and surface water from actual or potential soil contamination. Possible further indirect impacts from potential contaminated groundwater and/or surface water to other receptors are discussed in **Chapter 15** and **Chapter 16** of this volume, respectively. Potential impacts to ecological receptors including trees, and other vegetation are discussed in **Chapter 20** of this volume. Potential impacts to soils and crops are considered in **Chapter 13** of this volume.

Appropriate mitigation measures aimed at preventing, reducing or off-setting any potential adverse impacts on geology and land contamination that are identified to be of significance are presented in Section 14.7. The assessment of residual impacts following implementation of the mitigation measures is presented in Section 14.8. The assessment of cumulative impacts of HPC with other elements of the HPC Project, and other proposed and reasonably foreseeable projects are considered in **Volume 11** of this ES.

14.2.5 The objectives of the geology and land contamination assessment are to:

- identify the geology and land contamination characteristics within the study area which may be affected by, or be relevant to, HPC;
- characterise the baseline conditions for geology and land contamination within the study area;
- assess the impacts of HPC on geology and land contamination within the study area;
- recommend mitigation measures, if considered necessary, to reduce the potential adverse impacts on geology and land contamination; and
- assess the residual impacts on geology and land contamination.

14.3 Legislation, Policy and Guidance

14.3.1 This section identifies and describes legislation, policy and guidance of relevance to the assessment of potential geology, land contamination and groundwater impacts associated with the construction, operation and restoration phases of the proposed development.

14.3.2 As stated in **Volume 1**, **Chapter 4** of this ES, the Overarching National Policy Statement (NPS) for Energy (NPS EN-1) when combined with the NPS for Nuclear Power Generation (NPS EN-6) provides the primary basis for decisions by the IPC on applications for nuclear power generation developments that fall within the scope of the NPSs.

14.3.3 Notwithstanding this, the IPC may consider other matters that are both important and relevant to its decision-making. This could include Planning Policy Statements (PPSs), Planning Policy Guidance Notes (PPGs), regional and local policy

[1] The risks posed by actual and potential land contamination to the on or off site soil environment has mainly been assessed in terms of potential impact to soil quality through possible ecotoxicological effects (i.e. toxicological risk to ecological receptors and ecosystems). In terms of soils, this is predominantly intended to mean soil flora and fauna (e.g. invertebrates), however it may also include higher animals (mammals, avian receptors).

documents, although, if there is a conflict between these and the NPS, the NPS prevails for the purposes of IPC decision making.

14.3.4 Further, the Planning Act 2008 provides that the IPC must, in making its decision on an application, have regard to any Local Impact Report (LIR) prepared by relevant local authorities. It is anticipated that the LIRs will rely in part on PPSs, PPGs, regional and local policy to provide a context for their assessment. On this basis, regard has been given to these documents (where relevant to the technical assessment) since they are likely to inform the LIRs prepared by the relevant local authorities.

a) International

14.3.5 There is no European Union (EU) legislation which is directly relevant to the subjects of geology and land contamination apart from the Environmental Liability Directive (2004/35/EC) (Ref. 14.3). There are various pieces of EU Legislation (see below) which are indirectly relevant. Details of the indirectly relevant EU legislation are contained within other chapters (i.e. **Chapter 15** and **Chapter 16** of this volume) and although not repeated here the relevant EU legislation is listed below for completeness:

- The Water Framework Directive (2000/60/E) (Ref. 14.4).
- Groundwater Directive (80/68/EEC) (Ref. 14.5).

i. Environmental Liability Directive (Ref. 14.3)

14.3.6 The Environmental Liability Directive is based on the "polluter pays" principle and requires EU member states to impose obligations and liabilities on operators whose activities cause or threaten environmental damage. Environmental damage specifically includes land contamination where there is a significant risk of adverse effects to human health.

14.3.7 The Environmental Liability Directive requires an operator to take preventative, as well as remedial, measures. It applies both to damage that has occurred and where there is an imminent risk of it occurring, but does not apply to damage that occurred prior to 30 April 2007. The Environmental Liability Directive is implemented in England by the Environmental Damage (Prevention and Remediation) Regulations 2009 (SI 2009/153) (Ref. 14.6).

b) National Legislation

i. Geology

The Wildlife and Countryside Act 1981 (Ref. 14.7)

14.3.8 The Wildlife and Countryside Act (1981) covers the protection of wildlife, the countryside, National Parks and the designation of protected areas, and Public Rights of Way (PRoW). It provides the designation of Sites of Special Scientific Interest (SSSI), which are areas of special scientific interest due to their flora, fauna, or geological or geophysical features, as well as National Nature Reserves (NNR) or Marine Nature Reserves (MNR).

14.3.9 SSSIs have specific guidelines to protect the area of special interest from damage or deterioration. Consultation with the appropriate conservation agencies must be made prior to any development or activities which could impact these sites. They are subject to legal protection and are managed to conserve their habitats or to provide special opportunities for scientific study.

The Countryside and Rights of Way Act 2000 (Ref. 14.8)

14.3.10 The Countryside and Rights of Way Act (CRoW) (2000) puts responsibility onto relevant authorities to "*take reasonable steps to further the conservation and enhancement of … geological and physiographical features by reason of which the site is a SSSI*".

ii. Land Contamination

14.3.11 There are several items of legislation and/or guidance that aim to deal with the prevention of land and groundwater contamination and others which aim to address and remediate contamination once it has occurred. As with European legislation, several of these regulations are more indirectly relevant to the management and prevention of land contamination. Examples of indirectly relevant regulations are listed here for reference but are not discussed in detail within this chapter:

- Water Resources Act 1991 (SI 57) (as partly amended by the Water Act 2003) and associated Anti-pollution Works Regulations 1999 (SI 1999/1006) (Ref. 14.9).
- Control of Pollution (Oil Storage) (England) Regulations 2001 (SI 2001/2954) (Ref. 14.10).
- Water Environment (Water Framework Directive) (England and Wales) Regulations 2003 (SI 2003/3242) (Ref. 14.11).
- Nuclear Installations Act 1965 (Ref. 14.12).

Environmental Protection Act 1990 Part 2A (Ref. 14.1)

14.3.12 The key piece of legislation which is directly relevant to contaminated land in the UK is Part 2A of the Environmental Protection Act (EPA) 1990 and associated Contaminated Land Regulations (England) 2006 (SI 2006/1380) (Ref. 14.18). The Environment Act 1995 added Part 2A to the Environment Protection Act 1990 and Part 2A came into force in 2000. This contains the primary legislation with respect to identification, assessment and where necessary determining liability for the remediation of contaminated land and groundwater in England and Wales. Part 2A (as it is more commonly known) created a statutory definition of 'Contaminated Land' as follows:

> "*any land which appears to the Local Authority in whose area it is situated to be in such a condition, by reason of substances in, on or under the land, that;*
>
> *a) significant harm is being caused or there is the significant possibility of such harm being caused, or*
>
> *b) pollution of controlled waters is being, or is likely to be caused."*

14.3.13 Section 86 of the Water Act 2003 (Ref.14.9) sets out an amendment to this definition by introducing the thresholds of "significant pollution of controlled waters" and "significant possibility of significant pollution of controlled waters". However, this section is not yet in force and the Government has not announced an anticipated commencement date.

14.3.14 Tables A and B of the statutory guidance provided in Defra circular 01/2006 (Ref. 14.13) define statutory receptors under Part 2A, which include;

- human beings;
- various ecological systems and designated ecological sites;
- property including crops, produce, livestock and wild animals which are the subject for shooting or fishing rights; and
- buildings.

14.3.15 The Radioactive Contaminated Land (Modification of Enactments) (England) Regulations 2006 (SI 2006/1379) (Ref.14.14) extended Part 2A to include some, but not all, land contaminated by radioactive substances. The Regulations only apply to radioactivity arising from historical practice or works activity not naturally occurring (e.g. radon is a naturally occurring radionuclide). The Regulations reserve to the Health and Safety Executive (HSE) the power to deal with radioactive contaminated land on a site licensed under the Nuclear Installations Act 1965 (Ref. 14.12). The Radioactive Contaminated Land (Modification of Enactments) (England) (Amendment) Regulations 2007 (SI 2007/3245) (Ref.14.15) add the category of radioactive contaminated land caused by off-site nuclear occurrences. Radioactive Contaminated Land (Modification of Enactments) (England) (Amendment) Regulations 2010 (SI 2010/2147) (Ref.14.16) extended Part 2A again to include radon and radionuclides present as a result of radioactive decay, where they are the result of the after-effects of a radiological emergency or a past activity. The application of Part 2A to radioactive contamination differs in some respects from its application to non-radioactive contamination. In particular, in relation to radioactive contamination, the definition of 'Contaminated Land' is modified such that it only covers harm to human health and not pollution of controlled waters, and there is no requirement for such harm to be 'significant' as for non-radioactive contamination.

14.3.16 The assessment and determination of contaminated land is based around the ‘source-pathway-receptor’ approach, whereby, linkage(s) (known as a ‘pollutant linkage’ in Part 2A) must be shown to exist between the source of contamination and a receptor (target). A pathway could be any feature which connects a source to a target, for example, it could be a drain, service trench or permeable ground.

14.3.17 Part 4 A.37 of Defra statutory guidance circular 01/2006 (Ref. 14.13) states that land should not be designated as contaminated land where:

- a substance is already present in controlled waters;
- entry into controlled waters of that substance from the land has ceased; and
- it is not likely that further entry would take place.

14.3.18 Part 2A imposes liability for the clean-up of contaminated land in the first instance, on those who caused or knowingly permitted the contaminating substances to be present in, on or under the land (by applying the "polluter pays" principle). If no such person can be found, liability passes to the current owners and occupiers of the site (regardless of whether they were aware of the contamination). Currently, the

Secretary of State is liable for the remediation of radioactive contaminated land caused by nuclear occurrences.

14.3.19 Further to the legislation described above, a consultation report was issued by Defra in 2010 (Ref. 14.17), which stated proposals for updating and revising the Statutory Guidance (Ref. 14.13). The consultation also includes proposed minor amendments to the Contaminated Land (England) Regulations 2006 (Ref. 14.18). The proposed updates and revisions provide guidance on how the Local Authority should go about deciding whether significant pollution of controlled waters is being caused, or whether there is a significant possibility of such pollution being caused. The consultation period for the consultation report was held between December 2010 and March 2011.

Environmental Damage (Prevention and Remediation) Regulations 2009 (Ref. 14.6)

14.3.20 The Environmental Damage (Prevention and Remediation) Regulations 2009 (Ref 14.6) implement the provisions of the Environmental Liability Directive (Ref 14.3) in England. The Regulations follow the provisions of the Directive closely and accordingly impose obligations and liability on operators for environmental damage caused or threatened by their activities, specifically including damage to land by contamination by substances, preparations, organisms or micro-organisms that results in a significant risk of adverse effects on human health. The Regulations only apply to damage that takes place after the Regulations come into force on 1 March 2009.

14.3.21 If an operator of an activity causes an imminent threat of environmental damage the operator must immediately take all practicable steps to prevent the damage and provide all relevant details to the enforcing authority. Where environmental damage has been caused, the authority must require the operator to undertake remedial works, subject to certain exemptions. In relation to land, the remediation must ensure, as a minimum, that the contaminants are removed, controlled, contained or diminished so that the land, taking account of its lawful current use or any planning permission in existence at the time of the damage, no longer poses any significant risk of adverse effects on human health.

The Environmental Permitting (England and Wales) Regulations 2010 (Ref. 14.19)

14.3.22 The Environmental Permitting (England and Wales) Regulations 2010 superseded the Environmental Permitting (England and Wales) Regulations 2007 (SI 2007/3538) which were intended to create a single permitting and compliance scheme for sites and processes previously regulated under the Integrated Pollution Prevention and Control (IPPC), Pollution, Prevention and Control (PPC), Waste Management Licensing (WML) and Landfill Regulations. Under the 2010 Regulations an Environmental Permit is required for specified processes and activities including (for example) energy, metals, mineral, chemicals and waste management activities. Some waste management operations are excluded from environmental permitting because they are regulated under other regimes or because they are lower risk activities which can be undertaken under a registered/approved exemption.

14.3.23 The 2010 Regulations aim to ensure a high level of environmental protection by preventing, or where this is not practicable, reducing emissions to air, land and/or water from regulated processes. The permits must include conditions to ensure that no significant pollution is caused and that all necessary measures are taken to prevent pollution. These measures include the use of conditions prescribing Best Available Techniques (BAT) to prevent or reduce emissions. In determining BAT, the regulator must have regard to any statutory BAT guidance, e.g. sector and process guidance notes and/or EU BREF guidance notes.

14.3.24 Permits also must include conditions to ensure:

- protection of soil and groundwater;
- suitable emissions monitoring and environmental monitoring is in place;
- the application of measures to prevent accidents and accidental releases; and
- when activities cease on-site, the site is returned to a satisfactory condition and any residual pollution risk removed.

Environment Agency Pollution Prevention Guidelines (Ref. 14.20)

14.3.25 A number of Pollution Prevention Guidelines (PPG) have been produced by the Environment Agency (EA) covering a range of subject areas. They aim to provide practical advice to industry and the public on legal responsibilities, and good environmental practice and management to prevent pollution of surface water, groundwater and land from activities such as storage of oils and fuels, refuelling activities, construction and demolition, fire water management and vehicle washing.

Environment Agency CLR 11, Model Procedures for the Management of Land Contamination (Ref. 14.21)

14.3.26 CLR 11 provides the technical framework for applying a risk management process when dealing with land impacted by contamination. The technical approach presented in the Model Procedures is designed to be applicable to a range of non-regulatory and regulatory contexts. These include:

- development or redevelopment of land under the planning regime;
- regulatory intervention under Part 2A of the Environment Protection Act 1990;
- voluntary investigation and remediation; and
- managing the potential liabilities of those responsible for individual sites or a portfolio of sites.

UK Best Practice Guidance

14.3.27 In addition to the above legislation and policies, there is a large amount of UK best practice guidance documentation which is relevant to geology and land contamination. Some of the key pieces of guidance are listed below (the list provided below is indicative only, i.e. not exhaustive):

- BS10175:2001 Investigation of Potentially Contaminated Sites – Code of Practice (Ref. 14.22). This guidance was re-issued in March 2011; however the 2001 version of the guidance was current and applicable at the time of the intrusive investigations used to inform this ES chapter (July 2008, August to December 2008, and November 2009 to August 2010).

- BS5930:1999 + A2:2010 Code of practice for site investigations (Ref. 14.23).
- EN ISO 14688-2002-1: Geotechnical investigation and testing – Identification and classification of soil – Part 1: Identification and description (Ref. 14.24).
- BS EN ISO 10381-2:2002 Soil Quality - Sampling – Part 2: Guidance on sampling techniques) (Ref. 14.25).
- Department of the Environment. Prioritisation and categorisation procedure for sites that may be contaminated. Contaminated Land Report 6 (Ref. 14.26).
- Environment Agency. Human health toxicological assessment of contaminants in soil. (Science Report SC050021/SR2) (Ref. 14.27).
- Environment Agency. An ecological risk assessment (ERA) framework for contaminants in soil (Ref. 14.28).

c) National Planning Policy

i. Planning Policy Statement 1: Delivering Sustainable Development (PPS1) (2005) (Ref. 14.29)

14.3.28 PPS1 was published in 2005 and sets out the Government's overarching planning policies on the delivery of sustainable development through the planning system.

14.3.29 Paragraph 5 states that planning should facilitate and promote sustainable and inclusive patterns of urban and rural development by, amongst other things: protecting and enhancing the natural and historic environment, the quality and character of the countryside, and existing communities.

ii. Planning Policy Statement 9: Biodiversity and Geological Conservation (PPS9) (2005) (Ref. 14.30)

14.3.30 PPS9 was published in 2005 and sets out planning policies on the protection of biodiversity and geological conservation through the planning system. The broad aim of the policies is to ensure that planning, construction, development and regeneration should have minimal impacts on biodiversity and enhance it wherever possible.

14.3.31 Key objectives of PPS9 (page 2 of the policy) include:

> *"To promote sustainable development by ensuring that biological and geological diversity are conserved and enhanced as an integral part of social, environmental and economic development, so that policies and decisions about the development and use of land integrate biodiversity and geological diversity with other considerations.*
>
> *To conserve, enhance and restore the diversity of England's wildlife and geology by sustaining and where possible improving the quality and extent of natural habitat and geological and geomorphological sites; the natural physical processes on which they depend; and the populations of naturally occurring species which they support."*

iii. Planning Policy Statement 23: Planning and Pollution Control (PPS23) (2004) (Ref. 14.2)

14.3.32 PPS23 is intended to complement the pollution control framework under the Pollution Prevention and Control Act 1999 and the Pollution Prevention and Control Regulations 2000. The policy sets out the importance of the planning system in determining the location of development which may give rise to pollution, either directly or indirectly. The policy also seeks to ensure that other uses and developments are not, as far as possible, affected by major existing or potential sources of pollution.

14.3.33 Paragraph 23 of PPS23 states that, in considering individual planning applications, the potential for contamination to be present must be considered in relation to the existing use and circumstances of the land, the proposed new use and the possibility of encountering contamination during development. Local Planning Authorities (LPAs) should satisfy themselves that the potential for contamination and any risks arising are properly assessed and that the development incorporates any necessary remediation and subsequent management measures to deal with unacceptable risks.

14.3.34 Paragraph 24 of PPS23 states that LPAs should pay particular attention to development proposals for sites where there is a reason to suspect contamination. If the potential for contamination is confirmed, further studies to assess the risks and identify and appraise the options for remediation should be undertaken. Paragraph 25 of PPS23 advises that the remediation of land affected by contamination through the granting of planning permission (with the attachment of the necessary conditions) should secure the removal of unacceptable risk and make the site suitable for its new use.

14.3.35 PPS23 also states that, amongst other things, the following matters may be material in the consideration of individual planning applications where pollution considerations arise:

> *"…the need to ensure that land, after development, is not capable of being determined as contaminated land under Part 2A of the EPA 1990 and that all unacceptable risks have been addressed; and*
>
> *…the possible adverse impacts on water quality and the impact of any possible discharge of effluent or leachates which may pose a threat to surface or underground water resources directly or indirectly through surrounding soils."* (page 12 of the policy)

iv. Consultation Paper on a New Planning Policy Statement – Planning for a Natural and Healthy Environment (2010) (Ref. 14.31)

14.3.36 In its final form, it is intended that this PPS will replace PPS9. The draft PPS contains policies to maintain and enhance, restore or add to biodiversity and geodiversity through the planning system. It includes policies to promote opportunities for the incorporation of beneficial biodiversity and geological features within the design of development, and to maintain networks of natural habitats by avoiding their fragmentation and isolation.

14.3.37 A key objective of this PPS is to bring together related policies on the natural environment and on open space and green spaces in rural and urban areas to ensure that the planning system delivers healthy sustainable communities which adapt to and are resilient to climate change and gives the appropriate level of protection to the natural environment (page 10 of the policy).

d) Regional Planning Policy

14.3.38 The Government's revocation of regional strategies was quashed in the High Court on 10 November 2010. However, on that same date the Government reiterated in a letter to Chief Planners its intention to revoke regional strategies through the Localism Bill. This letter was also challenged but, on 7 February 2011, the High Court held that the Government's advice to local authorities that the proposed revocation of regional strategies was to be regarded as a material consideration in their planning development control decisions should stand. The decision of the High Court was upheld by the Court of Appeal on 27 May 2011. Therefore, the regional strategies remain in place but in the case of development control decisions it is for planning decision makers to decide on the weight to attach to the strategies (see **Volume 1**, **Chapter 4** of this ES for a full summary of the position regarding the status of regional planning policy).

i. Regional Planning Guidance 10 for the South West 2001-2016 (RPG10) (2001) (Ref. 14.32)

14.3.39 RPG 10 sets out the broad development strategy for the period to 2016 and beyond. Policy EN1 (Landscape and Biodiversity) seeks the protection and enhancement of the region's internationally and nationally important landscape areas and nature conservation sites. The protection and, where possible, enhancement of the landscape and biodiversity should be planned into new development.

14.3.40 Policy RE1 (Water Resources and Water Quality) states that to achieve the long-term sustainable use of water, water resources need to be used more efficiently. The policy also states that local authorities, the Environment Agency, water companies and other agencies should seek to, amongst other things, protect groundwater resources.

ii. The Draft Revised Regional Spatial Strategy (RSS) for the South West Incorporating the Secretary of State's Proposed Changes 2008-2026 (July 2008) (Ref. 14.33)

14.3.41 Chapter 7 of the RSS deals with Enhancing Distinctive and Cultural Life. Policy ENV1 states:

> *"The quality, character, diversity and local distinctiveness of the natural and historic environment in the South West will be protected and enhanced, and developments which support their positive management will be encouraged. Where development and changes in land use are planned which would affect these assets, Local Authorities will first seek to avoid loss of or damage to the assets, then mitigate any unavoidable damage, and compensate for loss or damage through offsetting actions. Priority will be given to preserving and enhancing sites of international or national landscape, nature conservation, geological, archaeological or historic importance. Tools such as characterisation and surveys will be used to enhance local sites, features and distinctiveness through development,*

including the setting of settlements and buildings within the landscape and contributing to the regeneration and restoration of the area."

14.3.42 Policy RE6 (Water Resources) states that the region's network of ground, surface and coastal waters and associated ecosystems will be protected and enhanced. It also advises that surface and groundwater pollution risks must be minimised so that environmental quality standards are achieved and where possible exceeded.

iii. Somerset & Exmoor National Park Joint Structure Plan Review 1991-2011 (2000) (Policies 'saved' from 27 September 2007) (Ref. 14.34)

14.3.43 The Somerset & Exmoor National Park Joint Structure Plan was adopted in 2000 with relevant policies saved from 27 September 2007. All policies have been saved with the exception of Policy 53 which is unrelated to geology, land contamination or groundwater impacts. The Plan provides a strategic base for all land use planning within the plan area for the period up to 2011.

14.3.44 Policy 1 (Nature Conservation) states that the biodiversity of Somerset and the Exmoor National Park should be maintained and enhanced. The greatest protection will be afforded to nature conservation sites of international and national importance. In addition, Local Plans should include policies to maintain and enhance sites and features of local nature conservation importance including landscape features which provide wildlife corridors, links or stepping stones between habitats.

14.3.45 Policy 15 (Coastal Development) states that provision for any development along the coast, including the Exmoor Heritage Coast, should be made within towns, rural centres and villages. Where development requires an undeveloped coastal location it should respect the natural beauty, biodiversity and geology of the coast and be essential in that location. New coastal developments should minimise the risk of flooding, erosion and landslip.

14.3.46 Policy 59 (Safeguarding Water Resources) states that protection will be afforded to all surface, underground and marine water resources from development which could harm their quality or quantity.

e) Local Planning Policy

i. West Somerset Local Plan (2006) (Policies 'saved' from 17 April 2009) (Ref. 14.35)

14.3.47 The West Somerset Local Plan forms part of the development plan for West Somerset. The Local Plan was adopted in April 2006 (with relevant policies saved from 17 April 2009).

14.3.48 The Proposals Map indicates that the HPC development site itself is not subject to any specific geology, or land contamination or groundwater designations. The foreshore, which lies just outside of the northern red line boundary of the site, is designated a SSSI (Policy NC/1) and National Nature Reserve (Policy NC/1). The SSSI designation also abuts the eastern boundary of the HPC development site. The Proposals Map also shows the Special Protection Area (SPA) and Ramsar designations which affect the foreshore ('unsaved' Policy NC/2).

14.3.49 The following saved policies are considered to be potentially relevant:

- Policy NC/1 (Sites of Special Scientific Interest) states that development proposals which may, directly or indirectly, adversely affect SSSIs will not be permitted unless: there are no alternative means of meeting the development need, and the reasons for the development clearly outweigh the value of the site and the national policy to safeguard the nature conservation value of the national network of such sites.
- Policy NC/1 also states that, where the site is a National Nature Reserve (NNR) or a site identified under the Nature Conservation Review or Geological Conservation Review, particular regard will be paid to the site's national importance. Where development is permitted, the use of conditions or planning obligations to ensure the protection and enhancement of the site's nature conservation interest will be considered.
- Policy NC/3 (Sites of Local Nature Conservation and Geological Interest) states that planning permission will not be granted for development which has a significant adverse effect on local nature conservation/geological interests or integrity of landscape features, unless the importance of the development outweighs the value of the substantive interests present.
- Policy PC/4 (Contaminated Land) states that all development proposals on or in proximity to land known to be, or which may be, contaminated will include measures designed to prevent an acceptable risk to public health and the environment.
- Policy CO/1 (The Coastal Zone) states that development proposals in any part of the Coastal Zone, including those areas of existing developed coast, will only be permitted where: the development and its associated activities are unlikely to have an adverse effect, either directly or indirectly, on heritage features, landscape character areas, nature conservation interests, including sub-tidal and marine habitats, and residential amenities; the development is unlikely to have an adverse effect on the character of the coast and maintains and where possible, enhances, improves or upgrades the environment particularly in derelict and/or despoiled coastal areas; the development requires a coastal location.

ii. West Somerset District Local Development Framework (LDF) Core Strategy (Options Paper) (January 2010) (Ref. 14.36)

14.3.50 The Core Strategy is at a preliminary stage of preparation and the Options Paper does not include any specific policies relating to geology and land contamination impacts which are of relevance to the HPC development site.

iii. Supplementary Planning Guidance

14.3.51 WSC and SDC have jointly prepared draft supplementary planning guidance in relation to the Hinkley Point C Project. Public consultation on the Consultation Draft version of the Hinkley Point C Project Joint SPD (the draft HPC SPD) (Ref. 14.37) commenced on 1 March 2011 and concluded on 12 April 2011. EDF Energy has submitted representations which object to the draft HPC SPD. See **Volume 1,**, **Chapter 4** for a full summary of the position regarding the status of the draft HPC SPD.

14.3.52 The draft HPC SPD does not set out specific guidance in relation to geology and land contamination impacts at the HPC development site.

14.3.53 Further planning policy context is provided in the Legislative Planning Policy Context chapter (**Volume 1**, **Chapter 4**) and the Introduction chapter (**Chapter 1** of this volume).

14.4 Methodology

14.4.1 The baseline environmental studies, surveys and impact assessment for geology and land contamination have been conducted in accordance with relevant best practice and standard methodologies as detailed under Section b) (Baseline Assessment) below:

a) Study Area

14.4.2 The baseline assessment of land contamination and geology is concerned with the establishment of current conditions within the HPC Development Site, which is divided into three separate areas of land:

- Built Development Area West (BDAW) - this area of land lies approximately 400m to the west of the existing Hinkley Point Power Station Complex and forms the western part of the HPC development site. The area currently comprises agricultural land and woodlands with associated derelict farm buildings.
- Built Development Area East (BDAE) - this area is located immediately adjacent and to the west of Hinkley Point A (HPA) and forms the eastern part of the HPC development site. The area is currently operational land and lies within the Nuclear Licensed Site area.
- Southern Construction Phase Area (SCPA) - this area is located to the south of the Built Development Areas East and West and extends to the southern boundary of the HPC development site.

14.4.3 The subsequent impact assessment relating to land contamination includes potential impacts to human health and other receptors (i.e., ecology, crops and livestock, built environment, soil environment and controlled waters) from soil contamination within the HPC development site and any potential impacts to off-site receptors up to a distance of approximately 500 metres from the HPC development site boundary, including ecology, crops/livestock and soil in adjacent fields, local residents of Shurton and Knighton and people using the public footpaths. A distance of 500m was selected as this was considered to be the maximum distance over which contamination could feasibly migrate to or from the site under extreme circumstances.

14.4.4 The extent of the geological impact assessment includes consideration of the geological conditions and exposed cliff and the foreshore geomorphology within the HPC development site.

14.4.5 The study area for the assessment also includes the ten locations constituting the off-site highway improvement works.

14.4.6 The study area as described above is illustrated in **Figure 14.1**. A detailed description of the proposed HPC development site is provided in **Volume 1**, **Chapter 2** of this ES.

b) Baseline Assessment

14.4.7 The baseline assessment for geology and land contamination is based upon:

- review of desk based information;
- design and undertaking of intrusive investigations and surveys;
- reporting and risk assessment; and
- consultation with appropriate Statutory Bodies (including the Environment Agency, Natural England, Somerset County Council, West Somerset Council and West Somerset District Council).

14.4.8 The approach and methodologies used within the assessment are in accordance with the phasing and guidance contained within CLR 11: Model Procedures for the Management of Land Contamination (Ref. 14.21) and BS10175:2001 Investigation of Potentially Contaminated Sites – Code of Practice (Ref. 14.22) (this guidance was superseded in March 2011, however, the earlier version of the guidance was current and applicable at the time of the intrusive investigations and assessments). CLR 11 details the UK's technical framework for structured decision making about land contamination. Other key guidance documents and standards relating to investigations of contaminated land have also been considered and details presented in the relevant section (Section 14.3) of this chapter.

14.4.9 Preliminary assessments of the HPC development site were undertaken (Phase 1 desk-studies) using desk based information which was reviewed in order to identify potential salient features and identify potential hazards and risks. As part of the desk based assessment a 1km search area was applied to the area boundary to identify environmental setting information. It should be noted that the baseline general environmental context search area of 1km is larger than the 500m radius that has been used for the purpose of impact assessment. This included an assessment of geological, hydrogeological and hydrological conditions and the identification of potential salient features, through the review of the environmental data report (GroundSure report Ref.14.38), current and historical maps, plans and photographs and, where available, review and synthesis of existing reports. The sources reviewed as part of the desk based assessment included the following (this list is indicative and not exhaustive):

- GroundSure. Environmental Data Report, Geology and Ground Stability Report and Historical Map Pack. 2008. (Ref. 14.38).
- Ordnance Survey. Explorer Map 1:25,000 scale Quantock Hills & Bridgwater Sheet 140. 2005. (Ref. 14.39).
- British Geological Survey (BGS). 1:50,000 BGS Sheet 279; Weston-Super-Mare. 1980. (Ref. 14.40).
- Geological Survey of Great Britain. 1:10,560 Somerset Sheets: ST4 NE, ST24 NW and ST25 SW. 1980. (Ref. 14.41).
- Whittaker, A and Green, G.W. Geology of the Country Around Weston-Super-Mare: Memoir for 1:50000 Geological Sheet 279, New Series, with parts of sheets 263 and 295. Institute of Geological Sciences. London. 1983. (Ref. 14.42).

- Environment Agency. Policy and Practice for the Protection of Groundwater, Groundwater Vulnerability of the Somerset Coast, Sheet 42. Scale 1:100,000. EA. 1996 (Ref. 14.43).
- Environment Agency. Superficial and Bedrock Aquifer Designation Maps. 2011. (Ref. 14.44).

- Aspinwall & Company. Analysis of Groundwater Conditions at Hinkley Power Station. Report Ref: NU5101B for Nuclear Electric. 1996. (Ref. 14.47).
- Serco Assurance. Baseline Survey of an Area of Land to be Leased from British Energy at Hinkley Point. Report Re: SA/Env/0878/Issue 01. 2006. (Ref. 14.48).
- Serco Technical & Assurance Services. Pre-Closure Contamination Survey (C Station Land), Hinkley Point A. Report Ref: TAS/002838/001 Issue 01. December 2008. (Ref. 14.49).

14.4.10 Baseline non-intrusive radiological surveys have been undertaken across the different areas of land within the HPC development site. Measurements were taken using a Mini 6-80/MC7, a low-background Geiger-Muller detector designed for environmental gamma dose rate measurement using the methods outlined in the Environment Agency Guidance TGNM5 – Monitoring (Ref. 14.50).

14.4.11 To complement the gamma dose rate measurements, a walkover survey was completed using a Thermo G2 probe and an Electra ratemeter, which is a sodium iodide scintillation detector designed for the detection of gamma radiation. Survey locations were randomly selected to afford good coverage of the different areas of land within the HPC Development Site, a number of targeted survey points were also selected to cover areas of interest on the BDAE identified in the desk based assessment.

14.4.12 The field readings were compared to background concentrations taken at a cemetery site near Bridgwater using both the G2/Electra and the Mini 6-80/MC71. Measurements were taken over undisturbed ground within the cemetery where no grave digging had occurred. Following the review of desk based information and baseline surveys the findings were used to design and undertake intrusive investigations at the HPC Development Site to collect site-specific data (Phase 2 investigations). The intrusive investigations were undertaken as part of wider geological and geotechnical on-shore investigations (two on-shore campaigns have been undertaken with the first campaign in 2008-2009 and the second campaign in 2009-2010) and comprised the excavation of a series of exploratory holes (including boreholes, trial pits, hand pits and windowless sampling holes) to establish ground conditions and collect representative soil samples. Selected soil samples collected during the investigations were subject to chemical analysis for a range of radiochemical and non-radiological contaminants, which included selected samples for leachate and Waste Acceptance Criteria (WAC) analysis.

14.4.13 Following the preliminary assessments, surveys and the completion of intrusive investigations and associated risk/data assessments, the baseline land contamination characteristics have been determined through the development and subsequent validation of a Conceptual Site Model (CSM). A CSM has been produced to identify potential risks posed to human health and other receptors as a result of soil contamination which may be present within the HPC development site.

i. Development of Conceptual Site Model

14.4.14 A CSM is developed as an initial step in the process of assessing the risks related to contaminated land and groundwater. A CSM is defined within the British Standard BS 10175 – Investigation of Potentially Contaminated Sites – Code of Practice (2011) (Ref. 14.51) as follows (note that whilst the intrusive investigations were undertaken in accordance with the 2001 version of this guidance (Ref. 12.22), the 2011 guidance has been considered to be appropriate for the development and refinement of the conceptual model presented herein):

> *"Characteristics of a site that are relevant to the occurrence and potential effects of ground contamination that describe the nature and sources of contamination; the ground, groundwater, surface water, ground gases and volatile organic compounds (VOCs) that could be present; the environmental setting; potential migration pathways; and potential receptors."*

14.4.15 The CSM provides a three-dimensional picture of a site, presenting and illustrating the potential pollutant linkages that may exist at the site. A pollutant linkage may exist where a source of contamination is present that may interact with a receptor (target) via a pathway. The contaminant source, pathway and receptor are defined as follows:

- CONTAMINANT SOURCE – Location or feature from which contamination is, or was, derived.
- PATHWAY – Mechanism or route by which a contaminant could come into contact with, or otherwise affect, a receptor.
- RECEPTOR – Entity that could be adversely affected by a contaminant(s) (examples of receptors include persons, other living organisms, ecological systems, controlled waters, atmosphere, structures and utilities).

14.4.16 The CSM evolves through the various phases of an investigation as more detailed information becomes available, allowing potential pollutant linkages to be validated or discounted. The baseline CSM for land contamination is presented in Section 14.5 b) **Figure 14.17** and **Appendix 14G**.

c) Assessment Criteria

14.4.17 The non-radiochemical data collected during the intrusive investigations have been used to conduct a generic Tier 1 risk assessment, where observed concentrations of contaminants in soil have been compared against relevant Tier 1 Soil Screening Values (SSVs) comprising applicable Soil Guideline Values (SGVs) or other Generic Assessment (or screening) Criteria (GAC) as appropriate. GACs have been developed in order to assess the potential risk to different receptors including human health, the built environment and the soil environment including potential phytotoxic and ecological (i.e. ecotoxicological) risk. A summary of the sources of the SSVs and GACs is summarised in **Table 14.1**, and details of the adopted approaches are provided below.

Table 14.1: Generic Environmental Assessment Criteria

Environmental Media	Generic Screening Criteria
Soil	**Human Health Risk** • Derived Soil Screening Values (SSV) using the Environment Agency's Contaminated Land Exposure Assessment (CLEA) model (v1.06), which has adopted all the same standard parameters the Environment Agency used to derive standard UK Soil Guideline Values (SGV) for commercial and industrial end use, with the exception of soil organic matter which has been set to 1%, to reflect the site specific soil conditions. Note that assessment criteria for a residential without consumption of home grown vegetables receptor have been used as the basis for SGV, GAC and SSVs for the Southern Construction Phase (SCPA) area. This is because the development proposals show that a significant part of this area will be used for temporary contractors accommodation. • Defra/EA 2002. Research and Development Publication SGV 10. Soil Guideline Values for Lead Contamination. (Ref. 14.55). • Hazardous Waste (England and Wales) Regulations 2005/Chemical (Hazard Information and Packaging Supply) Regulations 2002. (Ref. 14.56). • BS3882:2007 Specification for topsoil requirements for use. (Ref. 14.57). **Phytotoxic Risk** • Sludge (Use in Agriculture) Regulations 1989 – Statutory Instrument 1989 No. 1263 (Ref. 14.58). • Former Inter Departmental Committee for the Redevelopment of Contaminated Land (UK) (ICRCL) 59/83 (N.B. Paper withdrawn by Defra in 2004). (Ref. 14.59). **Built Environment Risk** • Water Regulations Advisory Service (WRAS) Guidance Note 9-04-02 2002. i. Approach to Human Health Risk Assessment

14.4.18 In October 2009 the Environment Agency released a new version of the CLEA Model (version 1.06).

14.4.19 The Environment Agency intend to publish revised SGVs and toxicological (TOX) reports for a list of priority substances identified by the SGV taskforce which includes many of the most commonly occurring contaminants. At the time of this data assessment, the Environment Agency had published SGV reports and associated TOX reports for eleven substances; arsenic, nickel, mercury, selenium, cadmium, phenol, 'dioxins, furans and dioxin-like PCBs', benzene, xylenes, toluene and ethyl benzene.

14.4.20 The published SGVs are based on a sandy loam soil type with a Soil Organic Matter (SOM) of 6%. In order to ensure that the Tier 1 SSVs are conservative and more site-specific, a series of internally-derived human health SSVs were generated using the CLEA model (v 1.06). For the BDAE and BDAW, SSVs have been generated using identical input parameters and assumptions to those adopted by the Environment Agency in the published SGVs for commercial and industrial end use (which is appropriate given the proposed development of the site for a new power station), with the exception that the SOM has been reduced from 6% to 1% (a more conservative SOM). A non-standard land use is proposed for the SCPA, i.e. to include a workers accommodation campus, therefore as a conservative approach SSVs have been generated using identical input parameters and assumptions for the residential without the consumption of homegrown vegetables land use, with the exception that the SOM has also been reduced to 1%. Note that it is recognised that the standard input parameters used in the derivation of residential without the consumption of homegrown vegetables land use SGVs/GACs and SSVs do not match the receptor types, exposure frequencies and durations of the proposed temporary contractors accommodation land use. However, as the input parameters for residential without the consumption of homegrown vegetables land use are more health protective than would be used for a temporary contractors accommodation land use, this approach is considered appropriate for a generic quantitative risk assessment.

14.4.21 The Land Quality Management Ltd (LQM) and Chartered Institute of Environmental Health (CIEH) (Ref. 14.52) and Contaminated Land: Applications in Real Environments (CL:AIRE) (Ref. 14.53) have generated Generic Assessment Criteria (GAC) for a number of metals and organic contaminants, including the 16 Environmental Protection Agency (EPA) priority Polycylic Aromatic Hydrocarbons (PAHs), Total Petroleum Hydrocarbons (TPH) and several Semi-Volatile Organic Compounds (SVOCs) and Volatile Organic Compounds (VOCs) . LQM/CIEH used the CLEA model v1.04 to derive their GACs, with CL:AIRE utilising the current CLEA model v1.06. The Tier 1 values derived internally by EDF Energy for the purpose of assessing these substances were generated using the CLEA model (v 1.06) and the same input criteria and assumptions as the LQM/CIEH and CL:AIRE input parameters.

14.4.22 In addition to the CLEA SGV, LQM/CIEH and CL:AIRE contaminants, an extensive literature review was carried out by EDF Energy in order to derive suitable assessment criteria for cyanide. As a result of the review, the use of the health criteria values provided by the Environment Agency within their document – Environment Agency TOX Report 5 (March 2002) (Ref. 14.54), were adopted as these provide a conservative approach for assessing the risks posed by cyanide at the HPC development site.

14.4.23 For the purpose of the human health risk assessment, EDF Energy internally-derived Tier 1 SSVs were used for all metals (with the exception of lead), PAHs and speciated TPHs. In the absence of published Tier 1 SSVs for the remaining contaminants the following alternative sources were used for the purpose of the human health risk assessment:

- for lead the 2002 Environment Agency SGV (Ref. 14.55) has been used in the absence of a published UK alternative (the SGV has been withdrawn, however the toxicology report and methodology are still valid);
- for Total/Sum TPH the Hazardous Waste (England and Wales) Regulations 2005 (Ref. 14.56), inert waste threshold has been applied;
- for pH the value within the BS3882:2007 Specification for Topsoil and Requirements for Use (Ref. 14.57), has been applied; and
- for asbestos the significance threshold is the presence or absence of detectable fibres in soil.

ii. Approach to Phytotoxic Risk Assessment

14.4.24 Certain soil contaminants may pose a risk to plant establishment and growth (phytotoxicity). As there are no published UK screening values for assessing phytotoxic risk, in order to undertake a Tier 1 assessment of risks to plants the thresholds recommended in the Sludge (Use in Agriculture) Regulations 1989 – Statutory Instrument 1989 No. 1263 (Ref. 14.58) for the potentially phytotoxic contaminants copper, nickel and zinc were used. Water soluble boron is also a potential phytotoxic contaminant and in the absence of any other available guidelines the value provided by the former ICRCL Guidance Note 59/83 (Ref. 14.59) (paper withdrawn by Defra in 2004) was used.

14.4.25 To assess the potential risk of pH effects on plants the pH value presented within the BS3882:2007 Specification for Topsoil and Requirements for Use (Ref. 14.57) was adopted as the Tier 1 assessment criteria.

iii. Approach to Built Environment Risk Assessment

14.4.26 Contamination may pose risks to the built environment (e.g. buried water pipes and concrete). The thresholds used within this assessment for potable water supply pipes have been taken from the Water Regulations Advisory Scheme (WRAS) Guidance Note 9-04-03 (Ref. 14.60), and the Wessex Water Soil Survey Guidance (WWSSG) (Ref. 14.61). The Building Research Establishment (BRE) Special Digest 1:2005, Concrete in Aggressive Ground (Ref. 14.62) were used to assess potential chemical attack to buried concrete structures. The above guidance documents were used in order to undertake a Tier 1 assessment of the risk to built environment receptors. Note that the WRAS Guidance Note (Ref. 14.60) has recently been withdrawn and WRAS intends to prepare and publish a replacement Guidance Note making reference to UK Water Industry Research Ltd (UKWIR) guidance (Ref.14.63) which was issued in March 2011.

14.4.27 It is not considered that potential changes to risk thresholds which may result from the updated Guidance Note would change the built environment impact assessment ratings or overall conclusions and recommendations presented within this chapter.

14.4.28 The comparison of the analytical results with the thresholds specified in the above guidance enabled an initial assessment of the risk posed by the HPC development site soils to buried water services and concrete. In terms of assessing the potential for soil to attack/degrade buried concrete, this assessment provides an initial screening analysis on the basis of the total observed sulphate concentrations and pH conditions.

iv. Approach to Ecological Risk Assessment

14.4.29 Criteria for assessing the risk from contaminated soils to ecological systems are currently not well developed in the UK. In October 2008 the Environment Agency published an ecological risk assessment (ERA) framework for contaminated soils (Ref. 14.28) in collaboration with Defra, Natural England, Welsh Assembly Government, the Countryside Council for Wales, local authorities and industry. Guidance document ERA2b (Ref. 14.64) contains guidance on the use of ecological/ecotoxicological Soil Screening Values (SSVs). Table 17 of the ERA2b document provides proposed SSVs for selected contaminants. For those contaminants not covered by the Environment Agency document (Ref. 14.28), the guidance (Ref. 14.64) suggests using alternative sources, of which the following were used in this assessment: US EPA Eco SSLs (Ref. 14.65), Canadian Soil Quality Guidelines (Ref. 14.66), Oak Ridge National Laboratory Screening Benchmarks (Ref. 14.67) and/or Dutch RIVM Serious Risk Concentrations for Ecosystems (SRCeco) (Ref. 14.68).

14.4.30 The proposed SSVs given in the Environment Agency Guidance document (Ref. 14.64) and the other sources have been used as an initial (Stage 1) screening tool to assess whether or not the concentrations of soil contaminants may pose a risk to ecology and ecosystems. The risks posed by contaminants in soil are chiefly determined on the basis of soil environment specific receptors (i.e. invertebrates), however may also include higher animals (i.e. mammals, avian receptors).

14.4.31 These ecological risk SSVs are very conservative, i.e. highly precautionary. There are no statutory designated ecosystems within the HPC development site. However, there are designated sites in adjacent areas (e.g. the Severn Estuary and a SSSI to the south-east).

14.4.32 A staged approach to the assessment of ecological risk has been adopted, whereby observed contaminant concentrations were initially compared with the ecological SSVs described above. Where concentrations exceeded the relevant SSVs a further Stage 2 assessment was carried out where contaminant concentrations were compared to the background concentrations recorded in rural soils in England as published by the Environment Agency in the UK Soil and Herbage Pollutant Survey Reports (Ref. 14.69 and Ref. 14.70).

14.4.33 For soils on the BDAE and SCPA only, a Stage 3 assessment was undertaken where contaminants were recorded at concentrations exceeding the rural England background concentration range for soils. Under the Stage 3 assessment contaminants were compared with site-specific concentration ranges, i.e. the range of concentrations recorded within soils on the BDAW, which are considered to be representative of local background concentrations (as detailed in Section 14.5 b) ii). A Stage 3 assessment for the BDAW area was not undertaken, primarily as this was not required (i.e. because there were no exceedences of Stage 2 screening criteria) but also because the BDAW data was the source of the Stage 3 local background screening concentrations.

Statistical Assessment

14.4.34 Where appropriate, the soil analytical results were subject to statistical tests, using the statistical approach recommended by CL:AIRE/CIEH Guidance on Comparing Soil Contamination Data with a Critical Concentration (Ref. 14.71). The guidance takes two different approaches to statistical analysis of the data based on the aims and context of the investigation. The statistical analysis (using the ESI Statistical analysis tool (Ref. 14.72)) of the contamination data is based on the planning scenario adopted in the current guidance. The 95th Upper Confidence Level (UCL) of the true population mean for each contaminant has been compared to the Critical Concentration (Tier 1 SSVs) to determine whether the site soils contain a potential source of contaminants which may pose an unacceptable risk. For the purpose of the statistical analysis the data are divided into 'populations' (in statistical terms), based on the material characteristics (i.e. Made Ground or natural ground), and where relevant, by geographical area.

v. Approach to Controlled Water Risk Assessment

14.4.35 To assess the risks to groundwater and surface waters, soil leachate concentrations have been compared to appropriate Drinking Water Standards (DWS) (Ref. 14.73) and Environmental Quality Standards (EQS) (Ref. 14.74 and 14.75) for freshwater and coastal and other non-freshwater surface waters. In accordance with the requirements of the Water Framework Directive (WFD) (Ref. 14.4), the published Tier 1 screening values taken from the document, The River Basin Districts Typology, Standards and Groundwater threshold values (Water Framework Directive) (England and Wales) Directions 2010 (Ref. 14.75) have been used where available. All EQS values have been revised in line with the WFD (where applicable).

vi. Ground Gas Risk Assessment

14.4.36 A programme of ground gas monitoring has been undertaken at the HPC development site in accordance with the requirements set out in the guidance document Construction Industry Research and Information Association (CIRIA) 665 Assessing risk posed by hazardous ground gases to buildings (2007) (Ref. 14.76), which is the main UK guidance document for ground gas monitoring and risk assessment. A programme of monitoring has been undertaken on the BDAW in 2009 and on the BDAE and SCPA in 2010, subsequent to the first and second on-shore investigations respectively.

14.4.37 The data collected during the monitoring programme has been used to undertake a Ground Gas Risk Assessment (GGRA) in accordance with the methodology detailed within the guidance document CIRIA C665 (Ref. 14.76). The GGRA is a Tier 1 generic quantitative risk assessment relating to certain high risk gases to human health and buildings. The gas risk assessment methodology is based on the calculation of a Gas Screening Value (GSV) for each of the key parameters (methane and carbon dioxide) which is then compared to the threshold values provided in Table 8.5 of CIRIA C665 (Ref. 14.76). These threshold values determine the gas Characterisation Situation (CS) and the level of risk posed by any exceedence of acceptable ground gas conditions, based on the flow rates and gas concentrations recorded. A gas CS is then described that corresponds to a defined level of protection required to mitigate the risk (Table 8.6 of CIRIA 665, Ref. 14.76).

14.4.38 Hydrogen sulphide and carbon monoxide concentrations recorded during the monitoring programme have been compared to the Health and Safety Executive Workplace Exposure Limits provided in the EH40 guidance document (2007) (Ref. 14.77). An initial screening value of 10ppm for VOCs has been adopted based on the range of concentrations for individual VOC compounds (typical range 1–100ppm) within the EH40 guidance document (2007) (Ref. 14.77).

vii. Approach to Radiochemical Data Assessment

14.4.39 There are no soil guideline values which have been specifically derived to assess contamination with respect to radioactivity. However, the Environmental Permitting (England and Wales) Regulations 2010 (EPR 2010) (Ref. 14.19) provide activity concentration limits for specified naturally occurring radioelements in soil materials. In order to provide a preliminary assessment of the data, threshold values for specified radionuclides were derived from these EPR2010 limits.

14.4.40 For the purposes of the assessment of radiochemical data, threshold values for individual isotopes of the EPR2010-specified elements included in the analysis suite were derived by dividing the elemental limit for each isotope by the number of radioactive isotopes of the element present in the three natural radioactive decay series (uranium-238, thorium-232 and uranium-235). **Table 14.2** presents the derived threshold values for isotopes of the EPR2010 specified elements adopted for the assessment of data.

Table 14.2: Derived Threshold Values for Isotopes of the EPR2010 Specified Elements in Solids

Determinand	Other isotopes in the natural decay series	Total number of isotopes of the determinand in the natural decay series	EPR2010 specified elemental limit for the determinand /Bq g^{-1}	Derived threshold value for the determinand /Bq g^{-1}
Actinium-228⁺	Actinium-227#	2	0.37	0.19
Lead-210*	Lead -211# Lead -212⁺ Lead -214*	4	0.74	0.19
Lead-212⁺	Lead -210* Lead -211#	4	0.74	0.19

Determinand	Other isotopes in the natural decay series	Total number of isotopes of the determinand in the natural decay series	EPR2010 specified elemental limit for the determinand /Bq g^{-1}	Derived threshold value for the determinand /Bq g^{-1}
	Lead -214*			
Lead-214*	Lead -210* Lead -211# Lead -212+	4	0.74	0.19
Protactinium-234m*	Protactinium -234* Protactinium -231#	3	0.37	0.12
Radium-226*	Radium -228+ Radium -224+ Radium -223#	4	0.37	0.093
Thorium-234*	Thorium-232+ Thorium -231# Thorium -230* Thorium -228+ Thorium -227#	6	2.59	0.43
Uranium-235#	Uranium-238* Uranium-234*	3	11.1	3.7

* Present in the uranium-238 natural decay series.
# Present in the uranium-235 natural decay series.
+ Present in the thorium-232 natural decay series

14.4.41 A number of exemption orders have been made under radioactive substances regulations that specify the conditions under which materials or wastes defined as radioactive under EPR2010 are exempt from some or all of its provisions. There are two key exemption orders that are relevant to radioactively contaminated land:

- Statutory Instrument 1986, No. 1002 and amended 1992, No. 647. The Radioactive Substances (Substances of Low Activity) Exemption Order (the SoLA Exemption Order) (Ref. 14.78); and
- Statutory Instrument 1962, No. 2648. The Radioactive Substances (Phosphatic Substances, Rare Earths etc.) Exemption Order (the PSRE Exemption Order) (Ref. 14.79).

14.4.42 The SoLA Exemption Order (Ref. 14.78) exempts solid materials from the provisions of EPR2010 provided that they are substantially insoluble in water and have an activity concentration that is below 0.4Bq g^{-1}. The SoLA Exemption Order is applicable to both natural and anthropogenic radionuclides and the 0.4Bq g^{-1} limit specified is considered to be additional to the background levels of radionuclides (both natural and anthropogenic).

14.4.43 The PSRE Exemption Order (Ref. 14.79) states that material that is radioactive solely because of the presence of one or more of the EPR2010 specified elements (actinium, lead, polonium, protactinium, radium, radon, thorium and uranium) and is substantially insoluble in water, is unconditionally exempted from the provisions of

EPR2010 provided that the activity concentration of each of the specified elements present does not exceed 14.8Bq g^{-1}.

14.4.44 Comparison of results obtained with the threshold values derived from EPR2010 and with the relevant Exemption Order limits provides a preliminary quantitative assessment that determines whether or not the soil could be subject to radioactive substances regulation.

14.4.45 The data derived from the analysis of site soils has also been compared with adopted background values derived from a number of sources. Background data for the HPC development site adopted for the purpose of the following data assessment are taken from a number of sources. Environmental monitoring data acquired from near to the HPC development site have been used preferentially where available, otherwise data relating more generally to the United Kingdom have been used.

14.4.46 Background data adopted for the assessment are taken from the following sources:

- Radioactivity in Food and Environment (RIFE) reports 13 (Ref. 14.80) and 14 (Ref. 14.81). These reports include radionuclide data for anthropogenic radionuclides and carbon-14 in soil samples collected from an unspecified location near the HPC development site in 2007 and 2008;
- DoE/HMIP/RR/93/063 (1993) (Ref. 14.82). This report, commissioned by Her Majesty's Inspectorate of Pollution (HMIP), includes data for naturally occurring radionuclides in soils from various locations in the United Kingdom; and
- UNSCEAR (2000) (Ref. 14.83). This report provides data for radium-226 in soil from the United Kingdom.

14.4.47 The adopted background data are summarised in **Table 14.3**. Values in parentheses indicate calculated mean values and other values are taken directly from the data sources.

Table 14.3: Adopted Radiological Background Values

Determinand	Background Value/Bq g^{-1}
Carbon-14*	0.010 - 0.012 (0.011)
Cobalt-60*	< 0.00023 - < 0.00041 (< 0.00032)
Zirconium-95*	< 0.00090 - < 0.0035 (< 0.0022)
Niobium-95*	< 0.0010 - < 0.0072 (< 0.0041)
Ruthenium-106*	< 0.0025 - < 0.0049 (< 0.0037)
Antimony-125*	< 0.00069 - < 0.0012 (< 0.0009)
Caesium-134*	< 0.00034 - < 0.00064 (< 0.00049)
Caesium-137*	0.0052 - 0.0068 (0.0060)
Cerium-144*	< 0.0020 - < 0.0038 (< 0.0029)
Europium-154*	< 0.00071 - < 0.0013 (< 0.0010)
Europium-155*	< 0.00094 - < 0.0018 (< 0.0014)
Americium-241*	< 0.00097 - < 0.0026 (< 0.0018)
Potassium-40#	0 - 3.2

Determinand	Background Value/Bq g^{-1}
Lead-210#	0.041
Radium-226+	0.037

Values in parentheses are mean values.
*Data from RIFE reports 13 (Ref. 14.80) and 14 (Ref. 14.81).
Data from DoE/HMIP/RR/93/063 (1993) (Ref. 14.82).
+ Data from UNSCEAR (2000) (Ref. 14.83).

14.4.48 In accordance with the methodology outlined above, surveys specifically carried out for the ES include:

i. Built Development Area West

- AMEC. Phase 1 Desk Study and Preliminary Non-Radiological Site Investigation for the Built Development Area West, BPE. Report Ref: 15011/TR/00022. 31 March 2010. (Ref. 14.84).
- AMEC. Baseline Radiological Survey. Report Ref: 15118/TR/00003, BPE. 7 November 2008. (Ref. 14.85).
- AMEC. Phase 2 Supplementary Investigation of Potential Radiological Contamination, BPE. Report Ref: 15011/TR/00091. 28 September 2011. (Ref. 14.86).
- AMEC. Final Ground Gas Assessment for Built Development Area West, BPE. Report Ref: 15011/TR/00123. 9 September 2010. (Ref. 14.87).
- Structural Soils Ltd. Factual Report on Ground Investigation: On Shore Investigations for Hinkley Site, Report Ref: 721763. August 2009. (Ref. 14.88).
- EDF. Onshore geological, geotechnical and hydrogeological interpretive report. Report Ref: EDTGG09014A. 14 October 2009. (Ref. 14.89).

ii. Built Development Area East and Southern Construction Phase Area

- AMEC. Desk Based Assessment and Synthesis Report for the Built Development Area East and Southern Construction Phase Area. Report Ref: 15011/TR/00121. 4 November 2010. (Ref. 14.90).
- AMEC. Radiological Survey Report for Hinkley Point. Report Ref: 15011/TR/00144, BPE. 23 July 2010. (Ref. 14.91).
- AMEC. Phase 2 Contamination Assessment (Non Radiological) of the Built Development Area East and Southern Construction Phase Area, BPE. Report Ref: 15011/TR/00151. 3 November 2010. (Ref. 14.92).
- AMEC. Phase 2 Contamination Assessment (Radiological) of the Built Development Area East and Southern Construction Phase Area, NNB BPE. Report Ref: 15011/TR/00150. October 2011. (Ref. 14.93).
- AMEC. Ground Gas Risk Assessment for the Built Development Area East and Southern Construction Phase Area, NNB BPE. Report Ref: 15011/TR/00166 October 2011. (Ref. 14.94).
- Structural Soils Limited. Final Factual Report on Second Campaign On-Shore Investigations at Hinkley Site. Report Ref: 723335. February 2011 (Ref. 14.95).

iii. Cliff and Foreshore Geology

- AMEC. Geological Survey and Mapping, BPE. Report Ref; 15122/TR/0011. 23 June 2009 (Ref. 14.96).

d) Consultation

14.4.49 Consultation was undertaken throughout the EIA process and further information may be found in the **Consultation Report**. **Table 14.4** summarises the consultation meetings/correspondence with key stakeholders. The scope of work described in this Chapter reflects their comments and advice, as appropriate.

Table 14.4: Key Consultation Meetings for Geology and Land Contamination

Date	Consultee	Type/Purpose of Consultation
09/12/2008	Natural England	Scoping meeting relating to foreshore and cliff geomorphology and geological issues. The purpose of the meeting was to discuss and clarify with Natural England aspects relating to the foreshore and cliff geomorphology and geological issues. Matters discussed included: • Bridgwater Bay National Nature Reserve (NNR) and possible geological designations or interest in the NNR; • clarifying the extent of the Blue Anchor to Lilstock Site of Special Scientific Interest (SSSI), requirements relating to fossil finds; • replication of cliff exposures would reduce Natural England's concerns if a similar quality of exposure could be found elsewhere that was publicly accessible; and • aims and objectives of the proposed geological mapping survey.
		Natural England confirmed that geomorphological designations do not extend to the east of the SSSI boundary and they did not require demonstration that such features are present. Photographing what was present by way of geomorphological features on the foreshore of the study area would be sufficient, i.e. no need to survey and map the geomorphological features (unlike the geological exposures in the cliff face). Natural England stated during consultation that the identification of a replicate, accessible section of units elsewhere within the 'Blue Anchor to Lilstock SSSI' is likely to be acceptable as an offset to the loss of the units exposed within the cliff and rock pavement at Hinkley Point. As a result of consultation, Natural England stated that 'it must be demonstrated that the same geological sequence that is observable and accessible at Hinkley Point is replicated elsewhere along the coastal section, which extends up to a distance of approximately 10km to the west, and that the replicated site is equally accessible to the public.'
09/01/2009	Natural England	Geology and geomorphology site walkover meeting with representatives from Natural England. During the meeting the work for the first section of geological surveying was discussed. The exposures within the stretch of cliff along the study area contain good examples of the interbedded limestones and mudstones of the Blue Lias formation, but in places the extent of the exposure is small (e.g. only 2m high cliffs). All observed that the cliff units at the study area are, in fact,

Date	Consultee	Type/Purpose of Consultation
		replicated in the foreshore. It was agreed that the geological mapping would continue for about 10km to the west of the study area (i.e. beyond the Lilstock section). Good exposures are documented further to the west and these might provide good examples of replicate sites. The outcome of the walkover meeting was that the geological mapping would continue as planned.
09/12/2008	Local Authorities (Sedgemoor and West Somerset)	Scoping consultation meeting. During the meeting a brief summary of the Phase 1 and Phase 2 contaminated land investigations on the Built Development Area West conducted to that point and their findings was presented to the Local Authorities along with the proposals for gas and groundwater monitoring.
01/10/2009	Local Authorities (Sedgemoor and West Somerset)	Presentation/Consultation meeting. The purpose of the meeting was to provide a more up to date and detailed presentation of the Phase 1 and Phase 2 investigations and gas and groundwater monitoring which had been completed at that time on the Built Development Area West and to discuss the future proposed investigations on the Built Development Area East and Southern Construction Phase Area and proposed assessment methodologies.
12/12/2008	Environment Agency	Copy of draft Outline Surface Water, Marine Water, Groundwater and Gas Monitoring Plan sent to Environment Agency for comment.
15/12/2008	Environment Agency	Scoping consultation meeting. During the meeting a brief summary of the Phase 1 and Phase 2 contaminated land investigations on the Built Development Area West conducted to date and their findings were presented to the Environment Agency along with the proposals for gas and groundwater monitoring. Environment Agency explained that as far as they were aware there is no real contaminative history on the Built Development Area West.
28/07/2009	Environment Agency	Presentation/Meeting. The purpose of the meeting was to provide a more up to date and detailed presentation of the Phase 1 and Phase 2 investigations and gas and groundwater monitoring which had been completed at that time on the Built Development Area West and to discuss the future proposed investigations on the Built Development Area East and the Southern Construction Phase Area and proposed assessment methodologies.
27/07/2010	Environment Agency	Presentation/Meeting. The purpose of the meeting was to provide an up to date presentation of the Phase 1 and Phase 2 investigations and gas and groundwater monitoring which had been completed at that time on the site. Also, included discussions on proposed groundwater ConSim modelling.
24/06/2009	Hinkley Point New Build – Water Liaison	During the meeting a brief summary of the Phase 1 and Phase 2 contaminated land investigations and monitoring conducted to date on the Built Development Area West and findings were presented. Discussed Phase 1 desk based assessment report for the

Date	Consultee	Type/Purpose of Consultation
		complementary lands (Built Development Area East and Southern Construction Phase Area) and Phase 2 investigation for these areas planned for August/September 2009.
28/07/2009	Hinkley Point New Build – Water Liaison	Environment Agency stated that all Strategic Siting Assessment (SSA) land would have to be investigated. Environment Agency stated they would like to see Phase 1 and 2 detailed data.
02/09/2009	Hinkley Point New Build – Water Liaison	Meeting to present plans for the second on-shore geophysics, geological and geotechnical works to start in September 2009 for the land to East and South of the SSA boundary (i.e. Built Development Area East and Southern Construction Phase Area).
06/01/2010	Hinkley Point New Build – Water Liaison	Environment Agency stated they would like to see Phase 1 and 2 detailed data.
28/07/2009	Marine Authorities Liaison Group (MALG)	Meeting/presentation at which Phase 1 and Phase 2 non-radiochemical results and findings were discussed and proposals for further site investigation initiated.

e) Assessment Methodology

14.4.50 **Volume 1**, **Chapter 7** of this ES describes the assessment methodology for this EIA. In addition the following specific methodology was applied for the determination of receptor value and sensitivity (see **Table 14.5**) and of impact magnitude (see **Table 14.6**) for geology and land contamination.

i. Value and Sensitivity

14.4.51 Receptors relevant to geology and land contamination that may be impacted by the HPC development were assigned a level of importance in accordance with the methodology described in **Volume 1**, **Chapter 7** of this ES and the guideline definitions of value and sensitivity specific to geology and land contamination shown in **Table 14.5**.

14.4.52 Where a receptor could reasonably be placed within more than one value and sensitivity rating, conservative professional judgment has been used to determine which rating would be applicable.

Table 14.5: Guidelines for the Assessment of Value and Sensitivity

Value and Sensitivity	Guidelines
High	**Geology** Geology has an international or national designation (e.g. Blue Anchor to Lilstock SSSI which extends along approx. 40m of the frontage of the site) and/or has very low capacity to accommodate any change. **Land Contamination** Receptor of high sensitivity and high intrinsic value (e.g. humans, or habitats and ecology within area designated for conservation importance, groundwater abstraction).
Medium	**Geology** Geology has a local or regional designation (e.g. Local Geological Site or the exposed foreshore geomorphology and cliff along the frontage of the site) and/or has low capacity to accommodate any change.

Value and Sensitivity	Guidelines
	Land Contamination Receptor of medium sensitivity and value, i.e. possesses key distinctive characteristics (e.g. important buildings to be constructed on-site).
Low	**Geology** Geology not designated but possesses key characteristics which may be locally important and/or has a high capacity to accommodate change. **Land Contamination** Receptor of low sensitivity and value, i.e. possesses some distinctive characteristics (e.g. groundwater with no significant local use at or adjacent to the site in or down gradient of the likely area of influence).
Very Low	**Geology** Geology not designated and is non distinctive and/or is likely to tolerate the proposed change. **Land Contamination** Receptor of low sensitivity and value, i.e. possesses no distinctive characteristics (e.g. subsoil used for engineering fills).

14.4.53 The potential sensitivity of a receptor can be reduced following the application of standard good practice/control measures, as detailed in Section 14.6. For example, workers on-site may be exposed to (and subsequently impacted by) airborne contaminated dust if released from contaminated materials. However, if respiratory protection is worn, exposure is minimised and the sensitivity of the worker reduced as a result. In effect, if the pathway is not apparent or is managed, then value and sensitivity should be reduced.

ii. Magnitude

14.4.54 The magnitude of impact has been based on the consequences that the proposed development would have upon geology and land contamination receptors, and has been considered in terms of high, medium, low or very low magnitude (see **Table 14.6**). Potential impacts were considered in terms of whether they are permanent or temporary, adverse (negative) or beneficial (positive) and/or cumulative.

14.4.55 A permanent impact is considered irreversible and, consequently, often represents an impact of high magnitude. The sources of impact may arise during construction and/or operation.

14.4.56 Where impact magnitude could reasonably be placed within more than one severity rating, conservative professional judgement has been used to determine which rating would be applicable.

Table 14.6: Guidelines for the Assessment of Magnitude

Magnitude of Impact	Guidelines
High	**Geology** Very significant permanent change to solid geology over the whole site so that it is unrecognisable when compared to the baseline conditions down to substantial depths below the ground surface. **Land Contamination**

Magnitude of Impact	Guidelines
	Soil contamination is considered to pose a high risk to potential receptors with one or more pollutant linkage certain to be present. Site certain to be deemed as Part 2A and/or considered unsuitable for use.
Medium	**Geology** Significant permanent changes to solid geology over the majority of the site so that it is unrecognisable when compared to the baseline conditions down to substantial depths. **Land Contamination** Soil contamination is considered to pose a moderate risk to potential receptors with one or more pollutant linkages likely to be present. Site likely to be deemed as Part 2A and/or considered unsuitable for use.
Low	**Geology** Noticeable but not significant changes to the near surface geology (weathered material) covering a part of the site or a number of isolated locations. **Land Contamination** Soil contamination is considered to pose a low risk to potential receptors with one or more pollutant linkages possibly present. Site possibly deemed as Part 2A and/or considered unsuitable for use.
Very low	**Geology** Noticeable but insignificant changes to the near surface geology (weathered material only) at a small number of isolated locations across the site. **Land Contamination** Soil contamination is considered to pose a very low risk to potential receptors with one or more pollutant linkages unlikely to be present. Site unlikely to be deemed as Part 2A and/or considered unsuitable for use.

iii. Significance of Impacts

14.4.57 The significance of the impact is judged on the relationship of the magnitude of impact to the assessed sensitivity and/or importance of the resource. The methodology to assess the predicted significance of impacts, without mitigation, is outlined in **Volume 1, Chapter 7** of this ES.

14.4.58 The following impact assessment assumes that standard good practice working methods have been implemented on site and compliance with all rules and regulations governing the site. It should be noted that compliance with rules and regulations and standard good construction practices are not considered as formal mitigation (i.e. specific additional mitigation to reduce assessed moderate or major adverse impacts) within this ES.

iv. Cumulative Effects

14.4.59 **Volume 1, Chapter 7** of this ES sets out the methodology used to assess cumulative impacts. Additive and interactive effects between site-specific impacts are considered within this chapter. The assessment of cumulative impacts with other elements of the HPC Project and other proposed and reasonably forseeable projects are considered in **Volume 11** of this ES.

f) Limitations, Assumptions and Uncertainties

14.4.60 Intrusive investigations (i.e. boreholes, trial pits, hand pits and windowless sampling holes), carried out in line with accepted best practice and guidance, were undertaken on the proposed HPC development site to collect site-specific data and to establish robust baseline conditions.

14.4.61 Laboratory analysis was carried out by suitably accredited laboratories which have certified standards of quality control and assurance. The radiochemical analysis was undertaken by a United Kingdom Accreditation Service (UKAS) accredited testing laboratory and with the exception of carbon-14 testing, all tests employed for the work are UKAS accredited. The non-radiochemical analysis was undertaken by a MCERTS (Environment Agency Accreditation system) and UKAS accredited laboratory. However, there are some parameters within the testing suite for which accreditation is not available. The chemical analytical data, provided within the relevant site investigation reports present details of the accreditation status for each of the analytical parameters. All sampling and analysis has been carried out in accordance with appropriate UK best practice and guidance including appropriate quality assurance methods. As such, the analysis undertaken is considered to be reliable and representative of the baseline conditions.

14.4.62 The approach and methodology adopted for this chapter are considered to be both transparent and consistent with relevant guidance. The assessments made represent best professional judgement at the time of writing against the criteria specified.

14.4.63 Prior to site preparation and the main construction works a series of enabling works will be completed as described in **Volume 1, Chapter 6** of this ES. The effective completion of those enabling works is assumed as the baseline for the impact assessment presented in this Chapter. Note that this is different to the current baseline as described in Section 14.5.

14.5 Baseline Environmental Characteristics

a) Introduction

14.5.1 This section of the chapter describes the baseline geological and land contamination characteristics for the proposed HPC development site.

b) Study Area Description

14.5.2 The baseline assessment of land contamination is concerned with the establishment of current conditions within the HPC development site as illustrated in **Figure 14.1**. For the purposes of establishing the wider environmental context, a search radius of 1km has been used. Note that for the purpose of impact assessment, a smaller radius of 500m has been adopted as a realistic distance over which contamination may migrate or travel off-site from potential on-site sources and vice versa under exceptional circumstances.

14.5.3 Eleven off-site highway improvement schemes will also be included in the HPC Project DCO application. They are described in the **Volume 1, Chapter 2** of this ES. The schemes concern land that is presently within the highway, on highway land (such as verges), limited areas of hard surfacing and urban greenspace.

14.5.4 Due to the very minor extent (area and depth) of groundworks required for the delivery of these schemes and the fact that best practice environmental construction control measures will be adopted throughout, it is considered that no impacts associated with existing or future potential land contamination will occur as a result of the highway improvements. Therefore, all eleven schemes are scoped out of the baseline and hence further assessment within this chapter.

14.5.5 The topography of the HPC development site comprises undulating countryside, terminating at Bridgwater Bay to the north at a natural cliff line which descends to a wave-cut platform. The topography of the HPC development site is typical of that in the wider locality, with the exception of the BDAE where the topography has been influenced by a number of man-made features.

14.5.6 Across the built development areas, (i.e. that to be occupied by the built development and the main construction area) ground elevations range from approximately 10m above ordnance datum (AOD) to 35m AOD and across the SCPA ground elevations range from approximately 5m AOD to 28m AOD.

14.5.7 There are a series of man-made topographical features present within the HPC development site, the majority of which are located within the BDAE and which include: a double humped mound; the former Hinkley Point Power Station Visitor Centre (now the British Energy Nuclear New Build Induction Centre); an overflow car park and a helicopter landing pad in the north-eastern corner of the BDAE. There is also surface evidence (in the form of a degraded concrete slab) in the vicinity of the former sewage works which was located adjacent to the boundary between the BDAE and BDAW. As described in **Volume 1, Chapter 6** of this ES, a number of these features have been subject to alterations by way of remediation/removal works, or construction and installation of new features in the Spring and Summer 2011 as part of the enabling works.

14.5.8 Within the BDAW, there are three derelict barn buildings. One is located close to Wick Moor Drove, and the others are located towards the centre of the BDAW. The archaeological significance of these structures is considered within **Chapter 23** of this volume (Historic Environment).

14.5.9 Other man-made topographical features which characterise the HPC development site include a series of hedgerows which demark field boundaries. There are also isolated blocks of woodland present within the northern part of the HPC development site. Two of these blocks are located towards the centre of the BDAW (Newclose Covert and Haysgrove Brake); a further two along the boundary between the BDAW and the BDAE (Whitewall Brake and Seaberton Brake); one extending northwards from the southern boundary of the BDAE (Govetts Copse); and one towards the centre of the SCPA (Bishops Wood).

14.5.10 A number of minor surface watercourses are present within the HPC development site. Holford Stream runs west to east within the northern part of the SCPA. This watercourse flows under Wick Moor Drove and drains into Wick Moor to the east. There are also a series of agricultural drainage ditches present on-site, running along field boundaries. Two drainage ditches are present on the BDAW, one running west to east along a field boundary in the northern part of this land parcel before turning northwards towards the coastline (Hinkley Point C Drainage Ditch). The other drains run west to east at the base of the depression along the boundary of the BDAW and the SCPA. Site reconnaissance has confirmed these drainage ditches to be ephemeral (i.e. seasonally dry) water features (see Surface Water Monitoring Report (Ref. 14.97).

i. Geology

Made Ground

14.5.11 Intrusive investigations undertaken in the BDAW (Ref. 14.84, 14.86) confirmed the absence of any Made Ground (with ground conditions largely comprising topsoil over natural deposits), with the exception of localised deposits associated with the historical farm buildings (Benhole Farm) in the north-western part of the BDAW.

14.5.12 During the Phase 2 supplementary investigation (Ref. 14.86) one location (TRE21, see **Figure 14.5**) in the area of the former Benhole Farm footprint recorded Made Ground deposits comprising slightly gravely cobbly sandy clay with occasional gravel, bricks, glass and clay tile, to a depth of 0.33m. Further investigations targeting this area of Made Ground, conducted as part of the second on-shore investigation, identified Made Ground deposits at three locations (TE82, TE83 and TE84, see **Figure 14.5**) in this area, comprising typically soft dark brown slightly gravelly clay with rare fragments of red brick and mortar to depths of between 0.25m and 0.4m below ground level (bgl). The Made Ground was underlain in TE83 and TE84 by a layer of limestone gravel and cobbles extended to depths ranging from 0.3m to 0.4m bgl.

14.5.13 The investigations conducted as part of the Preliminary Phase 2 Contamination Assessment of the BDAE (Ref. 14.92) identified varying depths of Made Ground across this area, ranging from absent to proven depths of 9.0m within the mounds. Made Ground deposits were found to typically comprise either reworked natural soils (weathered Blue Lias Formation deposits comprising mudstone and limestone), or demolition and construction materials.

14.5.14 The Groundsure Geology and Ground Stability reports (Ref. 14.90) indicated the absence of any known Made Ground deposits on the SCPA, which is consistent with the recorded agricultural land use in this area. During the intrusive investigations undertaken as part of the Phase 2 investigation (Ref. 14.92) Made Ground was found in one location within the SCPA (WS75), which extended to a depth of 0.79m bgl. This was described as stiff dark brown/black gravelly clay, with the gravel comprising fragments of tile, occasional brick, coal and mixed lithology stone, organic rich material and a very low content of glass fragments to 0.59m bgl. This was underlain from 0.59m to 0.79m bgl by mid grey pliable gravelly clay.

Superficial Geology

14.5.15 The majority of the HPC development site is not overlain by significant drift deposits. From intrusive investigations (Ref. 14.86, 14.88), the drift deposits within the BDAW have been confirmed to depths of between 0.26m and 5.5m bgl. These deposits are classified typically as slightly gravelly locally sandy silty clay to a sandy silt/clay. Investigations within the BDAE (Ref. 14.92, 14.95) identified superficial drift deposits to depths of between 0.3m and 4.0m bgl, typically comprising slightly sandy slightly gravely clay.

14.5.16 Also, within the BDAE apparent sediment deposits, believed to be associated with former infilled ponds, were encountered at two isolated locations at depths of between 2.3m and 5.0m bgl.

14.5.17 Superficial deposits were found in a number of locations within the SCPA during intrusive investigations (Ref. 14.92, 14.95), extending to depths of between 0.21m and 4.64m bgl. Superficial deposits mainly comprised topsoil and gravelly clay. Horizons of peat and alluvium were encountered in WS79 and WS713 (both located within the northern part of the SCPA), extending to 3.60m and 4.64m bgl respectively. This correlates with a linear expanse of alluvial deposits (shown by published mapping sources) which is orientated approximately east-west along the boundary between the BDAW and the SCPA. This area of alluvium correlates with the alignment of a fault and the Holford Stream Valley.

14.5.18 Published data sources and earlier investigation reports (Ref. 14.90) indicate that there are certain areas where the drift geology differs from the general classification described above. These include:

- An expanse of alluvial deposits is associated with Bum Brook, which runs along the southern boundary of the HPC development site.
- Undifferentiated Tidal Flat Deposits are shown within three areas outside the HPC development site: the coastal area to the north-west; to the north-east (north-west of the existing Hinkley Point Power Station Complex); and on a large expanse to the east of the HPC development site in Bridgwater Bay.
- Tidal Flat Deposits are located to the east of the HPC development site within North Moor and Wick Moor.
- Drift deposits identified during the studies (Ref. 14.90) undertaken for the former proposed Central Electricity Generating Board (CEGB) Hinkley Point C PWR included head deposits around 1m in thickness, and estuarine alluvium up to 5m thick, comprising soft to firm organic clays. To the east of Hinkley Point B (HPB), fluvioglacial sands between 2.4m and 5.2m thick were found beneath the alluvium (Aspinwall & Company 1996) (Ref. 14.47) as well as a series of peaty deposits.

Solid Geology

14.5.19 The HPC development site is located within the Bristol Channel Basin which is a west-northwest to east-southeast trending basin approximately 30km wide and 150km long and contains a depth of approximately 3,000m of both Tertiary and Mesozoic sediments.

14.5.20 The solid geology in the locality of the HPC development site predominantly comprises the Blue Lias of the Lias Group (Lower Jurassic) and the Triassic Penarth and Mercia Mudstone Groups. The local area geology (which includes the HPC development site) is shown within **Figure 14.2** which is based in the electronic 1:50,000 British Geological Survey map (Sheet 279, 1980).

14.5.21 The BGS Sheet ST24NW (1:10,560 scale) shows the HPC development site to be located on the northern flank of an anticline with a crest orientation running generally east to west. Strata are seen to generally dip gently (10˚) in a direction ranging north-west through north-east. A major north-east to south-west trending faulted zone crosses the footprint of the existing Hinkley Point Power Station Complex, with part of this structure utilised as the cooling water outfall of the existing Hinkley Point Power Station Complex. To the north-west of this fault zone, Whittaker and Green (1983) (Ref. 14.42), as reported in the AMEC Geological Survey and Mapping report (Ref. 14.96), recorded that contours on the base of the Blue Lias bed 147 are parallel to the outcropping strata on the foreshore with a dip between 5˚ and 10˚ to north, north-east.

14.5.22 Fault zone drag is noted in the BGS Memoir (Ref. 14.42) to have resulted in the slight deflection of these strata towards an east-west trend. To the south-east of the fault zone the strata are noted to be folded into a slightly asymmetrical anticline, which plunges to 70˚. The fault zone is indicated in the Memoir to be poorly exposed on the foreshore, masked by the outflow channel. The net throw of the fault is recorded as approximately 4.5m at the foreshore with the downthrow to the south-east. The Memoir further asserts that the net throw on the fault increases to 10.6m further inland (NGR 2128 4624).

14.5.23 The AMEC Phase 1 Desk Study (Ref. 14.84) and Desk Based Assessment (Ref. 14.90) indicated (prior to the undertaking of any confirmatory intrusive investigations) that:

- The SCPA, according to the desk based sources of information, is underlain by the Penarth Group Langport Member, Blue Lias and Charmouth Mudstone Formations with the exception of a small area in the western section of the SCPA. This area is underlain by an inlier of the Mercia Mudstone and Blue Anchor Formations and corresponds with a topographic low to the immediate west of the SCPA.
- To the immediate north of the SCPA an uplifted linear exposure trends east-west and comprises mudstones, siltstones and nodular gypsum of the Triassic Mercia Mudstone Group and mudstones and limestones of the Penarth Group. This area corresponds with the linear depression in the local topography.
- The BDAE is underlain by the Penarth Group Langport Member, Blue Lias and Charmouth Mudstone Formations.

14.5.24 Intrusive investigations undertaken as part of the first on-shore investigation, conducted on behalf of EDF Energy by Structural Soils Ltd., in 2008 (Ref. 14.88), of the BDAW and the subsequent EDF Energy interpretative report (Ref. 14.89) have confirmed and characterised the sequence of geological strata present within this part of the HPC development site. The proven geological sequence comprises a basement of the Mercia Mudstone Group overlain by the Penarth Group, which is in turn overlain by Blue Lias. These deposits subcrop on the site and are covered by a thin veneer of superficial drift which is of variable thickness as detailed above. Cross sections illustrating the geological sequence identified on the BDAW are presented in **Appendix 14A**.

14.5.25 The solid geology of the BDAW area dips to the north by a relatively uniform 7° to 9°. Upthrown strata of the Mercia Mudstone Group outcrop in the southernmost part of the BDAW, in the fields to the south of the main east-west track (Green Lane) which crosses this part of the HPC development site. Penarth Group strata outcrop north of this on the east-west ridge of high ground, forming a steeper rock scarp outcrop succeeded northwards by the Blue Lias Formation which forms the geology all the way to the coastline. The mean dip direction of Blue Lias strata in BDAW (northern part) identified during AMEC mapping is 10˚. Slight deviations to this dip direction may occur due to the influence of small scale faults exhibiting drag/folding.

14.5.26 Previous investigations on the BDAE undertaken by Rendell Palmer and Tritton 1986 (Ref. 14.45) and subsequent cross sections presented within the Allot Atkins Mouchel report (Ref. 14.46) (copies of the relevant cross sections 'D-D', 'E-E' and 'F-F' are presented within **Appendix 14B**) indicate the geology of the BDAE to be similar to that underlying the BDAW, comprising varying thicknesses of Made Ground and natural soils overlying Blue Lias rocks (subcropping in a north to south direction, controlled by the northerly dip of the strata). Underlying the Blue Lias are rocks of the Lilstock and Westbury Formations of the Penarth Group which in turn overlie the Blue Anchor Formation of the Mercia Mudstone Group.

14.5.27 Intrusive investigations (Ref. 14.92, 14.95) undertaken as part of the second on-shore investigation on the BDAE (conducted on behalf of EDF Energy by Structural Soils Ltd.) have confirmed the presence of Blue Lias deposits, at depths starting from 0.1m bgl to 9.0m bgl. The deposits comprise an interbedded sequence of mudstone and limestone units. The upper mudstone units were frequently noted to have been significantly weathered to clay like deposits. Underlying the Blue Lias the top of the Penarth Group has been confirmed at depths of 9.0m and 11.1m bgl towards the southern boundary of the BDAE. This increases to confirmed depths of 68.6m and 71.8m bgl towards the coast. The top of the Mercia Mudstone Group was confirmed at depths of 80.2m and 83.9m bgl near the coast, decreasing to 23.45m bgl further inland.

14.5.28 Intrusive investigations undertaken as part of the second on-shore investigation on the SCPA (Ref. 14.92) have confirmed the presence of mudstone and limestone of the Blue Lias at contact depths ranging from surface to 1.04m bgl. Also, at three locations in the northern section of the SCPA superficial and alluvial deposits were underlain by the Mercia Mudstone Group, at contact depths ranging from 3.6m to 4.64m bgl, which is consistent with the linear expanse of alluvium identified from the desk based assessment.

14.5.29 The AMEC Geological Survey and Mapping report (Ref. 14.96) identifies the foreshore cliffs adjoining the HPC development site as comprising the Blue Lias Formation.

14.5.30 The Charmouth Mudstone Formation (referred to above) was not identified in the cliff sections or by Structural Soils Ltd., during the on-shore investigations of the BDAW, BDAE or SCPA. This formation is younger than the Blue Lias with the lower boundary taken as the top of the Blue Lias Formation (i.e. next formation within the regional stratigraphic sequence).

Stratigraphy and Lithology

14.5.31 A summary of the lithostratigraphical sequence identified within the HPC development site is provided in **Table 14.7**.

Table 14.7: Lithostratigraphical Sequence for the Post-Varsican Rocks of the East Bristol Channel Basin Identified within the HPC development site

Group and Formation			'up-to' thickness (m)	Lithology
Lower Lias	Blue Lias Fm		140	Alternation of shale/mudstone/limestone/mudstone sequences.
Penarth Group	Lilstock Fm	Langport Mb	2	Pale grey limestones with interbedded grey to bluish grey mudstones.
		Cotham Mb	2	Pale grey to greenish grey calcareous mudstones, limestones, siltstones and sandstones.
	Westbury Fm		14	Very dark shaley mudstones and dark grey argillaceous limestones
Mercia Mudstone Group	Blue Anchor Fm		38	Thin dark grey mudstone beds and green to greenish grey mudstone and siltstone beds. Some are dolomitic in part.
	Undifferentiated		484	Upper units are reddish brown mudstones and siltstones (occasionally greenish grey) with halite, gypsum and anhydrite as minor components. Nodules of gypsum and/or anhydrite. Halite as thin fracture infilling.

Table modified from Whittaker, A and Green, G. W. 1983 (Ref. 14.42).
Fm = Formation, Mb = Member

14.5.32 *Lower Lias, Blue Lias:* The Blue Lias comprises very weak to medium strong, thinly laminated to thinly bedded calcareous mudstone, alternating with weak, thinly laminated fissile mudstone and medium strong to strong thinly bedded argillaceous limestone.

14.5.33 *Penarth Group, Lilstock Formation (subdivided into Langport Member and Cotham Member):* The Cotham Member of the Lilstock Formation comprises weak to medium strong, thinly to thickly laminated, green-grey calcareous mudstone with some strong thinly bedded limestone beds, whilst the Langport Member comprises medium strong to strong, thinly bedded argillaceous and micritic limestone.

14.5.34 *Penarth Group, Westbury Formation:* The Westbury Formation mainly comprises very weak to weak, thinly laminated, fissile, dark grey-black calcareous mudstone and siltstone with limestone bands.

14.5.35 *Mercia Mudstone Group, Blue Anchor Formation:* The Blue Anchor Formation comprises mainly grey-green mudstone and siltstone. The siltstone is generally weak to strong thinly laminated to medium bedded, light grey-green with some nodules of gypsum and/or anhydrite and halite as thin fracture infilling. The mudstone is generally weak to strong thinly laminated to thinly bedded, grey (locally dark grey), sometimes calcareous, with some gypsum and anhydrite inclusions as veins or possibly of depositional origin. The Blue Anchor Formation also includes some dolomitic bands.

14.5.36 *Mercia Mudstone Group (Undifferentiated):* The undifferentiated component of the Triassic Mercia Mudstone Group comprises mainly reddish brown mudstones and siltstones. The mudstones are generally weak to strong thinly laminated to thinly bedded, red-brown with some grey colour. The siltstones are generally weak to strong thickly laminated to medium bedded, reddish brown, occasionally green-grey, with localised nodules of gypsum and/or anhydrite and halite as thin fracture infilling.

Designated Geological & Geomorphological Sites

14.5.37 The eastern extent of the 'Blue Anchor to Lilstock' Site of Special Scientific Interest (SSSI) extends into the western part of the BDAW frontage by approximately 40m (based on co-ordinates provided within English Nature 'Geological site documentation/management brief, Blue Anchor to Lilstock Coast', 1993 (Ref. 14.98)). The SSSI designation is for the outstanding series of cliff stratigraphy which comprises interbedded limestones, shale and mudstones of the Blue Lias units. Within the SSSI the exposed stratigraphic units are considered to be amongst the best examples of the Blue Lias outcrop in Europe. Furthermore, the SSSI also has a geomorphological designation for the exposed rock pavement on the foreshore. The location of the SSSI is presented in **Figure 14.3**. Natural England is the principal organisation with responsibility for the designation and management of the 'Blue Anchor to Lilstock' SSSI and Natural England have indicated that they consider the cliff exposure and foreshore geomorphology to be of significant value. The cliff exposure and foreshore along the majority of the frontage of the HPC development site (extending up to the existing seawall to the east of the HPC development site) are not designated but are considered by Natural England to include cliff stratigraphy of significant value and interest.

14.5.38 Consultation has taken place between Natural England and EDF Energy (detailed in **Table 14.4**) with the aim of identifying all potential issues associated with foreshore construction proposals. Of concern to Natural England is the possible loss of exposed Blue Lias units (**Plate 14.1**), together with the loss of the exposed rock pavement features (**Plate 14.2**) along the entire cliff section present within the HPC development site.

Plate 14.1: Looking East from HPC development site Boundary towards the Existing Power Station Complex

14.5.39 Natural England stated during consultation that the identification of a replicate, accessible section of units elsewhere within the ‘Blue Anchor to Lilstock’ SSSI is likely to be acceptable replication that will offset any loss of the units exposed within the cliff and rock pavement at Hinkley Point. Natural England required evidence to demonstrate that the same geological sequence that is observable and accessible at Hinkley Point is replicated elsewhere along the coastal section which extends up to a distance of approximately 10km to the west.

14.5.40 In response to the requirements of Natural England, a geological survey and mapping study (Ref. 14.96) was undertaken with the aim of identifying appropriate candidate sites within the ‘Blue Anchor to Lilstock’ SSSI at which the Hinkley Point Blue Lias units and rock pavement features are replicated and which are equally observable and accessible.

Plate 14.2: Looking North-west from Cliff-top from HPC development site Boundary Showing Hinkley Foreshore Geomorphology

Plate 14.3: Looking North-west from the Range Quadrant Hut, Lilstock towards Kilve Showing Replicate Section Foreshore Geomorphology

14.5.41 The Geological Survey and Mapping report (Ref. 14.96) provides details of the aforementioned study. In summary, the report concludes that a cliff section to the west of Lilstock within the 'Blue Anchor to Lilstock' SSSI provides a high quality replication of the geology found within the cliffs at Hinkley Point (**Plate 14.4**). Furthermore, the report concludes that the replicate section is a more complete example of the exposed units as the greater cliff height enables all of the units to be observed within one discrete section, as opposed to being exposed at a number of different locations throughout the Hinkley Point cliffs. It was also qualitatively demonstrated that the characteristics of the foreshore geomorphology adjacent to the site can be observed elsewhere within the SSSI to the west (**Plate 14.3**).

Plate 14.4: Looking South-east Showing Replicate Geological Section to the South-west of the Range Quadrant Hut, Lilstock

Hydrogeology

14.5.42 The following is a brief overview of the hydrogeology of the HPC development site and surrounding area. Further detail is provided in **Chapter 15** of this volume (Groundwater).

14.5.43 From April 2010, the Environment Agency changed their aquifer designations to be consistent with the Water Framework Directive (WFD). The aquifers previously designated as Major and Minor became Principal and Secondary respectively. The Secondary Aquifers are further divided into Secondary A, Secondary B and Secondary Undifferentiated categories based on the water permeability and storage characteristics of rock layers or drift deposits. The Environment Agency website provides maps of aquifer designations which are split into two different types; superficial and bedrock, these maps (Ref. 14.44) have been reviewed to establish the aquifer properties of the HPC development site. The previous Groundwater Vulnerability Maps (Ref. 14.99) have not been completely withdrawn and should still be referred to when details of soil classes are required. Information on surface soils is not provided on the new maps.

14.5.44 The Blue Lias comprises a Secondary A Aquifer (formerly a Minor Aquifer), with groundwater flow predominantly occurring via bedding planes, joints and fractures in the more competent limestone horizons within the formation. Rocks of the Penarth Group, especially the mudstone and limestone of the Westbury Formation (the lower component) are considered to be generally impermeable, although fault and fracture zones in the Cotham and Langport Members (approximately the upper 4m) may have minor transmissivity. The mudstones of the Mercia Mudstone Group (including the Blue Anchor Formation) are likely to be of insignificant permeability, however are designated as a Secondary B Aquifer (formerly Non-Aquifer).

14.5.45 The Environment Agency Maps (i.e. 1:100,000 scale Groundwater Vulnerability Map (Sheet 42, Somerset Coast) and Aquifer Maps) confirms the HPC development site as being situated on Secondary Aquifers (formerly Minor Aquifer) (variably permeable). Such aquifers can be "*fractured or potentially fractured rocks, which do not have a high primary permeability, or other formations of variable permeability including unconsolidated deposits. Although these aquifers will seldom produce large quantities for abstraction, they are important both for local supplies and in supplying base flow to rivers*".

14.5.46 The lower boundary on the effective groundwater regime in the area may be the base of the Lilstock Formation of the Penarth Group, possibly less than 4m below the base of the Blue Lias.

14.5.47 Regionally, groundwater in the fractures of the Blue Lias is fed by rainfall recharge and flows approximately south to north from the Mercia Mudstone outcrop at Stogursey to discharge into the Bristol Channel, either directly or following baseflow discharge to the surface water system. The Penarth Group/Mercia Mudstone forms a lower boundary to the system.

14.5.48 At the HPC development site, however, this general natural flow regime is intercepted by the upfaulted inlier of Mercia Mudstone along the boundary between the BDAW and the SCPA. The bedrock barrier might effectively 'dam' the groundwater flow sufficiently for water tables to rise and groundwater flow to be diverted into the surface water system as baseflow, especially (in relation to the SCPA) to the Holford Stream.

14.5.49 The HPC development site is likely to be self-contained as a groundwater system, bounded by the Mercia Mudstone/Penarth Groups beneath, the faulted inlier to the south, and the Bristol Channel to the north. There are some minor reversals of groundwater flow due to the geological structure and topography, with some groundwater flowing south into the site surface water drainage features. To the east and west, natural groundwater flow is also generally northwards.

Value and Sensitivity of Geological Receptors

14.5.50 The identified receptors are the on-site geology (i.e. inland geology), the sea cliff exposure and exposed foreshore geology.

14.5.51 The value and sensitivity of the inland on-site geology is assessed as low as no significant visible exposures of bedrock and/or designated/scientific/educational sites of interest occur within the HPC development site. The geology is only of relevance from an engineering perspective (i.e. acting as founding medium or source of engineering fill for the development).

14.5.52 As previously described the eastern limit of the 'Blue Anchor to Lilstock' SSSI extends along the western limit of the coastal frontage of the BDAW (see **Figure 14.3**) by approximately 40m. The value and sensitivity of this section of the cliff exposure and foreshore within the SSSI is considered to be high, as it is nationally designated.

14.5.53 The remaining cliff exposure and foreshore along the frontage of the HPC development site are not designated but are considered by Natural England to include cliff stratigraphy of significant value and interest and therefore the value and sensitivity is considered to be medium.

ii. Land Contamination

Introduction

14.5.54 This section focuses upon the characterisation of baseline soil conditions with respect to radiochemical and non-radiochemical chemical contamination. It also describes baseline contamination characteristics with respect to ground gases as these are often linked to physical and chemical soil conditions and contamination status.

Desk Based Assessment Findings

14.5.55 A review of historical maps and plans undertaken as part desk based assessments for the HPC development site (Ref. 14.84 and Ref. 14.90) has identified that both the BDAW and the SCPA have remained as greenfield agricultural land since the earliest available map (published in 1886). Within the BDAW, Benhole Farm was located in the north-western area until around 1976 when it was demolished to leave a single remnant outbuilding which is still present, along with two other derelict farm buildings. The historical maps and plans also indicate a number of historical ponds on the BDAW, some of which appear to have been infilled.

14.5.56 Within the SCPA a number of historical ponds have been identified, although all but one now appear to have been infilled. Also, a property is identified as being present from 1886 (Corner Farm) and which by 1975 had become derelict and by 2002 had been removed.

14.5.57 The BDAE comprised greenfield, predominantly agricultural land, until the late 1950s when a significant proportion of the BDAE was used during the construction of HPA for construction and fabrication, materials storage, spoil placement, a contractor's accommodation area with associated Above Ground Storage Tanks (ASTs) and boiler houses. Photographic evidence (presented in the desk based assessment (Ref. 14.90) shows the presence of a number of large fabrication buildings and cranes with associated trackways, an access route to the foreshore towards the north-east boundary and spoil deposition in the area of the existing mound feature until 1965 (see **Figure 14.4**).

14.5.58 In 1964, a small sewage treatment works (STW) was constructed towards the western boundary of the BDAE. Later in the 1970s (during the construction of HPB) a further accommodation camp, with associated electrical substations, was constructed on the south-eastern portion of the BDAE (same area as previous accommodation area for HPA).

14.5.59 By 2005 the accommodation camp no longer existed and a visitors' centre (now the British Energy induction centre) was constructed in this area. The BDAE lies within the existing Nuclear Licensed Site.

14.5.60 More recently, an area within the north-western quadrant of the BDAE was used as a temporary spoil placement area (the Nuclear Decommissioning Authority (NDA) temporary spoil mound) to accommodate spoil removed from the construction of the new Intermediate Level Waste (ILW) store on HPA (see **Figure 14.4**). This spoil has since been removed.

14.5.61 Surrounding the HPC development site, land use has remained predominantly agricultural with the exception of the construction and operation of the Hinkley Point Power Station Complex to the east.

14.5.62 From the desk based assessments a number of salient features and potential sources of contamination have been identified for each area. These are summarised as follows, with locations presented on **Figure 14.4:**

- BDAW - historical use of the site as agricultural land, i.e. agricultural crop management and possible sewage and sludge application, the possible storage and maintenance of vehicles and chemicals within farm buildings leading to potential isolated hotspots of contamination, derelict farm buildings and the potential for localised infilling of former pond areas. Possible radionuclide aerial deposition from the existing Hinkley Point Power Station Complex.
- BDAE – presence of infilled ponds, identified areas of materials deposition arising from the construction of the Hinkley Point Power Station Complex, a former waste transfer site (NDA temporary spoil storage area), historical sewage works, former contractor's accommodation areas and construction and fabrication area with associated electrical substations, oil storage tanks and boiler houses. Possible radionuclide aerial deposition from the existing Hinkley Point Power Station Complex.
- SCPA – historical use as agricultural land, i.e. agricultural crop management and possible sewage and sludge application, the possible storage and maintenance of vehicles and chemicals within farm buildings leading to potential isolated hotspots of contamination, derelict farm buildings. Possible radionuclide aerial deposition from the existing Hinkley Point Power Station Complex. The potential for

localised infilling of former pond areas and naturally enriched organic/alluvial deposits.

14.5.63 Within the BDAW and the SCPA the salient features and potential pollutant sources are largely limited to infilled ponds and historical farm buildings. Therefore, there are a limited number of potential contaminative sources including: infilling of historical ponds with potentially contaminated materials; leaks and accidental spills of fuel and oils from agricultural machinery; and use of pesticides, herbicides and fertilisers. A structural survey has identified that there is the potential for cement bonded asbestos to be present within the corrugated roof sheeting on one of the barns (western-most barn, towards the north-western area of the BDAW).

14.5.64 The majority of the identified salient features and potential pollution sources identified on the HPC development site are within the BDAE. Key features include the former sewage treatment works, a licensed waste management site associated with the former NDA temporary spoil placement area, areas of waste disposal/landfill (i.e. the double humped mound feature) and the former accommodation/fabrication compound and associated electrical substations and oil storage tanks and boiler houses (indicative locations are presented on **Figure 14.4**).

Results of the Intrusive Investigations

Intrusive Investigations: Built Development Area West

14.5.65 A series of intrusive investigations have been undertaken on the BDAW. A preliminary non-radiochemical site investigation of near surface soils (<0.3m bgl) was carried in July 2008 (Ref. 14.84). Supplementary investigations were undertaken as part of the extensive first on-shore investigation (August to December 2008) (Ref. 14.88 and Ref. 14.89), with the contaminated land investigations being undertaken in October 2008 (Ref. 14.86). Limited further investigations were also undertaken as part of the second on-shore investigation (November 2009 to August 2010), to target historical pond features and the Made Ground encountered in the vicinity of Benhole Farm (i.e. around exploratory location TRE21). Locations of the exploratory holes advanced on the BDAW are presented in **Figure 14.5**.

14.5.66 The ground conditions as described in Section 14.5 b) i of this chapter comprised natural superficial drift deposits and weathered bedrock, with the exception of a small localised area of Made Ground encountered in the vicinity of Benhole Farm. Selected samples were analysed for a range of chemical contaminants and a risk assessment was conducted in accordance with the methodology outlined in Section 14.4, b) of this chapter. The natural soils were subject to statistical tests using the statistical approach recommended by CL:AIRE/CIEH (Ref. 14.100), resulting in the Upper Confidence Level (UCL) being compared to the critical concentrations (Tier 1 SSVs).

14.5.67 A summary of the investigations including; the frequency and type of exploratory holes, chemical analysis undertaken, summary of the analysis results and risk assessment are presented in **Appendix 14C** and further details are provided in the investigation reports (Refs.14.84, 14.86, 14.88 and 14.89).

14.5.68 The Tier 1 risk assessment identified that all contaminants were recorded at concentrations below the relevant human health SSVs. Thus, it is concluded that there is no source of soil contamination within either the Made Ground or natural soils within the BDAW, which has the potential to pose a significant risk to human health considering a commercial and industrial end use.

14.5.69 The risks to other receptors (i.e. plants, buildings and ecological systems) were also considered as part of the Tier 1 assessment. All concentrations of potentially phytotoxic contaminants were below the SSVs within the natural soils, with the exception of one sample recording an elevated concentration of boron (TRE01, 5.1mg/kg). However, given that the calculated UCL for water soluble boron is below the SSV, water soluble boron at this concentration is not considered to pose a phytotoxic risk in the natural soils.

14.5.70 An elevated zinc concentration (687mg/kg) was identified in a sample of Made Ground (TRE21 0.0-0.3m bgl). The remaining three Made Ground samples taken in the vicinity of TRE21 (area of former Benhole Farm) did show slightly elevated zinc concentrations (328 - 446mg/kg) compared to natural soil concentrations but did not exceed the phytotoxic SSVs. These data along with the elevated concentration (TRE21 687mg/kg) identified in this area suggests the Made Ground does contain slightly elevated concentrations of zinc. However, as only one sample exceeded the phytotoxic SSV for zinc the phytotoxic risk on the BDAW as a whole is considered to be very low.

14.5.71 No concentrations of contaminants in the Made Ground samples exceeded any of the Tier 1 built environment SSVs. Within the natural soils, arsenic was detected at concentrations in excess of the level specified in the WRAS guidance (Ref. 14.60) (i.e. 10mg/kg) but all concentrations were below the WWSSG (Ref. 14.61) value (i.e. 50mg/kg) and therefore arsenic is not considered to pose a risk to water supply pipes. Isolated exceedences of selenium, total TPH and cadmium were identified in natural soils; however, given the isolated and marginal nature of the exceedences the risk posed to the built environment by these contaminants is (as a matter of professional judgement) considered to be negligible. Some slightly elevated pH levels (pH 8.1-8.5), indicating slightly alkaline soil conditions and concentrations of sulphate at two locations (WS85 ES2 0.26% and WS86 WS2 0.4%) were also identified in excess of the level specified in the WRAS guidance. However, given their presence in natural soils it is concluded that the risk posed to water supply pipes by soils within the BDAW is very low.

14.5.72 The slightly elevated concentrations of sulphate identified within the natural soils were also marginally above the BRE Special Digest threshold (0.24%) (Ref. 14.62); however, concentrations were typically low. The concentrations of soluble sulphate indicate that the natural soils pose a low risk of sulphate degradation of buried concrete.

14.5.73 With regards to ecological risk assessment, concentrations of heavy metals (arsenic, cadmium, chromium, copper, nickel, selenium and zinc) observed in both the Made Ground and natural soil samples exceeded the conservative Stage 1 ecological SSVs. Comparison of those elevated concentrations in natural soils with the rural England background soil concentrations (Ref. 14.69 and Ref. 14.70) shows that those concentrations are generally consistent with background levels with the exception of isolated elevated copper and nickel, and marginally elevated selenium and cadmium concentrations. A moderately elevated concentration of cadmium was recorded at one location (TE82, 6-12mg/kg), but this is also considered to be a naturally occurring concentration.

14.5.74 Given the type of materials encountered and that concentrations are largely consistent with rural England background concentrations, the risk posed to ecological systems from contaminants within the natural soils on the BDAW is considered to be negligible.

14.5.75 With respect to the Made Ground, recorded concentrations are generally consistent with rural England background levels (Ref. 14.69 and Ref. 14.70). One slightly elevated concentration of cadmium and a slightly elevated selenium concentration were identified; however, these concentrations are consistent with those found in the natural soils and are therefore not considered to pose a risk. Two elevated concentrations of zinc were identified (446mg/kg and 687mg/kg) which are not consistent with background concentrations and may pose a low risk to ecological systems.

14.5.76 In summary, the range of contaminant concentrations on the BDAW are generally low and considered to be consistent with natural background soil concentrations in the locality and across rural England.

14.5.77 Overall, the intrusive investigations of soils within the BDAW indicate that the risk of significant non-radiochemical contamination being present is very low.

Intrusive Investigations: Built Development Area East

14.5.78 Intrusive investigations have been undertaken on the BDAE as part of the extensive second on-shore investigation between November 2009 and August 2010 (Ref. 14.95). Investigations undertaken to assess the contamination status of this area were undertaken in two phases (November 2009 to February 2010, and June 2010 to July 2010) and comprised the excavation of boreholes, trial pits, windowless sampling holes and hand pits to establish ground conditions, collect soil samples and facilitate gas and groundwater monitoring. Exploratory locations were scoped to provide both representative coverage of the area and to target the identified potential sources of contamination identified during the desk based assessment (Ref. 14.90), (i.e. the former sewage treatment works, the double humped mound feature, areas of Made Ground and former fabrication and accommodation areas). The investigations also included additional exploratory holes advanced to delineate the presence of asbestos-containing materials and one hydrocarbon contaminated area.

14.5.79 In order to facilitate the investigation of the BDAE, the area was divided into six assessment areas based on current and historical land use and topography. Locations of the exploratory holes advanced on the BDAE and assessment areas are presented in **Figure 14.6**.

14.5.80 Intrusive investigations identified the presence of variable depths of Made Ground across the BDAE, ranging from none present to a depth of 9.0m (GB4) within the double humped mound feature. Made Ground deposits typically comprise either reworked natural soils (weathered Blue Lias Formation deposits comprising mudstone and limestone), or demolition and construction materials. Natural superficial (drift) deposits have only been rarely encountered within the BDAE, having been identified in DBH2_23, GB6 and TE61. Apparent sediment deposits (believed to be associated with former infilled ponds) were also identified within TE13 and Tr2_5. Natural Blue Lias deposits (bedrock) were observed at contact depths ranging from 0.1m bgl (DBH2_24) to 9.0m bgl (GB4). Further details on ground conditions are provided in Section 14.5, b).

14.5.81 Selected soil samples were analysed for a range of chemical contaminants and a Tier 1 risk assessment was conducted in accordance with the methodology outlined in Section 14.4 b). This included statistical tests resulting in the UCL of the true population mean (sample populations were dependent on material type, i.e. natural ground or Made Ground and by geographical area) for each contaminant being compared to the Critical Concentrations (Tier 1 SSVs). A summary of the investigations including; the frequency and type of exploratory holes, chemical analysis undertaken, summary of the analysis results and risk assessment are presented in **Appendix 14C** and further details are provided in the investigation reports (Refs. 14.92 and 14.95).

14.5.82 The UCL concentrations for the BDAE are generally below the Tier 1 risk assessment criteria (i.e. relevant SSVs) for risk to human health based on a commercial and industrial end use. However, a potential risk to human health has been identified in the form of the presence of: asbestos-containing materials (ACMs); hydrocarbon contaminated soils in Area 4; and isolated exceedences of PAHs in Area 6.

14.5.83 Asbestos-containing materials were positively identified in isolated areas, primarily associated with the presence of construction and demolition materials within Areas 3 and 4, and isolated locations within Areas 2, 5 and 6 (see **Figure 14.7**). ACMs are discussed in paragraph 14.5.107-14.5.109.

14.5.84 During the advancement of TE418 in Area 4, hydrocarbon-contaminated gravel hardcore (including free phase oil) was encountered between 0.60m bgl and 0.80m bgl. Similar hydrocarbon-impacted shallow Made Ground was also identified in TE418D and TE418E, which were advanced to identify the lateral extent of the contamination found in TE418 (locations presented in **Figure 14.6**). All concentrations of TPH from the visibly hydrocarbon-impacted materials at these locations were found to significantly exceed the relevant Tier 1 human health SSVs.

14.5.85 The contamination within the vicinity of TE418 represents a potential human health risk with the presence of volatile TPH contamination, in excess of the human health screening values. However, the contamination is below the surface beneath a confining layer of hardstanding at 0.6m bgl (exploratory holes logs are included in the Phase 2 Report (Ref. 14.92). Therefore in the current situation, the potential exposure of human receptors at surface is limited and therefore the current risk to human health is considered to be low.

14.5.86 A sample from a shallow horizon of ashy fill deposits in Area 6 (TE63 ES2) was found to exceed the human health Tier 1 SSVs for both total PAHs (100mg/kg) and benzo(a)pyrene (14.1mg/kg). This sample was identified as an outlier, i.e. not chemically representative of the remainder of the Made Ground soils in Area 6 and so was not included in the calculation of the UCL for Area 6. Due to the isolated and marginal nature of the exceedences and the fact that the sample was taken from below the site surface (TE63 ES1 0.5-0.6m bgl) the current risk to human health is considered to be negligible.

14.5.87 With the exception of the ACMs and hydrocarbon-impacted shallow soils, the only visual or olfactory evidence of contamination were observations of hydrocarbon staining in TE42 and the identification of elevated VOCs during in-situ screening of arisings from TE54 using a photoionisation detector (average 6.4 to 10.3ppm, peaks 23.7 and 31.9ppm at 0.3 to 0.5m bgl). The analysis of the soil samples from TE42 showed no elevated concentrations of hydrocarbons and the soil samples from TE54 showed no elevated concentrations of VOCs, therefore no significant contamination is considered to be present at these locations.

14.5.88 Soil pH levels were also identified in marginal exceedence of the BS3882:2007 (Ref. 14.57) limit value for topsoil (8.5pH units) in the natural soils and Made Ground. However, slightly alkaline pH levels are not considered to pose a risk to human health. Moderately alkaline pH levels have been identified in Made Ground in Area 2, 3, 4 and 5 (up to 11.4 units). These alkaline pH values are attributed to the presence of mortar and plaster within construction and demolition materials which can be an irritant to soft tissue. However, the risk to human health from these elevated pH levels is currently negligible.

14.5.89 Concentrations of contaminants in both Made Ground and natural soils within the BDAE were largely below the respective phytotoxic risk thresholds. The Tier 1 threshold for water soluble boron was exceeded in Made Ground in one sample from Area 3 (3.5mg/kg), and one sample from Area 1 (3.6mg/kg). One sample of natural soil was also marginally above the Tier 1 phytotoxicity threshold for boron (4.2mg/kg). Given the marginal and isolated nature of the exceedences the phytotoxic risk posed to vegetation from these concentrations is considered to be negligible.

14.5.90 Within the Made Ground, one sample from Area 5 (TE54 ES2, the location of a former access ramp to the foreshore) was noted to exceed the Tier 1 thresholds for copper (241mg/kg) and zinc (922mg/kg) and one sample from Area 4 (DBH2_27 ES3 at 0.8-0.9m bgl) was noted to exceed the Tier 1 threshold for zinc (589mg/kg). The Made Ground in these locations may pose a low phytotoxic risk to vegetation.

14.5.91 Alkaline pH, above the upper range value (pH 8.5) preferred by most plants (Ref. 14.57), was frequently noted in samples of Made Ground containing significant proportions of construction and demolition materials. Areas of elevated (alkaline) pH (i.e. pH 9.0 or greater, identified only in Made Ground) may therefore pose a low risk to vegetation.

14.5.92 With regard to the built environment, concentrations of total sulphate were frequently identified in Made Ground and, on occasion, in natural soils in exceedence of the BRE DS-1 sulphate class value (0.24%) (Ref. 14.62).

14.5.93 Within the Made Ground, alkaline pH, selenium, sulphate and TPH, and isolated polyaromatic hydrocarbon (PAH) concentrations were recorded slightly above the WRAS risk assessment values (Ref. 14.60). Occasionally elevated sulphate, alkaline pH and isolated selenium concentrations above the WRAS Guidance thresholds have also been recorded in natural soils. As such, the Made Ground, and to a lesser extent natural soils, across the BDAE may not be considered suitable where standard water supply pipes are proposed.

14.5.94 Concentrations of several heavy metals and metalloids and hydrocarbons within both Made Ground and, to a lesser extent, natural soils across the BDAE have been identified in exceedence of Stage 1 ecological soil screening values. Comparison of these concentrations with rural England background soil concentrations (Stage 2) and local background concentrations (Stage 3) identified on the BDAW show that the majority of sample concentrations recorded on the BDAE are consistent with background levels.

14.5.95 The exceptions, which exceed the ecological SSVs, rural England background soil concentrations and local background soil concentrations (i.e. all exceed Stage 2 assessment), in Made Ground are; marginally elevated selenium at isolated locations in Areas 2 and 3 (up to 3.9mg/kg), one sample in Area 4 containing elevated zinc (590mg/kg), one sample in Area 5 containing elevated copper (241mg/kg) and zinc (922mg/kg), elevated PAHs (up to 226.7mg/kg Total PAHs) in Areas 2, 3, 4 and 6 and elevated TPH and PAH in the vicinity of TE418 (up to total TPH Sum C6-C40 up to 28,898mg/kg).

14.5.96 Due to the marginal nature of the exceedences the elevated concentrations of selenium identified are not considered to pose a significant ecological risk. PAHs are present at concentrations which could pose a low ecological risk at one location in Area 2 (WS27), one location in Area 6 (TE63) and in the demolition and construction materials on Areas 3 and 4. Demolition and construction materials at DBH2_27 in Area 4 and TE54 in Area 5 also pose a low ecological risk from zinc and copper, respectively. The hydrocarbon-impacted materials in the vicinity of TE418 also pose an ecological risk.

14.5.97 In the natural soils, one sample in Area 2 and one in Area 4 recorded elevated selenium (3.4 and 3.6mg/kg) and one sample in Area 4 recorded elevated anthracene (2mg/kg). However, due to the marginal and isolated nature of these exceedences they do not pose a significant ecological risk.

14.5.98 No ecological SSV is available for pH, however comparison with background soil pH identifies elevated (alkaline) pH values (above maximum local background, 8.5pH units) in Made Ground and to a lesser extent natural soils. More alkaline pH (pH 9 units and above) which was identified in the Made Ground containing demolition and construction materials may pose an ecological risk, by restricting the range of plant species which may be able to establish and grow successfully in such materials.

14.5.99 In summary, the only significant evidence of contamination identified in site soils within the BDAE relates to the presence of asbestos-containing materials (described below) and a localised zone of hydrocarbon contaminated shallow Made Ground in Area 4 (described below).

Additional Hydrocarbon Analysis

14.5.100 As detailed above, an area of hydrocarbon contaminated soils was noted during the advancement in TE418. During routine groundwater monitoring in CBH2_54 evidence of hydrocarbon contamination was identified in the form of Light Non Aqueous Phase Liquid (LNAPL). A selection of soil, weathered rock and free-phase product samples taken from exploratory holes at and in the vicinity of TE418 (CBH2_56, CBH2_57) and CBH2_54 (CBH2_55) in Area 4 of the BDAE, were submitted for tiered forensic hydrocarbon analysis (Tiers 1 to 3). These forensic tests were largely to confirm the source of the hydrocarbon (i.e. natural or man made), the type of oil, its age and degree of weathering. The initial sampling and testing had already demonstrated that there was an unacceptable risk to human health from the hydrocarbon hotspot around TE418. Therefore the forensic results were not used to further characterise soils within Area 4 for human health risk assessment purposes. A summary of the results of forensic analysis are presented in **Appendix 14C**.

14.5.101 Monitoring and sampling and analysis of groundwaters has been undertaken at the hydrocarbon affected boreholes CBH2_54, and also in CBH2_55, CBH2_56 and CBH2_57. Details of this monitoring are provided in **Chapter 15** of this volume (Groundwater).

14.5.102 In addition to the analysis of the samples identified above for forensic hydrocarbon testing, three samples of shallow natural soil (CBH2_56 ES3 (3.0-3.15m bgl), CBH2_56 ES4 (4.4-4.5m bgl) and CBH2_57 ES1 (6.0-6.1m bgl)) were scheduled for analysis for speciated PAHs, TPH CWG and BTEX testing. A summary of the results is presented in **Appendix 14C**.

14.5.103 The results of analysis show significantly lower hydrocarbon concentrations than those found in Made Ground in TE418, TE418D and TE418E, with a maximum recorded TPH C5-C35 concentration of 308mg/kg (CBH2_56 ES3) and maximum total PAH concentration of 1.25mg/kg.

14.5.104 The results of chemical analysis show marginal exceedences of the human health risk assessment criterion for aliphatic TPH in the carbon band range C12-C16 for the samples taken from CBH2_56 ES3 (3.0-3.15m bgl) and ES4 (4.4-4.5m bgl), and CBH2_57 ES1 (6.0-6.1m bgl), which incorporates volatile contaminants that may pose a potential vapour inhalation risk even in the event that no direct soil particle inhalation or dermal contact pathways may exist. The Tier 1 Human Health SSV for aliphatic C12-C16 is however very conservative as, in line with Environment Agency guidance (Ref. 14.27), the SSV is set at the theoretical solubility saturation limit (24mg/kg) for the specific soil type and fraction of organic carbon. The actual risk based SSV (when not limited by solubility saturation) is 61,000mg/kg, which the concentrations in CBH2_56 and CBH2_57 are significantly below.

14.5.105 The results also indicate a risk may be posed by elevated Total TPH concentrations to potable water services, as the concentrations in all three analysed samples exceeds the 50mg/kg WRAS materials selection threshold (Ref. 14.39) for Total TPH and for some ‘high end' hydrocarbon fractions.

14.5.106 The results are all below the relevant ecological risk assessment criteria with the exception of one sample, CBH2_56 ES4, which at 1.25mg/kg exceeds the most conservative Total PAH SSV (1.1mg/kg). This is however within the rural England background concentration range (up to 16.8mg/kg), and as such is not considered to be significant.

Asbestos Containing Materials

14.5.107 Suspected ACMs have been identified at several locations across the BDAE. **Figure 14.7** shows the locations of the occurrence of suspected and confirmed ACMs identified during site investigation works and **Table 14.8** summarises the locations and types of ACM found. ACMs (confirmed by laboratory testing) have been identified at sixteen locations as both competent, cemented materials (asbestos cement) and as fibrous lagging and insulation materials. The presence of ACMs is restricted to Made Ground and appears to be associated with the occurrence of construction and demolition materials.

14.5.108 The analysis of the soil samples targeting ACMs or suspected ACMs, and further soil samples from elsewhere on the BDAE which were screened for diffuse asbestos fibres, have not been found to contain asbestos fibres in quantities greater than 0.01%w/w (ICRCL 64/85 Asbestos on Contaminated Sites threshold (Ref. 14.101)) with the exception of one location (TE55/WS55A ES2 (0.5-0.8 m bgl), free fibres 2.74% by w/w), in the northern part of Area 5 (within fill occupying the probable former access ramp to foreshore, now infilled). As such the risk from these ACMs and free fibre release from the soils in their current state on the Built Development East is considered to be low.

Table 14.8: Locations of Suspected and Confirmed Asbestos Containing Materials on the Built Development Area East

Location	Depth (m)	Material Type	Ground Conditions & Location
GB2	0.0-2.0	Asbestos cement board	MG Area 6
TE312EX	0.0-0.8	Painted cement with fibres	MG Area 6
TE55/WS55A	0.3-1.2	Fibrous board bonded to wire, fibrous clusters	MG Area 5
	1.2-1.35	Bonded asbestos fibres	
	1.45-1.5	Bonded asbestos fibres	
	1.5-3.8	Loose and bonded asbestos fibres	
TE51	0.1-0.2	Asbestos bonded cement	MG Area 5
TE54 (S)	0.3-0.5	Asbestos pipe lagging	MG Area 5
TE54A	0.3-0.5	Cream and white lagging	MG Area 5
TE54B	0.4-1.7	Asbestos pipe lagging and hard set product	MG Area 5
TE54C	0.2-0.7	Cream and pink lagging	MG Area 5
H2 (Serco sample)	0.4	Asbestos bonded cement and potential asbestos lagging	MG Area 5
BH4 (Serco sample)	0.0-0.5	Asbestos bonded cement	NP Area 5
TE411	0.7-0.9	Amosite pipe lagging	MG Area 4
TE411A	0.0-1.1	Off-white fibres	MG Area 4
TE411B	0.0-1.35	White fibres	MG Area 4
TE412	0.2-0.5	Asbestos bonded cement	MG Area 4
TE415	0.7 and 0.9	Asbestos bonded cement	MG Area 4
TE417	0.4-0.8	Cement bonded tile	MG Area 4
TE418	0.0-0.3	White fibres	MG Area 4
TE418E	0.4-0.6	Tar bound concrete gravel (visible fibres)	MG Area 4
TE425	0.3-0.7	Asbestos cement tiles	MG Area 4
TE426	0.5-0.7	Asbestos cement tiles	MG Area 4
CBH2_57	0.0-0.28	Asbestos bonded cement	MG Area 4

Location	Depth (m)	Material Type	Ground Conditions & Location
DBH2_27	0.5-0.75	Asbestos fibres (crysotile)	MG Area 4
DBH2_27a	0.4-0.8	Black and pale fibres	MG Area 4
DBH2_27b	0.5-0.8	Pale fibres	MG Area 4
DBH2_22	0.0-0.35	Asbestos corrugated cement	MG Area 4
DBH2_22c	0.4-0.5	Asbestos bonded cement	MG Area 4
CBH2_30	0.2-0.4	Vinyl Bonded Asbestos Tile	MG Area 4
TE31	0.3-0.4	Mill board or lagging material	MG Area 3
TE34	0.5-0.8	Asbestos insulation material	MG Area 3
TE34A	0.6-0.8	Asbestos insulation material	MG Area 3
TE34B	0.3-0.4	Asbestos insulation material	MG Area 3
TE37	0.8-1.6	Asbestos bonded cement	MG Area 3
TE37d	0.7-1.5	Asbestos bonded cement	MG Area 3
TE216	0.0-0.3	Asbestos bonded cement	MG Area 2

14.5.109 At the time of writing, further asbestos investigations (principally within Areas 3, 4 and 5) are being undertaken by EDF Energy. These investigations are still 'work in progress', however, any additional areas of ACM that may be found will (wherever possible) be dealt with ahead of the site preparation works as part of the enabling/remedial works consented by Somerset County Council (see paragraphs).

Waste Acceptance Criteria (WAC)

14.5.110 As part of the investigation WAC analysis has been scheduled on 23 samples from across the BDAE to provide an initial assessment of the waste acceptance classification which materials may fall into should they require disposal off-site. All samples analysed were of Made Ground material with the exception of two samples of natural soil materials (weathered Blue Lias mudstone in TE12 ES2 and apparent pond sediment in TE13 ES4). A summary table of results and comparison with assessment criteria is presented in **Appendix 14C**.

14.5.111 The results of WAC testing indicate that exceedences of the leachable criteria for inert waste have been recorded for molybdenum (four samples of Made Ground within Area 3 containing demolition and construction materials and four samples of Made Ground from Area 4) and sulphate (three samples from Made Ground comprising natural reworked soils in Area 3). The two samples taken from the localised zone of visible hydrocarbon contaminated soils in Area 4 (TE418 ES2 and TE418D ES1) also recorded exceedences of the inert waste threshold for mineral oil and Total Organic Carbon (TOC). Concentrations of TOC in these samples also exceeded the threshold for stable non-reactive waste threshold and the concentration recorded in TE418D ES1 also exceeded the threshold for hazardous waste.

14.5.112 The results of WAC testing indicate that concentrations of contaminants are generally below the inert and hazardous waste criteria. However, Made Ground containing construction and demolition materials and some of the natural reworked soils would appear more likely to be categorised as non-hazardous for disposal purposes based on the exceedences of the leachable criteria for inert wastes.

14.5.113 In addition to the standard WAC testing described above, an assessment of the type and concentration of non-radiochemical contaminants in the soils of the BDAE was undertaken to see if they may contain any Dangerous Substances and/or possess any of the Hazard Properties (H1 to H14). The conclusion of this assessment is that with the exception of ACMs and the hydrocarbon contaminated soils present in Area 4 around TE418, the soils on the BDAE would not be deemed to be hazardous waste. Soils containing ACM, or elevated concentrations of hydrocarbons (usually >1000 or 10,000 mg/kg) are likely to be deemed as hazardous waste.

14.5.114 Consultation with the Environment Agency and the receiver of the wastes will be necessary, in the event that off-site re-use or disposal of soil material is required, to determine whether the materials can be accepted as inert waste or alternatively whether a non-hazardous or even hazardous (e.g. in the case of ACMs and the hydrocarbon hotspot at TE418) classification will be applied with respect to chemical contamination.

Soil Leachability Analysis

14.5.115 Soil leachability testing has been carried out on fifteen samples comprising two samples of natural soils, eight samples of Made Ground containing construction and demolition materials (including two samples from the hydrocarbon impacted trial pit TE418, which were analysed for PAHs and TPHs only) and five samples of Made Ground comprising reworked natural soils. The soil leachability results have been used to conduct a Tier 1 controlled waters risk assessment in accordance with the methodology presented in Section 14.4, b). A summary of the results and risk assessment are presented in **Appendix 14C**.

14.5.116 The analytical results for the soil leachate tests indicate concentrations are generally below the Tier 1 assessment criteria with the exception of isolated exceedences of chromium, lead, copper, selenium, cyanide and TPH. These exceedences of metals and cyanide were confined to locations in Area 3 (TE38; copper), Area 4 (TE415; copper, chromium, WS48; cyanide and WS75; chromium) and Area 6 (GB2; copper, lead and TE63; copper, lead) and do not represent a significant source of leachable contaminants which may pose a risk to controlled waters. The leachate analysis for TPH in TE418 (two samples) showed elevated concentrations of aromatic and aliphatic hydrocarbons (mainly aliphatic TPH in the carbon range C16 to C35). The TPH concentrations from both samples (879µg/l and 390µg/l respectively) significantly exceed both the DWS and freshwater EQS Tier 1 screening values, indicating that this contamination poses a potential risk to controlled waters via leaching.

14.5.117 With the exception of the localised zone of hydrocarbon-contaminated soils in the vicinity of TE418, no other mobile contaminant soil source term has been identified within the exploratory holes advanced during the intrusive investigations. Within the BDAE contaminant concentrations in soils do not indicate the presence of gross contamination or a significant potential source of leachable contamination.

Chapter 15 of this volume provides further assessment of groundwater conditions with respect to these hydrocarbon contaminated soils.

Intrusive Investigations: Southern Construction Phase Area

14.5.118 Intrusive investigations have been undertaken on the SCPA as part of the extensive second onshore investigation between November 2009 and August 2010 (Ref. 14.95). Investigations undertaken to assess the contamination status of this area were undertaken in June 2010 and comprised the excavation of boreholes, windowless sampling holes and hand dug pits to establish ground conditions, collect soil samples and facilitate gas and groundwater monitoring. Exploratory locations were positioned to provide coverage of the SCPA in general and to target possible infilled former ponds. Locations of the exploratory holes advanced on the SCPA are presented in **Figure 14.8**.

14.5.119 During the intrusive investigations Made Ground was encountered at one location only (WS75) extending to 0.79m bgl and at the other locations ground conditions generally comprised of topsoil over natural superficial deposits or weathered mudstone. Further details on ground conditions are provided in Section 14.5, b), i. The soils samples were collected and analysed for a range of chemical contaminants and a Tier 1 risk assessment was conducted in accordance with the methodology outlined in Section 14.4, b). The analytical results were subject to statistical tests, the UCL of the natural ground for each contaminant being compared to the relevant Critical Concentration (Tier 1 SSVs). A summary of the investigations including: the frequency and type of exploratory holes, chemical analysis undertaken, summary of the analysis results and risk assessment are presented in **Appendix 14C** and further details are provided in the investigation report (Refs. 14.92, 14.95).

14.5.120 The concentrations recorded in the soil samples from both Made Ground and natural soils were below the human health Tier 1 assessment criteria for residential without plant uptake land use. Levels of pH were in slight exceedence of the BS3882:2007 Topsoil Specification (Ref. 14.57) limit value (8.5pH units) in four natural soil samples (up to 8.9pH units), however, these slightly alkaline pH levels do not pose a risk to human health. No asbestos-containing materials were found in any of the exploratory holes in the SCPA.

14.5.121 Contaminant concentrations in soil samples from both the Made Ground and natural soils were below the phytotoxic SSVs, with the exception of one sample of natural soil (WS713 ES4) which exceeded the water soluble boron phytotoxicity SSV (31.6mg/kg compared to 3mg/kg). This sample was taken from a horizon of peat extending to depths ranging from 1.71m bgl to 3.59m bgl and the elevated boron concentration is of natural origin. This isolated exceedence does not pose a significant phytotoxic risk.

14.5.122 In general, the concentrations of the determinands which may pose a risk to concrete structures and water supply pipe materials have been recorded below the Tier 1 criteria with the exception of sulphate and pH levels. The single sample of Made Ground sample (WS75 ES1) and six of the seventeen natural soil samples exceed the WRAS (Ref. 14.60) sulphate limit (0.2%) and all but one natural soil sample also exceed the BRE SD1 (Ref. 14.62) sulphate value (0.24%). The elevated sulphate concentrations noted in the natural soils are of natural origin, as no physical evidence of anthropogenic contamination of the natural soils was noted, and the SCPA has no history of potentially contaminative use with respect to sulphate. Eleven of the natural soil samples and the Made Ground samples also exceeded the WRAS Tier 1 upper threshold for pH. The presence of naturally elevated pH and sulphate levels may pose a very low risk to potable water supply pipes and buried concrete structures.

14.5.123 One sample of natural soil (WS714 ES4), taken from natural alluvial strata, was found to exceed the WRAS threshold for cadmium. The cadmium concentration (5.2mg/kg) in this sample is noticeably higher than in other natural soil samples on the SCPA. However, this concentration is considered to be naturally occurring, as an elevated cadmium concentration was also identified in natural soil on the BDAW and the sample was taken from a significant depth with natural ground (1.50 – 1.80m bgl).

14.5.124 Elevated concentrations of chromium, mercury, zinc and selenium were recorded in the Made Ground sample when compared to the conservative ecological SSVs, however concentrations are within the rural England background soil concentration ranges. Concentrations of arsenic, chromium, cadmium, mercury, copper, nickel, zinc and selenium in natural soils were also found to exceed the ecological SSVs. Comparison with the rural England and local background concentration ranges indicates marginally elevated cadmium and nickel in one sample (TE714 ES4). However, these concentrations are naturally occurring and given that concentrations of contaminants on the SCPA are generally consistent with rural England background concentrations, the risk posed to ecological systems from contaminants within the soils on the SCPA is considered to be negligible.

14.5.125 Overall the intrusive investigations of soils within the SCPA identified the risk of significant non-radiochemical contamination being present to be very low.

Results of Radiological Surveys and Investigations

Built Development Area West

14.5.126 A series of assessments relating to the radiological conditions on the BDAW were undertaken. A Baseline Radiological Survey (Ref. 14.85) was undertaken in July 2008, which involved a radiological walkover survey and the collection and radiochemical analysis of surface soil samples (surface scrapes <0.2m bgl). This information was augmented by a Phase 2 Supplementary Investigation of Potential Radiological Contamination (Ref. 14.86). Soil samples were collected from the trial trenches excavated as part of the first on-shore investigations in 2008 (Ref.14.88 and 14.89) and selected samples were subjected to analytical testing for a range of radiochemical contaminants. Locations of the radiological survey and sampling on the BDAW are presented on **Figure 14.9**.

14.5.127 A summary of the surveys and investigations including; the frequency and type of exploratory holes, radiochemical analysis undertaken, summary of the analysis results and data assessment are presented in **Appendix 14D** and further details are provided in the investigation reports (Refs. 14.85 and 14.86).

14.5.128 The site radiation walkover survey recorded measurements that were low, being at or below expected background values for the area.

14.5.129 The radiochemical analysis results for the soil samples from the BDAW show that there is no evidence of significant contamination with anthropogenic radionuclides, and that the levels of radionuclides present are generally consistent with background levels. This conclusion is based on the following observations:

- The only anthropogenic radionuclide measurable by gamma spectrometry detected in any of the samples was caesium-137. Caesium-137 was detected in all of the surface samples at levels consistent with background due to global atmospheric fallout and significantly below.
- Carbon-14, which can be present both naturally and from anthropogenic sources, was detected in one of the samples at levels consistent with adopted background values. The level detected was significantly below The Radioactive Substances (Substances of Low Activity) Exemption Order (Ref. 14.78) limit of 0.4Bq g^{-1}.
- Tritium was detected in two of the samples at levels below The Radioactive Substances (Substances of Low Activity) Exemption Order (Ref. 14.78) limit of 0.4Bq g^{-1}.
- There were three instances of naturally occurring radionuclides (one for protactinium-234m and two for radium-226) exceeding screening values derived from the EPR2010 (Ref. 14.19). In all cases, the levels were below the EPR2010 limits for the relevant specified elements.

14.5.130 The results of the radiological investigation of the BDAW were the subject of a paper produced by the Green Audit organisation. This paper alleged, that on the basis of the radiochemical analysis results reported, the BDAW was contaminated with 10 tonnes of enriched uranium. The allegation was based on the derivation of uranium isotope ratios from the high-resolution gamma spectrometry results reported for the soil samples analysed. Green Audit calculated the uranium isotope ratio by taking the ratio of the thorium-234 result (which is an indicator of uranium-238) to the uranium-235 result. Their calculation showed, that in some cases, the isotope ratio was lower than that expected if the uranium was present in the natural isotope ratio, i.e. it was enriched. However, the calculation failed to take into account the analytical uncertainties associated with the results, which for the thorium-234 and uranium-235 measured by high-resolution gamma spectrometry were relatively high. If these were accounted for, the observed isotope ratio for an individual soil sample would range from lower than the natural ratio (enriched) to higher than the natural ratio (depleted) and would include the natural ratio. Due to the high uncertainties associated with the isotope ratio measurement determined by high-resolution gamma spectrometry, the approach adopted by Green Audit for establishing the presence of enriched uranium cannot be considered reliable. The use of high-resolution gamma spectrometry in the BDAW investigation was never intended to be used for determining uranium isotope ratios; it was used to identify and quantify a range of fission and activation products and to provide some quantitative information with regard to naturally occurring radionuclides. A more appropriate technique for measuring uranium isotope ratios reliably is mass spectrometry.

14.5.131 In addition to the unreliable methodology used by Green Audit to establish the presence of enriched uranium on the BDAW, it was considered implausible that 10 tonnes of enriched uranium could be present on the site. Hinkley Point A did not use enriched uranium fuel; hence the origin would be assumed to be from Hinkley Point B. The alleged quantity of enriched uranium present on the BDAW would equate to the entire uranium content of 200 fuel elements from Hinkley Point B, which corresponds to approximately 8000 fuel pins. Leaks from fuel pins are rare and predominantly involve the release of fission products; hence it is inconceivable that large amounts of irradiated fuel could have been lost without a significant release of fission products. Such a release would have been picked up by monitoring carried out by the site operator and the Environment Agency. In addition, the results from the BDAW did not identify the presence of significant levels of fission products. There is therefore not a credible mechanism for the losses of enriched uranium claimed by Green Audit.

14.5.132 In response to Green Audit's enriched uranium allegations, the Environment Agency commissioned a follow-up survey of the BDAW (Ref 14.102), which involved sampling of soil and its analysis specifically for uranium isotope ratios and uranium concentrations. Samples were collected from locations on the BDAW and for comparison purposes from farm land at distances ranging from five to 11km outside the BDAW. The samples were measured by high-resolution inductively coupled plasma mass spectrometry to provide precise and reliable uranium isotope ratio measurements. The results of the survey showed that the uranium isotope ratios were consistent with natural uranium; hence confirmed that enriched uranium was not present on the BDAW. In addition, the uranium concentrations measured were found not to be significantly higher than those expected.

Built Development Area East and Southern Construction Phase Area

14.5.133 A series of assessments relating to the radiological conditions on the BDAE and SCPA were undertaken. A non-intrusive radiological survey (Ref. 14.91) was undertaken on the BDAE and SCPA in October 2009. The survey locations are presented in **Figure 14.10** and **Figure 14.12**. This was augmented by the collection of soil samples during the investigations into the contamination status of the BDAE and SCPA (Ref. 14.92), undertaken from November 2009 to February 2010 and from June 2010 to July 2010. Selected samples were submitted for a range of radiochemical analysis and the analytical data was used to undertake a Phase 2 Radiological Contamination Assessment of the BDAE and SCPA (Ref. 14.93). Sampling locations are presented in **Figure 14.11** and **Figure 14.12**.

14.5.134 During the Phase 2 intrusive investigation works (Ref. 14.92), two locations were identified along the western boundary of the BDAE (TE312 and GB2, see **Figure** 14.11) that provided elevated radiation readings during routine health physics monitoring which was undertaken throughout the on-site works. As a result of this, a further six samples were collected from the two locations and submitted for radiochemical testing for a range of determinands that would enable the identification and quantification of a wide range of both naturally occurring and anthropogenic radionuclides.

14.5.135 A summary of the surveys and investigations including; the frequency and type of exploratory holes, radiochemical analysis undertaken, summary of the analysis results and data assessment are presented in **Appendix 14D** and further details are provided in the investigation reports (Refs. 14.91 and 14.93).

14.5.136 In general, the walkover survey recorded measurements that were low, being at or below expected background values for the area. The environmental gamma dose rates measured were also generally consistent with background levels. The radiological survey did, however, identify an area of elevated radiation readings close to the eastern boundary of the BDAE land adjacent to HPA. These findings were consistent with a previous walkover survey carried out on the BDAE land by Serco Assurance in 2008 (Ref. 14.49). The annual dose in excess of background based on commercial occupancy of the most elevated survey location would be 0.071mSv a^{-1} based on external radiation only. This constitutes 7.1% of the annual dose limit for members of the public (1mSv a^{-1}) (Ref. 14.103), and is 23.8% of the dose constraint adopted by the Environment Agency (0.3mSv a^{-1}) in their contaminated land guidance (Ref. 14.104).

14.5.137 The radiochemical analysis results for the soil samples from the BDAE and SCPA show that there is no evidence of significant contamination with anthropogenic radionuclides and that the levels of radionuclides present are generally consistent with background levels:

- The only anthropogenic radionuclides detected were caesium-137 and americium-241. The levels of caesium-137 detected were consistent with background due to global atmospheric fallout. Americium-241 was detected in two samples at low levels. One of the positive americium-241 results was reported at a level close to the limit of detection and was for a duplicate sample (DBH2_27 ES1D). The americium-241 result for the associated sample from this location (DBH2_27 ES1) was reported as a “less than” value. The other positive americium-241 result reported (0.0140 ± 0.0024 Bq g^{-1}) was for Tr2_5 ES1D. In this case, there was no duplicate sample with which to compare the value reported and there was no analytical reason to discount the result. Overall, levels of anthropogenic radionuclides detected were significantly below The Radioactive Substances (Substances of Low Activity) Exemption Order (Ref. 14.78) limit of 0.4Bq g^{-1}.
- Carbon-14, which can be present both naturally and from anthropogenic sources, was detected in a number of the samples at levels consistent with adopted background values. The levels detected were significantly below The Radioactive Substances (Substances of Low Activity) Exemption Order (Ref. 14.78) limit of 0.4Bq g^{-1}.
- Tritium, which can be present both naturally and from anthropogenic sources, was detected in one sample at a level close to the limit of detection and significantly below The Radioactive Substances (Substances of Low Activity) Exemption Order (Ref. 14.78) limit of 0.4Bq g^{-1}.
- With the exception of samples collected from three locations in Area 6 (TE312, TE312A and GB2), gross alpha and gross beta results were consistent with values reported for the BDAW.
- With the exception of samples collected from three locations in Area 6 (TE312, TE312A and GB2), the levels of naturally occurring radionuclides present would not result in the levels of specified radioelements exceeding EPR2010 (Ref. 14.19) limits.

14.5.138 The results for the targeted samples collected from GB2, TE312, TE312A and TE312B provide no evidence of contamination by anthropogenic radionuclides. However, the levels of naturally occurring radionuclides from the uranium-238 and uranium-235 decay series from selected locations (GB2, TE312 and TE312A) were elevated when compared with the range of results observed for the rest of the BDAE. The levels of uranium-238 series radionuclides observed at these locations fell within the range of 1 - 2Bq g^{-1}. This compares with an upper level for these radionuclides in samples collected from the rest of the site of approximately 0.09Bq g^{-1}. The gross alpha and gross beta levels were also elevated compared with the rest of the site due to the elevated levels of these naturally occurring radionuclides.

14.5.139 The levels of uranium-238 and uranium-235 natural series radionuclides in the samples from these locations are such that the levels of lead, polonium, protactinium, radium and thorium exceed their respective EPR 2010 (Ref. 14.19) elemental limits. However, the levels of all of these elements are below the Radioactive Substances (Phosphatic Substances, Rare Earths etc.) Exemption Order (Ref. 14.79) limit of 14.8Bq g^{-1} and hence should be exempt from radioactive substances regulation. The elevated natural uranium is likely to be associated with granite chippings observed at these locations.

Quantitative Radiological Risk Assessment

14.5.140 The radionuclide data for the HPC development site was compared to adopted screening values derived from the EPR2010 limits and relevant Exemption Orders and with background values from a variety of sources (see **Table 14.3**) . With the exception of samples from three locations along the western boundary of the BDAE (TE312, TE312A and GB2), the soil sample results for the HPC development site are generally consistent with adopted background values and below the adopted screening values.

14.5.141 A generic quantitative risk assessment of the HPC development site was carried out on the basis of the elevated levels of natural uranium identified along the western boundary of the BDAE. The assessment was carried out using the Environment Agency's Radioactively Contaminated Land Exposure Assessment Methodology (RCLEA) which was updated and re-issued in June 2011 to include doses due to radon in buildings. The methodology makes use of a set of mathematical models and data that calculate radiation doses from radionuclides in soil. These are included in a Microsoft Excel® software application published as CLR15 (Ref. 14.105), which is accompanied by a detailed technical report, CLR14 (Ref. 14.106), and user guide, CLR13 (Ref. 14.107).

14.5.142 The assessment was made using the following assumptions and inputs into the RCLEA software:

- the activity concentrations for uranium-238 and uranium-235 were based on the results reported for sample TE312 RAD1D, which provided the highest values for these two radionuclides. The uranium-238 concentration used was calculated by averaging the thorium-234, protactinium-234m, radium-226, lead-214 and bismuth-214 results reported for TE312 RAD1D (1.82Bq g^{-1}) and the uranium-235 value used was the measured result for TE312 RAD1D (0.0902Bq g^{-1});
- the decay series progeny of uranium-238 and uranium-235 were in secular equilibrium with their respective parents;
- the RCLEA model assumes uniform contamination to a depth of 1m bgl;
- the land use is considered to be commercial/industrial;
- the fraction of the land potentially contaminated is set to 0.05 (this is higher than the actual fraction of the land affected on the BDAE); and
- the building type, receptor age and receptor sex are set to worst case.

14.5.143 The assumptions above are generally conservative; hence, the calculated doses are likely to be overestimates. The results of the assessment provided an effective dose and equivalent dose to the skin, based on the assumptions described above, of 11.8 and 0.002mSv per annum respectively.

14.5.144 The assessment showed that in accordance with the Environmental Protection Act 1990 Part 2A regime (Ref. 14.1) definitions of contaminated land where radioactive contamination is concerned, the HPC development site is not contaminated by radioactivity. Harm is not being caused nor is there a significant possibility of such harm being caused, where harm is defined as "lasting exposure to any person resulting from the after-effects of a radiological emergency, past practice or past work activity". Harm is regarded as being caused where lasting exposure gives rise to radiation doses equal to, or in excess of, one or more of the following:

- an effective dose of 3mSv per annum;
- an equivalent dose to the lens of the eye of 15mSv per annum; or
- an equivalent dose to the skin of 50mSv per annum.

Ground Gas Assessment

Built Development Area West

14.5.145 A programme of ground gas monitoring was undertaken within the Built Development Area West. Six gas monitoring visits were undertaken between January 2009 and April 2009 at ten piezometer locations (installed as part of the on-shore investigation undertaken by Structural Soils Ltd in 2008) in accordance with the requirements presented in guidance document CIRIA C665 (Ref. 14.76). During one visit, six gas samples were taken from selected locations and submitted for laboratory analysis for a range of gases. The laboratory analysis was carried out to confirm field data and provide confidence that the field monitoring technique was robust. A ground gas risk assessment was subsequently undertaken in accordance with the methodology presented in Section 14.4 b).

14.5.146 The monitoring locations are presented in **Figure 14.13**; and a summary of the gas monitoring results is presented in **Appendix 14E**. Further details are provided in the Ground Gas Risk Assessment report for the Built Development Area West (Ref. 14.87).

14.5.147 The monitoring and sampling data indicate that concentrations of ground gases during the monitoring period varied across the BDAW but were generally very low.

14.5.148 Concentrations of carbon dioxide were low, with a maximum concentration of 3.0% by volume, and concentrations of methane were very low, with all monitored and gas sample concentrations below the limit of detection (<0.1% by volume).

14.5.149 Trace levels of carbon monoxide were recorded at certain locations with a peak of three parts per million (ppm) being recorded in DBH04. However, all concentrations were below the Occupational Exposure Limits (Workplace Exposure Limits) within EH40 guidance document (2007) (Ref. 14.77) and are therefore not considered to pose a risk to human health.

14.5.150 No hydrogen sulphide or volatile organic compounds (VOCs) were detected within any of the piezometers during any of the monitoring visits.

14.5.151 Recorded gas flow rates were very low, with readings generally slightly above and below a zero flow rate. A maximum positive flow of 5.2l/hr was recorded in DBH09.

14.5.152 In accordance with the methodology in CIRA C665 (Ref. 14.76), Gas Screening Values (GSVs) were calculated for all monitoring locations for carbon dioxide and methane, using the formula: GSV (litres of gas per hour) = maximum gas concentration (%)/100 x maximum piezometer flow. The maximum value GSV was selected as the 'worst case'.

14.5.153 The calculations identified that for the BDAW, the 'worst case' GSV for methane was 0.0052l/hr (DBH09 0.1% by volume of methane (limit of detection taken as worst case) with a flow of 5.2l/hr), this is below the upper threshold limit of Characteristic Situation 1 (CS1). The 'worst case' carbon dioxide was 0.0736l/hr (CBH24 1.6% by volume of carbon dioxide with a flow of 4.6l/hr), this is marginally above the upper threshold for CS1 (<0.07l/hr).

14.5.154 During both field monitoring and laboratory analysis no concentrations of carbon dioxide or methane exceeded the threshold levels used within the CIRIA 665 (Ref. 14.76) guidance (5% by volume and 1% by volume, respectively). Within the BDAW no putrescible or biodegradable wastes were observed and no naturally organically enriched soils (e.g. peat) were found, indicating that the soils were naturally low in organic content and have a low ground gas generation potential. Given that the carbon dioxide GSV is very much a worst case assessment and that the monitoring has also been undertaken during low atmospheric pressure conditions, it is considered that the Characteristic Situation for the BDAW can be reliably defined as CS1 based on the guidance criteria within Table 8.5 of CIRIA 665 (Ref. 14.76). Given the proposed commercial/industrial end use, no special precautions or gas protection measures are required to be incorporated within the planned buildings to protect the end users and buildings themselves.

14.5.155 During the intrusive works, undertaken as part of the first on-shore investigation of the BDAW by Structural Soils Ltd in 2008 (Ref. 14.88) to determine the geotechnical and geological characteristics of the site, elevated concentrations of hydrogen sulphide (up to 17ppm CBH19), nitrogen (94 – 97.8% by volume DBH04 (balance calculation)), and carbon monoxide (up to 200ppm CBH19) were detected in some boreholes during drilling.

14.5.156 Elevated nitrogen concentrations (determined by) and associated depleted oxygen and high gas flow rates were recorded within DBH04 by Structural Soils Ltd immediately after the installation of the piezometer in 2009. The subsequent monitoring programme (2009) indicated a reduction of the nitrogen concentrations (shown by an increase in oxygen concentrations and no high flows).

14.5.157 Structural Soils Ltd undertook limited gas monitoring for the purposes of driller health and safety during the intrusive investigation works as part of the second on-shore investigation (Ref. 14.95). The majority of concentrations recorded by Structural Soils Ltd were consistent with background levels, and not considered to be indicative of a significant risk in the context of worker health and safety. However, during drilling at a limited number of locations (ISS-01A, CBH2_11, CBH2_27, CBH2_32 and CBH2_33) elevated concentrations of nitrogen (up to 98.1% volume, identified by balance calculation) and associated depleted oxygen levels (as low as 0% by volume), methane (up to 12% by volume), hydrogen sulphide (up to 43ppm) and low concentrations of carbon monoxide (up to 4ppm) were recorded. The gas monitoring conducted was for health and safety purposes and therefore not within properly installed standpipes or piezometers. Monitoring of existing piezometer DBH04 again also recorded elevated nitrogen (96% by volume, calculated by balance calculation), associated depleted oxygen levels (as low as 0% by volume) and high gas flow rates (>30l/hr). In order to investigate the elevated concentrations, two identified locations: DBH04 and CBH2_33 were monitored as part of the 2010 monitoring programme (Ref. 14.94) as detailed below.

14.5.158 During the 2010 gas monitoring programme (Ref. 14.94) the elevated nitrogen levels, associated depleted oxygen and high gas flow rates recorded within DBH04 and CBH2_33 by Structural Soils Ltd during drilling were not repeated, with concentrations and flow rates representative of typical site conditions. During the monitoring of DBH04 on one occasion the results showed slightly elevated nitrogen (87.7% by volume, calculated by balance calculation) and reduced oxygen (11.5% by volume) levels and CBH2_33 showed an elevated gas flow rate of 5l/hr, however, these concentrations are not consistent with the significantly elevated concentrations and gas flow rates encountered during drilling works.

14.5.159 The source of the gases identified during the drilling works is likely to be small pockets of gas trapped within the underlying geology or groundwater that have been released during drilling. In the case of hydrogen sulphide, this is thought to be associated with dissolved hydrogen sulphide in groundwater which is probably derived from the breakdown of natural organic matter in the underlying geology.

Built Development Area East and Southern Construction Phase Area

14.5.160 A programme of ground gas monitoring was undertaken within the BDAE and SCPA in accordance with the requirements presented in guidance document CIRIA C665 (Ref. 14.76). Eight monitoring visits were undertaken between June 2010 and September 2010. The monitoring programme was extended to eight monitoring visits to ensure that all piezometers had been monitored on at least six occasions, in accordance with the CIRIA C665 guidance. Monitoring was undertaken at 11 piezometers in the BDAE and seven piezometers in the SCPA, and to supplement existing data as described above, two piezometers in the BDAW were also monitored. During the fourth monitoring visit, eight gas samples were taken from selected piezometers and submitted for laboratory analysis for a range of ground gases and VOCs. The laboratory analysis was carried out to confirm field data and provide confidence that the field monitoring technique was robust. A ground gas risk assessment was subsequently undertaken in accordance with the methodology presented in Section 14.4 b)

14.5.161 The monitoring locations on the BDAE and SCPA are presented in **Figure 14.14** and **Figure 14.15** respectively and a summary of the gas monitoring results is presented in **Appendix 14E.** Further details are provided in the Ground Gas Risk Assessment report for the Built Development Area West (Ref. 14.94).

14.5.162 Across the BDAE and SCPA concentrations of carbon dioxide were low with a maximum concentration of 3.4% by volume in the BDAE (DBH2_20) and 1.2% by volume (WS73) in the SCPA. Concentrations of methane were very low with a maximum concentration of 0.1% by volume in the BDAE and concentrations below the limit of detection (<0.1% volume) in the SCPA.

14.5.163 Trace concentrations (up to 5ppm) of carbon monoxide were recorded in the SCPA and up to 3ppm in the BDAE. Table 1 of the Health and Safety Executive Workplace Exposure Limits within the EH40 guidance document (Ref. 14.77) indicates that the concentrations recorded are well below both the long and short-term exposure limits (30ppm and 200ppm respectively) and are therefore not considered to pose a risk to human health.

14.5.164 Hydrogen sulphide was not detected within any piezometer at a concentration above 1ppm during any of the monitoring visits. These results are in agreement with the gas sample analysis which show that concentrations of hydrogen sulphide were below the relevant limits of detection.

14.5.165 VOCs of up to a maximum (peak) concentration of 44.4ppm in the SCPA and 25.4ppm in the BDAE have been detected. The gas sampling data did not identify any VOCs above the limit of detection (0.2µg/l). During one monitoring visit VOCs above the adopted human health screening value (10ppm, based on the range of concentrations of individual compounds in the EH40 guidance (Ref. 14.77)) were detected in three locations (GB4, GB6 and DBH2_7) up to a peak concentration of 25.4ppm and steady concentration of 15ppm. Since the elevated concentrations were confined to one monitoring visit, they are not considered to represent a significant source of volatile hydrocarbons.

14.5.166 Gas flow rates were low with a maximum negative flow rate of -4.7l/hr and a maximum positive flow rate of 8.7l/hr.

14.5.167 In accordance with the methodology in CIRA C665 (Ref. 14.76) GSVs were calculated for all monitoring locations in the BDAE and SCPA for carbon dioxide and methane, using the formula: GSV (litres of gas per hour) = maximum gas concentration (%)/100 x maximum piezometer flow. The maximum value GSV was selected as the 'worst case'.

14.5.168 The calculations identified, for the SCPA, that both carbon dioxide (0.0272l/hr at WS711 (0.8% by volume carbon dioxide, flow rate 3.4l/hr)) and methane (0.0048l/hr at WS79 (0.1% by volume methane, flow rate 4.8l/hr)) ‘worst case’ GSVs fall below the upper threshold of Characteristic Situation 1 (CS1) (<0.07l/hr gas), therefore concentrations of these gases in the SCPA are considered to pose a very low risk to human health or buildings.

14.5.169 A gas screening value (GSV) for carbon dioxide, 0.2349l/hr (2.7% by volume of carbon dioxide with a flow of 8.7l/hr), was identified in borehole GB3B, located within the large double-humped mound feature within the BDAE. Elevated carbon dioxide and gas flow rates have been identified in GB3B and GB4 (both located in the mound) and are likely to be associated with the greater depth and volume of Made Ground materials in this area. The depth and volume of Made Ground materials present in the mound do not reflect ground conditions across the other areas of the BDAE. Therefore, concentrations at the locations in this area (GB3B and GB4) are not considered to be representative of general site conditions.

14.5.170 The highest GSVs for the BDAE, excluding the double-humped mound boreholes GB3B and GB4, are 0.0912l/hr for carbon dioxide and 0.0057l/hr for methane (GB6 carbon dioxide concentration 1.6% volume, methane concentration 0.1% volume, and maximum flow rate 5.7l/hr). At this location the GSV for methane is within the threshold for Characteristic Situation CS1. However, the GSV for carbon dioxide is very marginally above the upper threshold for CS1.

14.5.171 As stated in the CIRIA C665 (Ref. 14.76), the calculated GSV is a guidance value and not an absolute threshold. In accordance with the guidance it is considered that the gas regime of the BDAE site should remain as CS1 because of the ground conditions and soil types encountered (i.e. low organic content soils), the very low gas concentrations and flow rates in general across the site, the very marginal exceedence of the carbon dioxide GSV guidance threshold in GB6 and the fact that the concentrations of both carbon dioxide and methane have been recorded consistently below the 5% and 1% by volume thresholds respectively. These thresholds are still used as 'additional assessment factors' in Table 4.2 of CIRIA 665 (Ref. 14.76).

14.5.172 The additional monitoring of data for DBH04 and CBH2_33 on the BDAW does not change the original ground gas risk assessment (described above). Gas concentrations were low and largely consistent with previous monitoring, and the 'worst case' GSVs for carbon dioxide and methane at both locations are below the 'worst case' GSVs identified during the 2009 monitoring programme.

Ground Gas Summary

14.5.173 Gas monitoring data indicate that are no significant sources of ground gas within the BDAW, BDAE or SCPA and therefore there is no significant risk posed to human health or buildings by ground gas.

14.5.174 During the review of historical maps and plans (Ref. 14.90) of the HPC development site a small number of historic and potentially infilled ponds were identified. Intrusive locations during the second on-shore investigation (Ref. 14.92) were specifically targeted to investigate some of these former pond features. However, of the ten exploratory holes that were targeted to such features only one recorded ground conditions (e.g. silt and sediments) that were considered to be consistent with a former pond (TE13). Plans overlaying the exploratory locations and gas monitoring boreholes on the locations of the historical/infilled ponds are presented as **Figure** 14.13, **Figure 14.14** and **Figure 14.15**. Ground gas monitoring in a number of boreholes on the HPC development site has not identified any significant concentrations or flow rates of ground gases. Given the low number, small size and very limited potential volume of these historical features it is not considered that they pose a significant potential ground gas risk.

14.5.175 The ground gas risk assessment identified the BDAW, BDAE and SCPA as falling within gas Characteristic Situation 1. There is a negligible risk to human health or buildings by ground gases in the context of the permanent built development. Given the proposed commercial/industrial development (i.e. the power station) with the temporary workers accommodation (i.e. residential flats) no special precautions or gas protection measures are required to be incorporated within the planned buildings in order to protect either the end users or buildings themselves.

14.5.176 Elevated concentrations of nitrogen, hydrogen sulphide and carbon monoxide were occasionally noted during drilling works on-site. The Structural Soils Limited gas monitoring was conducted for the purposes of health and safety and not for the purpose of gas risk assessment. Typically the gas measurements were taken from uninstalled boreholes: this approach does not comply with good practice guidance for gas risk assessment (e.g. C665). Therefore the results of this gas monitoring (i.e. the observed elevated concentrations of nitrogen, hydrogen sulphide and carbon monoxide) may not be reliable for the purposes of gas risk assessment. The significantly elevated gas concentrations and flow rates identified during drilling were not repeated during the subsequent gas monitoring programmes. However, the data generated from the drilling programme cannot be completely ignored and as a precaution a low risk to human health should be assumed via the inhalation of gases potentially present in pockets within the underlying geology or groundwater during confined space working or works which are carried out in deep excavations during construction.

Animal Burial Pits

14.5.177 The Animal Health Division of Defra has been consulted on the potential presence of any animal burial pits arising from foot and mouth or other disease outbreaks. No such pits are recorded within the HPC development site (see email confirmation presented in **Appendix 14F**).

14.5.178 It should be noted that burial pits were not registered before 1972, and individual animals could still be buried without registration up to the early 1990s. The potential for unrecorded burials being present within the HPC development site, although low, cannot be completely discounted (for further details see **Chapter 13** of this volume (Soils and Land Use)).

Existing Baseline and Baseline Prior to Main DCO Works Starting

iii. Conceptual Site Model for Land Contamination

14.5.179 Following a review of the available desk based and site investigation information, a Conceptual Site Model (CSM) has been produced to identify potential risks posed to human health and other receptors by soil contamination which may be present on and adjacent to (i.e. within a 500m radius) the HPC development site given the proposed development and its future use.

14.5.180 Three Conceptual Site Models have been developed to reflect the changes in anticipated site conditions (principally changing source characteristics) throughout the different phases of the development, namely:

- Baseline Conceptual Model Prior to Enabling/Remedial Works;
- Baseline Conceptual Model at start of Construction Phase i.e. post Enabling/Remedial Works; and
- Operational Phase Conceptual Model (i.e. post construction phase).

Schematic diagrams of the CSM models above are presented as **Figures 14.17**, **14.18** and **14.19.** The CSMs are also presented in tabular format in **Appendix 14G.**

Potential Sources of Contamination - On-Site Baseline before Enabling/Remedial Works

Human Health

14.5.181 The Phase 1 desk studies (Ref. 14.90 and Ref. 14.84) concluded that the BDAW and SCPA have remained largely undeveloped agricultural land with no significant historical contaminative uses identified. A number of potentially contaminating activities were identified within the BDAE including a double-humped mound feature containing surplus spoil arising from the construction of the HPA site in the 1960s, a former sewage treatment works, former NDA spoil storage area, general Made Ground deposits and former fabrication/construction facilities and accommodation areas. However, limited visual or olfactory evidence of gross contamination was identified during the site investigations, with the exception of locations where suspected and confirmed ACMs have been identified and the presence of a localised hotspot of hydrocarbon contaminated soils.

14.5.182 Concentrations of non-radiochemical contaminants within soils in the BDAW and SCPA were all below the human health Tier 1 screening values, relevant to the proposed end use, therefore no risk is posed to human health receptors from soils on these areas of the site.

14.5.183 On the BDAE concentrations of non-radiochemical contaminants were generally below the Tier 1 human health screening values for a commercial and industrial end use, with the exception of alkaline pH in Made Ground containing demolition and construction materials, elevated PAHs at one location (TE63), elevated hydrocarbons in the zone of hydrocarbon impacted soils around TE418 and the identification of ACMs at a number of locations in the Made Ground.

14.5.184 Elevated concentrations of total PAHs and benzo(a)pyrene have been identified in ashy materials in TE63 and moderately alkaline pH levels have identified in the Made Ground containing demolition and construction materials. During the construction works there is considered to be a low risk to human health from these materials.

14.5.185 The localised zone of hydrocarbon impacted soil around TE418 in Area 4 is currently confined below surface, therefore the current risk to end users is very low.

14.5.186 The presence of ACMs within the Made Ground at a number of locations presents a theoretical risk to human health. However, only limited quantities of asbestos have been identified and analysis of soils associated with suspected and confirmed asbestos containing materials have not detected diffuse free fibres above 0.01%w/w with the exception of one location (TE55/WS55A). The current risk to end users provided the ground remains undisturbed is very low.

14.5.187 The results of the WAC testing undertaken on the BDAE indicate limited exceedences of the inert waste criteria for molybdenum and sulphate; however concentrations are below the non-reactive hazardous waste and hazardous waste thresholds. Therefore, the soils on the BDAE would typically not be classified as hazardous waste. The exceptions to this are the zone of hydrocarbon impacted soils which identified concentrations of Total Organic Carbon above the non-reactive hazardous waste and hazardous waste thresholds and the ACMs which are likely to be classified as hazardous waste.

14.5.188 The radiological investigations (Ref. 14.86 and Ref. 14.93) determined that the HPC development site is not contaminated by radiochemical contaminants. Generally concentrations of radiochemical contaminants were not in excess of regulatory thresholds and levels were consistent with background values in the UK and as a result the risk to human health within the study area is considered to be negligible.

14.5.189 The results of the RCLEA assessment demonstrate that the calculated effective dose and equivalent dose to the skin, based on the assumptions described above, are 1.8 and 0.002mSv per annum respectively. The assessment shows that in accordance with Part 2A regime definitions of contaminated land where radioactive contamination is concerned, the BDAE and SCPA land areas are not contaminated by radioactivity. Harm is not being caused nor is there a significant possibility of such harm being caused, where harm is defined as "*lasting exposure to any person resulting from the after-effects of a radiological emergency, past practice or past work activity*". Harm is regarded as being caused where lasting exposure gives rise to radiation doses equal to or in excess of one or more of the following:

- an effective dose of 3mSv per annum;
- an equivalent dose to the lens of the eye of 15mSv per annum; or
- an equivalent dose to the skin of 50mSv per annum.

Soil Quality and Ecological Systems (Ecotoxicity)

14.5.190 Contaminant concentrations in the majority of the soils within the HPC development site are considered to be reflective of natural background concentrations and do not pose a significant ecological or phytotoxic risk. However, some Made Ground materials on the BDAE and the isolated area of Made Ground on the BDAW contain contaminant concentrations which may pose a low risk to ecological systems should they be re-used in areas of soft landscaping or agricultural and habitat restoration.

14.5.191 Isolated contamination by heavy metals was encountered in the highly localised area of Made Ground on the BDAW (zinc) and in isolated locations (zinc in DBH2_27 and copper in TE54) within the BDAE. Also within the BDAE, elevated concentrations of hydrocarbons were identified at specific locations (WS27 and TE63) and in Made Ground containing demolition and construction materials. Materials of this type and/or at these locations may also pose a low risk to ecological systems.

14.5.192 Also, within the Made Ground containing demolition and construction materials on the BDAE, moderately alkaline pH levels (>9pH units) were identified which could restrict the number of plant species which may establish successfully in such materials. The high pH levels associated with these materials may also pose a low risk to ecological systems.

Controlled Waters

14.5.193 No significant sources of soil contamination have been identified on the BDAW or SCPA therefore the risk to controlled waters from soils in these areas is considered to be negligible. Soil leachability testing on the BDAE does not indicate the presence of significant mobile contamination in soils, with the exception of the isolated area of hydrocarbon contaminated soils. Therefore the potential for soils to impact controlled waters via leaching on the BDAE in general is considered to be negligible. Leachate testing of the hydrocarbon contaminated soils indicates leachate concentrations in two samples (TE418 ES2 and ES3) to exceed the screening criteria for TPH and therefore this small, isolated area of soil contamination is considered to pose a moderate risk to controlled waters.

Ground Gases

14.5.194 Gas monitoring data indicate that there are no significant sources of ground gas within the HPC development site and therefore there is no significant risk posed to human health or buildings by ground gas given the proposed site end use.

14.5.195 However, elevated concentrations of nitrogen, hydrogen sulphide and carbon monoxide were occasionally noted during drilling works on-site. There is therefore a low risk to human health via the inhalation of gases potentially present in pockets within the underlying geology or groundwater, confined space working or works which are carried out in deep excavations during the construction phase.

Potential Sources of Contamination - On-Site Baseline Post Enabling/Remedial Works

14.5.196 It should be noted that the above summary of contamination sources represents a summary of the baseline conditions, before, the enabling/remediation works covered by Planning Application are completed. Remediation works to be completed as part of the enabling works include removal of hotspots of ACM contamination from within the BDAE (apart from the known ACMs under the location of the new HPA and HPB car park) identified during the intrusive investigations, removal of the hydrocarbon hotspot around TE418 and removal of the double humped mounded feature and areas of known ACM within it for off-site disposal. The baseline contamination sources included in the Conceptual Model Post Enabling/Remedial Works assume that these known areas will have been removed before the site preparation works (bulk earthworks) and main construction works begin. This will significantly reduce (but not entirely eliminate) the potential for encountering ACM during the preliminary and main site works.

Potential Sources of Contamination - On-Site Operational Phase (Post Construction Works)

14.5.197 A number of potential contaminant sources will be present on the site during the operational phase, including for instance (note that this list is not meant to be exhaustive):

- fuel storage tanks;
- hazardous waste storage areas;
- electrical sub stations and switchgear;
- chemical storage areas;
- generators, boilers and turbines;
- radioactive waste and materials storage areas and ponds; and
- drainage systems and sumps.

14.5.198 Soils remaining on-site during the operational phase (i.e. those soils and other materials re-used during the construction works) will be suitable for use and therefore unlikely to be significantly contaminated.

Off-Site Sources of Contamination

14.5.199 A Phase 1a desk study (Ref. 14.90 and Ref. 14.84) and review of available reports relating to HPA and HPB identified some potential and confirmed contamination sources. Given that the topographical, geological and hydrogeological gradients generally fall towards the north/north-east, the likelihood of any contamination migrating onto the HPC Development Site from off-site sources under existing conditions is considered to be low. Hydrogeological modelling has been undertaken, which has included modelling of the effects on the groundwater regime as a result of the dewatering of deep excavations during the construction phase. This model has been used as part of the assessment of impacts associated with the mobilisation and migration of contaminants in groundwater. The hydrogeological model is detailed in **Chapter 15** of this volume (Groundwater).

14.5.200 With the exception of the existing Hinkley Point Power Station Complex, the majority of the land surrounding the HPC development site is currently (and has been since at least the 1880s) agricultural/greenfield land. In view of this, the likelihood of significant off-site sources within these areas is considered to be 'unlikely'. In addition, the potential physical extent of any such off-site sources on these lands is as assumed to be small/localised, therefore the potential magnitude of contamination is assumed to be 'very low' (i.e. as per the BDAW and SCPA).

Potential Pathways and Exposure Mechanisms

14.5.201 The following potential pathways/exposure mechanisms are relevant in the context of the proposed development. Note that not all pathways will be active during all phases of the development. For instance, indoor soil and vapour and ground gas inhalation is not relevant to the baseline prior to the construction phase, as there are no significant buildings currently on-site. Likewise, the potential for direct contact/ingestion of contaminated soils during the operational phase is very unlikely due to the amount of buildings and hardstanding that will be present on the site:

- indoor soil vapour and ground gas inhalation from ingress of ground gases and vapours via service entry points and cracks/joints;
- migration via man made pathways such as drains and underground services (includes permeation into and distribution via water service pipes);
- phytotoxic risk to vegetation via plant uptake;
- inhalation of soil vapours or soil particles/wind blown particulates, dermal contact/ingestion of soil particles and direct exposure;
- migration via permeable ground;
- transfer of contaminants via surface run-off (see **Chapter 16** of this volume (Surface Water));
- transfer of contaminants via groundwater flow (see **Chapter 15** of this volume (Groundwater));

- air/windborne transport (on-site and off-site) of soil and dust from areas of exposed soils;
- ingestion, inhalation, dermal contact by ecological fauna and flora; and
- predation / bioaccumulation by ecological fauna.

14.5.202 The following activities may create and/or introduce new pathways and/or disturb and mobilise contamination during the proposed development:

- excavation and filling operations ('Cut and Fill') particularly using granular and permeable soils and fills;
- general earthworks/regrading;
- groundwater dewatering (see **Chapter 15** of this volume (Groundwater)); and
- installation of drainage network.

Potential Receptors

14.5.203 The following are considered to be potential receptors for soil contamination in the context of the proposed development:

- Human health: On-site – construction workers, future end users and future maintenance/construction works during the operational phase of the development.
- Human health: Off-site – local residents (e.g. Doggetts Farm, Shurton, Knighton), adjacent site workers (existing HPA and HPB), farm workers on adjacent agricultural land, members of the public using public footpaths across and adjacent to HPC development site.
- Terrestrial ecological receptors (animals, wildlife, plants, trees, and other vegetation (excluding crops)) on-site and off-site. Details of terrestrial ecology are contained in **Chapter 20** of this volume (Terrestrial Ecology and Ornithology).
- Crops and livestock on-site and off-site (for details see **Chapter 13** of this volume (Soils and Land Use)).
- Soil Environment: On-site and off-site soils from land contamination including a basic assessment of soil ecological risk (soil ecotoxicity).
- Built Environment: On-site and off-site buildings, infrastructure and/or services.
- Controlled Waters: On-site groundwaters – on-site Secondary Aquifers and on-site surface waters – drainage ditches and Holford Stream (the scope of this assessment is the direct impact to on-site controlled waters from actual or potential land contamination only, any further indirect impacts are considered in **Chapter 15** of this volume (Groundwater) and **Chapter 16** of this volume (Surface Water).

Receptor Value and Sensitivity

14.5.204 The value and sensitivity of the identified potential receptors for soil contamination are detailed below:

- On-site humans (i.e. construction workers or future maintenance works and end users): Construction/maintenance workers and future end users are considered to have high value and sensitivity to contaminants. However, health, safety and environmental legal requirements, and good practices which would be adopted, specifically those relating to the use of appropriate personal protective equipment (PPE) and hygiene, would reduce this. Therefore, the overall value rating for value and sensitivity of on-site humans is considered to be low, as possible exposure to land contamination should be prevented or minimised through normal good practices.

- Off-site humans (i.e. users of local footpaths and local residents): Off-site humans are considered to be of high value and sensitivity as they would not be using appropriate PPE and are clearly of high intrinsic value.
- On-site ecology is considered to be of medium value/sensitivity overall, based on the presence of protected species (bats) and Nationally Scarce invertebrates within the site as well as the range of habitats present. (see **Chapter 20** of this volume for further details).
- The off-site ecology value and sensitivity is considered to be high, due to the presence of statutory designated sites and protected species near to the site, including Bridgwater Bay SSSI, and the Severn Estuary SPA and Ramsar Site, (see **Chapter 20** of this volume for further details).
- On-site and off-site crops and livestock: This is primarily through potential phytotoxic/toxic effects from exposure to soil contamination. For the purposes of this ES, the value and sensitivity of crops and livestock has been based on the agricultural land use classification (ALC) as detailed in **Chapter 13** (Soils and Land Use) of this volume. The value of the on-site crops and livestock is medium on the basis of the potential of the on-site land, in terms of its ALC, for productive farming activity. The value and sensitivity of the off-site crops and livestock has been rated as medium to high on the basis of its ALC grade for productive farming activity (medium) and sensitivity of stock and (potentially) household pets (high) to diseases from disturbed animal burial pits (see **Chapter 13** of this volume for details). As a conservative approach, a high value and sensitivity has been selected for off-site crops and livestock for this assessment.
- On-site soil environment (including soil ecotoxicity): The value and sensitivity of the on-site soils to current or future land contamination[2] is considered to range from very low for Made Ground/engineering fills, to high for soils (topsoils and subsoils) scheduled for potential re-use in more sensitive areas such as soft landscaping and agricultural/habitat restoration. The soil ecology (i.e. soil organisms) is important in maintaining the structure and nutrient content of the soils, through the processes of organic matter decomposition and nutrient cycling. Therefore the value and sensitivity of soil ecology also ranges from very low for engineering fills to high for soils scheduled for re-use in soft landscaping and agricultural/habitat restoration, where the maintenance of good soil structure and nutrient cycling by soil organisms are important to ensuring the integrity of the resource. As a conservative approach, a high value and sensitivity has been selected for the on-site soil environment for this assessment.

[2] The value and sensitivity given above is on the basis of existing soil types to current and potentially future land contamination. The ranges of value and sensitivity may therefore be different to those used in Chapter 13 (Soils and Land Use) as Chapter 20 is concerned with potential impacts to soils from physical disturbance, compaction and handling rather than contamination impact and therefore the value and sensitivity of the soil may be different.

- Off-site soil environment (including soil ecotoxicity): The value and sensitivity of the off-site soil environment to current or future land contamination[2] ranges from very low in adjacent commercial and industrial areas, i.e. the existing Hinkley Point Power Station Complex to high in adjacent agricultural and designated areas. The soil ecology (i.e. soil organisms) is important in maintaining the structure and nutrient content of the soils. Therefore the value and sensitivity of soil ecology also ranges from very low for soils in the adjacent existing Hinkley Point Power Station Complex to high in adjacent agricultural and designated areas, where the maintenance of good soil structure and nutrient cycling by soil organisms are important in ensuring the integrity of the resource. As a conservative approach, a high value and sensitivity has been selected for the off-site soil environment for this assessment.
- The built environment: The value and sensitivity of the built environment is considered to range from very low (e.g. potable water pipes and car park areas) to high (for main nuclear island buildings and structures). This evaluation is based on the economic cost, structural sensitivity and strategic importance of the structures with respect to energy supply and the requirement that they remain in a safe structural and operating condition throughout their design life. As a conservative approach, a high value and sensitivity has been selected for the on-site built environment for this assessment.
- Controlled waters (i.e. on-site groundwaters and on-site surface waters): The value and sensitivity of controlled waters is considered to be low for on-site groundwater (see **Chapter 15** Groundwater of this volume) and low to high for on-site surface water (see **Chapter 16** of this volume (Surface Water)). As a conservative approach, a high value and sensitivity has been adopted for on-site surface waters.

14.6 Assessment of Impacts

a) Introduction

14.6.1 This section provides an assessment of the key project elements which have the potential to impact on geology and land contamination during the Hinkley Point C development.

14.6.2 Prior to the construction of HPC, it is intended that a series of enabling works will be completed within the BDAE, which have been progressed and are ongoing (as at October 2011) under a planning consent from Somerset County Council. **The effective completion of these enabling works is assumed as the baseline condition for the following impact assessment**. Note that this is different to the baseline condition described above in Section 14.5 which is the baseline condition before the enabling works.

14.6.3 The enabling works will include the removal and disposal of any contaminated soils (principally soils contaminated with ACM within Areas 3, 4 and 5) within the BDAE, apart from known hotspots currently below inaccessible areas (e.g. ground under the enabling works contractors compound and under the location of the new HPA and HPB car park). Within this car park area there are a number of asbestos hotspots and the area of hydrocarbon contaminated soils in the locality of TE418 (illustrated on **Figure 14.16**). The car park has been constructed over the identified hotspots and the resultant hard surface will act as a physical barrier, preventing both contact with contaminated soils and the generation of contaminated dusts. Therefore there will be no risk to human health during the period when the car park is in use. The areas of contamination beneath the contractors compound and car park will be remediated, with associated verification and validation reporting, when the contractors compound and car park are no longer required and prior to any construction works commencing in this part of the BDAE.

14.6.4 All the other known hotspots within the BDAE would be removed and the remediation works would be verified and validated prior to the commencement of the bulk earthworks associated with site preparation works in the relevant areas. With the exception of the hotspots beneath the contractors compound and car park, the existing consent requires all on-site remediation works within the BDAE to be completed by 31 August 2011 (a formal request has recently been made by EDF Energy to extend this until the end of February 2012). The provision of a validation report for the BDAE should not preclude site preparation works commencing elsewhere on-site or other site preparation activities commencing on the BDAE.

14.6.5 In addition to the removal of the known contamination hotspots, the consented works also include for the transfer of 50,000m^3 of suitable materials arising from the existing double-humped mound within the BDAE to the HPA turbine hall, where they will be used to backfill the basement of this building.

14.6.6 As detailed in Section 14.4 the potential land contamination impacts are assessed in terms of potential receptors i.e. human health (on-site and off-site), ecology (on-site and off-site), crops and livestock (on-site and off-site), the soil environment (on-site and off-site) the built environment (on-site and off-site site) and controlled waters (on-site groundwater and surface water).

14.6.7 Currently there are no UK soil guidelines or threshold values for assessing the health risk to construction workers from soil contaminants. As a result the guidelines and methodologies used to assess whether soils and other materials are ‘hazardous’ under the Chemical (Hazard Information and Packaging Supply) Regulations 2009 (CHIP4) (Ref. 14.108), Hazardous Waste (England and Wales) Regulations 2005 (Ref. 14.56) and Approved Supply List Edition 8 (Ref. 14.109), have been used for this impact assessment. This is because many of the criteria for hazardous wastes are based on short-term, i.e. acute hazard properties (such as toxicity, corrosivity, flammability and irritability, etc.), which are relevant to the short-term exposures that may be experienced by construction workers.

b) Environmental Management and Protection Measures

14.6.8 In the UK, modern construction and operational sites are subject to a number of ‘standard’ health, safety and environment control requirements. These include both legal requirements and/or standard good health, safety and environment practices. Adoption of these practices is assumed as a baseline for this impact assessment.

i. Legal Requirements

14.6.9 In some cases there are basic legal requirements which prescribe in detail and/or set overarching objectives, for health, safety and/or environmental protection. **Table 14.9** lists some of the key UK health, safety and environmental legislation which relates to construction works and the operational phase and development of land which may be contaminated.

Table 14.9: Key UK Construction and Operation Health, Safety and Environment Legislation

Legislation	Main Requirement/Objectives
The Control of Asbestos at Work Regulations 2006 (SI 2739)	These regulations relate to asbestos in non-domestic premises. Requires management of the risk from asbestos by: • determining whether asbestos is present within the premises, the amount and what condition it is in, • presuming materials contain asbestos, unless there is strong evidence that they are not present, • making and maintaining an up to date record of the location and condition of asbestos containing or assumed asbestos containing materials within premises, • carrying out a risk assessment on materials containing asbestos, • preparing and implementing a plan that sets out in detail how the risk from this material is going to be managed; • reviewing and monitoring the plan and the arrangements, and • providing information on the location and condition of the material to anyone who is liable to work on or disturb it (including staff).
Health and Safety at Work Act 1974 (as amended)	This is the main piece of UK health and safety legislation. It places a duty on all employers "to ensure, as far as is reasonably practicable, the health, safety and welfare at work" of all their employees. Among other provisions, the Act also requires: • safe operation and maintenance of the working environment, plant and systems, • maintenance of safe access and egress to the work place, • safe use, handling and storage of dangerous substances, • adequate training of staff to ensure health and safety, and • adequate welfare provisions for staff at work.
The Management of Health and Safety at Work Regulations 1999	These regulations place a duty on employers to assess and manage risks to their employees and others arising from work activities. Employers must also make arrangements to ensure the health and safety of the workplace, including making arrangements for emergencies, adequate information and training for employees, and for health surveillance where appropriate.
Workplace (Health, Safety and Welfare) Regulations 1992	These regulations are concerned with the working environment. They place a duty on employers to make sure that the workplace is safe and suitable for the tasks being carried out there, and that it does not present risks to employees and others. The regulations cover all aspects of the working environment, including: • maintenance of the workplace, equipment, devices and systems, • ventilation, • cleanliness and waste materials, • washing facilities, • drinking water, • accommodation for clothing, • facilities for changing clothing, and • facilities for rest and to eat meals.

Legislation	Main Requirement/Objectives
The Personal Protective Equipment at Work Regulations 1992	These regulations seek to ensure that where the risks cannot be controlled by other means, Personal Protective Equipment (PPE) is correctly selected and used.
Construction (Design and Management) Regulations 2007	The key aim of the CDM regulations is to integrate health and safety into the management of the project and to encourage everyone involved in the design and construction of a development to work together to : • improve the planning and management of the project, and • identify hazards early on so they can be eliminated or reduced at the design stage and any remaining risks properly managed. Under CDM requirements any hazards or risks associated with the design, construction and future operation of a building(s) or structure(s) should be taken into account to eliminate, reduce or manage any associated hazards and risks to the people involved in the construction and operation of the buildings and the buildings infrastructure itself.
Site Waste Management Plans Regulations (2008)	The regulations set out the requirements for a site waste management plan (SWMP) to be produced by any party who intends to carry out a project on a construction site with an estimated cost of £300,000 or more. A SWMP conforming to these regulations must be prepared before construction work begins. The regulations set out the requirements for the SWMP, including the requirement for a declaration that "all waste from the site is dealt with in accordance with the waste duty of care in Section 34 of the Environmental Protection Act 1990 and the Environmental Protection (Duty of Care) Regulations 1991".
Nuclear Installations Act 1965	The Nuclear Installations Act 1965 is the primary legislation which covers the issuing of Nuclear Site Licence. As part of this process and the GDA process any hazards and risks associated with the construction, commissioning, operation and decommissioning of the site must be assessed and where possible eliminated, reduced or otherwise managed. This will include potential risks to the end users of the site, the public, the wider environment and the buildings and associated infrastructure itself.
Environmental Permitting (England and Wales) Regulations 2010 (SI 675)	For main requirement/objectives see Section 14.3 of this chapter.
Control of Pollution (Oil Storage) (England) Regulations 2001 (SI 2954)	For main requirement/objectives see Section 14.3 of this chapter.

ii. Construction Phase Measures

Standard Good Practices/Control Measures

14.6.10 The following impact assessment has been undertaken assuming legislative compliance and the adoption of standard good practice.

14.6.11 Legislative compliance and good practice require that the manner in which materials arising from earthworks are controlled and re-used is subject to appropriate planning and management decisions.

14.6.12 Other plans that are of relevance and which will be adopted for the construction works will include:

- Materials Management Plan; and
- Soil Management Plan.

14.6.13 These documents will describe how excavated materials are to be screened against acceptability criteria as they arise during the works and how their chemical and geotechnical suitability will be determined for specific re-use on the site. The documents will also set out procedures for the tracking and recording of the placement of different material types on-site and describe how any unforeseen ground conditions are to be dealt with. Typical requirements in this context include quarantining of any unexpected material and subjecting it to representative sampling and analysis to inform appropriate decision making with respect to the fate of the material.

14.6.14 Typical measures to be employed on-site include standard procedures to prevent contamination occurring from construction operations and which will incorporate the appropriate use and storage of fuel oils and other chemicals and dust and surface run off controls.

Control Measures for Contaminated Soils

Human Health

14.6.15 Asbestos contamination has been identified at a number of locations across the BDAE. The risk of mobilising potential ACMs and free fibres is increased during proposed earthworks and construction. Exposure to free fibres can result in permanent health effects and there is a moderate risk to human health from asbestos contamination on the BDAE. However, the asbestos contamination is limited to localised specific areas of the BDAE associated with the presence of demolition and construction materials in Made Ground.

14.6.16 As part of the enabling works ACMs within the BDAE, apart from the known ACMs under the location of the contractors compound and new HPA and HPB car park, will undergo removal, disposal and associated verification and validation reporting. In the area of the contractors compound and car park the resultant hard surface will act as a barrier, preventing both contact with contaminated soils and the generation of contaminated dusts. Therefore there will be no risk to human health during the period when the car park is in use and the ACMs will be remediated when the car park is no longer required. However, there is still the possibility that further pockets of ACMs will be encountered during further earthworks in certain areas of the BDAE. As such, a watching brief will be maintained throughout the site preparation earthworks within the BDAE and any significant asbestos contamination (should it be found) will be removed off-site, through appropriate procedures specifically orientated to the effective identification, segregation and management of any ACMs.

14.6.17 The hydrocarbon-contaminated soils identified around TE418 in the north-eastern area of the BDAE could pose a risk to human health during earthwork activities. However, the isolated area of hydrocarbon-contaminated soils is within the footprint of the new HPA and HPB car park and will be confined by the resultant hard surface. Therefore it will not pose a risk to human health during the period when the car park is in use. When the contractors' compound and car park are no longer required the contamination will be remediated, with associated verification and validation reporting. This will also remove the risk to water supply pipes, controlled waters and ecological receptors posed by the hydrocarbon contaminated soils.

14.6.18 The elevated Total PAH and benzo(a)pyrene concentrations identified in TE63 were in exceedence of the Tier 1 human health risk assessment screening criteria. The contamination is associated with the presence of localised ashy deposits. The risk posed by this material can be managed by selective excavation and segregation of the ashy material within this area and careful materials management to ensure that such materials are only re-used below areas of hardstanding or buildings. No significant volatile hydrocarbon risk has been identified associated with the material.

14.6.19 Moderately alkaline pH levels (up to 11.4pH units) have been identified in Made Ground materials containing demolition and construction materials. The alkaline pH levels are considered to be due to the presence of plaster, concrete and mortar within this specific type of Made Ground. Elevated pH (for example in plaster dust) can be an irritant therefore exposure to high pH materials is not desirable. Any risk can be managed by appropriate materials management including the exclusion of Made Ground materials containing demolition and construction materials from the upper 1m of the soil profile in areas of soft landscaping, agricultural restoration or new habitat creation.

14.6.20 The results of the ground gas monitoring indicate there are no significant sources of ground gases within the HPC development site and therefore there is no significant risk posed to human health or buildings by ground gases. However, elevated concentrations of nitrogen, hydrogen sulphide and carbon monoxide have been identified during drilling investigations. Therefore as a precautionary measure during the construction phase, contractors should have due consideration for, and assess the health and safety risk of potential ground gas concentrations and adopt appropriate mitigation measures, in particular during confined space working or during works which are carried out in deep excavations.

Built Environment

14.6.21 Investigations on the BDAE have identified generally low concentrations of contaminants (e.g. sulphate, hydrocarbons, pH and ground gases) which could potentially attack, degrade or otherwise damage the built environment. Furthermore, the HPC permanent development will be designed and constructed with appropriate and suitable specifications of building materials which will ‘design out’ any risk from potential impacts from ground contamination during the construction and/or operational phases.

Ecological Systems including Plants, Trees, Crops and Other Vegetation

14.6.22 The majority of the soils within the HPC development site pose no significant ecological or phytotoxic risk, with contaminant concentrations considered to be reflective of natural background concentrations. However, some Made Ground materials in specific locations within the BDAE and the localised area of Made Ground on the BDAW pose a low risk of potential phytotoxic effects and a low risk to ecological receptors from alkaline pH levels (> 9pH units), and from limited hydrocarbon, copper and zinc contamination.

14.6.23 Although no specific criteria are available for assessing the risk to ecological receptors from pH, the presence of moderately elevated soil pH values (> 9 pH units) may pose a risk to ecological systems in that high pH may restrict the range of plant and animal species which will be able to establish and grow successfully. The highest pH levels have been identified in the Made Ground soils containing construction and demolition materials.

14.6.24 A potential low risk to ecological receptors has been identified at the following isolated locations on the BDAE; WS27 within shallow Made Ground (Total PAH); DBH2_27 within Made Ground containing ash and slag (zinc); TE54 within Made Ground in area of the former access route to the foreshore (copper and zinc); ashy materials in TE63 (Total PAH and benzo(a)pyrene), and in the isolated area of Made Ground on the BDAW at TRE21 (zinc).

14.6.25 Management of the ashy materials in TE63 and the Made Ground in the area of the former access route to foreshore in TE54 is required to control the risk to human health from elevated PAHs and asbestos, respectively. The management measures which are described above will also facilitate management of any risk posed to ecological systems.

14.6.26 The risk to ecological systems including plants, trees, crops and other vegetation from the areas of Made Ground in DBH2_27 and WS27, the Made Ground containing demolition and construction materials on the BDAE and the localised area of Made Ground on the BDAW, can be managed by ensuring that these materials are not placed within the upper 1m of the soil profile within any areas proposed for soft landscaping, agricultural land restoration or new habitat creation.

14.6.27 It is considered that the delineation and management of materials at specific ‘hotspot’ locations can be conducted as part of the construction earthworks given the employment of appropriate management methods. Thus there is no requirement to undertake a specific independent delineation and removal/remediation of individual hotspots.

Summary

14.6.28 In accordance with standard good practice, appropriate materials management will be employed to ensure that any unsuitable materials (e.g. ACMs, wood, paper, plastic metals, old drums, etc.) and/or soils contaminated above acceptable thresholds[3] will be removed, remediated and/or re-used (in appropriate locations and at appropriate depths) during the enabling works and subsequent site preparation earthworks.

14.6.29 An awareness flag will then be maintained during any subsequent construction earthworks, so that in the event that additional areas of unsuitable materials or suspected contaminated soils are encountered, these areas will be isolated, segregated (e.g. in a specific ‘quarantine’ area) and tested to decide whether they are suitable for re-use on-site, require further remediation on-site to enable re-use, or will be disposed off-site.

[3] the criteria for ‘unacceptable’ contamination thresholds will be developed but may include any soils with contaminant concentrations in excess of commercial and industrial land use Soil Screening Values (SSVs) and residential land use without plant uptake for SCPA – accommodation blocks/areas and Hazardous Waste/Material thresholds.

14.6.30 A **LCMP** has been prepared which also outlines measures to be implemented with respect to planned activities and the discovery of any unexpected contamination. The mitigation requirements are also outlined. The mitigation requirements are stated within this chapter and other supporting land contamination related general control measures using best practice guidance. In summary the measures for controlling risk from contaminated soils will include:

- Removal and off-site disposal of any asbestos-containing materials (ACMs) which may remain after the completion of the enabling/remediation works. A monitoring plan, (possibly inclusive of asbestos air fibre monitoring) specific health and safety risk assessments and the definition of appropriate working practices will be required to support the remediation of any remaining ACM contamination during construction earthworks;
- The remediation or removal of the hydrocarbon contaminated soils identified in the vicinity of TE418 in the north-eastern area of the BDAE;
- Appropriate management and re-use of materials to ensure that potentially unsuitable Made Ground materials (either because of slightly elevated ecological and/or phytotoxic contaminants, elevated pH (pH9.0 or greater), contaminants above human health risk assessment criteria, high proportions of construction and demolition materials, poor substrate, poor grading of materials, low nutrient and/or organic content, etc.) are not re-used within the upper 1m of the soil profile in soft landscaped, ecological habitat creation or agricultural restoration areas;
- The use of the appropriate specification of potable water service pipes, e.g. 'Protecta-Line' type barrier pipe. The specification will need to be agreed with Wessex Water.
- Appropriate specification of sulphate resistant concrete for use in buried structures will be necessary.
- Removal of any significant quantities of putsrescible materials from existing site won Made Ground and natural soils prior to re-use as general or engineering fill in areas where buildings and other structures will be placed.

iii. Operational Phase Measures

Standard Good Practices/Control Measures

14.6.31 The site will be regulated under an Environmental Permit and Radioactive Substances Authorisation. The Environment Agency has stipulated a series of indicative Best Available Techniques (BAT) within several of their recent guidance documents on environmental permitting for a variety of process industries and large installations such as nuclear power stations. Examples of indicative BAT practices which represent standard control measures are described below.

14.6.32 For subsurface structures, the indicative BAT requirements are:

- engineer systems to minimise leakages from pipes and ensure swift detection if they do occur, particularly where hazardous substances (i.e. substances in List I or List II of the Groundwater Regulations) are involved; and
- provide secondary containment and/or leakage detection for subsurface pipework, sumps and storage vessels.

14.6.33 For surface features, the indicative BAT requirements are:

- ensure that surfacing and containment or drainage facilities are adequate for all operational areas, taking into consideration collection capacities, surface thicknesses, strength/reinforcement, falls, materials of construction, permeability, resistance to chemical attack, and inspection and maintenance procedures;
- implement an inspection and maintenance programme for impervious surfaces and containment facilities; and
- provide secondary containment for all liquids, whose emission to water or land could cause pollution, unless the operator has used other appropriate measures to prevent or, where that is not practicable, to minimise, leakage and accidental spillage from the primary container.

14.6.34 For bunds, the indicative BAT guidance requires that bunds should:

- be impermeable and resistant to the stored materials;
- have a capacity greater than 110 percent of the largest tank or 25 percent of the total tankage, whichever is the larger; and
- be fitted with a high-level probe and an alarm, where not frequently inspected.

14.6.35 For storage areas for intermediate bulk containers (IBCs), drums, and bags, the indicative BAT requirements state that such areas should be designed and operated to minimise the risk of releases to the environment, including:

- Undercover storage should be considered where pollution can be significantly reduced by so doing.
- The maximum storage capacity of storage areas should be stated and not exceeded, and the maximum storage period for containers should be specified and adhered to.
- Containers should be stored with lids, caps and valves secured and in place (this also applies to emptied containers).
- Procedures should be in place to deal with damaged or leaking containers.

Control Measures for Contaminated Soils

14.6.36 Leaks and accidental spillages could potentially occur during the operational phase despite the BAT control measures outlined above, thus resulting in soil contamination. If such an event occurs the incident should be fully investigated, the environmental risks from the contamination assessed, and where necessary (i.e. where unacceptable environmental risks exist) a mitigation or remediation plan instigated.

c) Construction Impacts

i. Geology

Construction Activities on Geology

14.6.37 A number of activities such as fencing, ground preparation works, installation of the drainage system and the excavation of below ground structures and foundations to be undertaken as part of the construction phase have the potential to impact geology. The potential impacts to geology will be site-specific, permanent and direct.

14.6.38 The earthworks and site levelling/terracing element of the construction works would require the excavation of weathered rock from areas where deeper excavations are required using mechanised plant. The maximum depth of excavations during these works would be in those areas which would be occupied by deep foundations for buildings, or underground structures associated with the proposed power station. Intrusion into the geology would also occur during the installation of the deep drainage pipes, water management ponds and installation of wells for dewatering purposes as part of the drainage network and to a lesser extent during fencing activities (depending on the thickness of topsoil and subsoil materials in these areas).

14.6.39 The likelihood of an impact occurring is 'certain,' i.e. the impacts would definitely occur. The spatial extent of excavations during the site preparation works will include a significant proportion of the HPC development site, however deeper excavations during the main construction phase would be restricted to a smaller area. As a result, the magnitude of the impact is assessed as medium because a permanent change would occur to the existing geological conditions such that it is unrecognisable compared to baseline conditions.

14.6.40 The value and sensitivity of the on-site geology (notwithstanding the areas of cliff exposure and foreshore geomorphology which would not be impacted by the construction activities outlined above) is assessed as low as it has no significant scientific, educational or aesthetic value and sensitivity. The geology is thus only of relevance from an engineering perspective, i.e. acting as a founding medium or source of fill/aggregate for the development.

14.6.41 The significance of the impacts of the construction activities outlined above on geology is assessed as **minor adverse**, and therefore no mitigation is required.

Construction of Temporary Jetty, Sea Wall and Drainage Outfall

14.6.42 The proposed new sea wall will be a gravity, mass concrete wall of 760m in length, by approximately 10m wide with a crest level of 13.5m AOD and with rock armour protection at the toe (see **Chapters 2** and **3** of this volume for details). Also as part of the drainage network, a single discharge outfall point would be constructed along the frontage and incorporated into the sea wall (see **Chapters 2** and **3** of this volume for details).

14.6.43 Access onto the foreshore will be required during the construction of the sea wall and the drainage outfall. The access road would be located where there is a low point in the cliff with minimal cliff exposures present. The sea wall and drainage outfall will not extend into the Blue Anchor to Lilstock geological/geomorphological SSSI. The cliff section lies within the Bridgwater Bay National Nature Reserve (NNR), which is considered by Natural England to include cliff stratigraphy of significant value and interest.

14.6.44 Whilst most of the jetty's construction would take place from the sea using water based equipment, its initial bridge spans would be installed from the foreshore using land based equipment and, therefore, there would be a requirement for land based equipment to have limited temporary access to and along the upper foreshore. Access to the foreshore would be via a temporary service road via a low point in the cliff. Vehicle movements would be confined to a designated route along the upper foreshore to minimise the area of foreshore potentially impacted. Vehicle movements along the foreshore would be low; it is anticipated that approximately 10 vehicle movements per day would be required. Furthermore, access would only be required for a limited duration during the jetty's construction phase (i.e. during the installation of the furthest landward jetty bridge spans).

14.6.45 The construction works for the temporary jetty bridge would comprise 38 to 52 steel tubular piles approximately 864mm diameter installed approximately 4 to 5m into the bedrock layer. The current estimated spacing of the piles is between 25 and 35m, some of which would be installed within the foreshore.

14.6.46 The new sea wall and drainage outfall would directly impact the cliff exposure adjacent to the HPC development site. The sea wall would obscure the cliff exposure for the lifetime of the sea defence system and the toe and rock armour protection of the structure would extend a limited distance onto the foreshore and therefore have a limited spatial impact. During construction there would be a limited requirement for vehicles to track across the foreshore which could directly impact the foreshore. As stated above, the access road would be located in close proximity to the drainage outfall work site (within approximately 100m; see planning application drawing HPCSPW002a) to minimise the area of foreshore which may be impacted. Vehicle movements along the foreshore during the construction of the sea wall and drainage outfall would be confined to a designated route approximately along the upper foreshore to minimise the area of foreshore potentially impacted. As such the magnitude of the impact from vehicle movements on the foreshore is considered to be very low and the significance of the impact would be **minor adverse**.

14.6.47 The design of the jetty is such that it would not damage or destabilise the cliff during construction, operation and dismantling as the height of the jetty deck would lie above the existing cliff face, thus no cutting into the actual cliff face is assumed to be required. Therefore there would be no impact to the cliff exposure during the jetty development. A cliff stability assessment has been undertaken by Jacobs (14.110) to assess the specific aspects of the jetty development which might have a direct impact on cliff stability. The report concluded that the piles required for the jetty (landside and foreshore) are unlikely to impact the cliff stability.

14.6.48 A portion of the jetty development falls with the Blue Anchor to Lilstock SSSI, see **Figure 14.3**.

14.6.49 The area of foreshore to be impacted during piling is restricted to the footprint of each pile, therefore the spatial extent of the impacts is limited to small isolated locations. It is anticipated that an area in the region of approximately 18-21m^2 in the intertidal zone (approximately 25-30 piles) would be lost to piles from a total 28,000m^2 of designated foreshore adjacent to the HPC development site. It is envisaged that drilling arisings during piling works would be collected and appropriately disposed of off-site.

14.6.50 Consultation has been undertaken with Natural England over the potential loss of the exposed geological units and foreshore features adjacent to the HPC development site. Natural England has indicated during consultation that the identification of a replicate accessible section of units within the Blue Anchor to Lilstock SSSI (to the west) is likely to be acceptable to offset the loss of the units exposed within the cliff and foreshore at Hinkley Point. The geological mapping study (Ref. 14.96) has demonstrated that a section to the west of Lilstock within the SSSI provides a high quality replication of the geology found within the cliffs at Hinkley Point and characteristics of the foreshore can also be observed elsewhere.

14.6.51 The impacts from the construction of the sea wall and drainage outfall on the cliff geology would be site-specific, direct and permanent (i.e. irreversible: once the geology is lost it cannot be reinstated exactly how it was). The likelihood that this impact would occur is assessed as 'certain'. No impact on the cliff geology is predicted from the construction (and subsequent operation and dismantling) of the temporary jetty.

14.6.52 The loss of cliff exposure (sea wall and drainage outfall) and foreshore (temporary jetty, sea wall and outfall) will not result in a significant loss of the relevant geological or geomorphological features present at Hinkley Point as these are replicated elsewhere. As a result the magnitude of the impact to the cliff exposure and foreshore is considered to be low.

14.6.53 The value and sensitivity of the cliff and foreshore geology impacted by the temporary jetty, sea wall and drainage outfall construction are rated as medium, as they are not nationally designated but are considered to be of regional importance. The significance of the construction phase on the cliff exposure and foreshore is considered to be **minor adverse**, therefore no mitigation is required.

ii. Land Contamination

14.6.54 Construction phase impacts relating to land contamination can principally arise from:

- the potential for existing contamination on-site and/or off-site to be mobilised, by construction activities e.g. soil disturbance and dust generation during earthworks; or
- the potential for contamination of the soils to occur during construction works (e.g. from escape of fuels and oils from plant and storage tanks).

14.6.55 A construction phase schematic Conceptual Site Model is presented as **Figure 14.17** and in tabular format in **Appendix 4G**.

Construction Activities on On-Site Human Health

14.6.56 During activities to be undertaken as part of the construction phase there is the potential for the health of construction workers on-site to be impacted from any existing on-site contamination and from any contaminated soils as a result of leakage and spillage from mechanised plant. These activities include those undertaken as part of the site preparation works, site clearance, fencing, ground preparation works, demolition of barns, installation of the drainage system, construction of the temporary jetty and other activities undertaken as part of the main construction works. Construction workers may also be impacted via the inhalation of ground gases during works in confined spaces or during deep excavations.

14.6.57 Potential impacts to construction workers could occur via direct contact, inhalation and/or ingestion and could be adverse, temporary or possibly (depending on the nature of the health impact) permanent, direct and indirect.

14.6.58 The value and sensitivity of the construction workforce personnel on-site in the absence of any standard good practice measures is high. However, no member of the construction workforce would be permitted to work on-site without adequate training in, and use of, appropriate full personal protective equipment (PPE); such measures reduce the overall sensitivity of the construction workforce to low.

14.6.59 The likelihood of impact to construction workers being exposed to contaminated soils varies according to the different parcels of land. Within the BDAW and SCPA, no known soil contaminants are present at concentrations which exceed any of the hazardous waste threshold criteria presented in regulations and guidance citied in **Table 14.1**. The likelihood of construction workers being exposed to potentially hazardous concentrations of soils contamination on the BDAW and the SCPA is assessed as unlikely.

14.6.60 Within the BDAE, no known soil contaminants are present which exceed any of the hazardous waste threshold criteria, with the exception of the hydrocarbon contaminated soils in the north-eastern area of the BDAE (TE418) and hotspots of ACMs. These works will significantly reduce the likelihood and risk of construction workers being exposed to ACMs on the BDAE during the construction phase. However, there is still the limited potential for unidentified asbestos contamination and/or other contamination to be present in other areas of the BDAE. Accordingly, the likelihood of construction workers being exposed to potentially hazardous concentrations of soil contamination on the BDAE following the enabling remedial works is assessed as possible.

14.6.61 Any potential asbestos contamination which may be present on-site following the enabling remedial works will be localised and of limited quantity and could be dealt with through the implementation of appropriate control procedures. The roofing material within one of the existing on site barns comprises asbestos bonded cement, from which the risk of free fibre release is low during mechanical handling. Furthermore the asbestos sheeting would be removed in a safe and controlled manner prior to the demolition of the barn structure. Appropriate control measures will be employed in order to prevent the generation of asbestos contaminated dust and free asbestos fibres during the removal process.

14.6.62 The spatial extent of the construction phase would cover the majority of the HPC Development, and the activities undertaken as part of this phase of works would include excavations which may result in the exposure of construction workers to isolated pockets of possible existing contamination (predominantly on the BDAE). However, the investigations across the HPC development site have only identified limited contamination (on the BDAE only) with respect to human health risk, therefore during the construction phase any remaining contaminated soils will be confined to small, localised areas of the BDAE. This is because any accessible areas of contamination would have been have been remediated as part of the enabling/remedial works.

14.6.63 The potential impact to construction workers would further be reduced by the adoption of standard good practices, particularly the dampening down of soils and appropriate materials management, which would be employed to ensure that any areas of unsuitable materials (e.g. ACMs, wood, paper, plastic metals, old drums, etc.) and/or soils contaminated above unacceptable thresholds identified during the construction works would be remediated or removed from site. The magnitude of potential impact to construction workers from contaminated soils during the construction phase works is therefore considered to be low and the significance of the impacts is assessed as **minor adverse**.

14.6.64 During the use of mechanised plant as part of the construction phase there is the potential for accidental spillage or leakages of contaminating liquids such as diesel and hydraulic oil. However, any accidental spills or leaks are likely to be of very low volume and highly localised, and the potential for construction workers to be exposed to contaminated soils as a result of such an event is considered unlikely. The potential impact can be further reduced by the application/adoption of standard good practices and control measures, particularly those relating to vehicle and equipment maintenance and dealing with associated leaks or accidental spills. The magnitude of the potential impact to construction workers from leakage or accidental spillage is therefore considered to be very low and the significance is assessed as **negligible**.

14.6.65 Construction workers could also be impacted via the inhalation of ground gases in confined spaces or during deep excavations. The programme of gas monitoring and subsequent ground gas risk assessment indicates that no significant sources of ground gas are present within the HPC development site. However, occasionally elevated concentrations of nitrogen, hydrogen sulphide and carbon monoxide at some locations on the BDAW have been identified during investigative drilling works. As a result there is a low risk to construction workers via the inhalation of gases potentially present in pockets within the underlying geology or groundwater during any confined space working or during works which are carried out in deep excavations. The risk would be managed through routine gas and vapour monitoring in such locations supported by appropriate exposure control measures. The magnitude of the impact to construction workers from pockets of ground gas in the underlying strata is therefore considered to be very low and the significance is assessed as **negligible**.

14.6.66 Given that the potential impacts to construction workers during the construction activities have been assessed as negligible to minor adverse, no specific formal mitigation is required.

Construction Activities on Off-Site Human Health

14.6.67 Risk to human health for off-site receptors from soil contamination could only occur in the event that contamination migrates off-site as a result of the ground preparation works. The most probable mechanism for such off-site migration would be via uncontrolled contaminated dust and/or odour generation, runoff and wind transport. This could occur if existing contaminated soils are disturbed during the topsoil strip and stockpiling and/or subsequent site levelling and terracing. Any potential contaminated soils generated by leakage or accidental spillage from the use of mechanised plant is unlikely to be of sufficient volume or extent to result in the generation of significant contaminated dust and/or odour generation or otherwise migrate off-site by other means. Potential impacts to off-site humans could be adverse, temporary or possibly permanent (depending on the nature of the health impact), and indirect.

14.6.68 As detailed above, the likelihood of encountering contaminated soils on the BDAW and SCPA is ‘unlikely’ and on the BDAE is ‘possible’. Any remaining hotspots of contaminated soils on the BDAE after the completion of the enabling/remediation works are expected to be few in number and localised in size and area.

14.6.69 The area immediately surrounding the site is sparsely populated, with all off-site residential receptors, including Doggetts Farm, located over 900m from the BDAE (where the isolated areas of contamination have been identified). The adoption of standard good practice, specifically those relating to dust control, would reduce the potential for the mobilisation of contaminants (see **Chapter 12** of this volume (Air Quality) for details). The potential for the transport of contaminated dust over such distance is considered to be unlikely. The magnitude of impact to off-site human receptors from contaminated dust (and odour generation) is therefore considered to be very low.

14.6.70 As the off-site human receptors are considered to have a high value and sensitivity, the significance of the impact to off-site humans from the mobilisation of potential existing contaminated soils via contaminated dust and/or odour generation during the construction activities is assessed as **minor adverse**. Therefore no specific formal mitigation is required.

Construction Activities to the On-Site Soil Environment

14.6.71 A number of activities during the construction phase have the potential for uncontaminated soils to be impacted by mixing with any existing contaminated soils on-site and for the generation of contaminated soils as a result of any leakage or accidental spillage from mechanised plant and equipment. These activities include those undertaken as part of the site preparation works, site clearance, fencing, installation of the drainage system, temporary jetty construction and other activities undertaken as part of the main construction works.

14.6.72 The potential impacts associated with existing contaminated soils and uncontaminated soil are likely to be adverse, temporary and/or permanent, direct and indirect.

14.6.73 The concentrations of ecotoxic contaminants on the BDAW and SCPA are reflective of natural background concentrations and are not considered to pose an ecological risk, with the exception of a localised area of Made Ground on the BDAW. On the BDAE isolated elevated concentrations of hydrocarbons and metals were identified in the Made Ground and these are considered to represent minor localised hotspots, which may pose a low ecological risk. Moderately alkaline pH levels in Made Ground containing demolition and construction materials have also been identified on the BDAE which may pose a low ecological risk. However, appropriate materials management would be employed to ensure that any soils contaminated above unacceptable thresholds would be removed and/or remediated during the preparatory earthworks. The likelihood of soil contamination, including ecotoxic soil contamination, being present is considered ‘unlikely’ on the BDAW and SCPA and ‘possible’ on the BDAE.

14.6.74 The construction works are on a large scale and would cover the majority for the HPC development site. However, as described above the likelihood of contaminated soils being present on the HPC development site ranges from ‘unlikely’ on the BDAW and SCPA to ‘possible’ on the BDAE (following the enabling/remedial works) and should any contaminated soils arise, they are likely to be localised and of low volume. Furthermore, the adoption of standard good practices such as dampening down of contaminated materials, controlling contaminated surface runoff and appropriate materials management to ensure that any soils contaminated above unacceptable thresholds would be removed and/or remediated during the preparatory earthworks, would reduce the potential for any impact to the uncontaminated soil environment during the construction works.

14.6.75 The use of mechanised plant as part of the construction phase creates the potential for accidental spillage or leakages of contaminating liquids such as diesel and hydraulic oil. However, as outlined in paragraph **14.6.64** above, the impact magnitude from these leaks and spills would be very low.

14.6.76 Therefore, given the adoption of standard good practice the magnitude of the impact from existing contamination, or soils contaminated as a result of the use of mechanised plant, on the uncontaminated soil environment during the construction works is considered to be very low.

14.6.77 The value and sensitivity of the on-site soil environment ranges from very low for engineering fills, to high for soils (topsoils and subsoils) which may be re-used in more sensitive areas such as soft landscaping and agricultural and/or habitat creation. For the purpose of this impact assessment, the worst-case value and sensitivity (i.e. high) has been chosen to make the assessment conservative. The significance is therefore assessed as **minor adverse**. Therefore no mitigation is required.

Construction Activities to the Off-Site Soil Environment

14.6.78 Risk to off-site soils could only occur in the event that soil contamination migrates off-site via uncontrolled contaminated dust generation, wind transport and/or surface runoff. This could occur if existing contaminated soils are disturbed during the topsoil stripping and stockpiling and/or subsequent site levelling and terracing as part of the site preparation works.

14.6.79 The likelihood of ecotoxic soil contamination being present is considered to be ‘unlikely’ on the BDAW and SCPA and ‘possible’ on the BDAE.

14.6.80 The magnitude of impact to off-site soils from the excavation, movement, stockpiling and placement of contaminated soils is considered to be very low since any effects are likely to be confined to a limited zone within a few tens of metres of the main construction area. During the construction works, there would be a buffer zone (approximately 250m wide) adjacent to the southern HPC development site boundary (southern extent of main construction works). This buffer zone together with the application of standard good practices, particularly those relating to dust control and surface water runoff, would minimise the potential for contaminant distribution into off-site areas. Furthermore any unsuitable materials and/or unacceptably contaminated soils identified would be remediated or removed from site.

14.6.81 The value and sensitivity of the off-site soil environment ranges from very low in adjacent commercial and industrial areas (Hinkley Point Power Station Complex) to high in adjacent agricultural areas and designated sites. For the purpose of this impact assessment, the worse case value and sensitivity (i.e. high) has been chosen to make the assessment conservative. The significance of the impact of from existing contaminated soils on the off-site soil environment during the construction works is assessed as **minor adverse**. Therefore no mitigation is required.

Construction Activities on On-Site Ecological Receptors

14.6.82 Any legally protected and/or high value and sensitivity ecology (e.g. badgers) that may be present on-site will have been removed under licence from the development area ahead of the construction works and hence will not be present on-site at the start of the construction works. Most of the lower value and sensitivity ecology (e.g. grassland and hedgerows) will be removed due to the construction works. Impacts to any remaining on-site ecological receptors could occur during the various construction activities as a result of mobilisation and/or mixing with any existing contaminated soils on-site and the generation of contaminated soils as a result of any leakage or accidental spillage from mechanised plant and equipment. These activities include those undertaken as part of the site preparation works, site clearance, fencing, ground preparation works, installation of the drainage system, construction of the temporary jetty and other activities undertaken as part of the main construction works.

14.6.83 The potential impacts of contaminated soils upon on-site ecology are likely to be adverse, temporary and/or permanent, direct and indirect.

14.6.84 Soil analysis has demonstrated that contaminant concentrations in the majority of the soils within the HPC development site are considered to be reflective of natural background concentrations and do not pose a significant ecological or phytotoxic risk. Some Made Ground materials on the BDAE and the isolated area of Made Ground on the BDAW have been identified which contain contaminant concentrations which may pose a low risk to ecological systems should they be re-used in the upper 1m of the soil profile within areas of soft landscaping, agricultural land restoration or habitat creation. However, appropriate materials management would be employed to ensure that any soils contaminated above unacceptable thresholds would be removed, remediated during the ground preparation earthworks or only re-used in suitable locations and at suitable depths. The likelihood of soil contamination, including ecotoxic and/or phytotoxic soil contamination, is considered ‘unlikely’ on the BDAW and SCPA and ‘possible’ on the BDAE.

14.6.85 During the use of mechanised plant as part of the construction phase there is the potential for accidental spillage or leakages of contaminating liquids such as diesel and hydraulic oil. However, the impact magnitude from these leaks and spills would be very low.

14.6.86 Therefore, given the adoption of standard good practice the magnitude of the impact from existing contamination, or soils contaminated as a result of the use of mechanised plant, to the on-site ecology during the construction works is considered to be very low. The value and sensitivity of the on-site soil ecology is assessed as medium.

14.6.87 The significance is therefore assessed as **minor adverse**. Therefore no mitigation is required.

Construction Activities to Off-Site Ecological Receptors

14.6.88 Risks to off-site ecology could only occur in the event that soil contamination migrates off-site via uncontrolled contaminated dust generation, wind transport and surface runoff.

14.6.89 The likelihood of ecotoxic and/or phytotoxic soil contamination being present is considered 'unlikely' on the BDAW and SCPA and 'possible' on the BDAE.

14.6.90 The magnitude of impact to off-site ecological receptors from the excavation, movement, stockpiling and placement of contaminated soils is considered to be very low since any effects are likely to be confined to a limited zone within a few tens of metres of the main construction area. During the construction works, there would be a buffer zone (approximately 250m wide) adjacent to the southern HPC development site boundary (southern extent of main construction works). This buffer zone together with the application of standard good practices particularly those relating dust control and surface water run-off, would minimise the potential for contaminant distribution into off-site areas. Furthermore any unsuitable materials/contaminated soil identified would be remediated or removed from site or only re-used in suitable locations and depths.

14.6.91 The value and sensitivity of the off-site ecology is assessed as high.

14.6.92 The significance of the impact of from existing contaminated soils and/or spills and leaks from construction plant to off-site ecological receptors during the construction works is assessed as **minor adverse**. Therefore no mitigation is required.

Construction Activities to On-Site Crops and Livestock

14.6.93 No crops and livestock will be present on-site during the construction phase. As such **no impact** to on-site crops and livestock will occur during the construction works.

Construction Activities to Off-Site Crops and Livestock

14.6.94 Potential impacts to off-site crops and livestock could occur in the event that contamination on-site is mobilised during the construction works.

14.6.95 The likelihood of toxic, ecotoxic and/or phytotoxic soil contamination being present is considered 'unlikely' on the BDAW and SCPA and 'possible' on the BDAE.

14.6.96 The magnitude of impact to off-site crops and livestock is considered to be very low.

14.6.97 The value and sensitivity of the off-site crops and livestock ranges from medium to high. For the purpose of the impact assessment a worst-case of high has been adopted in order to make the assessment conservative.

14.6.98 The significance of the impact from existing contaminated soils and/or spills and leaks from construction plant to off-site crops and livestock during the construction works is assessed as **minor adverse**. Therefore no mitigation is required.

Construction Activities on the Built Environment – On-Site

14.6.99 Buried concrete (for example in the form of foundations and drainage pipes) can be degraded by inorganic contaminants, principally sulphates. Buried services such as plastic water pipes, gas pipes and electrical services can potentially be degraded and/or permeated by organic contaminants such as fuels and solvents which may be released into the soil environment from leaks or accidental spills. The potential impacts resulting from leaks and spills from contamination of soils to the built environment may be site-specific, adverse, permanent, direct and indirect.

14.6.100 The ground gas monitoring and subsequent ground gas risk assessment which has been undertaken, indicates the risk of ground gas ingress into buildings and buried structures on the HPC development site, and subsequent explosion/fire is negligible. As such, no special precautions or gas protection measures are required to protect buildings and their occupants.

14.6.101 Any accidental spills or leaks are likely to be of very low volume and highly localised. Therefore a direct impact to built environment receptors is considered to be unlikely. The magnitude of the impact from contaminated soils is therefore considered to be very low.

14.6.102 The inherent value and sensitivity of the buildings and infrastructure including services is considered to range from very low to high (very low for infrastructure such as buried water pipes and high for the main nuclear island buildings). This evaluation has been made on the basis of the importance of the built structures and infrastructure with respect to energy supply and the requirement that they remain in a safe structural and operating condition throughout their design life. However, all built infrastructure will be designed and constructed with appropriate specification of materials therefore any risk from land contamination will be designed out. As such, **no impacts** relating to land contamination are predicted to the built environment.

Construction Activities on the Built Environment – Off-Site

14.6.103 Off-site built environment receptors (i.e. buried concrete and services) will not be impacted by the proposed construction activities as with adoption of good practice the impacts of these works will be limited to the vicinity of the proposed development site.

Construction Activities to Controlled Waters – On-Site

14.6.104 Impacts to on-site controlled waters (i.e. on-site groundwater and surface waters) could occur through physical mobilisation (such as soil erosion, run-off and sediment deposition) and disturbance of existing contaminated soils during earthworks or increased infiltration and leaching once the topsoil is removed and areas of open excavations exposed. Impacts on controlled waters would be direct and adverse. The impacts would be typically temporary (although if contamination of groundwaters has occurred, depending on contaminant type, it could persist). For potential impacts from physical mobilisation see **Chapter 15** (Groundwater) and **Chapter 16 (**Surface Water) of this volume.

14.6.105 The ground preparation works cover the majority of the HPC development site. Despite the scale of the works the potential magnitude is assessed as very low because the likelihood of encountering any contaminated soils on the BDAW and the SCPA is considered 'unlikely' and, if present, such areas are likely to be very small and highly localised. On the BDAE, the results of WAC and soil leachability testing do not indicate the presence of significant contamination with the potential to impact controlled waters via leaching (with the exception of the hydrocarbon contaminated soils in the north-eastern area of the BDAE (TE418), which would be removed/remediated prior to commencement of any bulk earthworks or other construction activities in this area). Therefore the likelihood of any impact to controlled waters on the BDAE is also considered to be 'unlikely'.

14.6.106 The value and sensitivity of on-site groundwater is assessed as low on the basis that the site is underlain by a Secondary A Aquifer, has no significant local use at or adjacent to the site in or down-gradient of the likely area of influence and is not within a Source Protection Zone (see **Chapter 15** of this volume on Groundwater). The value and sensitivity of on-site surface watercourses ranges from low to high dependent on the watercourse. Hinkley Point C Drainage Ditch is assessed as low because it is an ephemeral agricultural drainage ditch with highly variable water quality conditions, including elevated suspended solids. Holford Stream has been assessed as high because it is of moderate water quality status and is an important water supply to freshwater wetland habitats of Wick Moor and Bridgwater Bay SSSI (see **Chapter 16** of this volume on Surface Water). For the purpose of this assessment, the worst-case value and sensitivity (high) has been adopted to make the assessment conservative.

14.6.107 The significance of the impact of contaminated soils on controlled waters during the activities is assessed as **minor adverse**. Therefore no mitigation is required.

Operation of Site Compounds to Human Health, Ecology, Crops/Livestock, Soil Environment, Built Environment and Controlled Waters – On-Site and Off-Site

14.6.108 Contractor's compound areas will be established on-site during the site preparation works. The compound areas would be covered by hardcore or asphalt in the case of the haul roads and other elements, e.g. the concrete batching plant and weighbridge. The covering of the surfaces would act as a physical barrier between any existing contaminated and/or uncontaminated land from potential receptors or potential new sources of contamination in this area. Therefore, no potential pollutant linkage exists and no associated potential impacts would arise.

14.6.109 The construction compounds would operate as a controlled environment, with the adoption of standard good practices and control measures and, as such, it is not considered that there will be any potential impacts to on-site or off-site receptors from any activities relating to the site compounds.

d) Cumulative Construction Impacts

i. Geology

Construction of Drainage Outfall, Sea Wall and Temporary Jetty on Foreshore Geology

14.6.110 During the construction works there is the potential for the foreshore geology to be impacted as a result of the construction of the drainage system outfall structure, sea wall and temporary jetty.

14.6.111 The magnitude of these impacts has been assessed as low. The foreshore geology also has the potential to be impacted by piling activities associated with the construction of the temporary jetty. The magnitude of this impact has been assessed as very low.

14.6.112 There is the potential for an additive cumulative impact to the foreshore geology as a result of these activities, which would be direct, permanent and certain to occur. The geological mapping study (Ref. 14.96) has demonstrated that the characteristics of the foreshore adjacent to the site can be observed elsewhere within the 'Blue Anchor to Lilstock' SSSI, therefore the loss of foreshore associated with the HPC Development would not result in an overall loss of the relevant foreshore geological features. The total area of foreshore which would be impacted by these project elements is very small when compared to the area of the foreshore adjacent to the HPC development site. The magnitude of the cumulative impact of the construction of the drainage outfall structure, the sea wall and the temporary jetty on the foreshore geology is therefore assessed as low.

14.6.113 The overall value and sensitivity of the foreshore for the purpose of this cumulative assessment is assessed as medium.

14.6.114 The significance of this cumulative impact is assessed as **minor adverse** and therefore no mitigation is required.

ii. Land Contamination

On-Site Human Health, On-Site Ecology, On-Site Soil Environment and On-Site Controlled Waters During Construction Works

14.6.115 There is the potential for an additive cumulative impact to the on-site construction workforce, any remaining on-site ecology, on-site soil environment and on-site controlled waters from land contamination generated as a result of leakage and accidental spillage and disturbance of existing land contamination during concurrent construction activities. However, given the adoption of standard good practice and appropriate control measures any potential accidental leakage or spillage would be very low volume and highly localised, and any existing land contamination would be of limited quantity, highly localised and managed through appropriate control procedures. The potential for receptors to be exposed to significant contamination from both sources at the same time is considered unlikely. Therefore there is considered to be no significant potential for cumulative impacts to the on-site construction workforce, any remaining on-site ecology and soil environment or to controlled waters from different sources of contamination during concurrent construction activities.

Off-Site Human Health, Ecology, Crops/Livestock, and Soil Environment During the Construction Works

14.6.116 During the construction works, potential impacts to off-site receptors (human health, ecology, crops/livestock, and soil environment), have only been identified as a result of single sources during the ground preparation works. It is not anticipated that these receptors will be subject to impacts during other construction activities or from greater than one source, therefore there would be no cumulative impacts to these receptors as a result of the construction works.

e) Operational Impacts

i. Geology

14.6.117 The operational phase (including commissioning) of the development would not result in any excavation into the underlying geology and therefore there would be **no impacts** on geology during the operational phase.

ii. Land Contamination

14.6.118 Following the completion of the construction works only soils which are suitable for use would be present on-site, i.e. all unacceptable contaminated soils would have been removed from site or remediated to render them suitable for use (e.g. only using contaminated soils in areas of hardstanding or at depths of greater than one metre in areas of proposed soft landscaping, agricultural land restoration or habitat creation). Contaminated soils above acceptability criteria[4] could potentially be re-used on-site during the construction phase (and hence very limited residual contamination could still be present during the commissioning and operational phase) provided that:

- they are managed in accordance with an agreed Materials Management and Land Contamination Management Plan and under the Code of Practice (Ref. 14.111);
- the soils are re-used in an appropriate manner (e.g. placed at greater than 1m if being re-used in areas of soft landscaping and/or agricultural and habitat restoration) and with supporting risk assessments to demonstrate they are 'suitable for use' even though they may be contaminated above acceptability criteria;
- testing demonstrates that the contaminants present in the soils are not readily mobile, leachable or otherwise bioavailable;
- they are re-used with the agreement of relevant stakeholders; and
- accurate records of the location, depth and type of contamination are kept.

14.6.119 A range of hazardous, non-radiochemical substances and materials including diesel, kerosene, solvents, oils, transformer oils, paints, acids, and alkalis would be stored and used on-site during the commissioning and operational phase of the development. These substances have the potential to cause land contamination if uncontrolled discharges to ground should occur.

14.6.120 An operational phase schematic Conceptual Site Model is presented as **Figure** 14.19.

14.6.121 In accordance with the Environmental Permit, pollution prevention infrastructure would be provided in accordance with BAT requirements which would significantly reduce the likelihood of any potential future accidental spillage or leakage and the resultant potential for ground contamination to occur. Therefore any potential contaminated soils arising as a result of operational activities are unlikely to be of sufficient volume to form a significant source of contaminated dust which could migrate off-site or alternatively constitute a source which could impact controlled waters on-site. As a result there are considered to be no potential impacts to off-site human health, off-site ecology, off-site crops/livestock, off site built environment, off-site soil environment, and/or off-site controlled waters during the operational phase (including commissioning).

[4] Acceptability criteria may vary depending on location of proposed re-use, depth of re-use, soil type, end use, environmental context/sensitivity, and contaminant type.

Operational Activities on On-Site Human Health

14.6.122 There is a potential risk to human health from soil contamination during the commissioning and operational phases to on-site maintenance and construction workers who may be required to undertake works in the subsurface environment (e.g. for repairs to underground infrastructure). These worker groups may come into close contact with potentially contaminated soil (particularly during excavations) arising as a result of commissioning and operational activities or residual contaminated soils placed there during the construction phase. Potential impacts to construction workers could be adverse, temporary, or possibly (depending on the nature of the health impact) permanent, direct and indirect.

14.6.123 The majority of the site would be covered by buildings and hardstanding. Therefore workers engaged in activities above ground would not be exposed to potential soil contamination via the direct contact or ingestion exposure routes.

14.6.124 In accordance with the Environmental Permit, pollution prevention infrastructure would be provided to significantly reduce the likelihood of any potential future accidental spillage or leakage and the resultant potential for ground contamination to occur. In addition, any future planned ground works during the operation of HPC would require a risk assessment to be undertaken in advance, which would consider the potential for ground contamination to be present. Exposure to potential in-ground contamination would then be managed if necessary through the use of appropriate control measures. Therefore the magnitude of the potential impact is considered to be very low.

14.6.125 The value of people on-site is high and therefore the initial significance of the impact is assessed as minor adverse. However, workers would not be permitted to be exposed to contaminated materials and would be provided with personal protective equipment (PPE) to prevent any adverse impact. Accordingly, the significance of the impact from commissioning and operational activities on on-site human health is considered to be **negligible**. Therefore no control measures beyond the standard good practice (as described above) are required.

Operational Activities to On-Site Ecological Receptors.

14.6.126 The presence of ecological receptors within the main nuclear island area of the proposed HPC site is likely to be very limited, and probably restricted to small areas of ornamental soft landscaping of very low value and sensitivity. As such, the potential for impacts to on-site ecology in these areas of the site during the commissioning and operational phases are considered to be negligible. However, ecological receptors will be present within the areas of agricultural land restoration new habitat creation that will principally be located in the areas to the south and west of the main nuclear island.

14.6.127 The potential for ecological receptors in these areas to be impacted by possible residual contamination deposited in these areas during the construction works and/or leaks and spills from the operational site area is very low. The potential for, and magnitude of, spills and leaks from the operational area will be controlled by good operational practice and pollution prevention infrastructure. Therefore the magnitude of potential impact to on-site ecological receptors during the operational phase is very low.

14.6.128 The value and sensitivity of the on-site ecology within the agricultural and natural habitat restoration areas is considered to be medium. The resulting impact significance is considered to be **minor adverse**.

Operational Activities to On-Site Crops and Livestock

14.6.129 Crops and livestock will not be present within the built development area. However, areas of arable farming (but not grazing i.e. livestock) will be present in the agricultural restoration areas. The magnitude of potential impacts to on-site crops either from residual contaminated soils deposited in the area during the construction phase and/or leaks and spills from the operational site is considered to be very low. The value and sensitivity of these arable areas is assessed as medium (see **Chapter 13** of this volume for details (Soils and Land Use)). The resulting impact significance is therefore **minor adverse**.

Operational Activities to the On-Site Soil Environment

14.6.130 There is the potential for the on-site soil environment to be impacted by possible residual contaminated soils deposited in the area during the construction phase and/or leaks and spills from the operational site. The potential impacts from such releases to the on-site soils are likely to be site-specific, adverse, permanent and direct.

14.6.131 The potential impact to soil is likely to be limited in extent and volume. Any contaminated soils that are re-used/re-deposited during the construction earthworks would only be done so if 'suitable for use'. During the commissioning and operational phase, the majority of the site would be occupied by hardstanding, particularly those areas used for the storage of chemical and fuels, therefore the amount of soil that could be potentially impacted is low. Further to this the Environmental Permit would require pollution prevention infrastructure to be provided, which would significantly reduce the likelihood of any potential future accidental spillage or leakage and the resultant potential for ground contamination to occur. Thus although the likelihood of potential impact to soil is considered to be 'possible', the magnitude of the potential impacts to soil is considered to be very low.

14.6.132 The value and sensitivity of the on-site soils within the permanent built development area which could be directly impacted is very low as the soils present would be engineering fills. The value and sensitivity of on-site soils used in the landscaped areas is high. For the purpose of this impact assessment a worst-case of high has been chosen to make the assessment conservative.

14.6.133 The significance of this impact is assessed as **minor adverse**. Therefore no specific mitigation is required.

Operational Activities to On-Site Built Environment

14.6.134 During the commissioning and operational phases, potentially aggressive chemicals (e.g. acids, alkalis, sulphates, chlorides, diesel and solvents) would be stored and used on-site, therefore there is the potential impact upon the built environment from uncontrolled releases of potentially aggressive contaminants. Any contaminated soils potentially re-used on-site during the construction phase would be demonstrated to be suitable for use. The potential impacts from contaminated soils to the on-site built environment are likely to be site-specific, adverse, permanent and direct and/or indirect.

14.6.135 The likelihood of potential impacts to the on-site built environment is considered to be unlikely. The Environmental Permit requires pollution prevention infrastructure to be provided, which would significantly reduce the likelihood of any potential future accidental spillage or leakage and the resultant potential for the release of chemically aggressive contaminants. Therefore the magnitude of the potential impact is considered to be very low.

14.6.136 The inherent value and sensitivity of the buildings, services and other infrastructure is considered to vary from very low to high (very low for pipes and high for buildings). However, the built infrastructure would be designed and constructed with appropriate specifications of materials such as potential impacts from land contamination will be designed out. As such, **no impacts** from uncontrolled release of aggressive contaminants during operational activities on buildings, services and other infrastructure are predicted.

f) Cumulative Operational Impacts

i. Geology

14.6.137 No impacts to any geological receptors have been identified during the commissioning or operation of HPC there is therefore no potential for any cumulative impacts.

ii. Land Contamination

14.6.138 The only potential impacts associated with land contamination identified during the commissioning or operation of Hinkley Point C are the potential impacts to on-site human health (workers), on-site ecology, on-site crops and the on-site soil environment from potential residual contaminated soils deposited during the construction phase and/or leakage or accidental spillage of contaminants. Given potential impacts are restricted to only two possible sources and in accordance with good practice, any potential leakage and accidental spillage will be located and remediated there is no potential for any cumulative impacts to receptors.

g) Landscape Restoration Impacts

14.6.139 On completion of construction, final landscaping works would be implemented, which would involve the non-operational areas of the HPC development site. The works would involve the re-use of stored topsoil, subsoil and other material to provide agricultural land and wildlife habitat creation.

14.6.140 The potential impacts relating to geology and land contamination from these elements are provided below.

i. Geology

14.6.141 The dismantling of the jetty is not anticipated to further impact foreshore geology beyond those impacts associated with its construction as no additional excavation of the on-site geology is anticipated and therefore there would be **no impact** to geology during the removal of the temporary jetty.

14.6.142 Following the dismantling of the jetty the aggregates storage area would be restored to its former agricultural use. This would be undertaken as part of the overall land restoration of the HPC development site. It is not anticipated that the restoration would involve excavation of the underlying geology and therefore **no impacts** to geology from restoration activities are anticipated.

ii. Land Contamination

14.6.143 Any unacceptable soil contamination identified during the construction works would have been remediated or removed from site therefore the restoration is unlikely to involve the disturbance of any potential previously existing contaminated soils. However, some contaminated soils above acceptability criteria[5] could potentially be re-used in areas of planned agricultural and habitat restoration provided that:

- they are managed in accordance with an agreed Materials Management Plan and Land Contamination Management Plan and under the Code of Practice;
- the soils are managed in an appropriate manner (e.g. placed at greater than 1m depth) and with supporting risk assessments to be suitable for use even though they may have be contaminated above acceptability criteria;
- testing demonstrates that the contaminants present in the soils are not particularly mobile, leachable or otherwise bioavailable/accessible;
- they are re-used with the full agreement of key stakeholders; and
- accurate records of the location, depth and type of contamination are kept.

14.6.144 The final landscaping works would require the use of mechanised plant, which has the potential to generate contaminated soils which may impact on-site human health (i.e. construction workers) and on-site soils. Any potential contaminated soil generated by leaks or accidental spills from the use of mechanised plant is unlikely to be of sufficient volume to result in the generation of significant quantities of contaminated soils.

h) Cumulative Restoration Impacts

i. Geology

14.6.145 Given no impacts to any geological receptors have been identified during restoration works there is no potential for any cumulative impacts.

ii. Land Contamination

14.6.146 The only potential impacts associated with land contamination identified during the restoration phase are the potential impacts to on and off-site human health, ecology, crops/livestock, soil environment and on-site controlled waters from the mobilisation and re-use of potentially contaminated soils and leakage or accidental spillage of contaminants from plant and machinery. The potential cumulative impacts are **minor adverse** assuming the worst-case.

[5] Acceptability criteria may vary depending on location of proposed re-use, depth of re-use, soil type, end use, environmental context/sensitivity, and contaminant type.

14.7 Mitigation of Impacts

a) Geology

14.7.1 As the geological units within the cliffs along the northern boundary of the HPC development site are fossiliferous, a watching brief would be maintained for identification of any finds of scientific importance during any excavations associated with the cliffs, such as during the construction of the drainage system outfall structure and construction of the sea wall

14.7.2 Paragraphs 14.5.37 – 14.5.41 identify that the eastern extent of the 'Blue Anchor to Lilstock' Site of Special Scientific Interest (SSSI) extends into the western part of the BDAW frontage by approximately 40m. The small area of the development site that falls within the SSSI is designated on the basis of the geological cliff exposures and limestone pavement (geomorphology) on the foreshore. The remaining cliff face and foreshore along the frontage of the BDAW and BDAE whilst not being within the SSSI still contains geology and geomorphology of significant value and interest.

14.7.3 Following consultation with Natural England, a geological survey along 10km of coastline identified a high quality, publically accessible replication of the geology found within the cliffs at Hinkley Point elsewhere within the SSSI. It was also qualitatively demonstrated that the characteristics of the foreshore geomorphology adjacent to the site can be observed elsewhere within the SSSI to the west and that these other examples are acceptable replication that will offset any loss of the units exposed within the cliff and rock pavement at Hinkley Point as part of the development. It should be stressed that this acceptable replication is not considered or proposed here as formal mitigation but, is mentioned here for completeness.

14.7.4 The foreshore along the northern boundary of the HPC development site is also fossiliferous, therefore, a pre-construction survey to identify any palaeontological finds of scientific importance is intended on the foreshore and intertidal wave-cut platform within the footprint of the jetty access road and the area to be impacted by piling works. A watching brief for fossils is not considered necessary during the jetty construction given the small diameter (864mm) of each pile and the very limited area of the foreshore to be excavated.

b) Land Contamination

14.7.5 Since the impact assessment is based on adherence to legislative requirements and adoption of standard good construction and operational practices (see Paragraphs 14.6.9 – 14.6.14 and 14.6.31 – 14.6.36), no moderate or major adverse impacts relating to contaminated soils have been identified.

14.8 Residual Impacts

14.8.1 As no mitigation measures are considered necessary none will be applied (see previous paragraph 14.7.5); therefore the residual impacts of the proposed development will be the potential impacts identified in Section 14.6.

14.9 Summary of Impacts

a) Geology

14.9.1 A summary of potential geological impacts during the proposed development are presented in **Table 14.10**.

b) Land Contamination

14.9.2 A summary of potential contaminated soils impacts during the proposed development are presented in **Table 14.11**.

Table 14.10: Summary of Impacts to Geology

Receptor	Potential Impact	Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact
Construction							
On-site surface geology	Construction activities on geology	Medium	Site specific Direct Adverse Permanent	Low	Minor adverse	None proposed	Minor adverse
Cliff and foreshore geology	Construction of sea wall and drainage outfall	Very low to Low	Site specific Direct Adverse Permanent	Medium (As area that will be impacted is **not** in SSSI but only in NNR)	Minor adverse	None proposed. However, a watching brief would be maintained for identification of any finds of scientific importance during any excavations associated with the cliffs.	Minor adverse
Foreshore geology	Temporary jetty bridge construction	Very low	Site Specific Localised Direct Adverse Permanent	High (As part of area that will be impacted is within the SSSI)	Minor adverse	None proposed in response to consultation with Natural England as geological exposures are not unique to HPC and are present elsewhere within the SSSI. However, a pre-construction survey to identify any palaeontological finds of scientific importance is intended on the foreshore and inter-tidal wave-cut platform.	Minor adverse
Foreshore geology	Operation of temporary jetty	N/A	N/A	N/A	N/A	N/A	N/A
Commissioning							
On-site surface geology	Commissioning activities	N/A	N/A	N/A	N/A	N/A	N/A

Receptor	Potential Impact	Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact
Operation							
On-site surface geology	Operational phase	N/A	N/A	N/A	N/A	N/A	N/A
Restoration							
On-site surface geology	Dismantling of jetty	N/A	N/A	N/A	N/A	N/A	N/A
On-site surface geology	Restoration works	N/A	N/A	N/A	N/A	N/A	N/A

Table 14.11: Summary of Impacts Relating to Land Contamination

Receptor	Potential Impact	Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact
Construction							
On-site human health (i.e. workers involved in demolition, preparation and construction works)	Construction activities	Very Low to Low	Site Specific Direct Indirect Adverse Temporary Permanent	Low (construction worker with full PPE)	Negligible to Minor Adverse	None proposed. However please see Section 14.6 (b).	Negligible to Minor Adverse
On-site human health (i.e. construction workers working in confined spaces or deep excavations)	Inhalation of ground gases	Very Low	Site Specific Direct Adverse Temporary Permanent	Low (construction worker with full PPE)	Negligible	None proposed. However please see Section 14.6 (b).	Negligible

Receptor	Potential Impact	Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact
Off-site human health (i.e. local residents and members of the public)	Construction activities	Very Low	Wider environment Indirect Adverse Permanent Temporary	High	Minor Adverse	None proposed. However please see Section 14.6 (b).	Minor Adverse
Controlled waters (i.e. on-site groundwater and surface water)	Construction activities	Very Low	Site Specific Direct Adverse Permanent Temporary	High	Minor Adverse	None proposed. However please see Section 14.6 (b).	Minor Adverse
On-site soil environment	Construction activities	Very Low	Site Specific Direct Indirect Adverse Permanent Temporary	High	Minor Adverse	None proposed. However please see Section 14.6 (b).	Minor Adverse
Off-site soil environment	Construction activities	Very Low	Wider Environment Direct Indirect Adverse Permanent Temporary	High	Minor Adverse	None proposed. However please see Section 14.6 (b).	Minor Adverse
On-site ecology (including plants, trees and other vegetation)	Construction activities	Very Low	Site Specific Direct Indirect Adverse Permanent Temporary	Medium	Minor Adverse	None proposed. However please see Section 14.6 (b).	Minor Adverse

Receptor	Potential Impact	Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact
Off-site ecology (including plants, trees and other vegetation)	Construction activities	Very Low	Wider Environment Direct Indirect Adverse Permanent Temporary	High	Minor Adverse	None proposed. However please see Section 14.6 (b).	Minor Adverse
On-site Crops and Livestock	Construction activities	N/A	N/A	N/A	N/A	N/A	N/A
Off-site Crops and Livestock	Construction activities	Very Low	Wider Environment Direct Indirect Adverse Permanent Temporary	High	Minor Adverse	None proposed. However please see Section 14.6 (b).	Minor Adverse
On-site built environment (i.e. water supply pipes and underground concrete)	Construction activities	N/A	N/A	N/A	N/A	N/A	N/A
Off-site built environment	Construction activities	N/A	N/A	N/A	N/A	N/A	N/A
On-site human health	Operation of site compound	N/A	N/A	N/A	N/A	N/A	N/A
Off-site human health	Operation of site compound	N/A	N/A	N/A	N/A	N/A	N/A
On-site ecology (including plants, trees and other vegetation)	Operation of site compound	N/A	N/A	N/A	N/A	N/A	N/A
Off-site ecology (including plants, trees and other vegetation)	Operation of site compound	N/A	N/A	N/A	N/A	N/A	N/A

Receptor	Potential Impact	Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact
On-site crops and livestock	Operation of site compound	N/A	N/A	N/A	N/A	N/A	N/A
Off-site crops and livestock	Operation of site compound	N/A	N/A	N/A	N/A	N/A	N/A

[This page is left intentionally blank]

15. GROUNDWATER

15.1 Introduction

15.1.1 This chapter of the Environmental Statement (ES) provides an assessment of the potential impacts to groundwater associated with the construction and operational phases of Hinkley Point C (HPC). Where required, mitigation measures are identified to prevent, reduce and where possible off-set any potential adverse impacts that are identified to be of significance.

15.2 Scope and Objectives of Assessment

15.2.1 The scope of the assessment has been determined through a formal Environmental Impact Assessment (EIA) scoping process undertaken with the Infrastructure Planning Commission (IPC). It has also been informed by formal consultation carried out during the Stage 1 and Stage 2 Consultations and specific additional consultation with the Environment Agency and local authorities as necessary. In the case of the former, meetings were held with various consultees as shown in **Table.15.1**.

Table.15.1: Groundwater Consultations

Date	Consultee	Type/Purpose of Consultation
09/12/2008	Local Authorities (Sedgemoor and West Somerset)	Scoping consultation meeting.
12/12/2008	Environment Agency	Copy of draft outline groundwater monitoring plan sent to the Environment Agency for comment.
15/12/2008	Environment Agency	Scoping consultation meeting.
04/02/2009	Environment Agency	Correspondence to discuss first results of groundwater monitoring etc.
28/07/2009	Environment Agency	MALG meeting/presentation at which Phase 1 and Phase 2 non-radiological groundwater quality results and findings were discussed and proposals for further site investigation presented; groundwater conceptual model also presented.
27/07/2010	Environment Agency	Presentation of groundwater and contaminant transport modelling and conclusions to date.
06/04/2011	Environment Agency	Presentation of updated groundwater and contaminant transport modelling and conclusions to date.
11/04/2011	Local Authorities (Sedgemoor and West Somerset)	Presentation of updated groundwater and contaminant transport modelling and conclusions to date.

Stage 2 Consultation

15.2.2 The Stage 2 consultation process resulted in the submission of a number of groundwater related comments from consultees on the Environmental Appraisal document. The principal comments related to groundwater, include the following:

- groundwater modelling;
- extent of site investigations;
- scope of assessment for the sea wall, jetty and pumping rates;
- impacts on groundwater quality; and
- impacts on the Bridgwater Bay SSSI.

15.2.3 Consultation on groundwater issues has formed part of the overall consultation process. Principally, the consultation comments raised have been resolved due to completion of BDAE and SCPA onshore investigations and subsequent development of the groundwater numerical model. BDAE and SCPA onshore investigations and the groundwater numerical model were not finalised prior to the Stage 2 consultation being undertaken.

15.2.4 The topics listed above were discussed during the stakeholder meetings listed in **Table.15.1** Further information may be found in the **Consultation Report**.

15.2.5 The assessment of groundwater impacts on key sensitive receptors arising from the proposed development has been undertaken adopting the methodologies described in Section 15.4 below. The existing baseline conditions, against which the likely environmental effects of the development are assessed, have been determined through a programme of site investigation (reported in more detail in **Chapter 14** of this volume), conceptual model development and groundwater modelling as described in Section 15.5; this section also identifies the existing and future receptors which are of relevance to groundwater.

15.2.6 The study area for this assessment, as illustrated in **Figure 15.1**, comprises the HPC Development Site and surrounding area off-site which may be influenced by construction and operational phase activities. The HPC Development Site comprises three separate parcels of land (**Figure 15.2**) which are referred to as the Built Development Area West (BDAW), the Built Development Area East (BDAE) and the Southern Construction Phase Area (SCPA).

15.2.7 The off-site highway improvements schemes have also been considered with respect to the scope of the groundwater assessment. The schemes principally represent modifications to roads that are already in place or would otherwise require physical works of a very limited nature. For existing roads which would be modified pollution control measures such as grit traps and interceptors will already exist as required to protect the road drainage and any seepage to subsoil from road-related contamination. It is assumed that the improvement schemes will augment these measures as appropriate. As the highway improvements would not involve extensive deep excavations, and any groundwater inflows from the anticipated superficial and/or solid formations would not be significant any dewatering would be of a temporary and minor magnitude. As a result there would be negligible impact on the groundwater environment and therefore none of the highway improvements schemes are considered further in the impact assessment.

15.2.8 Section 15.6 assesses the potential groundwater impacts on key sensitive receptors, including (where they have not previously been scoped out from baseline or modelling assessments):

- construction dewatering impacts on controlled waters, including groundwater and potential groundwater impact on surface water bodies such as Holford Stream and the drainage on Wick Moor (groundwater levels, groundwater quality, saline intrusion and abstractions);
- construction dewatering impacts on buildings and infrastructure; and
- impacts from building foundations and structures built below the water table on controlled waters (groundwater levels, sea water intrusion and groundwater quality).

15.2.9 Appropriate mitigation measures aimed at preventing, reducing and, where possible off-setting any potential adverse impacts that are identified to be of significance are presented in Section 15.7. The assessment of residual impacts, as required, following implementation of the mitigation measures is provided in Section 15.8.

15.2.10 The objectives of the assessment were to:

- interpret site investigation and other sources of information with respect to hydrogeology;
- construct a groundwater conceptual model to identify and describe likely baseline groundwater behaviour within the study;
- identify key sensitive receptors within the study area;
- design and build a groundwater model to replicate baseline groundwater conditions;
- predict construction and operational impacts on groundwater using the same model;
- predict groundwater quality impacts using a contaminant transport model;
- recommend mitigation measures, if considered necessary, to reduce potential adverse impacts of the proposed development on groundwater; and
- assess the residual impacts of the construction and operational phases of the proposed development on groundwater.

15.3 Legislation, Policy and Guidance

15.3.1 This section identifies and describes legislation, policy and guidance of relevance to the assessment of potential groundwater impacts associated with the construction and operational phases of the proposed development.

15.3.2 The Overarching National Policy Statement (NPS) for Energy (NPS EN-1) when combined with the NPS for Nuclear Power Generation (NPS EN-6) provides the primary basis for decisions by the IPC on applications for nuclear power generation developments that fall within the scope of the NPSs.

15.3.3 Notwithstanding this, the IPC may consider other matters that are both important and relevant to its decision-making. This could include Planning Policy Statements (PPSs), Planning Policy Guidance Notes (PPGs), regional and local policy documents, although, if there is a conflict between these and the NPS, the NPS prevails for the purposes of IPC decision making.

15.3.4 Further, the Planning Act 2008 provides that the IPC must, in making its decision on an application, have regard to any Local Impact Report (LIR) prepared by relevant local authorities. It is anticipated that the LIRs will rely in part on PPSs, PPGs, regional and local policy to provide a context for their assessment. On this basis, regard has been given to these documents (where relevant to the technical assessment) since they are likely to inform the LIRs prepared by the relevant local authorities.

a) International Legislation

i. Water Framework Directive (2000/60/EC)

15.3.5 The overall purpose of the Water Framework Directive (WFD) (Ref. 15.1) is to establish a framework for the protection of surface freshwater, estuaries, coastal water and groundwater. The objectives of the WFD are to enhance the status and prevent further deterioration of aquatic ecosystems and associated wetlands, promote the sustainable use of water, reduce pollution of water (especially by 'priority' and 'priority hazardous' substances), and ensure progressive reduction of groundwater pollution. The main features of the WFD are:

- Member states should take all necessary measures to ensure that groundwater quality does not deteriorate and to prevent the input of pollutants to groundwater.
- Discharges of hazardous substances must cease or be phased out within 20 years of their identification as a priority hazardous substance.
- All inland and coastal waters within defined river basin districts must reach at least good status by 2015. The WFD defines how this should be achieved through the establishment of environmental objectives and ecological targets for surface waters.

15.3.6 The WFD has an associated annex which comprises a list of 'priority' and 'priority hazardous' substances. This annex has now been replaced by the Directive on Priority Substances (2008/105/EC) (Ref.15.2), in which Annex II identifies 33 'priority substances' (including lead and nickel in addition to organic compounds) of which 20 are classified as 'priority hazardous' substances (including cadmium and mercury amongst organic compounds). It also includes a list of eight organic substances for determination whether they should be included in the list of priority substances or priority hazardous substances. In July 2006, the European Commission published a proposal for a directive on environmental quality standards in the field of water policy (COM 2006 397) (Ref. 15.3) which will set limits on concentrations in surface waters for the priority substances.

15.3.7 The WFD will ultimately lead to the repeal of several other long standing key directives, including the Protection of Groundwater from Dangerous Substances (80/68/EEC) (Ref.15.4) and Substances Discharged into the Aquatic Environment (76/464/EEC) (Ref. 15.5).

15.3.8 In England and Wales, the WFD is primarily implemented through the Water Environment (Water Framework Directive) (England and Wales) Regulations 2003 (Ref. 15.6). The Regulations establish a system of river basin management planning. The water bodies of England and Wales have been allocated to river basin areas depending on catchment areas and a plan drawn up for each. The plans contain a programme of measures tailored to each catchment designed to ensure that its water bodies achieve and maintain the appropriate status in accordance with the timelines set out in the WFD.

15.3.9 As part of the ongoing implementation of the WFD, the Environment Agency has recently been given the power to apply environmental standards to individually defined WFD water bodies via the River Basin Districts Typology, Standards and Groundwater Threshold Values (Water Framework Directive) (England and Wales) Directions 2010 (Ref. 15.7), and the River Basin Districts Surface Water and Groundwater Classification (Water Framework Directive) (England and Wales) Directions 2009 (Ref. 15.8). The thresholds and descriptions of water body typology within these Directives are largely based upon the research work by the United Kingdom Technical Advisory Group (UKTAG).

ii. Groundwater Directive (80/68/EEC and 2006/118/EC)

15.3.10 This Directive, which was adopted in 1979, aims to protect groundwater against pollution caused by dangerous substances. The Directive required the prevention of the discharge of List I substances (now ‘priority’ or ‘priority hazardous’ substances) to groundwater, and the investigation of List II substances (’non-hazardous’ substances) prior to direct or indirect discharge. The Directive is due to be repealed in 2013 by the Water Framework Directive (2000/60/E) (Ref. 15.1). The Directive is primarily implemented in England and Wales by the Environmental Permitting (England and Wales) Regulations 2010 (SI 2010/675) (Ref. 15.9).

15.3.11 The EU has now also adopted a more recent directive relating to groundwater, the Directive on the Protection of Groundwater Against Pollution and Deterioration (2006/118/EC) (Ref. 15.10). The aim of this Directive (the Groundwater ‘Daughter’ Directive) is to ensure good groundwater quality by 2015, in line with the requirements of the WFD. The Groundwater ‘Daughter’ Directive sets out specific measures for preventing and controlling groundwater against pollution and deterioration.

iii. Nitrates Directive (91/676/EEC)

15.3.12 The Nitrates Directive (Ref. 15.11) requires member states to identify waters which are, or could become, polluted by nitrates and to designate as Nitrate Vulnerable Zones (NVZs) all land which drains to those waters and which may contribute to the pollution.

15.3.13 The following criteria are laid down in the Directive for use in identifying polluted waters:

- surface freshwaters which contain or could contain, if preventative action is not taken, nitrate concentrations greater than 50mg/l;
- groundwaters which contain or could contain, if preventative action is not taken, nitrate concentrations greater than 50mg/l; and
- natural freshwater lakes, or other freshwater bodies, estuaries, coastal waters and marine waters which are eutrophic or may become so in the near future if protective action is not taken.

15.3.14 The whole of the HPC Development Site falls within an NVZ.

b) National Legislation and Guidance

15.3.15 All of the above Directives are implemented in the UK though a series of primary (Acts) and secondary legislation (Regulations); including those detailed below.

i. Environmental Permitting (England and Wales) Regulations 2010 (SI 2010/675)

15.3.16 The Groundwater Regulations 1998 (SI 2746) (Ref. 15.12) came into force in 1999 and implemented the 1980 EU Groundwater Directive. The Regulations are designed to protect groundwater from pollution arising mainly from industrial and agricultural activities. These were replaced from 31 October 2009 by the 2009 Groundwater Regulations (SI 2009/2902) (Ref. 15.13), and from 6 April 2010 by the Environmental Permitting (England and Wales) Regulations 2010 which harmonise the regulations with the Groundwater 'Daughter' Directive (2006/118/EC) (Ref. 15.10).

15.3.17 The main activities likely to lead to a direct or indirect discharge of priority substances or non-hazardous pollutants require formal authorisation. Direct discharges of hazardous substances are prohibited. Activities which may result in indirect discharges (from tipping or disposal) of hazardous substances may only be authorised if prior investigation shows that the groundwater is permanently unsuitable for other uses. Such authorisation should contain conditions to ensure that necessary technical precautions are taken to prevent an indirect discharge of priority substances. Non-hazardous discharges will only be authorised with conditions if prior investigation can demonstrate that groundwater pollution can be prevented. Where a discharge is authorised, the authorisation will specify the discharge to be made as well the quantities of any substances allowed in the discharge and monitoring requirements. Authorisations (permits) may be reviewed at any time.

15.3.18 A discharge may be taken to include leachate from waste materials or leakage from an above ground or below ground storage tank, soakaway etc.

15.3.19 It is an offence to "cause or knowingly permit" the discharge of hazardous substances or non-hazardous pollutants which might lead them to enter groundwater without an authorisation (permit).

ii. Water Resources Act (1991)

15.3.20 Part II of the Water Resources Act (WRA) 1991 (Ref. 15.14) covers the licensing of water abstractions (including groundwater).

15.3.21 Section 29 of the WRA, 1991 covers the exemption of construction dewatering from the abstraction licensing process by stating in S.29 (2) that:
