> *"the restriction on abstraction shall not apply to any abstraction of water from a source of supply in so far as the abstraction … is necessary (a) to prevent interference with any mining, quarrying, engineering, building or other operations (whether underground or on the surface); or (b) to prevent damage to works resulting from any such operations."*

15.3.22 The exemption of construction dewatering from the terms of Part II of the WRA is also explained on the Environment Agency's Netregs website http://www.netregs.gov.uk/netregs/businesses/construction/62335.aspx (Ref. 15.15):

15.3.23 "If, as part of your works, you are de-watering or pumping water that has gathered in an excavation, then you will not require an abstraction licence if the water is to be disposed of solely to prevent interference to your building operations. If you intend to use water from a de-watering operation for dust suppression or pressure testing on site, you may require an abstraction licence."

15.3.24 The WRA also empowers the Environment Agency to undertake anti-pollution works in relation to controlled water (including groundwater) and recover the expenses involved from the person who caused or knowingly permitted polluting substances to be present or pollution to have occurred. The Environment Agency may also serve a works notice upon such persons requiring them to undertake anti-pollution works.

iii. Water Act (2003)

15.3.25 The Water Act (2003) (Ref. 15.16) includes a provision to remove the exemption referred to in the previous paragraphs, but this has not yet been enacted. At present it is understood that an abstraction licence for construction dewatering will not be required, but ongoing liaison with the Environment Agency on this matter will be maintained.

iv. Environment Agency Groundwater Protection: Policy and Practice (GP3) 2008

15.3.26 This guidance document (Ref. 15.17) provides a framework for the regulation and protection of groundwater resources. It comprises a number of parts: Part 1 outlines the Environment Agency's approach to the management and protection of groundwater; Part 2 provides a technical framework which sets out key principles and concepts; Part 3 provides guidance in the tools available for analysing and assessing the risks to groundwaters and Part 4 provides the Environment Agency's position and polices with respect to developments and other activities which may present a risk to groundwater. It also provides guidance on the key groundwater legislation and how to interpret it.

15.3.27 The Environment Agency Groundwater Protection: Policy and Practice (GP3) 2008 is risk based. To assist in this, the Environment Agency has developed a series of Groundwater Vulnerability Maps and Source Protection Zones (SPZs). Vulnerability maps identify where a groundwater resource is at risk from pollution (should a pollution source exist) due to the nature of the soil, unsaturated zone or inherent characteristics of the aquifer. SPZs show the level of risk for water quality at and around abstraction points due to activity on or in the ground. They have three divisions, with SPZ1 (Inner) closest to the source indicating the area of highest risk.

15.3.28 The Environment Agency Groundwater Protection: Policy and Practice (GP3) 2008 document contains a series of general and specific policies as follows:

- general approach to groundwater protection (including storage of pollutants);
- solid waste management;
- discharge of liquid effluents into the ground;
- diffuse sources;
- management of groundwater resources;

- river augmentation from groundwater;
- contamination; and
- groundwater flooding.

c) National Planning Policy

i. Overarching National Policy Statement for Energy (NPS EN-1)

15.3.29 NPS EN-1 states that where the project is likely to have effects on the water environment, the applicant should undertake an assessment of the existing status of, and impacts of the proposed project on, water quality, water resources and physical characteristics of the water environment as part of the ES or equivalent (para 5.15.2).

ii. National Policy Statement for Nuclear Power Generation (NPS EN-6)

15.3.30 NPS EN-6 states that in carrying out an assessment, applicants should also consider the effects of the construction of a new nuclear power station on the groundwater regime and its effects on terrestrial/coastal habitats (para 3.9.3).

iii. Planning Policy Statement 1: Delivering Sustainable Development (PPS1) (2005)

15.3.31 PPS1 (Ref. 15.18) was published in 2005 and sets out the Government's overarching planning policies on the delivery of sustainable development through the planning system.

15.3.32 Paragraph 5 states that planning should facilitate and promote sustainable and inclusive patterns of urban and rural development by, amongst other things: protecting and enhancing the natural and historic environment, the quality and character of the countryside, and existing communities.

d) Regional Planning Policy

15.3.33 The Government's revocation of regional strategies was quashed in the High Court on 10 November 2010. However, on that same date the Government reiterated in a letter to Chief Planners its intention to revoke regional strategies through the Localism Bill. This letter was also challenged but, on 7 February 2011, the High Court held that the Government's advice to local authorities that the proposed revocation of regional strategies was to be regarded as a material consideration in their planning development control decisions should stand. The decision of the High Court was upheld by the Court of Appeal on 27 May 2011. Therefore, the regional strategies remain in place but in the case of development control decisions it is for planning decision makers to decide on the weight to attach to the strategies (see **Volume 1, Chapter 4** for a full summary of the position regarding the status of regional planning policy).

i. Regional Planning Guidance 10 for the South West 2001 – 2016 (RPG10) (2001)

15.3.34 RPG 10 (Ref. 15.19) sets out the broad development strategy for the period to 2016 and beyond. Policy RE1 (Water Resources and Water Quality) states that to achieve the long term sustainable use of water, water resources need to be used more efficiently. The policy also states that local authorities, the Environment Agency, water companies and other agencies should seek to, amongst other things, protect groundwater resources.

ii. The Draft Revised Regional Spatial Strategy (RSS) for the South West Incorporating the Secretary of State's Proposed Changes 2008 – 2026 (July 2008)

15.3.35 **Chapter 7** of the Draft Revised Regional Spatial Strategy for the South West Incorporating the Secretary of State's Proposed Changes 2008 – 2026 (July 2008) (Ref. 15.20) deals with Enhancing Distinctive and Cultural Life. Policy RE6 (Water Resources) states that the region's network of ground, surface and coastal waters and associated ecosystems will be protected and enhanced. It also advises that surface and groundwater pollution risks must be minimised so that environmental quality standards are achieved and where possible exceeded.

iii. Somerset and Exmoor National Park Joint Structure Plan Review 1991-2011 (2000) (Policies 'saved' from 27th September 2007)

15.3.36 The Somerset and Exmoor National Park Joint Structure Plan (Ref. 15.21) was adopted in 2000 with relevant policies saved from 27 September 2007. All policies have been saved with the exception of Policy 53 which is unrelated to groundwater impacts. The Plan provides a strategic base for all land use planning within the plan area for the period up to 2011.

15.3.37 Policy 59 (Safeguarding Water Resources) states that protection will be afforded to all surface, underground and marine water resources from development which could harm their quality or quantity.

e) Local Planning Policy

i. West Somerset District Local Plan (2006) (Policies 'saved' from 17 April 2009)

15.3.38 The West Somerset Local Plan forms part of the development plan for West Somerset. The Local Plan (Ref. 15.22) was adopted in April 2006 (with relevant policies 'saved' from 17 April 2009). The Proposals Map indicates that the Main Site itself is not subject to any specific groundwater designations. The site is outside of the defined Development Boundary.

15.3.39 The following saved policy is considered to be potentially relevant:

15.3.40 Policy W/2 (Surface Water Protection) states that development which would adversely affect the quantitative and quality aspects of surface, underground or coastal waters will only be permitted where acceptable mitigating works are undertaken as an integral part of that development.

ii. West Somerset District Local Development Framework (LDF) Core Strategy (Options Paper) (January 2010) (Ref. 15.23)

15.3.41 The Core Strategy is at a preliminary stage of preparation and the Options Paper does not include any specific policies relating to groundwater impacts.

iii. Supplementary Planning Guidance

15.3.42 Sedgemoor District Council and West Somerset Council have jointly prepared draft supplementary planning guidance in relation to the HPC Project. Public consultation on the Consultation Draft version of the Hinkley Point C Project Supplementary Planning Document (the draft HPC SPD) commenced on 1 March 2011 and concluded on 12 April 2011. EDF Energy has submitted representations which object to the draft HPC SPD. See **Volume 1, Chapter 4** for a full summary of the position regarding the status of the draft HPC SPD.

15.3.43 The draft HPC SPD provides advice in relation to the HPC proposals, expanding upon the policy context for the proposals. This includes associated development.

15.3.44 The draft HPC SPD does not set out any specific guidance in relation to groundwater impacts at the Main Site.

15.3.45 Further planning policy context is provided in the Legislative Planning Policy Context chapter (**Volume 1, Chapter 4**) and the Introduction chapter (**Volume 2, Chapter 1**).

15.4 Methodology

a) Study Area

15.4.1 The geographical extent of the study area for this chapter includes the HPC Development Site and extends to the adjacent Hinkley Point A (HPA) site and land as far south as Stogursey, covering the outcrop and recharge area of the Lower Lias strata which may influence groundwater behaviour within the development site (see **Figure 15.1**).

b) Baseline assessment

15.4.2 The two main documented sources of information which have been used to establish the existing topography of the study area are the Ordnance Survey (2005) Explorer Map 1:25,000 scale 'Quantock Hills & Bridgwater' Sheet 140 (Ref. 15.24) and digital topographic data (Ref. 15.25). These data sources have been augmented by information derived from site visits and reconnaissance.

15.4.3 The baseline geological conditions of the study area been determined with reference to historical intrusive investigations and associated factual and interpretive reports supported by other data sources including: the British Geological Survey (BGS) published geological maps, a commercially available GroundSure Geology and Ground Stability report, and direct evidence derived from recent intrusive investigations and geological field mapping undertaken for EDF Energy.

15.4.4 The hydrogeology of the site was assessed through reference to previous work (see below), site-specific ground investigation, monitoring, soil and groundwater analysis and groundwater modelling.

15.4.5 The groundwater baseline conditions presented in this chapter identify the following aspects:

- aquifer existence and type (as defined by Environment Agency vulnerability criteria);

- aquifer characteristics (permeability and storage, derived from reviewed documents and results from the onshore site investigation and a pumping test within the BDAW);
- groundwater levels and flow directions (groundwater levels from reviewed documents and from monitoring of boreholes within the HPC Development Site);
- groundwater quality, non-radiological and radiological, from reviewed documents and from monitoring of boreholes within the HPC Development Site; and
- groundwater use from licensed abstractions.

15.4.6 The main documented sources of information which have been used to determine the baseline assessment with respect to the geology of the study area are:

- British Geological Survey (BGS) 1:50000 BGS Sheet 279; Weston-Super-Mare (Ref. 15.26).
- Whittaker, A. and Green, G.W. (1983). Geology of the country around Weston-Super-Mare: Memoir for 1:50,000 geological sheet 279, New Series, with parts of Sheets 263 and 295. Institute of Geological Sciences. London (Ref. 15.27).
- Rendel Palmer and Tritton (1986). Hinkley Point 'C' Power Station Pre-Application Studies, Volume 2 Geotechnical Report (Ref. 15.28).
- Allot Atkins Mouchel (1988). Hinkley Point 'C' Power Station Geotechnical Studies, Geotechnical Summary Report – Chapter 7. Report Ref: HPC 1101/57 (Ref. 15.29).
- Aspinwall & Company (1996). Analysis of Groundwater Conditions at Hinkley Power Station. Report Ref: NU5101B for Nuclear Electric (Ref. 15.30).
- Structural Soils Ltd (August 2009). Factual Report on Ground Investigation: On Shore Investigations for Hinkley Site, Report Ref: 721763 (Ref. 15.31).
- EDF Energy (October 2010). Onshore geological, geotechnical and hydrogeological interpretive report. Report Ref: EDTGG090141A (Ref. 15.32).
- GroundSure (June 2008). Environmental Data Report (Ref. 15.33)

15.4.7 During the onshore investigation conducted by Structural Soils in 2008 (Ref. 15.31) (please refer to **Chapter 14** of this volume for a summary of this investigation), 36 rotary cored and 23 rotary open holed destructive boreholes were drilled within the BDAW. A total of 24 of these boreholes were completed with piezometers to allow groundwater level monitoring and sampling to be undertaken.

15.4.8 For groundwater level monitoring, transducers were installed to measure the pressure of the water column above them within each monitored borehole. These readings were taken automatically every hour. Periodically (usually during sampling) the readings stored in the transducers' dataloggers were downloaded for processing. Manual water level readings were taken at this time to calibrate the transducers, and the automatic readings were converted to water level in metres below ground and above sea level datum. Correction for barometric pressure was carried out automatically. The transducers also record water temperature and electrical conductivity.

15.4.9 Groundwater quality characterisation has made use of site-specific monitoring campaigns which have been carried out within the BDAW, BDAE and SCPA.

15.4.10 From the baseline geology and groundwater data a conceptual groundwater model was produced which assisted in the description and in some cases the scoping out of some potential impacts. A numerical model (see **Section 15.5** for details) has been developed to assess baseline behaviour in the Blue Lias aquifer, and groundwater flow and contaminant transport implications during construction dewatering.

15.4.11 The groundwater model has been developed using the United States Geological Survey (USGS) MODFLOW 2000 code running under Groundwater Vistas v5.51 Build 3. The model requires Groundwater Vistas v5.51 or later in order to run correctly.

c) Assessment Methodology

i. Value and Sensitivity

15.4.12 **Volume 1, Chapter 7** describes the assessment methodology for this EIA. In addition the specific methodology was applied for the determination of receptor value and sensitivity and impact magnitude as described in the following sections.

15.4.13 The value and sensitivity of groundwater as a receptor can be most readily defined from the following:

- environment Agency designated aquifer status (Primary Aquifer, Secondary A Aquifer, Secondary B Aquifer, Unproductive);
- presence of abstractions from within the study area;
- presence of groundwater Source Protection Zones (Inner, Outer, Catchment); and
- presence of any other specific groundwater uses (particularly abstraction and/or baseflow support to surface watercourses).

15.4.14 Sensitivity is based on the assessment of tolerance against a benchmark level of change in an environmental factor, and the likely recoverability from change. In order to help define the level of value and sensitivity, the generic guidance provided in **Volume 1, Chapter 7** has been tailored to be specific to groundwater (see **Table 15.2**, which sets out guidelines for the assessment of the value and sensitivity of groundwater as a receptor). With respect to groundwater, aquifers are more sensitive to changes in quality than level (the depth at which groundwater occurs) because of the timescales involved in groundwater flow and natural flushing/attenuation of any groundwater quality (contamination) impact.

Table 15.2: Guidelines for the Assessment of Groundwater Receptor Value and Sensitivity

Value and Sensitivity	Guideline
High	Primary Aquifer with significant public water supply abstractions. Site is within Inner or Outer Source Protection Zones.
Medium	Primary Aquifer with significant public water supply abstractions. Site is within a Catchment Source Protection Zone; or Minor Aquifer with significant water supply abstractions. Site is within Inner or Outer Source Protection Zones.

Value and Sensitivity	Guideline
Low	Secondary A Aquifer with water supply abstractions. Site is within a Catchment Source Protection Zone.
Very low	Secondary A/B Aquifer without abstractions in area of activity; or Unproductive.

ii. Magnitude

15.4.15 In addition to the generic guidance provided in **Volume 1, Chapter 7**, specific guidance on assessing the magnitude of impacts on groundwater has been developed and is presented in **Table 15.3**.

15.4.16 The magnitude of impact has been based on the consequences that the proposed development would have upon groundwater receptors and has been considered in terms of high, medium, low and very low magnitude ratings. **Table 15.3** provides a guide to the assessment of magnitude of impact for groundwater. Where an impact could reasonably be placed within more than one magnitude rating, conservative professional judgement has been used to determine which rating would be applicable.

Table 15.3: Guidelines Used in the Determination of Magnitude of Change for Groundwater Resources.

Magnitude	Guideline
High	Very significant change to key groundwater regime characteristics to the extent that UK and European legislation is contravened. Change in groundwater level, quality or available resource usefulness is chronic, permanent or prolonged significantly beyond the activity causing the change, and irreversible. Permanent loss of aquifer as useful groundwater resource. Changes are spatially extensive beyond the area in which the effect may occur (e.g. drawdown into adjoining areas or contamination down gradient of site into adjoining areas).
Medium	Significant change to key groundwater regime characteristics to the extent that UK and European legislation may be contravened. Groundwater quality may be affected permanently or at least for 10 years. Change in groundwater level, quality or available resource usefulness is prolonged more than two years beyond the activity causing the change, and only reversible after significant remediation activity. Permanent or long-term loss of aquifer as useful groundwater resource. Changes are spatially extensive beyond the area in which the effect may occur (e.g. drawdown into adjoining areas or contamination down gradient of site into adjoining areas).
Low	Noticeable but insignificant changes in groundwater levels or quality for more than two years, or significant changes for more than six months but less than two years, or barely discernible changes for more than two years. Reversible without external action required. Changes confined largely to the area of effect only. No contravention of UK or European legislation.

Magnitude	Guideline
Very low	Barely discernible changes in groundwater levels or quality for more than two years, or noticeable but insignificant changes for more than six months but less than two years. Changes confined largely to the area of effect only and reversible without external action. Changes of lower magnitude than baseline seasonal changes. No contravention of UK or European legislation.

iii. Significance of impacts

15.4.17 The significance of the impact is judged on the relationship of the magnitude of impact to the assessed sensitivity and/or importance of the resource. The methodology for rating of the significance of the impacts, without mitigation, is outlined in **Volume 1, Chapter 7**.

15.4.18 For the purpose of this assessment, mitigation measures have been proposed where there is an adverse impact of greater than minor significance and the impact magnitude, spatial scope and temporal nature make it appropriate to do so.

iv. Cumulative Impacts

15.4.19 **Volume 1, Chapter 7** of this ES sets out the methodology used to assess cumulative impacts. Additive and interactive effects between site-specific impacts are considered within this chapter. The assessment of cumulative impacts with other elements of the HPC Project and other proposed and reasonably foreseeable projects are considered in **Volume 11** of this ES.

d) Limitations, Assumptions and Uncertainties

15.4.20 The approach and methodology adopted for this chapter are consistent with relevant guidance, notably the Environment Agency Groundwater Protection: Policy and Practice (GP3) 2008 (Ref. 15.17).

15.4.21 A number of assumptions and limitations have been identified as follows:

- A range of enabling works will be completed within the BDAE prior to bulk earthworks associated with the site preparation works commencing in this area. The effective completion of the enabling works is assumed as the baseline for the impact assessment presented in this ES.
- Specific aquifer property data are relatively limited in spatial extent, essentially to the BDAW and BDAE, although there is no reason to suggest that there will be major differences beyond the two development areas within the modelled domain (see Model geometry and grid definition in Section 15.5 of this chapter, and **Figure 15.19**). There are, however, no specific data on the conditions on Wick Moor (alluvial thickness, permeability, groundwater levels) and assumptions have had to be made in accordance with informed professional judgement.
- Specific groundwater level data are limited spatially to the BDAW, BDAE and part of the SCPA; and to some data relating to the existing Hinkley Point Power Station Complex. The site-specific data are limited temporally to a maximum of just over two years on the BDAW, and less than one year on the BDAE and SCPA. The SCPA is to the south of the faulted inlier which is described below and is hence outside of the groundwater model domain. The groundwater model is described

later in this chapter. It is therefore not considered essential to have a complete temporal water level dataset for the SCPA.

- Rainfall recharge data are limited to estimates based on rainfall and available reports. Spatial distribution is estimated based upon distribution of known development and the reduction due to installed drainage and hardstanding. Temporal variation is limited to annualised average monthly values.
- Groundwater quality and baseline contaminant data outside the HPC Development Site are limited to accessible reports on HPA.
- Uncertainties regarding tritium (H-3) contamination on the Hinkley Point A (HPA) power station site. This has been modelled conservatively with the aim of bounding all reasonably foreseeable uncertainties.

15.5 Baseline Environmental Characteristics

a) Introduction

15.5.1 This section describes the groundwater baseline for the proposed HPC Development Site. Further details regarding baseline groundwater chemistry can be found at **Appendices 15E** and **15F**.

b) Study Area Description

i. Historical and Current Land-use

15.5.2 The HPC Development Site is generally open countryside, primarily in agricultural use (mixed pasture and arable) with some areas of woodland and minor development associated with the current nuclear installations within the BDAE. Adjacent land use (to the south and west) is also primarily agricultural with the exception of the Hinkley Point Power Station Complex to the east.

15.5.3 A review of historical maps and plans has identified that both the BDAW and SCPA have remained as greenfield agricultural land since the earliest available map was published in 1886. A farm (named Benhole Farm) was located in the north-western part of the BDAW until around 1976 when it was demolished to leave a single remnant outbuilding which is still present on site, along with two other derelict farm buildings.

15.5.4 The BDAE was historically undeveloped, agricultural land until the late 1950s when areas of the site were used for construction and fabrication of the adjacent Hinkley Point A (HPA) station. The activities carried out at this time included materials storage, spoil disposal, a contractor’s accommodation area with associated above ground storage tanks and boiler houses, and a small sewage works.

15.5.5 Later in the 1970s a further accommodation camp and associated electricity substations were constructed within the south eastern portion of the BDAE (using the same locations as the HPA accommodation area) during the construction of Hinkley Point B (HPB).

15.5.6 By 2005 the accommodation camp no longer existed and a visitor centre for the Hinkley Point Power Station (subsequently the British Energy induction centre) had opened on the eastern area.

15.5.7 Further details on current and historical land use are provided in **Volume 2, Chapter 14.**

ii. Topography and Drainage

15.5.8 The topography of the study area generally comprises undulating countryside, terminating at Bridgwater Bay to the north at a natural cliff line which descends to a shingle beach.

15.5.9 Across the BDAW and BDAE ground elevations range from approximately 10 to 35mAOD and across the SCPA ground elevations range from approximately 5 to 28mAOD (**Figure 15.3**).

15.5.10 Within the BDAW and SCPA are a series of east-west trending ridges and depressions. The lowest terrain within the study area is formed by an east-west trending linear depression which runs along the boundary between the SCPA and the BDAW. The base of the depression is occupied by a drainage ditch at an elevation ranging from 4.1 to 5.1mAOD.

15.5.11 North of this depression, within the BDAW, the ground rises sharply towards a ridge that crests at a maximum elevation of 35.3mAOD. North of the ridge, the topography comprises a series of east-west trending undulations and the ground generally falls towards the north before it is intercepted by the path of an agricultural drainage ditch (Hinkley Point C Drainage Ditch), which runs from west to east before changing course to head north towards the coastline, along the boundary of the BDAW and BDAE. To the north of the east-west trending length of the drainage ditch the land rises at a moderate gradient from around 19 to 22mAOD and then gently falls again to the coastline. Elevations near the cliff edge adjacent to the BDAW are typically around 15mAOD. In the north-eastern area of the BDAW the ground surface dips and a lower elevation along the cliff line is maintained through the BDAE area (ranging from 10.7 to 13.3mAOD).

15.5.12 Within the SCPA the gently undulating ground continues from the depression referred to above with the land gently rising to around 5.8mAOD and then increasing in gradient to a maximum of between 21.1 and 24.8mAOD. The land then gently falls towards the south where elevations typically range between 15 and 16mAOD adjacent to Bum Brook. A small hillock is located towards the south-west corner of the SCPA where the land crests at an elevation of 28.7mAOD.

15.5.13 The topography of the BDAE comprises areas of variable relief. The southern boundary of the BDAE is occupied by higher ground peaking at 26.2mAOD. The relief then falls northwards and levels out with a large proportion of the area lying at elevations ranging between 14mAOD and 16mAOD. The double-humped spoil mound on the BDAE reaches elevations of 21m and 24mAOD. As part of the enabling works a large proportion of the mound will be removed.

15.5.14 A number of surface watercourses are present within the study area. Holford Stream runs west to east within the northern part of the SCPA. This watercourse flows under Wick Moor Drove and drains into Wick Moor to the east. There are also a series of agricultural drainage ditches present on site, running along field boundaries. Two drainage ditches are present on the BDAW, one running west to east along a field boundary in the northern part of this land parcel before turning northwards towards the coastline (Hinkley Point C Drainage Ditch, as referred to above). The other drains west to east at the base of the depression along the boundary of the BDAW and SCPA.

15.5.15 **Figure 15.4** shows the main surface watercourses around Hinkley Point (these are described fully in **Volume 2, Chapter 16**). It is likely that some of the watercourses are originally structurally controlled, with those flowing west to east following the trends of the strike faults and fold axes, and those flowing south-west to north-east following structures parallel to the Hinkley Point Fault (as well as merely following the topography to the Bristol Channel). It appears that one of these streams (Bayley's Brook, joining Bum Brook) may follow an unmarked extrapolation of the Hinkley Point Fault.

15.5.16 Given the topography, geology and groundwater flow regime (see below) it is likely that the surface watercourses are in at least partial hydraulic continuity with the groundwater, probably with substantial groundwater contributions to baseflow and possible groundwater recharge in places. Streams from the south of Stogursey running off the Mercia Mudstones some 2km to the south of the Hinkley Point Development Site could contribute to groundwater recharge under some circumstances (during low water table conditions).

15.5.17 Rainfall recharge provides the principal input to the groundwater regime. Discharges from the groundwater regime can occur as springs at outcrops of lower permeability strata, where the water table intersects the surface (onshore or offshore), and also as baseflow to surface watercourses.

iii. Geology

15.5.18 A summary of the lithostratigraphical sequence identified within the study area is provided in **Table 15.4** and further described below.

Table 15.4: Lithostratigraphical Sequence for Rocks Identified within the Study Area.

Stage and Formation			'Up-to' Thickness (m)	Lithology
Lower Lias	Blue Lias (including the Angulata and Lower Liasicus Zones)		140	Alternation of shale/mudstone/limestone/mudstone sequences
Penarth Group	Lilstock Fm	Langport Member	2	Pale grey limestones with interbedded grey to bluish grey mudstones
		Cotham Member	2	Pale grey to greenish grey calcareous mudstones, limestones, siltstones and sandstones
	Westbury Fm		14	Very dark shaly mudstones and dark grey argillaceous limestones
Mercia Mudstone Group	Blue Anchor Fm		38	Thin dark grey mudstone beds and green to greenish grey mudstone and siltstone beds. Some are dolomitic in part.
	Undifferentiated		484	Upper units are reddish brown mudstones and siltstones (occasionally greenish grey) with halite, gypsum and anhydrite as minor components

Note: *Fm = Formation*

15.5.19 **Figure 15.4** shows geological information generated using the electronic British Geological Survey 1:50,000 scale published geological map which includes the HPC Development site. **Figure 15.5** shows the transect location plan and the lines of section are presented in detail in **Figures 15.6** and **15.7**, which are south-north cross-sections illustrating the principal features of the geology across the BDAW.

15.5.20 **Figure 15.4** and the BGS map sheet (Ref. 15.26) show that the areas to be occupied by the proposed site preparation works and deep excavations are underlain mostly by strata of the Jurassic Lower Lias. Between the BDAW and the SCPA is a faulted inlier of older Permo-Triassic strata of the Penarth Group, the Blue Anchor Formation, and Mercia Mudstones (the Penarth and Blue Anchor strata are essentially transitions between the red mudstones of the Mercia Mudstone Group and the Lower Lias).

15.5.21 An onshore investigation (Ref. 15.32) as detailed in **Chapter 14** of this volume) shows that there is a further likely fault north of those shown on the 1:50,000 scale published map. This brings another outcrop of Penarth Group strata within the study area as shown in the cross-section in **Figures 15.6** and **15.7**, with the postulated fault lying at about northing 145630 between boreholes CBH29 and CBH12 (Ref. 15.31).

15.5.22 The Lower (Blue) Lias consists of grey mudstone with varying proportions of dark blue-grey limestone. This tends to be well-jointed and the limestone layers provide groundwater-bearing material even though the Lias as a whole is not considered to be a significant aquifer. **Figure 15.8** shows the typical appearance of the strata at outcrop along the foreshore to the north of the HPC Development Site.

15.5.23 The Lower Lias overall is up to 175m in thickness, although only the lower sections are present at Hinkley Point, consisting of mudstones and shales with thin, nodular limestones and alternating limestones and shales.

15.5.24 Below the Lias, and outcropping in a band running across the site and briefly at the southern margin of the site, the Penarth Group generally comprises dark limestones and mudstones. It is subdivided into the upper Lilstock Formation (itself subdivided into the Langport and Cotham Members) and the Westbury Formation. The Lilstock formation is less than 4m in thickness, with the Langport Member consisting of interbedded limestone and mudstone and the Cotham Member being predominantly a grey/green calcareous mudstone. The Westbury Formation comprises over 10m of dark grey shaly mudstone with argillaceous limestone.

15.5.25 The Blue Anchor Formation consists of grey and green mudstone with minor limestone and dolomite, formerly known as the Grey Marl and Tea Green Marl at the top of the Mercia Mudstones. Veins and nodules of gypsum (hydrated calcium sulphate) are present.

15.5.26 The Mercia Mudstone Group comprises a thick sequence (over 400m) of red mudstone, sometimes silty or dolomitic and containing evaporite minerals including gypsum and halite (sodium chloride).

15.5.27 In places, and particularly in the areas around the villages of Shurton and Burton south of the site, the Lias is covered with Head, a poorly sorted sandy and silty periglacial weathering product which forms a mantle around 1m to 2m thick. The stream courses of Holford Stream and Bum Brook are infilled with alluvium, as is the expanse of Wick Moor to the south-east of the HPA and HPB stations. The latter comprises estuarine and marine alluvium rather than terrestrial material.

15.5.28 **Figure 15.4** shows the Hinkley Point Fault oriented northeast-southwest passing under the HPA and HPB sites and running past the south-east corner of the HPC Development Site. The Penarth Group/Mercia Mudstone inlier is fault-bounded, and the Lower Lias is subject to flexures, with east-west synclinal and anticlinal fold axes crossing the HPC Development site (which may be faulted locally).

15.5.29 The geological sheet memoir (Ref. 15.27) refers to general dips of strata in a direction just east of north at angles of 5–10 degrees.

15.5.30 The geological structure and its implications for the groundwater assessment are addressed in the conceptual model section (see Section 15.5).

iv. Hydrogeology

15.5.31 The baseline hydrogeology of the study area and its immediate surroundings is described in terms of:

- aquifers and aquifer characteristics;
- groundwater levels and flow;
- rainfall recharge;
- groundwater – surface water interactions;
- groundwater use; and
- groundwater quality.

15.5.32 In the following text, each of the above aspects of hydrogeology is described as appropriate, and data from current investigations is distinguished from data from past investigations. The adequacy and relevance of past data have been reviewed and if necessary included in the limitations, assumptions and uncertainties section of this chapter (Section 15.4 e).

Aquifer Characteristics - General

15.5.33 Groundwater flow in the Blue Lias Formation occurs predominantly via bedding planes, joints and fractures in the more competent limestone horizons within the formation. Rocks of the Penarth Group, especially the mudstone and limestone of the Westbury Formation (the lower component) are considered to be generally impermeable, although locally this may vary (see actual test results below) and in particular fault and fracture zones in the Lilstock Formation (the upper 4m of the Penarth approximately) may have higher permeability and transmissivity, albeit the latter is limited by formation thickness. The mudstones of the Mercia Mudstone Group (including the Blue Anchor Formation) are likely to be of very low permeability.

15.5.34 Until March 2010 aquifers were designated as Major, Minor or Non-aquifers, and these designations indicated spatially on 1:100,000 scale Groundwater Vulnerability Maps by the Environment Agency together with information on the leaching potential of the superficial soils. The Groundwater Vulnerability Map (Sheet 42) for the Somerset Coast indicates the HPC Development Site as being situated on a Minor Aquifer (variably permeable). The distribution of the designated groundwater units is shown on **Figure 15.9**. Under this previous aquifer classification system, the Blue Lias formation, which outcrops over most of the area, was designated as a Minor Aquifer, with varying degrees of leaching potential due to presence of drift deposits. The Penarth and Mercia Mudstone formations were designated as Non-Aquifers.

15.5.35 In April 2010, new aquifer designations (details of which are available on the Environment Agency website) were introduced to comply with the requirements of the Water Framework Directive, as follows (see **Figure 15.10**):

- Principal (generally equivalent to Major Aquifers): Layers of rock or drift deposits that have high intergranular and/or fracture permeability – meaning they usually provide a high level of water storage. They may support water supply and/or river base flow on a strategic scale.
- Secondary A (generally equivalent to Minor Aquifers): Permeable layers capable of supporting water supplies at a local rather than strategic scale, and in some cases forming an important source of base flow to rivers. It should be noted that this is a generic definition and the last point does not apply to conditions at Hinkley Point.
- Secondary B (generally equivalent to water-bearing parts of Non-Aquifers): Predominantly lower permeability layers which may store and yield limited amounts of groundwater due to localised features such as fissures, thin permeable horizons and weathering.
- Unproductive: These are rock layers or drift deposits with low permeability that have negligible significance for water supply or river base flow.

15.5.36 The Blue Lias is now Secondary A aquifer under the new classification system, and the similar lithologies of the Lilstock Formation of the Penarth Group are also likely to be Secondary A. The Westbury, Blue Anchor and Mercia Mudstones are Secondary B due to their low yield.

15.5.37 River alluvium in the Holford Stream valley is designated as Secondary A, and the marine alluvium to the south and east of Hinkley Point A and B (North Moor, Wick Moor etc) is designated as Secondary Undifferentiated, meaning it is not definitively attributable to either Secondary A or B.

15.5.38 The published Groundwater Vulnerability maps on which **Figure 15.9** is based are still valid for the definition of soil leaching potential, which is not covered by the new aquifer definition maps.

15.5.39 The lower boundary on the major active groundwater regime in the area may be the base of the Lilstock Formation of the Penarth Group, possibly less than 4m below the base of the Blue Lias.

Aquifer Characteristics - Previous Studies

15.5.40 Allott Atkins Mouchel Power Consultants (1988) (Ref. 15.29) and Aspinwall & Company (1996) (Ref. 15.30) contain extensive sections on hydrogeology and conceptualisation which are relevant to this assessment.

Hinkley Point A

15.5.41 With respect to the area occupied by the HPA station, tests reported by Foundation & Exploration Services Ltd (1989) (Ref. 15.34) provided permeability data for the Blue Lias derived from constant head, single packer and double packer tests in three boreholes, all sited immediately to the west of the Hinkley Point A turbine hall and reactor buildings and so fairly close to the shoreline. The logs are not geologically interpreted, and all the tests are in lithologies comprising mostly mudstones with some crystalline limestone bands. These tests gave ranges as shown in **Table 15.5**.

Table 15.5: Blue Lias Permeability Values from Hinkley Point A

Borehole	Depth (m bgl)	Method	Permeability (m/s)
GW1	10^{-13}	Constant head	9.8×10^{-7}
	17^{-21}	Double packer	2×10^{-6}
	27^{-31}	Double packer	<1 x 10-7 (no flow)
	43^{-47}	Single packer	$<7.5 \times 10^{-8}$ (no flow)
GW2	4^{-7}	Constant head	3×10^{-6}
	16^{-21}	Double packer	2×10^{-7}
	33^{-37}	Double packer	6×10^{-7} (no flow)
	48^{-52}	Double packer	$<7 \times 10^{-7}$
	65^{-70}	Double packer	$<9.5 \times 10^{-8}$
	75^{-79}	Double packer	$<7.5 \times 10^{-7}$
	80^{-84}	Single packer	$<8 \times 10^{-8}$ (no flow)
GW3	21^{-25}	Double packer	$<1 \times 10^{-7}$ (no flow)
	60^{-64}	Double packer	$<6.5 \times 10^{-7}$
	64^{-67}	Single packer	3×10^{-6}

15.5.42 The tabulated data show that permeability values are low to very low and generally decrease with depth in GW1 and GW2. In GW3 the data show an apparent increase in permeability with depth, although these types of tests are not very reliable for groundwater model scales since they sample a very localised volume of 'aquifer' which may be disturbed by the drilling process, and are subject to generally low test flows.

15.5.43 Because fractured limestone forms a small part of the Blue Lias, unless the testing was specifically targeted, these results may under-represent the few thin bands of high permeability that probably provide the bulk of the transmissivity.

Hinkley Point B

15.5.44 Rising head tests carried out by Foundation Engineering Ltd (1979) (Ref. 15.35) exhibited permeability values between 4.3×10^{-3} and 2.06×10^{-7}m/s; packer tests exhibited values between 0 and 4.79×10^{-5}m/s.

Hinkley Point C (former CEGB proposed PWR station)

15.5.45 Royal Haskoning (2009) (Ref. 15.36) summarised aquifer properties recorded in previous studies such as Aspinwall & Company (1996) (Ref. 15.30).

15.5.46 Aspinwall (Ref. 15.30) reported that permeability tests were undertaken in boreholes at Hinkley Point during the investigation by Soil Mechanics (1990) and by Norwest Holst (1983/84). These tests were carried out for different depth ranges. The average hydraulic conductivity (K) values calculated from the results of this test ranged from 10^{-6}m/s to 10^{-5}m/s.

15.5.47 Values of hydraulic conductivity (K) at shallow depths range from 10^{-6} to10^{-4}m/s, whereas below this zone the aquifer is described as being only slightly permeable, with K values reported to range from 10^{-8} to 10^{-7}m/s. As flow at depth is restricted, discharge to Bridgwater Bay and the Bristol Channel occurs by upward vertical movement through mudstone horizons via fractures (Aspinwall & Company, 1996) (Ref. 15.30).

15.5.48 As vertical groundwater movement is restricted by the lower permeability mudstones and shales, the aquifer is considered to be under semi-confined to confined conditions. As such, the aquifer has low storage coefficients ranging from 0.001 to 0.00008, which are reported to be typical of semi-confined to confined conditions (Aspinwall & Company, 1996) (Ref. 15.30).

15.5.49 The BGS Physical Properties of Minor Aquifers in England and Wales (Ref. 15.37) reports that six analyses from outcrop samples at Hinkley Point gave porosities ranging from 1.9% to 3.1%.

Aquifer Characteristics - Current Studies

Built Development Area West

15.5.50 **Table 15.6** shows permeability summaries from Lugeon (packer) Testing carried out in the BDAW by Structural Soils Ltd (SSL) on behalf of EDF Energy (Ref. 15.31)

Table 15.6: Indicative Permeabilities for Different Formations in BDAW from Lugeon Testing

Formation	Minimum (m/s)	Maximum (m/s)
Blue Lias 0-20m	$1.89x10^{-6}$	$1.61x10^{-5}$
Blue Lias 20-40m	$1.16x10^{-7}$	$1.25x10^{-5}$
Blue Lias >40m	$5.00x10^{-9}$	$7.15x10^{-7}$
Lilstock (Penarth Group)	$2.00x10^{-7}$	$4.50x10^{-7}$
Westbury (Penarth Group)	$4.19x10^{-7}$	$2.51x10^{-6}$
Blue Anchor Formation	$4.75x10^{-8}$	$6.11x10^{-6}$
Mercia Mudstone Group	$5.35x10^{-6}$	$8.59x10^{-6}$

15.5.51 A pumping test (PT1), with twelve piezometers arranged in a cruciform pattern, was conducted close to boreholes CBH13 and CBH16, at a discharge of 3l/s for four days in July 2010 (**Figure 15.11**). The tested section comprised about 14m of grey mudstone, belonging to the (weathered) Blue Lias and the top of the Lilstock Formation. In the first hour, drawdowns fell steadily in the pumping well and piezometers as expected for a confined aquifer, after which barrier boundary effects were observed, which probably correspond to the cone of depression intersecting one of the faults referred to earlier or the physical limit of the aquifer in the up-dip direction. After about a day of pumping, drawdown increased dramatically in the pumped well but not so much in the piezometers, suggesting that a major water producing fissure had been dewatered (about 5m below the top of the screen). As a consequence the discharge declined to only 2l/s by the end of the test. After pumping the well recovered to its pre-test level after about 10 days.

15.5.52 The transmissivity of the aquifer close to the well was estimated at about $80m^2/d$ ($9.3x10^{-4}m^2/s$), and permeability of $6.6x10^{-5}m/s$, and a storage coefficient of $2.0x10^{-4}$. The response was anisotropic and complex, with an apparent K (E-W):K (N-S) ratio of 1.3:1 indicating a slightly enhanced permeability perpendicular to the strata dip direction (i.e. along the strike) compared to that along the dip. Further details of the pumping test analysis are contained in **Appendix 15A**.

15.5.53 A second pumping test (PT2), also with twelve piezometers in a cruciform pattern, was conducted close to borehole CBH2_07, and about a hundred metres from the cliff line (**Figure 15.11**). The test was conducted at a discharge of 1.5l/s for four days. The tested section comprised about 13m of dark grey mudstone with about (at CBH2_07) a dozen interbedded limestone bands, of which none exceeded 0.5m, belonging to the Blue Lias Formation. For the first 12 hours, the response to pumping in the piezometers and pumping well approximated to the expected theoretical response of a confined aquifer, but later the rate of drawdown increased rapidly, displaying a classic barrier boundary response, suggesting the cone of depression had intersected a fault (faulting is not included in the numerical model explicitly because of uncertainty over its behaviour - barrier boundaries in the system are known to exist but their extent and their hydraulic properties are not known so the model has assumed (conservatively) their absence). The increase in drawdown in the pumping well is even greater because after about two hours the water level had fallen below the top of the screened section of the borehole. On the final day of the pumping test, the pumping water level dropped further, apparently due to dewatering of important fissures.

15.5.54 Interpretation of the results (see **Appendix 15A**) indicates an anisotropic confined aquifer with a transmissivity of about $40m^2/d$ ($4.6x10^{-4}$ m^2/s) and permeability of $3.6x10^{-5}$ m/s in the east-west direction, and about $20m^2/d$ (permeability of $1.8x10^{-5}$ m/s) in the north-south direction, indicating a more pronounced horizontal anisotropy than the test in the BDAW, at about 2:1. A storage coefficient of 1.0E-04 was inferred. It should be noted that the pumping test permeabilities are calculated from the length of the response zone, whereas flow will occur predominantly through the jointed limestones, and hence the actual permeability of the active aquifer horizons is probably about five to eight times higher.

15.5.55 In both of the four-day pumping tests described above, the recovery of water levels was incomplete, by the order of half a metre to a metre, after ten days of recovery. This behaviour is consistent with the hypothesis that the aquifer is divided into fault-bounded blocks with restricted flow between the blocks delaying the recharge of the aquifer in the vicinity of the pumping test.

Built Development Area East

15.5.56 **Table 15.7** summarises the results of Lugeon Testing of permeability carried out in the BDAE by SSL on behalf of EDF Energy.

Table 15.7: Indicative Permeabilities for Different Formations in BDAE from Lugeon Testing

Formation	Minimum (m/s)	Maximum (m/s)
Blue Lias 0-20m	$1.13x10^{-6}$	$1.70x10^{-5}$
Blue Lias 20-40m	$5.16x10^{-7}$	$6.82x10^{-6}$
Blue Lias >40m	$3.43x10^{-7}$	$2.33x10^{-6}$
Lilstock (Penarth Group)	$2.00x10^{-7}$	$7.36x10^{-7}$
Westbury (Penarth Group)	$1.87x10^{-7}$	$1.26x10^{-6}$
Blue Anchor Formation	$2.78x10^{-7}$	$2.57x10^{-6}$
Mercia Mudstone Group	$3.00x10^{-7}$	$6.00x10^{-7}$

Southern Construction Phase Area

15.5.57 There are no specific data available for aquifer properties on the SCPA. Monitoring boreholes on the SCPA were not cored so no packer testing was carried out. However, the geological information presented in **Figure 15.4** shows that the underlying geology also comprises Lias Group (predominantly represented by the Blue Lias) strata and so it is anticipated that permeability and storage values will show a similar range to equivalent strata elsewhere on Hinkley Point.

Horizontal and Vertical Anisotropy

15.5.58 As mentioned above in respect of the pumping tests, there appears to be a difference between east-west horizontal permeability and north-south horizontal permeability. This was observed from the distance-drawdown characteristics from the variably aligned observation piezometers. The ratio between K E-W and K N-S has been estimated to be between 1.3:1 and 2:1. Higher permeabilities in the east-west direction are related to alignments of joint sets and extensional characteristics of fold and flexure structures. This will have the effect (during pumping) of a preferential flow contribution along the strike of the strata compared to up and down dip.

15.5.59 Vertical anisotropy is difficult to measure, but must be a key characteristic of the Blue Lias Formation, as can be inferred from the layering of mudstones and limestones, and the observed lack of continuity of joints between successive limestone horizons. Moreover, the matrix of the mudstone will be intrinsically anisotropic due to the compaction of clay minerals. An estimate of the vertical anisotropy can be obtained from the proportions of limestone to mudstone, and assuming that vertical permeability is approximated by the minimum Lugeon values where packer tests are conducted against mudstone horizons only. Using the equations in Anderson & Woessner (Ref. 15.38) the following Kh:Kv ratios for the various formations are estimated (more details are provided in **Appendix 15B**):

Table 15.8: Indicative Kh:Kv ratios

Formation	Kh:Kv ratio (vertical anisotropy)
Weathered Blue Lias	800
Fresh Blue Lias	120
Lilstock	5
Westbury	100
Blue Anchor	5

15.5.60 The value of 800 for Weathered Blue Lias is very high but is based upon the available permeability data and heterogeneity of the Blue Lias and in accordance with the equations used. However, it is not implausible given the lithology and structural fabric of the formation, and still leaves a vertical permeability about an order of magnitude higher than the vertical permeability in the Fresh Blue Lias.

15.5.61 Localised exceptions to this pattern of high vertical anisotropy will occur along open fault zones, such as encountered at CBH2_29 (**Figure 15.12**). Given that ultimately groundwater levels are controlled by discharge to sea, there must be physical mechanisms for this to occur, so such fault zones are also likely in the areas of groundwater discharge in the Bristol Channel (details unknown) to allow for upward flow from the deeper Blue Lias and lower formations.

Groundwater Levels and Flows

Built Development Area West

15.5.62 Groundwater levels, both strikes and static water levels, were recorded during the Structural Soils Limited investigation (Ref. 15.31) and piezometers (24 in total) have subsequently been monitored. Twenty of the 24 piezometers were installed with response zones to target the 'shallower' groundwater in the Blue Lias, Penarth Group and/or Mercia Mudstone. Four of the 24 piezometers were installed with response zones to target the deeper groundwater in the Blue Anchor and/or Blue Lias. For the purposes of this EIA 'shallow groundwater' is generally that groundwater (and predominantly within the Blue Lias Formation) which is present between 0 and 30mbgl. 'Deeper' groundwater is groundwater (predominantly in the Blue Anchor Formation) at depths >30mbgl. This does not necessarily mean that the groundwater is discontinuous between the two levels of 'shallow' and 'deep' (although it is stratified to some extent) but indicates the depth at which response zones were installed. **Table 15.9** below summarises the response zone depth, formation, and aquifer targeted. Dataloggers have been installed in selected boreholes (see **Table** 15.9) as part of the environmental studies undertaken by AMEC for EDF Energy. The locations of the 'shallow' piezometers are shown on **Figure 15.12** and **Figure 15.13**.

Table 15.9: Summary of BDAW Piezometer Response and Formation Zones

Piezometer	Formation/Aquifer Targeted	Ground Level (mAOD)	Response Zone Depth (m bgl)	Aquifer Targeted ('shallow or 'deep')
DBH04	Penarth Group	26.06	12.0 – 19.00	'Shallow'
DBH05	Penarth Group	22.24	14.00 – 19.00	'Shallow'
DBH06	Blue Lias	15.66	4.50 – 19.50	'Shallow'
DBH07	Blue Lias	13.28	5.00 – 12.00	'Shallow'
DBH08	Blue Lias	17.78	5.50 – 20.00	'Shallow'
DBH09	Blue Lias	17.22	6.00 –16.00	'Shallow'
DBH10	Blue Lias	19.94	6.50 –14.50	'Shallow'
DBH11	Blue Lias	16.1	7.00 – 17.00	'Shallow'
CBH09	Blue Anchor	13.16	39.00 – 45.00	'Deep'
CBH10	Blue Lias	18.01	5.00 – 13.00	'Shallow'

Piezometer	Formation/Aquifer Targeted	Ground Level (mAOD)	Response Zone Depth (m bgl)	Aquifer Targeted ('shallow or 'deep')
CBH11	Blue Lias	17.75	30.00 – 40.00	'Deep'
CBH16	Blue Anchor	11.05	41.50 – 48.50	'Deep'
CBH17	Blue Lias	15.86	5.00 – 15.50	'Shallow'
CBH18	Blue Lias	15.27	23.00 – 33.00	'Shallow'
CBH19	Blue Lias	9.86	7.50 –14.50	'Shallow'
CBH20	Blue Lias	10.93	5.00 – 17.50	'Shallow'
CBH21	Blue Lias	19.48	3.50 – 15.00	'Shallow'
CBH24	Blue Lias	17.81	3.50 –18.50	'Shallow'
CBH25	Blue Lias	21.05	4.00 –17.00	'Shallow'
CBH26	Blue Lias	15.67	20.50 – 31.00	'Shallow'
CBH27	Blue Lias	18.93	6.50 – 12.50	'Shallow'
CBH29	Blue Anchor	22.18	41.00 – 55.00	' Deep'
CBH33	Blue Lias	14.67	5.00 –11.00	'Shallow'
CBH35	Mercia Mudstone	13.17	7.50 –11.50	'Shallow'

15.5.63 Summaries of manual observations made during groundwater sampling and subsequently, and hydrographs for the available records for the datalogger-equipped 'shallow' Blue Lias boreholes up to November 2010 are contained in **Appendix 15C**. Minimum observed levels were usually reached as late as November in 2009 after the summer recession, but during July and August in 2010 which overall was a much drier year (see **Figure 15.16**). Maxima in 2009 tended to occur around the end of November after the very heavy November rain (see below), although levels in some boreholes continued to rise into January 2010. **Table 15.10** shows observed minimum and maximum shallow Blue Lias water levels. Nominal low and high water levels maps for the BDAW are contoured in **Figure 15.12** and **Figure 15.13** for 1 August 2010 and 1 December 2009 respectively. A site-wide groundwater level map covering the BDAW and areas beyond is also included as **Figure 15.15**.

15.5.64 Hydrographs from the shallower Blue Lias piezometers (**Appendix 15C**) can be interpreted in accordance with the rainfall hydrograph (**Figure 15.16**). Water tables rise in response to sustained winter rainfall and then fall away again as recharge declines. Rainfall periods in spring and summer do not show a groundwater response because available recharge is taken up by the increasing soil moisture deficit and does not reach the unsaturated zone or the water table. The soil moisture deficit is only reversed at the end of October when recharge can start again. In 2010, the recession continued to the end of the available hydrograph records.

15.5.65 The main groundwater flow regime within the BDAW is controlled by local rainfall recharge. In general, groundwater flow is from south to north, from outcrop recharge to discharge offshore, although the watercourse crossing the HPC site from west to east and then turning north to the shoreline (Hinkley Point C Drainage Ditch) clearly receives some groundwater baseflow and can be seen from **Figure 15.12** and **Figure 15.13** to exert some control on local groundwater levels. The valley topography of this watercourse drainage also results in a zone of artesian conditions (see **Figure 15.12** and **Figure 15.13**) where, at high groundwater levels during winter, heads in the shallow Blue Lias piezometers can be several metres above surface elevation. Boreholes exhibiting these characteristics include CBH16, CBH19, CBH20, CBH33 and DBH11. In summer, after groundwater recession, levels in these artesian boreholes recede to ground elevation or just below. It is the topographic ‘low’ due to the small valley that causes these artesian or sub-artesian conditions.

15.5.66 Average general gradient from the groundwater contours is around 0.02 (1 in 50) but varies in detail with the level condition and the location within the BDAW.

Table 15.10: 2009/2010 Minimum and Maximum BDAW ‘Shallow’ Borehole Groundwater Levels

Borehole	Ground level (mAOD)	Minimum groundwater levels (m AOD)	Maximum groundwater levels (m AOD)	Difference (m)
CBH10	18.01	9.01 (19/7/10)	16.87 (29/11/09)	7.86
CBH17	15.86	6.50 (18/7/10)	15.36 (3/12/09)	8.86
CBH19	9.86	9.01 (11/5/10)	11.83 (4/7/09)	2.82
CBH21	19.48	9.21 (9/8/10)	15.23 (29/11/09)	6.02
CBH24	17.81	8.63 (8/8/10)	15.29 (29/11/09)	6.66
CBH25	21.05	13.49 (5/11/10)	20.37 (22/1/10)	6.88
CBH26	15.67	9.72 (23/7/10)	14.41 (29/1/10)	4.69
CBH27	18.93	10.32 (15/8/10)	17.32 (29/11/10)	7.00
CBH33	14.67	10.02 (13/8/10)	16.38 (11/2/09)	6.36
DBH06	15.66	7.38 (19/7/10)	12.93 (29/11/09)	5.55
DBH07	13.28	8.90 (21/7/10)	13.00 (24/11/09)	4.10
DBH08	17.78	7.59 (19/7/10)	14.25 (28/11/09)	6.66
DBH09	17.22	7.78 (3/8/10)	16.35 (10/2/09)	8.57
DBH10	19.94	11.67 (21/8/10)	17.37 (29/11/09)	5.70
DBH11	16.1	10.40 (8/8/10)	16.39 (29/11/09)	5.99

15.5.67 CBH20 values are not clear from the hydrograph (**Appendix 15C**), possibly due to irregularities from sampling events (removal of loggers, recovery from sample pumping, etc).

15.5.68 Piezometer pairs exhibit apparent vertical head differences (and therefore potential vertical groundwater flow components). The differences in gradient can be in either upward (e.g. CBH18 to DBH06) or downward (DBH07 to CBH09). In other cases where the deeper borehole is highly saline the apparent head difference can be due to density effects where the saline water is heavier and results in a depressed groundwater level as a result (when the density effect is removed the revised equivalent fresh water head can be up to several metres higher than that observed; for example in the case of CBH16 which contains hypersaline water with a total dissolved solids content of up to 150,000mg/l the corrected freshwater head is some 5m higher). Vertical differences otherwise are likely to be due to local characteristics of recharge and groundwater flow.

15.5.69 With respect to vertical gradients where the deeper borehole contains highly saline water, e.g.CBH16, this reflects the isolation from the active groundwater regime of this deeper water and explains why the hypersalinity has been preserved (see also paragraph 15.5.122).

15.5.70 There is not enough groundwater data from boreholes in the Blue Anchor Formation and Mercia Mudstone Groups to form reliable contours. However, groundwater/piezometric levels are all substantially lower than the Blue Lias levels, typically by around 6-8m. Therefore there is no evidence of a tendency for any upward groundwater flow into the Blue Lias from deeper formations, and no apparent substantial hydraulic continuity between the Blue Lias and either the Blue Anchor or Mercia Mudstone Groups.

Built Development Area East

15.5.71 Groundwater levels for the BDAE were obtained during the latter half of 2010 from the onshore investigation programme to augment what had already been undertaken on the BDAW. **Table 15.11** summarises the piezometer information for boreholes within the BDAE, and the locations are shown on **Figure 15.14**. In accordance with the distinction between ‘shallow’ and ‘deep’ piezometers identified for the BDAW above in **Table 15.9**, the BDAE targets are generally ‘shallow’, although CBH2_18, CBH2_29 and DBH2_7 have response zones extending below 30m depth and could be regarded as transitional. Hydrographs for the available data are included in **Appendix 15C**. It should be noted that the BDAE data was only available to December 2010 prior to groundwater modelling commencing, whereas the hydrographs at **Appendix 15C** show more recent data.

Table 15.11: Summary of BDAE Piezometer Response and Formation Zones

Piezometer	Ground level (mAOD)	Formation/Aquifer Targeted	Response Zone Depth (m bgl)
CBH2_18	16.36	Blue Lias	23.5-36.3
CBH2_28	18.77	Blue Lias	8.5-12.5
CBH2_29	15.55	Blue Lias	25.5-37.5
CBH2_30	12.08	Blue Lias	3.2-13.6
CBH2_33	24.31	Blue Anchor	25.5-40.0
CBH2_49	25.33	Blue Lias	9.5-22.0
CBH2_53	15.57	Blue Anchor	42.0-54.5
CBH2_54	13.86	Blue Anchor	81.0-89.5
DBH2_7	15.42	Blue Lias	25.5-34.7
DBH2_8	15.47	Blue Lias	1.5-14.5
DBH2_9	17.73	Blue Lias	5.0-15.5
DBH2_10	15.61	Blue Lias	4.7-13.8
DBH2_11	20.26	Blue Lias	1.0-11.0
DBH2_12	6.33	Blue Lias	3.5-11.5
DBH2_17	16.67	Blue Lias	1.5-5.5
DBH2_26	10.93	Blue Lias	4.0-12.0
DBH2_19	24.51	Blue Lias	2.4-13.0

Piezometer	Ground level (mAOD)	Formation/Aquifer Targeted	Response Zone Depth (m bgl)
DBH2_20	15.88	Blue Lias	4.5-14.5
DBH2_21	1.65	Blue Lias	4.75-15.25
DBH2_22	14.24	Blue Lias	3.5-13.0
DBH2_23	17.18	Blue Lias	2.0-14.5
DBH2_24	13.61	Blue Lias	2.5-14.5
DBH2_27	11.28	Blue Lias	2.8-15.3

15.5.72 The groundwater flow regime indicated for the BDAE is consistent with that previously determined for the BDAW, with a general flow from south to north. A site wide piezometric map (**Figure 15.15**) has been developed which includes these data (along with all other contemporaneous data where possible) and this is described separately below.

Southern Construction Phase Area

15.5.73 Groundwater levels for the SCPA have been obtained during the latter half of 2010 from the onshore investigation programme. **Table 15.12** summarises the piezometer information for boreholes within the SCPA, and the locations are shown on **Figure 15.14**. The records are not long enough for groundwater level minima, maxima and ranges to be defined.

Table 15.12: Summary of SCPA Piezometer Response and Formation Zones

Piezometer	Formation/Aquifer Targeted	Response Zone Depth (m bgl)
DBH2_13	Blue Lias	3.5-13.5
DBH2_14	Blue Lias	3.5-13.5
DBH2_15	Blue Lias	1.0-13.5
DBH2_16	Blue Lias	1.0-11.5
DBH2_18	Blue Lias	3.5-13.5

15.5.74 The groundwater flow regime indicated for the SCPA is tentatively identified on the site wide piezometric map described separately below (**Figure 15.15**).

15.5.75 Hydrographs for boreholes within the SCPA are provided in **Appendix 15C**. There is, however, an insufficient duration of available records to date to enable meaningful maxima and minima to be stated, since the record starts after the likely minimum and does not yet show the winter recharge response.

Hinkley Point A

15.5.76 SERCO (2010) (Ref. 15.39) describes groundwater levels for January 2009 consistent in general with the flow regime on the HPC Development Site. The gradient under Hinkley Point A is around 0.03, falling from 12mAOD in the south of the Hinkley Point A site to 4mAOD in the north adjacent to the foreshore.

Overall Hinkley Groundwater Flow Regime

15.5.77 **Figure 15.15** is a site-wide groundwater level map based on observation data, where available, and extrapolation by professional judgement elsewhere. Observed data are taken from December 2010. The map integrates the different sub-catchment flow regimes known for the BDAW and BDAE and areas to the west. These are all to the north of the Blue Anchor and Mercia Mudstone faulted inlier which forms the ridge to the south of the HPC Development Site footprint to the north of Green Lane; and that for the Holford Stream in the SCPA and its downstream catchment towards the Bristol Channel to the east of Hinkley Point B.

15.5.78 The map contours are shown as solid for areas where there is directly observed data; long-dashed for areas where there is some limited but not directly contemporaneous data (Hinkley Point A) and short-dashed where it is inferred elsewhere on the basis of topography and conceptual assumptions.

15.5.79 Groundwater flow features shown by the map **(Figure 15.15**) include:

- The groundwater sub-catchment divides between the BDAW/BDAE and the SCPA. North of this divide, groundwater flows generally northwards to the shoreline from around 14mAOD or higher (some levels are essentially perched on higher mudstone horizons that are not marked by groundwater contours), whilst south of the divide groundwater contours drop quickly to 6mAOD and below (that are not marked by groundwater contours), controlled by the topographic elevation of the Holford Stream. Within the BDAW, the contours follow the drain course of the Hinkley Point C Drainage Ditch corresponding to the artesian zone so there are also localised reversals of the general groundwater flow direction.
- The upper Holford Stream sub-catchment. This is fed mostly by groundwater rainfall recharge on the Blue Lias outcrop to the south which extends as far as the faulted boundary of the Mercia Mudstones around Stogursey. The groundwater contours closely follow the general pattern of the ground surface and the likely presence of groundwater mounds and ridges between surface watercourses is shown by the 20m contour northwest of DBH2_16 between Holford Stream and Bum Brook.
- The lower Holford Stream sub-catchment across Wick Moor. Here, the Blue Lias is overlain by estuarine and marine alluvium, which is of unknown thickness but is assumed to be of low permeability and so groundwater heads will be confined and direct recharge will be limited. In contrast to the upper Holford Stream sub-catchment to the west, where the Blue Lias is at outcrop and groundwater contributes baseflow directly to the Holford Stream via springs and seepages, in the lower sub-catchment any major seepage from the Blue Lias to the Holford Stream across Wick Moor via the alluvium is unlikely.
- At Hinkley Point B, groundwater contours are assumed to swing round to join the northern 'limb' of the Holford Stream 'groundwater valley'. Similarly, contours extending eastwards from the BDAW will also swing round creating a groundwater ridge east of the end of the Mercia Mudstone/Blue Anchor inlier. The apparent steepness of the groundwater gradient southwards from this ridge is indicative of low permeability conditions even though actual groundwater fluxes from recharge in that area are likely to be limited. This may also indicate the barrier effect created by the Hinkley Point Fault in this area.

v. Rainfall Recharge and Meteorology

15.5.80 Rainfall recharge provides the principal input to the groundwater system. The annual amount of recharge depends on annual rainfall, run-off, evaporation, crop uptake and on the transmissivity and the vertical hydraulic conductivity of the drift deposits. Considering that the transmissivity and the vertical hydraulic conductivity of the drift deposits are relatively low at HPC, Royal Haskoning (2009) (Ref. 15.36) estimated the maximum recharge to the aquifer at outcrop at one third of mean annual rainfall.

15.5.81 The Royal Haskoning (2009) (Ref. 15.36) report points out that

> *"in areas where the site is underlain by clay and silty clay to a depth of around 5m, the effective recharge to the aquifer will be significantly lower than that of the outcrop area."*

15.5.82 The recharge in areas of drift deposits was estimated to be one tenth of the mean annual rainfall. Considering a mean annual rainfall of 947mm/year (from records from 1971 to 2000 at Currypool Farm), Royal Haskoning (2009) (Ref. 15.36) finally estimated that the maximum recharge is 315mm/year at outcrop, and 95mm/year where drift deposits occur.

15.5.83 It is noted that Aspinwall & Company (1996) (Ref. 15.30), estimated recharge at 50 to 200mm/year, depending on land use or the presence of drift deposits.

Meteorology

15.5.84 Rainfall data acquired from the Meteorological Office provide daily rainfall records from 1962 until 1996 at Brymore School, the nearest available station some 8km from the HPC Development Site. Monthly averages from these data are shown in **Table 15.13**, with an annual average of 759mm. Average annual rainfall from Met Office HM33 data (**Appendix 15D**) is marginally higher at 763mm. Both are lower than the 30 year annual mean quoted above of 947mm, although the figure will vary depending on the length and period of data concerned. Applying the Royal Haskoning calculation to the lower rainfall estimate of 759mm a year results in maximum recharge estimates of 253mm over outcrop and 76mm over drift.

15.5.85 Rainfall data from December 2008 are available from a weather station installed on the HPC Development Site by AMEC on behalf of EDF Energy. **Figure 15.16** shows the data from December 2008 to December 2010, with fill-in data obtained from the Met Office from radar analysis for January, March and April 2009, when the site station was experiencing technical problems. Highest daily rainfall recorded on site was 37.8mm on 3 November 2009. The annual total recorded on site in 2009 was 740mm (including some radar data fill-in). Monthly totals are also shown in **Table 15.13**, including data for 2010 up to November. 2010 was a much drier year than 2009, totalling 329.7mm (up to 17 December, there is also a gap in the record between 18 March and 1 April). Snow and freezing conditions prevailed in December 2010 which may also have impacted on the record.

Table 15.13: Monthly Rainfall (mm) for 1962-1995 and 2009/2010

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Year
Brymore School 1962-1995 average	82	59	60	50	56	49	48	58	67	71	77	82	759
Hinkley Point C 2009	67.0	58.3	54.8	34.8	39.2	73.9	96.1	34.9	25.6	57.2	140.1	58.5	740.4
Hinkley Point C 2010	45.0	44.8	2.3*	19.2	8.0	26.3	28.8	55.7	11.4	38.5	46.4	3.3*	329.7*

* *Gap in record 18 March – 1 April, record ends 17 December*

15.5.86 Data from the Meteorological Office Surface Exchange System (MOSES) database for the period 1961-2001 provide for an analysis of rainfall, evaporation and soil moisture deficit through the year that can inform the likely temporal distribution of groundwater recharge. This is summarised in **Appendix 15D** and shown in **Figure 15.17** which illustrates:

- Potential Evapotranspiration (PE) and Actual Evapotranspiration (AE) monthly average values, derived using Penman-Monteith equations, for average rural land use surfaces;
- Soil Moisture Deficit (SMD) which increases through the late spring and summer and declines in early autumn;
- Effective Precipitation (EP) which is the part of precipitation that reaches stream channels as run-off; and
- actual rainfall monthly averages (for the period 1962-1995) for the Brymore School rain gauge.

15.5.87 Annual average totals are 452mm AE, 534mm PE and 759mm rainfall. SMD reaches a maximum of 77mm in July and August.

15.5.88 The seasonal distribution of rainfall, evaporation and soil moisture deficit restricts the periods during which direct rainfall recharge is likely to the late autumn and winter when the soils are at field capacity and a proportion of excess precipitation can percolate below the soil zone to the water table. In spring, the higher temperatures result in a build up of soil moisture deficit which lasts until at least early autumn. During this period direct recharge is unlikely unless there is enough persistent precipitation to remove the soil moisture deficit. Consequently, and as shown in the borehole hydrographs for 2008-2010 (**Appendix 15C**), the groundwater level hydrographs for 2009 exhibit a steady recession from March or April through to late October when the final removal of soil moisture deficit coincides with a period of intense rainfall (see **Figure 15.16**) and the groundwater levels show a sudden rise. Rainfall events during June, July and August, some of which are quite substantial, are not reflected in a rise in groundwater levels because of the prevailing high SMD.

15.5.89 shows that although the annual average rainfall for Brymore School for the period 1962-1995 (759mm) is similar to the total for 2009 (740mm), the summer months for

2009 were much wetter than the 1962-1995 average (see Figure 15.16). The wettest month in 2009 was November at 140.1mm, nearly twice the 1962-1995 average. From Figure 15.17 and the borehole hydrographs in Appendix 15C (CBH24 is overlain on Figure 15.17 as an example) it is clear that there was no substantial recharge between March/April and October, despite the high summer rainfall.

15.5.90 2010 was a much drier year, and the period from March to July 2010 was especially dry, and would have allowed a greater soil moisture deficit to build up; moreover, the autumn rain that coincided with groundwater level rises in 2009 did not occur. For 2010, rainfall until the middle of December totalled 330mm, less than half of the 2009 total or the long-term average.

15.5.91 **Figure 15.16** also includes an example borehole hydrograph (CBH24) to illustrate the relationship between rainfall and groundwater level (influenced by recharge). There is a long recession from spring to autumn in 2009, where soil moisture deficits have built up and summer rainfall events, some of which are substantial (two days in June over 20mm), do not produce any apparent recharge manifested in the hydrograph. However, substantial rain in late October and early November clearly bring the soil to field capacity since groundwater levels respond quickly and recharge results in a rapid rise of over 5m in the level in CBH24. After March 2010, levels recede and the dry months to August allow a substantial soil moisture deficit to build up, which remains unsatisfied by rain in August and any other rain until December 2010, at which time the winter recharge rise has still not commenced.

15.5.92 The apportionment of excess precipitation between run-off and recharge is uncertain. Although the hydrological analysis in **Chapter 16** concentrates on extreme rainfall events and floods, it is possible to derive an approximation for potential recharge by subtracting the SMD from the effective precipitation in the autumn and winter months when SMD is zero or low enough to be overcome by the rainfall. This gives a potential recharge of 217mm, and is likely to represent a lower bound on the total value of run-off and recharge. This value is similar to the estimation from Aspinwall & Company (1996) (Ref. 15.30).

15.5.93 An alternative calculation was also undertaken based on the MOSES EP of 383mm/yr by using the CEH/BGS Hydrometric Register. The Hydrometric Register gives a base flow index value for the Currypool Stream catchment (off the Quantock Hills north of Taunton, from Secondary A Devonian sandstone and Secondary B Mercia Mudstone) of 0.71. This suggests a recharge value of 272mm/yr which is considered to be a more likely value for recharge and compares more favourably with the Royal Haskoning (2009) (Ref. 15.36) estimate of 315mm/yr. Ultimately however, the recharge may be best estimated from the model calibration process since there is a direct relationship between permeability (for which there is considerable data) in order to maintain the observed groundwater head distribution.

Recharge

15.5.94 On the existing neighbouring HPA and HPB sites, a recharge value of 25mm/yr is considered appropriate to represent a low recharge situation where the ground surface is covered mainly by buildings, roads and hardstandings. To the south-east in the area of high alluvial content in shallow soils, a recharge value of 50mm has been applied in the assessment as discussed above.

15.5.95 It is acknowledged that there may be areas of lower recharge based on localised artesian conditions across certain areas of the HPC Development Site, and possibly elsewhere in areas of lower permeability superficial or mudstone-dominant Blue Lias cover where recharge could be reduced locally from the current nominal condition. However, this is likely to be patchy and sufficient data to fully conceptualise these effects does not exist. Moreover, substantial reduction in general recharge would require lower model permeabilities to support the observed groundwater heads, which would not compare well with measured permeability values.

15.5.96 The adoption of a recharge value that may be slightly overestimated is conservative from a dewatering perspective. Prior to any major construction dewatering the artesian cover and other superficial deposits will have been stripped and replaced with higher permeability engineered platforms at different elevations than the current surface topography. Within the area where all dewatering will occur, the development platform will be at 14mAOD.

15.5.97 The recharge value used for non-developed areas of the groundwater model is therefore fixed to 272mm/yr.

15.5.98 It is important to recognise that this estimate of potential recharge applies only to the amount of rainwater that might percolate through the soil zone (i.e. beyond the reach of plant roots) to reach the water table. The quantity that actually reaches the water table at particular locations will be substantially lower because of the following three factors. First, the area of the existing Hinkley Point Power Station Complex (and also HPC during the operational phase) will have a reduced recharge in view of the hardstanding and engineered drainage. Second, there will be reduced recharge in areas of clayey superficial deposits such as along the Holford Stream flood plain, south-east of Hinkley Point B. Third, where groundwater levels are artesian, such as in parts of the north-west of the development site, no recharge can occur.

vi. Groundwater Use

15.5.99 Within the area detailed in **Figure 15.9**, including the 2km search radius from the GroundSure Report (Ref. 15.33) and beyond, there are no potable water abstractions and no associated Source Protection Zones.

15.5.100 In the nominal 2km search area for the GroundSure Report (Ref. 15.33), 17 licensed groundwater abstractions have been identified. These are shown in **Table 15.14** with distances adjusted to show nominal distance and direction from the BDAW, BDAE and, where appropriate, the SCPA boundaries.

Table 15.14: Licensed Groundwater Abstractions

Groundsure Groundwater Abstraction ID	Grid Reference	Licence No. And Details Of Use	Nominal Distance (m) and Direction from BDAW/BDAE Boundary
16A	319400E 144600N	16/52/007/G/109 General farming and domestic, well, Stogursey	650m SW; 400m W of SCPA
17A	319400E 144600N	16/52/007/G/10 General farming and domestic, well, Stogursey	650m SW; 400m W of SCPA

Groundsure Groundwater Abstraction ID	Grid Reference	Licence No. And Details Of Use	Nominal Distance (m) and Direction from BDAW/BDAE Boundary
18	321300E 143480N	16/52/007/G/178 General farming and domestic, Farringdon Hill Farm	1950m SSE; 1175m SSE of SCPA
19B	323200E 145800N	16/52/007/G/109 General farming and domestic, borehole, Stogursey	2340m E
20B	323200E 145800N	16/52/007/G/109 General farming and domestic, borehole, Stogursey	2340m E

22C	323110E 145090N	16/52/007/G/105 General farming and domestic, well, Yearmoor Lane	2295m E
n/a	323600E 145400N	16/52/007/G/108 General farming and domestic, well, Stogursey	2735m E
n/a	323600E 145400N	16/52/007/G/108 General farming and domestic, well, Stogursey	2735m E
25	323000E 143500N	16/52/007/G/154 General farming and domestic, Stogursey	2920m SE
n/a	323800E 144300N	16/52/007/G/062 General farming and domestic, well, Stogursey	3200m ESE
n/a	323800E 144300N	16/52/007/G/062 General farming and domestic, well, Stogursey	3200m ESE
n/a	320300E 142300N	16/52/007/G/116 General farming and domestic, well, Stogursey	3200m S
n/a	320300E 142300N	16/52/007/G/116 General farming and domestic, well, Stogursey	3200m S
n/a	321000E 142300N	16/52/007/G/077 General farming and domestic, well, Stogursey	3200m S
n/a	321000E 142300N	16/52/007/G/077 General farming and domestic, well, Stogursey	3200m S
n/a	320940E 141960N	16/52/007/G/180 General farming and domestic, borehole, Higher Monkton Farm	3320m S

15.5.101 All these wells and boreholes are for general farming and domestic purposes. The nearest abstraction is 650m south-west of the BDAW/BDAE boundary and 400m west of the SCPA). All the others are over 2km distance from the BDAW.

vii. Groundwater Chemistry

15.5.102 Detailed descriptions of the existing non-radiological groundwater chemistry can be found in **Appendix 15E** and in **Appendix 15F** for radiological groundwater chemistry. A summary of the groundwater chemistry on site is provided below.

15.5.103 Five sampling campaigns for radiochemical and non-radiochemical analysis of groundwaters have been undertaken on BDAW (11 piezometers), four sampling campaigns on BDAE (1st campaign only 13 piezometers sampled, 21 piezometers in following campaigns), and three campaigns on SCPA (7 piezometers).

15.5.104 Non-radiochemical determinands were analysed by the range of methods detailed in **Appendix 15H**. The suite of baseline groundwater quality determinands was selected to include a wide range of determinands and quality indicators frequently tested for in preliminary UK groundwater quality assessments, as well as a wide range of potential contaminants that are commonly associated with current and historical contaminative activities. The suite includes basic indicators of potential pollution e.g. ammonia, electrical conductivity, chloride, and biochemical oxygen demand (BOD). Inorganic parameters such as nitrate, nitrite and phosphate have been included particularly given the current and historical agricultural use (i.e. to see if any impact to groundwater from the application of fertilisers may have occurred) and given that the area is within a Nitrate Vulnerable Zone. Electrical conductivity, chloride and sodium have also been included as these are key parameters which can help to evaluate the origins of more saline groundwaters. Other major anions and cations (e.g. sodium, chloride, calcium, magnesium, potassium, and sulphate) have been included as indicators of general groundwater quality but are also useful in helping to assess potential geological/geochemical impacts to groundwater (e.g. mineralisation/salinisation caused by mineral deposits in the bedrock).

15.5.105 Radiochemical samples were scheduled for laboratory analysis with the following radiochemical suite:

- High Resolution gamma spectrometry.
- Gross alpha, (calibrated with Am-241), and Gross beta, (calibrated with K-40).
- Tritium (as tritiated water).
- Carbon-14.

15.5.106 The suite was selected to provide a general screen for alpha, beta and gamma-emitters and to provide information with regard to soft beta-emitters (tritium and carbon-14). The inclusion of gross alpha, gross beta and tritium also meets the requirements for drinking water monitoring. The inclusion of gamma spectrometry provides quantitative data with regard to a range of natural and anthropogenic radionuclides.

c) Summary of Non-Radiological and Radiological Groundwater Quality

15.5.107 In general, the shallow groundwaters across the BDAW, BDAE and SCPA show very little evidence of any notable contamination by non-radiochemical or radiochemical contaminants, with the exception of very isolated and occasional occurrences of slightly elevated concentrations of certain inorganic salts, heavy metals, ammonia and nitrate. The exception to this is the shallow groundwater quality in a number of piezometers in the northern area of the BDAE (particularly the north-eastern area of the BDAE) which shows more consistent evidence of slightly elevated concentrations of inorganic salts, certain total and dissolved metals and metalloids and ammonium.

15.5.108 The source of the slightly elevated contaminant concentrations in several of the piezometers in the northern and north-eastern areas of the BDAE is believed to be historical leaching from:

- the large double-humped spoil mound in the centre of the BDAE which will be removed as part of the enabling works;
- other general Made Ground deposits and historical activities which are widespread across the northern and north-eastern areas of the BDAE (e.g. Area 4); and
- the former NDA temporary waste storage area (since removed) which was present on Area 5 for a period of two to three years (possible but less likely).

15.5.109 The concentrations (where elevated) are generally only 1-3 times the conservative Tier 1 screening criteria which have been applied and given their origin, planned removal of the spoil mounds during the enabling works, and known direction of groundwater flow are not considered to be significant or of concern (see **Chapter 14** Geology and Land Contamination for more details.)

15.5.110 Slightly elevated nitrate concentrations are occasionally present in the shallow groundwater on the BDAW, BDAE and SCPA (in one case (CBH35) this is more significantly elevated). The source of these nitrate concentrations is likely to be due to the application of nitrogenous fertilisers or ploughing of organic-rich soils. With the exception of CBH35, all of the slightly elevated concentrations were well below the nitrate drinking water and environmental screening concentration of 50mg/l. The Hinkley Point area is a designated Nitrate Vulnerable Zone, which means that from an environmental impact assessment point of view, the groundwaters and surface waters in the area are sensitive to activities during the construction and operation of the proposed development that could give rise to nitrate pollution.

15.5.111 Slightly elevated concentrations of tritium have been found in three piezometers (CBH2_56, CBH2_57 and DBH2_26) in the north-eastern area of the BDAE close to the boundary with the Hinkley Point A station. Whilst the concentrations are slightly above the adopted RIFE background value (< 4Bq/l) the activities are below the acceptable drinking water screening level of (100Bq/l) and as such are not significant or of concern.

15.5.112 With the possible exception of the slightly elevated tritium noted above, there is no evidence of any cross boundary migration of non-radiological or radiological contaminants onto the BDAE from the adjacent Hinkley Point A.

15.5.113 The deeper groundwater on the BDAE and BDAW has been found to contain very high concentrations of salts and minerals and also elevated concentrations of several heavy metals and metalloids and ammonium. The source of these elevated concentrations is considered to be related to the natural salt and mineral deposits in the surrounding bedrock and the natural geochemistry of the deep groundwater.

15.5.114 A review of the SERCO data (Ref. 15.39) has revealed that shallow groundwater in several locations across the adjacent HPA site is contaminated by hydrocarbon and radiological contaminants. The baseline description for HPA is discussed with the contaminant transport modelling section later in this chapter, together with its potential for this contamination to impact the HPC site.

15.5.115 In summary, the current environmental risks from existing non-radiological and/or radiological contamination in the shallow and/or deep groundwaters on the BDAW, BDAE and SCPA are considered to be low to very low.

15.5.116 The concentrations of several determinands, particularly suspended solids, have been regularly found to exceed freshwater and to a much lesser extent saline EQS standards. Assessment of the potential impacts from the discharge of potentially contaminated dewatered groundwater to surface waters is contained in **Volume 2, Chapter 16**.

d) Groundwater Conceptual Model

i. Previous conceptual models

15.5.117 The Aspinwall & Company (1996) (Ref. 15.30) and Allott Atkins Mouchel Power Consultants (1988) (Ref. 15.29) reports contain extensive sections on hydrogeology and conceptualisation which are relevant to this study.

15.5.118 The Environmental Statement (ES) for the formerly proposed Central Electricity Generating Board (CEGB) HPC Pressurised Water Reactor (PWR) Station (August 1987) (Ref. 15.40) includes as its **Figure 11.1** a conceptual model in the form of a block diagram which extends to cover an area to the west of the Hinkley Point A and B sites (i.e. BDAW and BDAE).

15.5.119 The Royal Haskoning (2009) (Ref. 15.36) report refers to previous conceptual models undertaken by Allott, Atkins and Mouchel (1988) (Ref. 15.29) and Rendel, Palmer and Tritton (1986) (Ref. 15.28) which are described in the report by Aspinwall & Co.(1996) (Ref. 15.30).

15.5.120 Both of these investigations produced hydrogeological models for the site. Allott, Atkins and Mouchel (Ref. 15.29) considered the aquifer properties beneath the site in five separate layers (made ground, sands and gravels, Angulata Zone, Lower Liasicus Zone and Penarth Group), whereas the Rendel, Palmer and Tritton (Ref. 15.28) model considered only two layers, an upper weathered zone and an unweathered zone. The permeabilities (or hydraulic conductivities, K) used in these models range from 1.0×10^{-9} to 1.0×10^{-3} m/s, but are on average (arithmetic) 1.0×10^{-5} m/s.

15.5.121 In general these previous models are consistent with the conceptual model developed for this EIA which is described below.

ii. Hydrogeological Basis of Current Conceptual Model

15.5.122 The spatial limits of the conceptual model developed for the EIA are taken to be from approximately easting 318000 in the west (where the Penarth Group intersects the shoreline) to 323000 in the east (where Holford Stream discharges to the Bristol Channel); and from the shoreline in the north to Stogursey in the south (i.e. the outcrop boundary between the Blue Lias and the Mercia Mudstones).

15.5.123 **Figure 15.6, Figure 15.7**, and **Figure 15.15** summarise the conceptual understanding of the local hydrogeological system that was described in detail above. The aquifer system is considered to extend down to the Blue Anchor Formation, although the base of the system is not well defined stratigraphically. Locally, in association with fault zones, the Mercia Mudstone can be fractured, and locally shallower layers contain hypersaline water that must have been isolated from active circulation over geological periods of time. These waters are found below the level of construction dewatering for HPC and do not take an active part in the baseline groundwater flow regime (if they did, they would have been already diluted by throughflow of fresher water). The most permeable units are the weathered Blue Lias and the Lilstock Formation. The Planorbis zone at the base of the Blue Lias can also exhibit higher permeabilities than the Blue Lias in general. Flow in the Blue Lias occurs extensively along joints in limestone horizons, and in a more concentrated fashion along fault zones, where these coincide with laterally persistent fracturing. Because the limestones are typically 0.5m thick, their lateral continuity will be readily disrupted by faults. The faults themselves will tend to act as barriers to flow normal to the fault plane, but may provide high permeability pathways along their length. The barrier-boundary responses seen in pumping tests thus support the interpretation that the aquifers behave as a series of compartments where faulting is present, with dimensions of the order of hundreds of metres and which have limited hydraulic continuity across faults between compartments.

15.5.124 At the regional scale (**Figure 15.7**) the Blue Lias aquifer is fed by rainfall recharge, either directly or, where present, through the sand and gravel and/or Made Ground. Groundwater flows approximately south to north from the area of Mercia Mudstone outcrop south of Stogursey (about northing 145300) to discharge directly into the Bristol Channel, or indirectly following baseflow discharge to the surface freshwater network. The Penarth Group/Mercia Mudstone forms the lower boundary to the system.

15.5.125 However, at the scale of the HPC Development Site (i.e. the BDAW and BDAE) (**Figure 15.6**), this general natural flow regime is intercepted by another upfaulted inlier of Mercia Mudstone on the southern margin of the BDAW (about northing 145600). The BDAW and the BDAE are therefore likely to be largely self-contained as a groundwater system, bounded by the Mercia Mudstone and Penarth Groups beneath, the faulted inlier to the south (about northing 145600), and the Bristol Channel to the north.

15.5.126 The groundwater flow system across the whole model domain as described above is illustrated in the site-wide piezometry map (**Figure 15.15**).

Streams and Wetlands

15.5.127 As noted earlier, Holford Stream originates in low lying land on the south of the Mercia Mudstone – Blue Anchor inlier, and runs approximately along its southern (faulted) contact before crossing the Hinkley Point Fault and entering the broader wetland area of Wick Moor. Although not measured directly, groundwater levels are inferred to rise to more than 20mAOD beneath the topographic high points of the ridge formed by the inlier (south of BDAW). This ridge represents a divide in the groundwater system, separating the Blue Lias aquifer in the SCPA from that in the BDAE/BDAW. North of the inlier, groundwater flows towards the coast.

15.5.128 South of the ridge, in the SCPA, the dominant flow direction is also to the north, but the low groundwater elevations at the southern margin of the ridge (4 – 6mAOD in CBH35 and DBH2_13) prove the geological inference (and the assumption for the EIA) that the two aquifers are hydraulically isolated. The low groundwater elevations suggest that the faulted contact of Blue Lias and Mercia Mudstone, in the north of the SCPA, is a spring line that supports flow in Holford Stream (otherwise, the area would either be permanently waterlogged or subject to strongly artesian conditions).

It follows that abstraction to the north of the inlier will not affect groundwater levels or flows in this section of Holford Stream.

15.5.129 Where the inlier terminates against the Hinkley Point Fault (on the eastern boundary of the BDAW), its topographic expression (i.e. the ridge) is less pronounced, and furthermore the Blue Lias is present at outcrop on both sides of the fault. However, this gross geological continuity is almost certainly not matched by hydraulic continuity of the aquifers. There are several lines of conceptual argument to support this. Firstly, permeable limestone horizons will likely not be in continuity, except where different limestones have fortuitously been brought into contact. Secondly, in many locations the fault surface will have been smeared by clayey fault gouge. So although fracturing may have produced a permeable zone along the fault, this should be distinguished from its effect on restricting flow perpendicular to the fault. Moreover, east of the Hinkley Point Fault, a NE-SW anticline will tend to introduce greater anisotropy, facilitating flow parallel to its axis, and further restricting flow in the NW-SE direction.

15.5.130 Thus, overall it is inferred that the BDAW/BDAE will have a substantially restricted hydraulic connection with the Blue Lias beneath Wick Moor, which, due to the low permeability alluvial cover described earlier, will have restricted continuity with overlying surface water bodies due to the presumed, but unproven, low vertical permeability of the alluvial deposits.

15.5.131 In order to provide confirmatory evidence on the conceptual assessment of potential impacts on Wick Moor, it is planned to install monitoring boreholes between the main construction dewatering areas and Wick Moor. This is likely to include boreholes in the south-east corner of the development areas, and also on the alluvium on Wick Moor itself. Piezometers will record groundwater levels in both the alluvium and underlying Blue Lias.

Flow to and from the Bristol Channel

15.5.132 In addition to discharge to streams and drains, and diffuse seepage to the land surface, the other major potential discharge mechanism is vertical leakage to the Bristol Channel. In addition, due to the northerly dip of strata, there is a narrow strip of land close to the coast which could discharge via a seepage face along the cliff line, although observation of the cliff suggests that any such flows are very small. Therefore the bulk of any coastal discharge must occur offshore by upward leakage from confined aquifers.

15.5.133 Under natural conditions, the net discharge, after averaging out tidal fluctuations in the estuary, will always be from the land to the sea. The Blue Lias aquifers identified onshore have no direct connection with the Bristol Channel. The strata dip more or less uniformly beneath the Bristol Channel at about 10 degrees, and the shallowest aquifers that are likely to be pumped are expected to have a cover of more than 10m of mudstones at the coastline. The aquifers could extend for several kilometres beneath the estuary, to its centre line, or more likely until disrupted by faulting. In either case there is no point of lateral discharge to the Bristol Channel. Moreover, with increasing distance from the shoreline, there is not only an increasing thickness of sediment but also, as the Blue Lias is succeeded by the Charmouth Mudstone Formation, the cover will have an increasingly low permeability. Because of the layering, and the lack of vertical continuity of joints between limestone beds, the overlying sediments will have an extremely low vertical permeability, dominated by that of the mudstone layers, and as noted earlier exhibiting strong vertical anisotropy. Hence, offshore, the aquifers can only discharge by vertical leakage through these strata. The measurement of minimal tidal fluctuations, a few centimetres only, in boreholes close to the coast support the notion of very poor hydraulic connection between the aquifers and the Bristol Channel. As a consequence, when pumped, little water will be drawn in from the offshore sections of the aquifers, with this mainly by release from artesian storage, and therefore there will be very limited potential for saline intrusion. The offshore sections of these aquifers are probably best viewed as closed bodies of almost stagnant groundwater.

15.5.134 It is noted here that although saline groundwater has been identified onshore, as described below, this probably originates from dissolution of evaporite minerals, and does not constitute evidence for ongoing saline intrusion (see also 15.5.122).

iii. Groundwater Numerical Model

15.5.135 A numerical groundwater model has been developed to represent as closely as possible the observed baseline groundwater regime in the vicinity of the HPC Development Site and to provide a basis for assessment of scenarios relevant to the construction phase of the proposed development. The principal objectives of the model simulations were:

- to predict the magnitude and lateral extent of drawdowns during construction dewatering; and
- to determine the effect of construction dewatering on groundwater flow from beneath the Hinkley Point A station, and hence provide the basis for assessing the possible mobilisation of contaminants from beneath that site.

15.5.136 The groundwater numerical model was designed primarily to investigate the effects of dewatering within the development area and under HPA, not to produce definitive results concerning the aquifer east of the Hinkley Point Fault and under Wick Moor. The model in its current form does not represent the discontinuities across the Hinkley Point Fault as described above, but rather presents a continuum in the Blue Lias aquifer up to the south-east boundary of the model. As such the numerical model is very conservative with respect to the estimation of effects on the lower reaches of Holford Stream and across Wick Moor. This will have the opposite effect on dewatering predictions as it will allow dewatering drawdown to extend over the Hinkley Point Fault towards the eastern part of the HPA site and to the south east towards Wick Moor. In reality the Hinkley Point Fault may act to prevent drawdown extending this far.

15.5.137 An important part of model development is calibration. Options for calibration of this model are constrained to:

- a pumping test carried out as part of the BDAW onshore investigation in August 2010, repeating one from December 2008;
- a second pumping test in the BDAW undertaken in July 2010; and
- the groundwater hydrographs from up to 24 months of data (between December 2008 and December 2010) collected from the transducers installed in some of the monitoring boreholes. The locations of the two pumping tests are shown on

Figure 15.11, and their detailed configurations are shown in **Figure 15.H.10** and **Figure 15.H.11**.

15.5.138 The calibration process is constrained by the interdependence of hydraulic conductivity and infiltration recharge in generating a water table surface. The former is estimated from permeability and pumping tests, whilst the latter is subject to temporal and spatial variability in a parameter that cannot be measured directly. Moreover, the multi-layered and faulted nature of the Blue Lias aquifer makes comparison of monitoring points difficult.

15.5.139 It has been possible to develop a calibrated model that is suitable to make construction phase development scenario projections which are considered valid for EIA purposes. The development of the model has been a progressive process, subject to the availability of data which has been made available as site investigations and monitoring works have progressed over time.

Model Geometry and Grid Definition

15.5.140 The model grid configuration is shown in **Figure 15.19**. A rectilinear finite difference grid is made up of 172 columns and 135 rows. These vary in resolution from 50m at the margins to 10m, both in the development area (which is the principal zone of main interest in relation to dewatering activities) and to the north and south where the topography and layers dip relatively steeply and a more closely spaced grid is required to ensure that sloping layers are sufficiently continuous from one row to the next.

15.5.141 The total model domain extends 4800m east-west and 1500m north-south. To place the model in geographical context, **Figure 15.19** also shows the grid overlaid on an outline map of the Hinkley Point area. Outside the BDAW, BDAE and part of the SCPA there is little or no validated site-specific data for the model and input data has been inferred from earlier reports and desk study information.

15.5.142 The model comprises five geological layers, two in the Blue Lias, and one each in the Lilstock, Westbury and Blue Anchor formations. The Planorbis zone is included in the lower of the Blue Lias layers (Layer 2) but hydrogeologically assigned to Layer 3 which is of higher permeability. The base of the model is defined by the top surface of the Mercia Mudstones aquiclude below the Blue Anchor formation. It should be noted that relatively few boreholes penetrated to this depth.

15.5.143 The model layer geometry has been developed as follows:

- Existing borehole information from the BDAW, BDAE and the former CEGB Hinkley Point C investigation were imported and gridded in the software package Surfer.
- For the base of the Blue Lias (base of Layer 2) the gridded data are replicated directly to the east (as far as the Hinkley Point Fault) and to the west to the edge of the model; extrapolated to north in accordance with the geological formation dips identified from a dip angle calculated from the gridded BDAW/BDAE data (calculated to be 11 degrees) and south, maintaining a minimum thickness of 5m below Layer 1 (see below).
- The base of Layer 1 was derived from the surface topography since the geotechnical interpretation of the on-shore investigation data (Ref. 15.31)

concluded that there was a change in the degree of weathering (and therefore permeability) related to depth below ground surface. The surface topography was derived from an EDF supplied topographical data set (UKE-2009-54521-FR.pdf) (**Figure 15.3**). Where the thickness of the Blue Lias formation exceeds 40 m, the base of Layer 1 was fixed to 40m below topography, thereby wedging out to the south on the west side of the Hinkley Point Fault. It is shown in plan form in **Figure 15.20** (the trend of the Hinkley Point Fault and the anticline to the east can be seen).

- East of the Hinkley Point Fault the base of the Blue Lias was modified according to downthrow and structural information in the British Geological Survey Sheet Memoir 10 to incorporate variable downthrows and an anticline with an axis running west-east. The Hinkley Point Fault is represented in the model as a shift in layers, the eastern side of the fault being the downthrown side. However no horizontal barrier (including the Horizontal Flow Barrier package) has been implemented. The dry cells occur to the south of the main Nuclear Island, to the north of the Blue Anchor outcrop in an area where the Blue Lias is very thin. It is therefore very likely that this part of the Blue Lias aquifer will actually dry out during dewatering and will hence form a flow barrier to the south/south east. Should the Hinkley Point Fault have been represented in the model as a horizontal flow barrier, this drying of cells would have been exacerbated due to the extra compartmentalising of the aquifer around the HPC site.
- Apart from the above, the faulting in the formations has not been explicitly modelled. Results of the impact assessment (see below) are of sufficient low significance to make their inclusion unnecessary as they are conceptually interpreted to present barriers to groundwater flow. Their inclusion in the model would therefore probably further reduce predicted impacts as a result of drawdowns in the Blue Lias aquifer. It is considered that the results of the impact assessment do not therefore warrant the inclusion of faults in the model.
- MODFLOW requires that all layers are in sequence throughout the model domain. Thus Layer 1 cannot be situated directly on Layer 3 where the ‘real’ Layer 2 is absent (total Blue Lias thickness less than 40 m). In order to preserve model functionality therefore, Layer 2 was extended across the whole model so that it remained at least 5m thick. The value of 5m was chosen so that cell-to-cell continuity would be maintained in the areas of steeper layer gradients. Layer 2 was allocated the same aquifer properties as Layer 1 in these areas.
- The average thicknesses of Layers 3 (Lilstock), 4 (Westbury) and 5 (Blue Anchor) were determined from evaluation of the BDAW and BDAE borehole logs, giving thicknesses of 5.0 m, 9.2m and 38.2m respectively. These thicknesses were subtracted from the base of Layer 2.

15.5.144 In MODFLOW, Layers 1 to 3 were assigned as convertible, such that transmissivity varies depending on saturated thickness, and the appropriate value of storage (specific yield or specific storage) is automatically assigned according to whether the water level is above or below the top of the cell at the beginning of each time step. Layers 4 and 5 were specified as confined.

15.5.145 The starting head values in the initial steady state models were set at a uniform 15mAOD – close to real values to enable the model to start efficiently. Note that this results in some Layer 1 cells being dry from the beginning, however the calibration has been repeated by setting the starting heads to at least 1m above the cell bottoms to confirm that this has no effect on the calibration achieved. Cell rewetting is enabled, so cells that dry out can refill if groundwater levels rise again rather than being switched off. The calibrated steady state heads were exported to form the first stress period for all the transient models (see below).

iv. Boundary Conditions

15.5.146 **Figure 15.19** indicates the type of boundary conditions used in the model.

15.5.147 Overall, there are very few surface water features in the model through which groundwater can discharge locally under baseline conditions. The drainage ditch on BDAW is the only such feature on or near the HPC site which may allow this to occur. Holford Stream is the only other surface water feature, forming the south east boundary condition of the model (the model domain does not include the upper part of the Holford Stream across the SCPA), but is several hundred metres from the main site. Hence the groundwater conceptualisation is for the majority of recharge to enter the Blue Lias aquifer, flow north towards the Bristol Channel, and exit the aquifer under the Bristol Channel at some point off-shore. There are no specific data to allow a full conceptualisation of these flows or discharges to be undertaken. Whilst flow in deeper layers such as the Lilstock may occur further out into the Bristol Channel this cannot be quantified. Hence a simple northern boundary in the model was implemented.

15.5.148 The natural discharge regime of groundwater to the Bristol Channel is represented by fixed heads along the north of the model domain at 0mAOD. The groundwater surface is still at an elevation of up to 10m at the cliff line, so it is assumed that the discharge of the natural groundwater flow regime into the Bristol Channel takes place several hundred metres off-shore. In the model, the fixed head cells are approximately 300m from the cliff line. This distance in the BDAW was estimated by extrapolating the groundwater gradient at the coast beyond the shoreline. It is a conceptual assumption since there are no off-shore data available. In this case, the boundary condition could be more complex, involving vertical leakage over an extended area. However, in the absence of evidence, it was considered prudent to apply a simple numerical condition.

15.5.149 The Holford Stream, and its associated surface drainage system in the south-east corner of the model, rests on (presumed) low permeability marine/estuarine alluvium which probably results in the Blue Lias being semi-confined or confined in this area. This means that the groundwater/surface water interactions are limited and, further that this lower permeability cover will also restrict aquifer recharge and discharge in this zone.

15.5.150 Holford Stream and its associated surface water drainage system are therefore not represented explicitly in the numerical model and a drain boundary was applied to the south-eastern limit of the model domain, with a stage set at the topographic surface elevation of the Holford Stream bed (6mAOD adjacent to the Hinkley Point Fault falling to 2mAOD at the eastern boundary of the model). As this limit is relatively far from the BDAW and BDAE, the type of boundary condition applied has a limited effect on the groundwater levels simulated within the development area where the main construction dewatering will take place. Again, a more complex condition could be applied, but given that Holford Stream is not in the main area of interest, a simple condition is considered appropriate. The drain bed was assigned the following parameters:

- Stage 6m in the west falling to 2m in the east – intermediate values interpolated by Groundwater Vistas.
- Width of 1m.
- Length, variable as assigned by Groundwater Vistas based on the cell dimensions in each case. In the west the cells are 20m wide, in the east 50m wide. Groundwater Vistas selects the largest of cell width or length for this parameter for a digitised polyline of cells used to specify a drain.
- Bed thickness, 1m.
- Hydraulic conductivity, 1000m/d (high value to provided unimpeded transfer).

15.5.151 The model was found to be relatively insensitive to these parameters and the resulting conductance values are considered to be an appropriate estimate.

15.5.152 The remainder of the southern boundary of the model, to the west, is represented by no-flow boundary (inactive) cells that follow the physical northern boundary of the faulted inlier of Mercia Mudstones (see **Figure 15.4** and **Figure 15.6**).

15.5.153 Across the Built Development Area (BDAW and BDAE) the existing drainage ditches (which locally control groundwater levels, see **Figure 15.12** and **Figure 15.13**) are represented in MODFLOW by internal boundary conditions in the form of drains (see **Figure 15.19**), with stage elevations between 10 and 16mAOD, derived from the surface topography. This includes a former drain channel now buried beneath Made Ground on the BDAE, which joins the existing drain where it alters course from east to north. In the absence of any other data, the drain beds were allocated hydraulic conductivity values of 1m/d (about twice the highest initial Blue Lias permeability in Layer 1), with an assumed thickness and width of 1m. From this the MODFLOW model calculates a drain conductance of 10m^2/d which is considered appropriate for these drains in the absence of field data.

v. Hydrodynamic Parameters and Recharge

15.5.154 **Table 15.15** summarises the final calibrated parameter values used for the model. Further details are contained in **Appendix 15G** and background baseline descriptions are contained above.

15.5.155 Kx (horizontal permeability) values are based on the results of the pumping tests and the various packer (Lugeon) tests where available. Horizontal anisotropy in the Blue Lias and Lilstock formations (Layers 1-3) are set at 2:1 (E-W:N-S) based on the observations of the distance-drawdown relationships in the pumping tests. The low permeability and low groundwater activity regimes in the Westbury and Blue Anchor formations (Layers 4 and 5) do not justify any horizontal anisotropy and there is a lack of data to calculate anisotropy for these layers.

15.5.156 Vertical anisotropy is a result of lithology and sedimentary structure, with vertical permeability being substantially lower. Horizontal permeability is facilitated by mineral alignments within the mudstones and the predominance of fractures and joint sets parallel with bedding planes. Vertical permeability reflects the resistance to groundwater flow across these structures. The estimation of vertical permeability uses the lower bound values of Lugeon tests, assumed to represent matrix or minimally fractured mudstone horizons, and the Kh:Kv ratio uses equations such as those contained in Anderson & Woessner (Ref. 15.38) and described in **Appendix 15B**.

Table 15.15: Final Calibrated Parameter Values in Groundwater Model

		Kx (east-west)		Ky (north-south)		Kx/Ky	Kz (vertical)		Kx/Kz	Sy	Ss	Layer type
		m/d	m/s	m/d	m/s		m/d	m/s		(-)	(-)	
Layer 1	Weathered Blue Lias	0.38	$4.40x10^{-6}$	0.19	$2.20x10^{-6}$	2	$4.74x10^{-4}$	$5.49x10^{-9}$	800	0.02	$3.00x10^{-5}$	Convertible
Layer 2	Fresh Blue Lias	0.0039	$4.51x10^{-8}$	0.0019	$2.20x10^{-8}$	2.1	$3.25x10^{-5}$	$3.76x10^{-10}$	120	0.02	$3.00x10^{-5}$	Convertible
Layer 3	Lilstock	4.41	$5.10x10^{-5}$	2.21	$2.56x10^{-5}$	2	0.882	$1.02x10^{-5}$	5	0.02	$3.00x10^{-5}$	Convertible
Layer 4	Westbury	0.25	$2.89x10^{-6}$	0.125	$1.45x10^{-6}$	2	$2.50x10^{-3}$	$2.89x10^{-8}$	100	0.01	$3.00x10^{-6}$	Confined
Layer 5	Blue Anchor	0.1	$1.16x10^{-6}$	0.05	$5.79x10^{-7}$	2	0.02	$2.31x10^{-7}$	5	0.01	$3.00x10^{-6}$	Confined

15.5.157 Estimated Kh:Kv values in the Blue Lias range from around 800 in the weathered Blue Lias of Layer 1 (strong horizontal fracturing and lithological fabric, minimal cross-cut fracturing through the weathered mudstones), to 120 in the fresh Blue Lias of Layer 2. The Lilstock (Layer 3) has a Kh:Kv of 5 influenced by its limited thickness and the limestone lithology of its active groundwater flow zone. Estimated (calculated) values for the Westbury and Blue Anchor are 100 and 5 respectively.

15.5.158 Specific yield in Layer 1 was initially set at 0.03 based on EDF fracture analyses and BGS outcrop values, reducing in Layers 2 and 3 to 0.02 due to compaction, and to 0.01 in Layers 4 and 5 due to compaction and lack of weathering. Final calibration resulted in Layer 1 specific yield also being set at 0.02.

15.5.159 Calibrated confined storage coefficients were set at $3x10^{-5}$ for Layers 1-3, and $3x10^{-6}$ for Layers 4 and 5.

15.5.160 Recharge and its relationship to rainfall records and soil moisture deficit etc is discussed above. Allocation of general values to the model is shown in **Figure 15.21**, taking account of the areas of reduced recharge due to hardstanding and surface drainage systems on Hinkley Point A and Hinkley Point B, the alluvium on Wick Moor, and the sea.

15.5.161 General recharge values are:

- Blue Lias outcrop 272mm/yr
- Hinkley Point A and B stations 25mm/yr
- Wick Moor alluvial plain 50mm/yr
- Sea 0mm/yr

15.5.162 The Blue Lias outcrop recharge is varied in the model during transient calibration against hydrographs in order to emulate the reduced and zero recharge in summer months when soil moisture deficit restricts or prevents effective recharge from taking place. The remaining values were derived from previous model calibrations.

vi. Calibration

15.5.163 An important part of groundwater model development is calibration which is detailed in **Appendix 15H** and summarised here. The overall calibration process was performed to achieve a representative groundwater model for the Built Development Area against the baseline conditions shown in **Figure 15.5**, and involved both steady state and transient regimes. The calibration process was undertaken in the following order (explained in more detail in the following sections):

15.5.164 A sensitivity analysis (**Appendix 15H**) was undertaken to assess horizontal and vertical permeability and recharge for all layers of the model. The results of this sensitivity analysis identified which parameters the model was more sensitive to, and hence formed the primary part of the calibration process. If the model was found to be insensitive to certain parameters, these parameters were fixed and not changed initially.

15.5.165 A steady state model was constructed in order to determine the general piezometric head pattern across the model.

15.5.166 The recharge associated with the alluvial flood plain in the east of the model was then modified in order to represent likely heads on the Hinkley Point B site.

15.5.167 A transient model was then constructed to represent the 2008 BDAW pumping test (**Appendix 15H**) by matching the maximum drawdowns in a selection of monitoring wells in the model to those observed in the field. This was achieved by varying model hydraulic conductivity values in all three principal axes (Kx, Ky and Kz) in Layer 3 (as detailed below).

15.5.168 A further transient model was constructed to represent the 2010 BDAW pumping test (**Appendix 15H**) following the same process as described above for assessing the 2008 pumping test.

15.5.169 It should be noted that the 2010 repeat test of the BDAW pumping well provided additional support information on horizontal permeability anisotropy – in general however, the pumping test calibrations provided little insight into the model behaviour compared with the hydrograph calibration. The pumping tests were more useful in determining the presence of barrier boundaries representing internal compartmentalisation in the aquifer.

15.5.170 A final transient model was then constructed using calibrated hydraulic conductivity values from the pumping test model. This model was designed to investigate the appropriate general recharge value assumed in the model, and its temporal distribution in 2009/2010 by attempting to match modelled heads in a selection of boreholes on the BDAW with observed field hydrographs. It is this final transient model that was used to assess environmental impacts.

vii. Modelled Development Scenarios

Preliminary Works Drainage

15.5.171 The ‘deep’ (9mAOD) spine drains proposed for the Preliminary Works drainage are not designed to collect water themselves, but rather to serve as discharge pipes for dewatering arisings and other surface drainage as required. As such they do not in themselves impact on the groundwater regime.

15.5.172 It is however proposed as part of the preliminary works to excavate the down to 3mAOD for Unit 1 and 6mAOD for Unit 2 (**Figure 15.18**). The steady state dewatering volume for this scenario is approximately 4l/s.

15.5.173 During construction dewatering the baseline groundwater conditions in the Blue Lias will be affected (**Figure 15.15**). During preliminary works when the site preparation works will be undertaken and the temporary jetty constructed the drawdown will be minor compared to main construction when dewatering levels are far deeper. However during both phases the hydraulic gradient under the HPA site will remain low. Under baseline conditions the hydraulic gradient under both the HPA and HPC sites is low and towards the north (Bristol Channel). During preliminary works dewatering this hydraulic gradient is largely maintained despite the minor drawdown. During main construction phase dewatering, the hydraulic gradient under the north-eastern HPC and north-western HPA site switches to a westerly direction (from northerly). However the magnitude of the hydraulic gradient is not greatly affected away from the area immediately surrounding the construction works.

Deep Dewatering

15.5.174 The planned deep dewatering to allow construction of the Nuclear Islands and other deep infrastructure, and in particular for the excavations for the cooling water pumping stations and Interim Spent Fuel Store (ISFS), have been simulated in the model. This was undertaken for environmental assessment purposes by introducing drain cells in Layers 1 and 2 at the locations of the cooling water pumping stations together with shallower drain cells in the remainder of the Nuclear Islands, based upon the planned deep excavation depths (based on finalised platform levels plus 3m extra to allow for a safety margin). The ISFS is to be dewatered to a level of -2mAOD, 3m below the base of the structure.

15.5.175 The main Nuclear Island drain cells were assigned the following parameters:

- stages: -4.2, -12.5 and -25m (to match each of the dewatering levels);
- width: 1m;
- length: 1m;
- bed thickness: 1m; and
- hydraulic conductivity: 5m/d (a suitable value for model stability).

15.5.176 The ISFS drain cells were assigned a stage of -12m, with all other properties being the same as stated above for the main Nuclear Island.

15.5.177 The model has an initial steady state period based upon the heads from the calibrated steady state model in order that the effects of dewatering over time from the baseline could be established. The following dewatering depths (drain stages) in **Table 15.16** were derived for modelling purposes:

Table 15.16: Modelled Deep Dewatering Depths

Deep pumping station excavations	Nuclear Island north	Nuclear Island south	Interim Spent Fuel Store
-25mAOD	-12.5mAOD	-4.2mAOD	-12mAOD

15.5.178 The deep dewatering simulation assumes (conservatively) no residual drawdown from any previous dewatering in the Preliminary Works, and lasts for eight years in total and is comprised of the following:

- Five years of main Nuclear Island dewatering. Five years is a conservative assumption and is one year longer than the design duration.
- Two and a half years of ISFS dewatering, immediately following the cessation of main Nuclear Island dewatering.
- Six months of recovery where no dewatering on the HPC site takes place.

15.5.179 Water level conditions for Layer 1 during dewatering are shown in **Figures 15.23 to 15.26**. **Figure 15.23** shows water levels in the second January of the simulation period (representative of a wet period). **Figure 15.24** (plan) and **Figure 15.25** (section) show water levels after five years which presents heads in a dry period (fifth October of the simulation period). **Figure 15.26** shows water levels after two and a half years of ISFS dewatering.

15.5.180 The influence of the dewatering can clearly be seen in the groundwater contours on the HPC Development Site. The flow direction under HPA is modified during dewatering such that flow to the west from this site and towards HPC is possible. However, it should be recognised that the hydraulic gradient under HPA is very shallow and the groundwater velocities are likely to be very slow and accelerating on the HPC site within a few tens of metres of the actual earthworks locations.

15.5.181 Changes to the groundwater regime from main Nuclear Island dewatering in terms of modification of gradients establishes quickly and the condition away from the immediate vicinity of the pumping does not change substantially after the first 30 days. It is assumed that the ISFS dewatering begins immediately after the five years of main Nuclear Island dewatering, and continues for a further two and a half years. During the ISFS dewatering period, groundwater under the western part of the main Nuclear Island begins to recover back towards the baseline condition (**Figure 15.15**), but will not fully achieve this state due to ISFS dewatering and operational drainage. Influent water quality is addressed in 15.5.122.

15.5.182 'Pumping rates' generated from the main Nuclear Island drain cells total around 12l/s on average after 5 years. The average ISFS dewatering rate is 4l/s. These dewatering rates were derived from the zone budget output of the model by specifying the drain cells used to simulate dewatering as a set of specific reaches in the model.

Operational Conditions

15.5.183 Modelling of operational conditions is not considered to be appropriate due to the intended construction of a peripheral drain around the site at 8mAOD. This drain will passively control groundwater levels within the site to this level, will be maintained for the operational life of the site and forms part of the safety case.

e) Contaminant Transport Assessment

15.5.184 Following the general groundwater modelling described above, the potential for mobile groundwater contaminants on the Hinkley Point A site to be mobilised by construction dewatering became apparent. The following section summarises the risk assessment which has been undertaken to inform the impact assessment. More details of the risk assessment for the main Nuclear Island dewatering can be found at **Appendix 15I**.

Main Nuclear Island Contaminant Assessment

15.5.185 The main Nuclear Island contaminant transport assessment followed current UK best practice by applying a tiered methodology whereby a number of contaminants were considered qualitatively at Tier 1 by both screening and conceptual argument, with only those failing this assessment being considered for further assessment at Tier 2 which may have included modelling.

15.5.186 A number of contaminants from 2004/5 data (Ref. 15.39) at a variety of locations on the HPA site were identified, including:

- Strontium-90 (Sr-90).
- Tritium (H-3).

- Diesel range organics (DRO).
- Hydrocarbons (unspeciated) both dissolved and free phase.
- Mercury (Hg).
- Other metallic compounds.
- PCBs.

15.5.187 At Tier 1, the various sources of the above contaminants were assessed both qualitatively (location on HPA site with respect to the main Nuclear Island dewatering zone of influence) and by simple numerical screening. To derive the main Nuclear Island dewatering zone of influence, a number of particle tracing models were used to derive a capture zone whereby any contamination outside of this zone would either remain largely uninfluenced or not be substantially drawn into the dewatering location over an assumed 5 year dewatering period. Those contaminants residing inside this capture zone were considered for further assessment, namely:

- Sr-90.
- H-3.
- Hg.
- Naphthalene (chosen as a mobile hydrocarbon analogue most suitable with respect to Total Petroleum Hydrocarbons).

15.5.188 Of these contaminants, H-3 was determined to be much more mobile than Sr-90, Hg or naphthalene. It was therefore decided to undertake Tier 2 modelling of H-3 to determine its significance to the dewatering location and HPC site (at the HPA/HPC site boundary) as discussed at **Appendix 15I**.

15.5.189 The results for H-3 show that over the assumed main Nuclear Island five year dewatering period, H-3 from the HPA site is not likely to be drawn on to the HPA site or into the extracted dewatering water at a significant concentration compared to the current UK drinking water standard of 100Bq/l.

15.5.190 Sr-90, Hg and naphthalene are all retarded contaminants and thus as such are even less likely to migrate a substantial distance during the period of dewatering. However, some sources of these contaminants are closer to the HPA/HPC site boundary than for H-3, so some confirmatory modelling was undertaken. The results of this modelling confirmed that these contaminants are highly unlikely to present a risk to the HPC site or the main Nuclear Island dewatering location during dewatering.

15.5.191 In summary, there is no known contamination on the HPA site which presents a risk to the HPC site or main Nuclear Island dewatering location under anticipated dewatering conditions.

15.5.192 In addition to the above modelling conclusions, it is also useful to consider the additional factor of dilution at the point of dewatering, since the potential contaminant flows only represent a fraction of the total inflow to the dewatering system. Based on MODFLOW calculations the flow over the site boundary from HPA to HPC in Layer 1, representing the H-3 plume (see Section 15.6 below), is approximately 26m^3/d or 0.3l/s. This is approximately 2.5% of the whole dewatering extracted volume (12l/s) during main construction dewatering. Therefore, the peak H-3 concentration from the aquifer adjacent to the main Nuclear Island (predicted value of 7.7Bq/l, Section 15.6) would be diluted down to 0.19Bq/l of H-3 within the discharged water, which is far below the standard limit of detection (5Bq/l). Please refer to Section 15.6 below for details of the contaminant transport assessment.

Interim Spent Fuel Store Contaminant Assessment

15.5.193 The ISFS is assumed to be constructed immediately after the main Nuclear Island dewatering has ceased. The ISFS dewatering is assumed to last for two and a half years and dewater to a level of –12mAOD.

15.5.194 During the period of ISFS dewatering, there are two potential sources of contamination that could be drawn into the excavations: H-3 contamination drawn onto the HPC site from HPA as a result of the preceding main Nuclear Island dewatering (see above) or contamination directly from the HPA site itself.

15.5.195 As detailed above for the main Nuclear Island dewatering contaminant risk assessment, predicted H-3 contamination is not significant, with peak H-3 concentrations falling below the current UK Drinking Water Standard of 100Bq/l by a substantial margin. Therefore this contamination will not present a significant risk to the ISFS excavations.

15.5.196 The second potential source of contamination is directly from the north-western part of the HPA site. As discussed in **Appendix 15I**, the geological layers underlying the HPA and HPC sites dip northwards at approximately 11 degrees. The groundwater monitoring boreholes on the HPA site are comparatively shallow and are not deep enough to penetrate to the potential depths where contamination from southerly HPA sources may reside as it is transported northwards to the Bristol Channel under baseline conditions. Thus the presence of deeper groundwater contamination in the north-western part of the HPA site is an uncertainty within this assessment.

15.5.197 It is possible, however, to address this uncertainty conceptually by calculating in reverse the H-3 concentration levels that would have to be present on the north-western part of the HPA site in order to breach the current UK Drinking Water Standard during ISFS dewatering. By applying the 100Bq/l H-3 limit to the eastern boundary of the ISFS excavations, it has been calculated that a H-3 concentration of up to 6,470Bq/l could be present 100m to the east of the ISFS excavations on the HPA site without breaching the adopted 100Bq/l limit in the ISFS excavations during dewatering. These calculations assumed dilution in groundwater, longitudinal and transverse dispersion and radioactive decay. As detailed above for the main Nuclear Island contaminant assessment, there are no known current or historical sources of H-3 groundwater contamination anywhere on the HPA site that breach 2,000Bq/l, less than one third of 6,470Bq/l.

15.5.198 In summary, there is no known contamination on the HPA site which will present a significant risk to the ISFS excavations during dewatering. Furthermore, H-3 contamination drawn onto the HPC site during main Nuclear Island dewatering has already been assessed as insignificant and will therefore not present an additional risk to the ISFS excavations.

f) Groundwater Receptors and Value

15.5.199 Groundwater receptors and their designated sensitivities are provided in **Table 15.2** and **Table 15.17** below.

Table 15.17: Summary of Groundwater Receptors and Their Value/Sensitivity Local to HPC

Receptor	Value/ Sensitivity	Comment
Blue Lias in proximity to coastal waters	Low	No abstractions and no Source Protection Zone designations, however, proximity to the foreshore and associated ecological receptors are taken into consideration.
Groundwater quality/aquifer properties	Low	Secondary A Aquifer. No significant local use at or adjacent to the site in or down-gradient of the likely area of influence. No Source Protection Zone designations.
Groundwater recharge/groundwater levels	Very low	Secondary A Aquifer tolerant of change.

15.5.200 **Table 15.17** is based upon Environment Agency groundwater vulnerability classifications, with Principal Aquifers being designated as High or Medium value, depending on the presence and location of water supply abstractions, and Secondary Aquifers being designated as Low or Very Low value. Low sensitivity sites are within the Catchment Source Protection Zone of a water supply abstraction.

15.5.201 As far as Hinkley Point is concerned, the Blue Lias is a Secondary A Aquifer, and the similar lithologies of the Lilstock Formation of the Penarth Group are also likely to be Secondary A. The Westbury, Blue Anchor and Mercia Mudstones are Secondary B Aquifers due to their yielding limited amounts of groundwater from minor fractures or thin permeable horizons.

15.5.202 River alluvium in the Holford Stream is designated as Secondary A, and the marine alluvium south and east of Hinkley Point A and Hinkley point B (North Moor, Wick Moor etc.) is designated as Secondary Undifferentiated, meaning it is not definitively attributable to either Secondary A or B.

15.5.203 On the basis of **Table 15.17** therefore, the whole of the HPC Development Site and its surroundings would be classified as Very Low groundwater value because all formations are Secondary A or poorer, and there are no water supply abstractions which invoke the need for Source Protection Zones.

15.5.204 Nevertheless, it is deemed prudent and conservative to limit the Very Low value only in respect of groundwater level change, and to use Low for groundwater quality aspects in view of the proximity of the HPC site to the shoreline and the presence of marine ecology receptors (**Table 15.17**).

15.6 Assessment of Impacts

15.6.1 This section provides an assessment of the key project elements which have the potential to impact on or be impacted by groundwater during the construction and operational phases of HPC (including dismantling and removal with respect to the temporary jetty).

a) Environmental Management and Protection Measures

15.6.2 The following impact assessment has been undertaken assuming legislative compliance and the adoption of standard good practice.

15.6.3 Environmental impacts arising from construction activities would be managed through specified mitigation and a range of control measures and monitoring procedures which are outlined in the **Environmental Management and Monitoring Plan (EMMP)** and the subject specific management plans (SSMPs) **(see Annex 3)**.

15.6.4 The SSMPs that are of relevance to groundwater include:

- Water Management Plan;
- Land Contamination Management Plan;
- Materials Management Plan; and
- Emergency Incident Control Plan.

15.6.5 The site will be regulated under an Environmental Permit and Radioactive Substances Authorisation. The Environment Agency has stipulated a series of indicative Best Available Techniques (BAT) within several of their recent guidance documents on environmental permitting for a variety of process industries and large installations such as nuclear power stations. Relevant selected examples of indicative BAT practices which represent standard control measures are provided below for illustrative purposes.

15.6.6 For subsurface structures, the indicative BAT requirements relevant to groundwater include:

- engineer systems to minimise leakages from pipes and ensure swift detection if they do occur, particularly where hazardous substances are involved; and
- provide secondary containment and/or leakage detection for subsurface pipework, sumps and storage vessels.
- for bunds the indicative BAT guidance requires that bunds should:
- be impermeable and resistant to the stored materials;
- have a capacity greater than 110 percent of the largest tank or 25 percent of the total tankage, whichever is the larger; and
- be fitted with a high-level probe and an alarm, where not frequently inspected.

b) Potential Impacts during both Construction and Operation

15.6.7 The following activities may take place during both construction and operation, therefore the impacts are only described once to avoid repetition.

Groundwater Impacts due to Accidental Spillages or Leakage from Mechanised Plant

15.6.8 Construction works and operation would require the use of mechanised plant and, therefore, have the potential to impact upon groundwater quality from the accidental spillage or leakage of contaminating liquids such as diesel fuel and hydraulic oil. Unmitigated, such spillages could seep through the unsaturated zone and contaminate the groundwater. It is, however, assumed that standard good practices would be observed, such as:

- maintenance of plant in good and clean condition;
- use of drip trays beneath hydraulic connections and sumps; and
- refuelling only in specified hardstanding areas protected by oil separators and with fuel stored in suitably bunded compounds.

15.6.9 Vehicle parking area drainage would include appropriately placed oil interceptors to remove contamination prior to release to the drainage system.

15.6.10 The scale of the impact is local since the potential impact is confined to the location of the plant activity and its immediate vicinity.

15.6.11 Minor contamination impacts result in a magnitude determination of low. On the basis of the low sensitivity (Secondary Aquifer with no abstractions in the vicinity and outside any SPZ) and low magnitude, the significance of the impact to groundwater is assessed as **minor adverse.**

Groundwater impacts due to Hardstanding Areas

15.6.12 Construction of hardstanding and road construction to groundwater is minimal. The only two factors that have any environmental relevance are:

- increase in hardstanding and impermeable surface areas which could reduce recharge to groundwater and increase run-off; and
- potential impact to groundwater quality from the accidental spillage or leakage of contaminating liquids such as road vehicle fuel and oil via road drainage and/or soakaways.

15.6.13 In hardstanding areas (car parks and metalled roads) there could be some minor but probably indiscernible impact on groundwater recharge and groundwater levels as recharge is reduced due to the diversion of run-off away from the hardstanding areas and into the surface water system.

15.6.14 The scale of this impact is local since the potential impact is confined to the location of the hardstanding and its immediate vicinity. It is likely that the impact would occur but any impact would be barely discernible.

15.6.15 Barely discernible impacts on a Secondary A Aquifer result in a magnitude determination of very low. On the basis of the very low sensitivity (Secondary Aquifer with no abstractions in the vicinity and outside any SPZ) and very low magnitude the impact significance is assessed as **negligible**.

Impacts on Humans (Site Workers) Relating to Groundwater Quality

15.6.16 Compliance with standard health and safety legislation and construction site practice is regarded as the baseline for the assessment and not considered as a separate specific mitigation. Hence, potential exposure to groundwater containing contaminants at the concentrations described above would not be considered to be an environmental impact. Any such 'impacts' are automatically mitigated by the adoption of exposure control measures including the wearing of appropriate Personal Protective Equipment (PPE) if required thus **no impacts** are anticipated.

c) Construction Impacts

15.6.17 Potential construction impacts include impacts that could occur during preliminary works (for the site preparation and temporary aggregates jetty) as well as during the main construction works. A number of impacts such as site clearance will be similar no matter what time in the process they occur so they are only discussed once. Where impacts are confined to a specific construction phase that phase is identified. The following construction impacts are addressed:

- site clearance (vegetation removal);
- ground preparation;
- site drainage;
- retaining wall (preliminary works);
- Holford Stream drainage;
- soil contamination;
- dewatering (main site construction);
- groundwater levels;
- groundwater quality;
- saline intrusion;
- other abstractions; and
- buildings and infrastructure.

i. Site Clearance (Vegetation Removal) – Impacts on Recharge and Groundwater Levels

15.6.18 Site clearance will involve the removal of vegetation including arable crops, grass, trees and hedgerows. Although trees and hedgerows have an enhanced potential for evapotranspiration compared with arable crops, grass or bare soil, this is not considered to be a major factor in the groundwater recharge regime in the study area overall, especially compared with the likely background seasonal variation in rainfall. Removal would increase groundwater recharge very slightly by reducing losses from evapotranspiration and consequently causing a slight increase in groundwater levels in aquifer outcrop areas.

15.6.19 In many cases site clearance will be followed by soil stripping and platform creation in the same areas, and so impacts in relation to site clearance would be incorporated within the subsequent activities. There would nevertheless be some areas where site clearance is the only activity.

15.6.20 Any impact upon groundwater recharge and levels arising from vegetation removal would be local (i.e. confined to the area of clearance) and likely to be indiscernible from, and lower in magnitude than, seasonal variation. The impact is reversible because re-vegetation of cleared areas would offset any potential change. As a result, the magnitude of impact is assessed as very low. On the basis of the very low sensitivity of the aquifer (Secondary Aquifer with no abstractions in the vicinity and outside any SPZ), the impact significance is therefore assessed as **negligible**.

ii. Ground Preparation (Topsoil Stripping and Materials Stockpiling) – Impacts to Recharge, Groundwater Levels and Aquifer Properties

15.6.21 Ground preparation activities have the potential to cause the following types of impacts:

- changes in recharge and groundwater levels in soil-stripped source areas;
- changes in recharge and levels in the stockpiled areas; and
- changes in aquifer properties in the stockpiled areas.

15.6.22 Removal of topsoil material would reduce the thickness of the unsaturated zone above the water table and could facilitate more rapid recharge locally. However, any enhanced local recharge and water table rise would be relatively quickly dispersed into the wider aquifer regime as water levels adjust to restore shallower gradients and smoother water table topography. These changes in water level (increases) would also be influenced by, and probably masked by, the impact of the new drainage works on groundwater levels (decreases).

Impact to Recharge and Groundwater Levels in Stripped Source Areas

15.6.23 Topsoil or subsoil removal is not likely to have a significant impact on groundwater recharge in the source areas. The absence of soil water retention properties (especially at times of soil moisture deficit) due to loss of topsoil may result in a slight and localised increase in groundwater recharge as recharge is enhanced due to the removal of soil moisture retention characteristics. This is, however, unlikely to be discernible in the context of normal seasonal variations in rainfall.

15.6.24 The scale of the impact is local since the potential impact is confined to the location of the subsoil and rock stripping and its immediate vicinity. It is certain that the impact would occur; however, the impact is reversible.

15.6.25 Such impacts result in a magnitude determination of very low to low. On the basis of the very low sensitivity (Secondary Aquifer with no abstractions in the vicinity and outside any SPZ see **Table 15.17**) and very low to low magnitude, the impact significance is assessed as **negligible**.

Impact to Recharge and Groundwater Levels in Stockpile and Aggregate Storage Areas

15.6.26 Stockpiling of soils and rock will principally take place within the SCPA. The water table in the Blue Lias in the SCPA reflects the surface topography and is controlled by the levels of Bum Brook and Holford Stream to which it discharges as baseflow (see **Figure 15.7** and **Figure 15.15**). Between the watercourses the natural water table is likely to be slightly higher than the surface drainage, the actual level being dependent on permeability, storage and recharge rate.

15.6.27 As for soil stripped areas, stockpile areas would affect local drainage and reduce or slow down groundwater recharge under their footprints. These effects would also be dissipated as the surrounding groundwater levels change to adjust to the new local recharge regime. These changes in water level would also be influenced by, and probably masked by, the impact of the new drainage works on groundwater levels.

15.6.28 Stockpiling may result in a reduction in direct recharge to the stockpile footprint in areas where the Lower Lias aquifer outcrops. This results from the enhanced run-off from the stockpile slope faces. However, this enhanced run-off could then recharge the aquifer away from the stockpile footprint if not carried directly to the surface water drainage, which in any event receives groundwater baseflow. The stockpile areas would form a small proportion of the total groundwater catchment.

15.6.29 The scale of this impact is local since the potential impact is confined to the location of the stockpiling and its immediate vicinity. It is likely that the impact would occur but only possible that any impact would be discernible. The impact is reversible because stockpile removal would offset any potential impact.

15.6.30 Barely discernible impacts on a Secondary A Aquifer result in a magnitude determination of very low. On the basis of the very low sensitivity (**Table 15.17**, Secondary Aquifer with no abstractions in the vicinity and outside any SPZ) and very low magnitude, the impact significance is assessed as **negligible**.

Impact to Aquifer Properties in Stockpile and Aggregate Storage Areas

15.6.31 Stockpile areas could change groundwater properties in the aquifer material beneath them. This would be due to the loading resulting in the squeezing of pore spaces and fractures and a consequent reduction in permeability and storage. For a given recharge condition this would result in a rise in shallow groundwater levels, which increases the groundwater gradient required to allow the throughflow of the same volume of groundwater.

15.6.32 The scale of the impact would be local, since the potential impact is confined to the location of the stockpiling and its immediate vicinity. It is very unlikely that the impact would occur given geological preconsolidation, and unlikely that any impact would be discernible. Any impact, however unlikely, would however be permanent because compression effects would remain after removal of the loading.

15.6.33 Barely discernible impacts would cause an effect of a very low magnitude to arise. On the basis of this and the very low sensitivity of the receptor (Secondary Aquifer with no abstractions in the vicinity and outside any SPZ), the impact significance is assessed as **negligible**.

iii. Retaining Wall (Preliminary Works) – Impacts to Groundwater Levels

15.6.34 Prior to the site levelling activities a soil retaining structure (retaining wall), would be constructed in the area where the proposed platform elevation at 14mAOD is greater than the existing ground level.

15.6.35 No dewatering is required for the retaining wall, so the only potential impacts are related to increased groundwater levels behind the wall.

15.6.36 There could be localised increases in groundwater level that are not collected by the drainage relief pipework incorporated in the retaining wall design.

15.6.37 The scale of the impact is local since the potential impact is confined to the location of the retaining wall and its immediate vicinity. The sensitivity with respect to groundwater is assessed as very low (Secondary Aquifer with no abstractions in the vicinity and outside any SPZ). It is possible that the impact would occur and possible that any impact would be discernible. The impact is likely to be temporary. The potential groundwater impacts result in a magnitude determination of very low; hence, the groundwater impact significance is assessed as **negligible**.

iv. Holford Stream Drainage and Interactions with Groundwater

15.6.38 The groundwater conceptual model suggests that the Holford Stream is partially fed by groundwater baseflow where the Blue Lias water table intercepts the surface in the western part of the Holford Stream catchment in the SCPA. This groundwater component augments the surface water run-off component.

15.6.39 The general catchment characteristics would not be altered during the site preparation works as the area would be used for the stockpiling of soils and rock until a substantial proportion of them can be reused in subsequent construction works and site restoration after the completion of construction. Culverted drainage would be installed below the stockpiles to ensure the upper surfaces of the soil are suitably drained, especially of water caused by the consolidation of the ground during loading by stockpiles.

15.6.40 The engineering design of the culverting would incorporate construction of sufficient permeability (as in a French drain, for example) to allow for continued flow of groundwater into the culverted section of the Holford Stream. Without such a design it is possible that groundwater heads would rise in the vicinity of the culverted section leading to localised temporary flooding and/or saturation of the lower parts of stockpiled materials.

15.6.41 Given appropriate design the impact on groundwater behaviour will be permanent and local in spatial scale, i.e. in the near vicinity of the culvert drainage system. The potential groundwater impacts result in a magnitude determination of very low; hence, the groundwater impact significance is assessed as **negligible**.

v. Existing Soil and Groundwater Contamination

15.6.42 Known contamination ‘hot spots’ from the spoil mounds or elsewhere in the BDAE would be removed for appropriate offsite disposal during the enabling works, and it is assumed that any other contamination identified subsequently during the site preparation works would be dealt with similarly. Any material remaining will be suitable for use (after treatment if necessary). Accordingly, there is no known potential for groundwater contamination arising from the topsoil or spoil stockpiles. These stockpiles are addressed in terms of potential soil impacts in **Chapter 14** of this volume.

15.6.43 Groundwater sampling campaigns undertaken within this area, (Ref. 15.41 and Ref 15.42) have not indicated the presence of significant contamination affecting the groundwater quality within the BDAE, apart from some exceedences of groundwater constituents in relation to screening values. Such exceedences in themselves do not indicate that the water is unsuitable for discharge to the marine environment and thus **no impacts** are anticipated in this context.

vi. Dewatering – Impacts to Groundwater Behaviour and Quality

15.6.44 Following the completion of the preliminary works, and specifically the site preparation works, the remaining earthworks and main construction phase works will be undertaken; these will include further deep excavations for Units 1 and 2; construction of the Nuclear Island and associated buildings and infrastructure; and construction of the sea wall.

15.6.45 Dewatering of deep excavations for buildings and other sub-surface structures is required to enable safe and efficient construction of foundations and the construction of any section of the building(s) below the baseline water table. Dewatering operations will start in advance of excavations so that the working areas are as dry as possible.

15.6.46 The assessment of dewatering effects has been carried out largely with the use of the groundwater numerical model and contaminant transport model described above in Section 15.5.

15.6.47 The extent of the main Nuclear Island deep excavations will cover an area of some 500 x 400m. This area extends to within about 50m of the shoreline. The deepest excavations are for the cooling water pumping stations, nearest to the shoreline, which will be excavated to around -22mAOD. The rest of the main Nuclear Island will be excavated to various depths but for dewatering purposes a depth of -9.5mAOD for the northern part of the area, and -1.2mAOD for the southern part are assumed. In order to be conservative for the assessment, modelled dewatering is to 3m below these levels (main Nuclear Island only). For the ISFS, dewatering to a level of -12mAOD is assumed.

15.6.48 The sea wall design includes passive drainage features (150mm drainage pipes coupled with an engineered drainage layer behind the wall) with invert levels of 4.5 to 5.5mAOD to prevent groundwater mounding behind the sea wall and hence the build up of hydrostatic pressure. These drainage pipes are designed to ensure that groundwater behind the wall (northern part of the HPC Development Site) will not exceed 6mAOD. As such it is assumed that the sea wall will effectively be ‘transparent’ with respect to groundwater flow and thus **no impact** on groundwater behaviour is anticipated.

15.6.49 Dewatering could result in:

- dewatering cones of depression creating new gradients which result in the flow of contaminated groundwater from adjacent areas into the abstraction point(s);
- dewatering cones of depression creating reversal of the baseline groundwater gradient to the Bristol Channel and intrusion of saline water to the Secondary A Aquifer; and
- dewatering cones of depression creating new gradients under buildings in adjacent areas, notably the Hinkley Point A and B power stations.

15.6.50 The assessment of dewatering impacts considers:

- the likely volumes and rates over time of water needing to be removed from the aquifer for effective dewatering (this will be a function of excavation depth, saturated aquifer characteristics, recharge and construction timescale);
- the estimated extent of the dewatering cones of depression using the numerical groundwater model; and
- from the gradients and the aquifer characteristics, estimates of the possible ranges of groundwater contaminant flow rate and travel distances from identified contaminated groundwater sources to the dewatering abstraction.

15.6.51 Comparison with groundwater level maps shows that the platform elevations are generally above existing groundwater levels, although existing natural groundwater levels under part of Unit 1 in the BDAE may be over 14mAOD. **Figure 15.12** and **Figure 15.13** show the nominal groundwater contours derived from water table levels in the shallow Lower Lias piezometers installed on the BDAW. The highest water levels are based on water table data from December 2009.

15.6.52 Without additional water management, the presence of high groundwater levels would make the cut and fill activities associated with the site preparation works in the low platform areas difficult and potentially unsafe. However, the surface water drainage component of the site preparation works would be augmented by spine drains running south-north which would receive groundwater pumped from the deeper excavations in these works. These drains are currently proposed to discharge to the upper shore via a single outfall at an invert level of 7.5mAOD. The spine drains proposed are not designed to collect water themselves, but rather to serve as discharge pipes for dewatering arisings and other surface drainage as required. As such they do not in themselves impact on the groundwater regime.

15.6.53 Deeper excavations for both units would be undertaken during the site preparation works to 3mAOD for and 6mAOD for Units 1 and 2 respectively. This excavation scenario has been modelled. **Figure 15.H.17** (in **Appendix 15H**) indicates that the resulting modelled drawdown cones do not extend outside the development areas. The steady state dewatering volume for this scenario is approximately 4l/s. The detailed earthworks design would also include an additional surface water and rainwater capacity component of the drainage as appropriate. Boreholes for future deep dewatering would also be installed by the dewatering contractor during the site preparation works phase. These will be subject to detailed method statements and risk assessments, although it is not anticipated that there will be any specific groundwater impact to be considered in relation to the borehole drilling; moreover, the boreholes are only temporary but will be retained throughout the period of subsequent construction for as long as dewatering is required.

15.6.54 From the above it is apparent that during the site preparation works drainage and excavation of the areas proposed for the two units would have a local impact confined to the BDAE and BDAW. In any other sensitive areas of the groundwater or surface water/groundwater regimes such as beneath the existing HPA or HPB or in relation to water levels beneath Wick Moor no impact is predicted (see Section 15.5 for further conceptual discussion on the hydrogeological isolation of Wick Moor from the construction dewatering at HPC). The overall magnitude of the impact during site preparation works is rated as low. On the basis of the very low sensitivity (Secondary Aquifer with no abstractions in the vicinity and outside any SPZ) and low magnitude, the impact significance is assessed as **negligible**.

15.6.55 Following the site preparation works, excavations for the building foundations and structures would progress. The planned deep dewatering for the two units and ISFS, and in particular for the excavations for the cooling water pumping stations, has been simulated in the groundwater model.

15.6.56 Most of the dewatering abstraction volume will arise from drainage of the fractures and larger pores in the saturated zone in its area of influence; some water will still be present in the unsaturated zone above the water table as transitional recharge water moving downwards or held in small pores and pore connections by capillary forces in the pre-dewatering saturated zone. The latter will be released into the excavation as the rock material is broken up and removed.

15.6.57 The depth of deep dewatering modelled is specified in **Table 15.16**. In the deepest part of the excavations, dewatering depth is to -25mAOD which is 39m below the level of the development platform at 14mAOD.

15.6.58 Water level conditions in the base case for Layer 1 in the model in the second January of the five year simulation period (representative of a wet period) are represented by **Figure 15.23**, and after five years by **Figure 15.24** (plan) and **Figure 15.25** (section) which present heads in a dry period (final October of five year simulation period). **Figure 15.26** shows Layer 1 water levels after two and a half years of ISFS dewatering.

15.6.59 The influence of the dewatering can clearly be seen in the groundwater contours on the HPC Development Site. The flow direction under Hinkley Point A is modified during dewatering such that flow to the west and towards HPC is possible. However, it should be recognised that the hydraulic gradient under Hinkley Point A is very shallow and the groundwater velocities within the HPA site are likely to be very slow.

15.6.60 Impact on the groundwater regime in terms of modification of gradients establishes quickly. For the main Nuclear Island dewatering, water levels away from the immediate vicinity of the pumping do not change substantially after the 30 day period. ‘Pumping rates’ for the main Nuclear Island dewatering are calculated by the model to be 12l/s (43.2m^3/hr). For ISFS dewatering (by which time main Nuclear Island dewatering has ceased) the average dewatering rate is calculated to be approximately 4l/s.

15.6.61 When considering groundwater impacts, it is very important to recognise the following in respect of the model results and their relation to actual conditions:

- The modelled behaviour is solely in response to the aquifer parameters adopted following calibration. Aquifer permeability, storage, recharge and horizontal/ vertical anisotropy are the principal factors in the response.
- In some areas, recharge may be less than that modelled due to presence of lower permeability made ground or Blue Lias mudstones at the surface. This is in addition to the low recharge zones already included for hardstanding areas on Hinkley Point A and B, and for the alluvium overlying the Blue Lias on Wick Moor. This issue is, however, less important for deep dewatering when any low permeability made ground or superficial deposits over the BDAW and BDAE will have been removed in production of the construction and development platforms and replaced with more permeable engineered backfill.

- The Blue Lias is present at outcrop on both sides of the Hinkley Point Fault. However, this gross geological continuity is almost certainly not matched by hydraulic continuity of the aquifers. Permeable limestone horizons will likely not be in continuity, except where different limestones have fortuitously been brought into contact. Also, in many locations the fault surface will have been smeared by clayey fault gouge. So although fracturing may have produced a permeable zone along the fault, this should be distinguished from its effect on restricting flow perpendicular to the fault. Moreover, east of the Hinkley Point Fault, a NE-SW anticline will tend to introduce greater anisotropy, facilitating flow parallel to its axis, and further restricting flow in the NW-SE direction.

15.6.62 With regard to the contaminant transport modelling, described in detail in **Appendix 15I**, identified sources of contamination at Hinkley Point A that might become environmental issues if mobilised and drawn during dewatering into the HPC site were first subjected to tiered risk assessment as per current UK best practice. This process eliminated sources that were already at concentrations below drinking water standards (DWS) or other appropriate EQSs, or were at a distance beyond the extent of the dewatering capture zone which reached partly into Hinkley Point A. Only four contaminants remained to be investigated after this initial screening, i.e. Sr-90, naphthalene, Hg and H-3.

15.6.63 The list of sources remaining was evaluated using a tiered assessment process, including the retardation of organic and metallic components. In the deterministic (best estimate) assessment, no failure of any contaminant (assessed as exceedences of relevant risk assessment screening criteria) was calculated at any of the receptors (i.e. the HPA/HPC site boundary or dewatering location).

15.6.64 For the more conservative Monte Carlo (statistical) assessments (**Appendix 15I**) it was concluded that:

- Sr-90, naphthalene and Hg do not present a risk of impact at any receptor location.
- H-3 due, to its unretarded nature, may present a potential risk at the HPA/HPC boundary from several of the Monte Carlo assessments.
- None of the contaminants (95th percentile) exceed the DWS or EQS at the dewatering location after four years (five years was also modelled to provide an additional conservative margin).
- No contaminants from Hinkley Point A would reach the dewatering abstraction during the dewatering period of up to five years, but there is a possibility that H-3 could cross the HPC boundary during that time, but only at the 95th percentile level of significance.
- Moreover, the above assessment, like the numerical groundwater model, assumes no additional conservative factors such as the presence of faults that in reality would reduce the propagation of the dewatering cone of depression and thereby also reduce the likelihood of movement of groundwater contaminants from Hinkley Point A which would also have to pass along the fault.

15.6.65 Following the initial contaminant transport modelling, the results of which were presented to the Environment Agency in July 2010, additional data became available and also subjected to review in case any further modelling was necessary. Three new potentially significant sources of contamination on Hinkley Point A were assessed:

- a source of hydrocarbon contamination from borehole G2B measured at 141 mg/l (on the basis of TPH banded solubilities, this could potentially be free phase hydrocarbon contamination);
- a source of free phase hydrocarbon contamination in borehole G40, i.e. not dissolved in the groundwater; and
- H-3 contamination in borehole G35 measured at 89.5Bq/l, which is below drinking the water standard.

15.6.66 The assessment concluded that on the basis of distance and/or concentration none of these additional sources altered the conclusions from the original assessment.

15.6.67 Contaminant transport modelling in GoldSim has shown that attenuation processes such as adsorption on clay minerals severely restrict the mobility of metals in the groundwater environment. Evaporite minerals are only found in low permeability formations, and their survival at all is a strong indication that they reside in a very low activity groundwater environment (see Section 15.5). Moreover, the discharge of salt mineral species into a marine environment is unlikely to be an environmental issue even if they were to be mobilised. In either case, these potential contaminants are not considered to present a significant source of concern.

15.6.68 The possibility of groundwater contamination in the BDAE which is as yet unidentified has been considered. If it occurs at all, it is likely to involve metals and/or hydrocarbons within Made Ground across the northern and north-eastern areas of the BDAE (see Section 15.5). Should any contamination be discovered, and not already removed with contaminated soil as part of managed removal operations, then the same retardation constraints on movement due to dewatering will prevail as discussed above. The management of any discharge of metals or hydrocarbons that potentially reach the dewatering abstraction points are addressed in **Chapter 16** of this volume. No radiological contamination of concern on BDAE has been identified. The concentration of H-3 near the Hinkley Point A boundary is lower than the limit set as the drinking water standard.

15.6.69 For the ISFS which is located closer to the HPC/HPA site boundary than the main Nuclear Island, it was determined in **Section 15.5** that it is highly unlikely that there are sources of groundwater contamination on the north-western part of the HPA site that would result in an exceedence of the adopted 100Bq/l limit with respect to tritium and thus pose a significant risk to human health during dewatering for this building.

15.6.70 It is possible to derive the following conclusions regarding environmental impacts, following the assessment methodology described in Section 15.4. These assessments are also summarised in **Table 15.18**.

Impacts to Controlled Waters (Groundwater Levels)

15.6.71 As described in **Section 15.5,** the dewatering activity will result in the drawdown of groundwater to create cones of depression. These drawdowns are assumed to reach a maximum of -25mAOD at the deep pumping station excavation abstraction points, and -12mAOD for the ISFS excavations which follow.

15.6.72 The cones of depression extend to the southern edge of the BDAW where further propagation is blocked by the upfaulted Mercia Mudstones inlier (as a result the Holford Stream in the SCPA is not affected), and partially across the area of Hinkley Point A. Neither Hinkley Point B nor Holford Stream across Wick Moor are affected – this is the case even without invoking the additional constraints on groundwater flow due to faulting as discussed in **Section 15.5** above where further conceptual discussion on the hydrogeological isolation of Wick Moor from the construction dewatering is presented. Holford Stream in Wick Moor is, moreover, assumed to be separated from the Blue Lias aquifer by low permeability marine and estuarine alluvium which provides a further 'barrier' to any impact on Holford Stream.

15.6.73 The impact on groundwater levels due to dewatering is both site-specific and local. The impact is adverse and direct because it occurs as a direct consequence of the dewatering activity.

15.6.74 The sensitivity of the groundwater environment is assessed as very low (**Table 15.17**). The groundwater body concerned is designated as a Secondary A Aquifer, and there is no current use of the resource at or adjacent to the HPC Development Site in the likely area of dewatering drawdown influence.

15.6.75 It is certain that the impact will occur in the Built Development Areas because the activity itself is the impact. It is likely that the dewatering cone of depression will extend beyond the Built Development Areas into adjacent land during the 4-5 year dewatering programme. The activity of dewatering is temporary but greater than two years. The impact is reversible because the drawdown recovers when abstraction stops.

15.6.76 Temporary and reversible impact on a Secondary A Aquifer results in a magnitude determination of low-medium. Groundwater levels may take more than two years to recover after the dewatering activity, but they are anticipated to recover without any additional action. On the basis of the very low sensitivity and low-medium magnitude the impact significance is assessed as **negligible** to **minor adverse** and no specific mitigation is considered to be necessary.

Impacts to Controlled Waters (Groundwater Quality)

15.6.77 The dewatering activity will cause the movement of groundwater in the cone of depression towards the abstraction point, i.e. the deep excavations. If the groundwater contains contaminants then the contaminants could also move.

15.6.78 The contaminant transport modelling (**Section 15.5**) indicates that contaminant movement into the BDAE or BDAW from Hinkley Point A will be minimal. Sources are either at concentrations below the DWS or EQS risk assessment criteria adopted, too distant, or metal and hydrocarbon contaminants are rapidly retarded by attenuation processes such that they do not migrate beyond the HPA/HPC boundary. It has been calculated using MODFLOW that the flow over the site boundary from HPA to HPC in layer 1 coincident with the extent of the H-3 plume is approximately $26m^3/d$ or 0.3l/s. This is approximately 2.5% of the whole dewatering extracted volume (12l/s) during main construction phase dewatering. Diluting the peak H-3 concentration from the aquifer adjacent to the main Nuclear Island from GoldSim of 7.7Bq/l down to 2.5% of the dewatered water gives a likely concentration of 0.19Bq/l of H-3 within discharged water, which is far below the standard limit of detection for laboratory analysis of 5Bq/l.

15.6.79 Potential for increase and/or mobilisation in existing baseline contaminants in the BDAE will be prevented by removal of the spoil mounds and any other soil "hot-spots" during the enabling works. Similarly, any new "hot-spots" which may be identified during the enabling works or subsequent site preparation works will also be removed. It is unlikely that any remaining groundwater contaminants (potentially metals or hydrocarbons) will be of sufficient concentration or mobility to arrive at the abstraction points at concentrations of concern. The assessment of this potential impact to controlled waters beyond the abstraction, i.e. at discharge to the Bristol Channel, is addressed in **Chapter 16** of this volume.

15.6.80 Whilst there is saline groundwater at depth beneath the HPC Development Site (different origin to saline water in the Bristol Channel), this is not considered sufficiently mobile, or if mobile, to be of environmental concern should it be encountered (see Section 15.5).

15.6.81 Sensitivity of the aquifer with respect to groundwater quality is assessed as low (**Table 15.17)**. The groundwater body concerned is designated as a Secondary A Aquifer, although there is no current use of the resource at or adjacent to the HPC Development Site in the likely area of dewatering drawdown influence.

15.6.82 It is possible that the impact will occur. The activity of dewatering is temporary but greater than two years; however the groundwater flow does not reverse when abstraction stops, it just reverts to its pre-abstraction condition. Therefore any mobile contaminants which have migrated towards the abstractions during dewatering (such as H-3) will revert to moving towards the coast. In both cases they will eventually discharge at some point offshore via vertical fractures through the Blue Lias aquifer beneath the bed of the Bristol Channel, which is the current baseline condition. However, H-3 concentrations on the HPC Development Site are unlikely to breach UK DWS during construction dewatering for either the main Nuclear Island or ISFS.

15.6.83 Permanent and irreversible impact could only occur if mobile contaminated groundwater is present initially on the HPC Development Site. This would potentially result in a magnitude assessment of low-medium. On the basis of the low sensitivity and low-medium magnitude the impact significance is assessed as **minor adverse**.

15.6.84 In any event, no contaminant concentrations are increased by dewatering, they can only migrate and be subjected to dilution and attenuation.

Impacts to Controlled Waters (Saline Intrusion)

15.6.85 Because the dewatering abstraction points are close to the shoreline, there is a potential for saline intrusion to occur during the dewatering programme.

15.6.86 The principal 'barriers' to saline intrusion are the lithological and structural characteristics of the Blue Lias aquifer. The Blue Lias is dipping northwards, so any movement of seawater from the north will have to pass through the formation across the 'grain' of its mudstone and limestone layering. In this direction, permeability is very low due to the predominance of mudstone over limestone and the absence of vertical persistent joints that would facilitate such flow. Vertical permeability has been estimated as being only 1/800th of horizontal permeability.

15.6.87 Sensitivity of the aquifer with respect to groundwater quality is assessed as low (**Table 15.17**). The groundwater body concerned is designated as a Secondary A

Aquifer, although there is no current use of the resource at or adjacent to the site in the likely area of dewatering drawdown influence.

15.6.88 It is possible that the impact will occur. The activity of dewatering is temporary, but greater than two years, however the groundwater flow will reverse to its baseline condition when abstraction stops. Therefore any saline intrusion will begin to reverse after dewatering. Furthermore, saline intrusion should not occur further south than the deep pumping station excavations, which are the closest part of the abstraction to the shoreline.

15.6.89 Any seawater component contributing to the dewatering abstraction will be discharged back to the sea, so no further impacts with respect to discharge to controlled waters need to be considered. In relation to Holford Stream and Wick Moor, further conceptual discussion on the hydrogeological isolation of Wick Moor from the construction dewatering at HPC is presented in Section 15.5. Any saline intrusion that does occur will be confined to the immediate vicinity of the EPR units. There is no dewatering activity that will invoke saline intrusion in Holford Stream or Wick Moor, nor is there any secondary risk from recharge of pumped water since the discharge will be to the sea.

15.6.90 Long-term impact could only occur if any saline intrusion is delayed from recovery after dewatering by the flow rate of the natural groundwater regime. This would potentially result in a magnitude assessment of low-medium, although the extent of aquifer so affected will be small, at most as far as the deep pumping station excavations. On the basis of the low sensitivity and low-medium magnitude the impact significance is assessed as **minor adverse**.

Impacts to controlled waters (other groundwater abstractions)

15.6.91 In theory dewatering could impact the water levels and yields of any abstractions in the cone of depression of the dewatering.

15.6.92 The only licensed abstractions in the study area are to the south of the BDAW/BDAE and outside the SCPA.

15.6.93 Sensitivity is assessed as very low. The nearest licensed abstractions are outside the likely dewatering cone of depression and any changes in groundwater level would be likely to be no more than the seasonal changes already experienced naturally.

15.6.94 The impact is assessed as very unlikely because the licensed abstractions are distant from the dewatering and separated hydrogeologically by the upfaulted impermeable Mercia Mudstones barrier between the BDAW/BDAE and the SCPA. The activity of dewatering is temporary but greater than two years, and the impact is also temporary if it occurs. The impact is also reversible because of the temporary nature of the dewatering activity and the reverting of the groundwater regime to its pre-dewatering configuration subsequently.

15.6.95 Magnitude is assessed as very low, since any changes are unlikely to be anything more than barely discernible (or none at all) over a short period. On the basis of the very low sensitivity and very low magnitude the impact significance is assessed as **negligible**.

Impacts to buildings and infrastructure

15.6.96 If groundwater gradients under a structure increase substantially it is possible that stresses can be generated due to the differential hydrostatic pressures under the structures and potentially cause damage to the foundations due to differential settlement.

15.6.97 The impact could affect buildings with foundations or subsurface structures under the Hinkley Point A site. This impact should it occur would be an indirect consequence of the proposed dewatering.

15.6.98 Sensitivity is assessed as low, because major structures will have deep foundations and will therefore be tolerant to any changes. Moreover, increase of settlement due to drawdown of groundwater is assumed to be low. Such differential stresses are not significant taking the ground conditions into account.

15.6.99 Modelling suggests that groundwater level changes under buildings on adjacent HPA land due to dewatering will not be substantially different to those which occur already in the current baseline groundwater regime. Likelihood is therefore assessed as unlikely. The activity of dewatering is temporary but greater than two years, but the impact could be permanent and irreversible if it occurs.

15.6.100 Magnitude is assessed as very low since barely discernible (or no) changes would occur over a short period. On the basis of the low sensitivity and very low magnitude the impact significance is assessed as **negligible**.

vii.Cumulative Construction Impacts

15.6.101 There are no cumulative construction impacts to groundwater. Each of the construction activities detailed above in **Section 15.6** is spatially or temporally discrete and will therefore not act together to form a set of cumulative impacts.

viii. Dismantling of Temporary Jetty

15.6.102 After the operational life of the temporary aggregates jetty (following main construction), it would be dismantled and the site restored. This would involve dismantling/removal of all added features such as fences, areas of hardstanding, temporary drainage and the service road to return to the baseline environment as far as practicable. The groundwater regime would return to its previous state passively.

15.6.103 These works would involve the use of similar machinery and plant to the construction phase. Accordingly, it is anticipated these actions would result in similar impacts with respect to groundwater levels and recharge to those described for jetty construction. This impact would therefore remain as **negligible**.

d) Operational Phase Impacts

15.6.104 Once the sub-water table buildings are in place and the site is operational the baseline groundwater regime will be altered. Portions of the baseline aquifer system will be replaced by effectively impermeable blocks which will possibly result in localised rises in the groundwater level on the upgradient side, drops in groundwater level on the downgradient side, and consequent changes to localised groundwater flow directions.

15.6.105 Permanent site drainage will include deep drains running south-north, at a level which would drain groundwater local to the sea wall to that level and intercept future groundwater flows. These drains are currently proposed to discharge to the upper shore at an invert level of 7.5mAOD. Also to be constructed is a passive peripheral drain at 8mAOD around the site to control groundwater levels during the operational phase of HPC. Groundwater collected will be discharged to sea via the cooling water outfall.

15.6.106 Operational impacts related to groundwater include:

- change in the groundwater flow regime due to placement of new building foundations, resulting in a rise in groundwater levels;
- change in local recharge to groundwater;
- change in the distribution of offsite contaminated groundwater due to the altered groundwater flow regime; and
- longer term intrusion of sea water due to the altered groundwater flow regime.

15.6.107 Post-construction, the HPC Development Site platform level will be at 14mAOD, overlying several metres of engineered fill which will have been used as backfill around deep foundations and sub-surface structures.

15.6.108 During construction, a major proportion of the shallow Blue Lias formation across the development platform will be removed, along with any confining layers which may have restricted groundwater movement.

15.6.109 During the construction phase a passive groundwater control system will be installed around the south and western edges of the main nuclear and conventional islands and cooling water infrastructure. The drainage system will have an invert level of approximately 8mAOD. This drainage system is designed to intercept shallow groundwater and limit groundwater levels within the main Nuclear Island, conventional Island and pumping station area, i.e. in the area surrounded by the drainage gallery, to a maximum of 8m to 9.5mAOD throughout the operational life of the power station. South of the gallery, the effect of the drainage gallery is anticipated to be less important. The system provides for the required degree of geotechnical safety. In particular, it has been designed to prevent the potential flotation of built structures due to upward groundwater pressure. This drainage system is critical to the safe operation of the HPC site and thus forms part of the required nuclear site safety case. As a result the drainage system will be inspected and maintained on a regular basis to ensure its integrity during power station operation.

15.6.110 Furthermore, during the operational phase there will be less groundwater recharge within the HPC Development Site due to presence of roads, buildings and hardstanding. Thus as the construction dewatering scenario shows no adverse impacts, it is extremely unlikely that the passive drainage system will cause any adverse impacts upon groundwater behaviour due to the higher groundwater levels that will be maintained.

15.6.111 The largest potential impact from the operational groundwater drainage system will be to exert control over the seasonal variation in groundwater levels (approximately 4m) by limiting the winter peak groundwater levels to 8mAOD. Groundwater levels in the summer under baseline conditions are of the order of 8mAOD and are unlikely to be significantly affected.

Impacts on Controlled Waters (Groundwater Levels)

15.6.112 New impermeable sub-water table structures could cause a rise in groundwater level on their up-gradient side. Groundwater levels are controlled at 8 mAOD by the passive groundwater control system as described above.

15.6.113 The scale is site specific (within the BDAW and BDAE only). The impact is direct because it occurs as a direct consequence of the proposed operational groundwater level control system.

15.6.114 Sensitivity is assessed as very low (**Table 15.17**), since the resource is a Secondary A Aquifer and will not be used in the Built Development Areas. The groundwater resource is not a major local feature and is tolerant to groundwater level changes. Any changes will be offset by reduced recharge (due to impermeable surface features such as roads, buildings and hardstanding) and ultimately managed by the groundwater control system.

15.6.115 Some change will occur because impermeable structures are replacing parts of the permeable aquifer. The placement of the structures below the water table and therefore the impact that results is permanent and irreversible. The likelihood is certain.

15.6.116 Magnitude is assessed as low, due to a noticeable but insignificant permanent change within the existing natural range of variation. On the basis of the very low sensitivity and low magnitude the impact significance is assessed as **negligible**.

Sea Water Intrusion

15.6.117 The likely overall continuity of an operational phase groundwater regime that is little changed from the baseline is not expected to result in any changes to the existing limited sea water intrusion. The principal 'barriers' to saline intrusion are the lithological and structural characteristics of the Blue Lias aquifer. As described in Section 15.5, the Blue Lias is dipping northwards, so any potential movement of sea water from the north will have to pass through the formation across the 'grain' of its mudstone and limestone layering. In this direction, permeability is very low due to the predominance of mudstone over limestone and the absence of vertical persistent joints that would facilitate such flow. Vertical permeability has been estimated as being only 1/800th of horizontal permeability.

15.6.118 Impact would be site-specific, confined to the BDAW and BDAE only. The impact would be direct as it occurs as a direct consequence of the proposed development. Changes in groundwater gradients and flow rates are not likely to be outside existing baseline ranges. Sensitivity is therefore assessed as low.

15.6.119 Likelihood is assessed as unlikely. Magnitude is assessed as very low, with barely discernible changes over a small area. On the basis of the low sensitivity and very low magnitude the impact significance is assessed as **negligible**.

Contaminated Groundwater

15.6.120 The operational phase groundwater regime is not expected to significantly change the baseline distribution of any contaminated groundwater. The risk of contamination from surface activities (leakages of fuel, hydraulic fluids, etc.) reaching groundwater will be managed by the EMMP protocols identified in the operational environmental permit and subject-specific management plans, surface water drainage systems and interceptors.

15.6.121 The scale would be local, within the BDAW and BDAE. It is assessed as direct because it occurs as a direct consequence of the proposed development.

15.6.122 Sensitivity is assessed as low. The groundwater body concerned is designated as a Secondary A Aquifer (**Table 15.17**), although there is no current or likely future use of the resource at or adjacent to the HPC Development Site.

15.6.123 Likelihood is assessed as possible. Some change may occur if contaminated groundwater is present because impermeable structures are replacing parts of the permeable aquifer.

15.6.124 Magnitude is assessed as low, with barely discernible changes over a small area. On the basis of the low sensitivity and low magnitude the impact significance is assessed as **minor adverse**.

i. Cumulative Operational Impacts

15.6.125 There are no cumulative operational phase impacts to groundwater as negligible impact significance has been predicted with respect to changes in groundwater levels and saline intrusion with only minor adverse significance applying to one potential source of impact (contaminated groundwater).

15.7 Mitigation of Impacts

15.7.1 There are no impacts assessed in this chapter that result in a significance other than negligible or minor adverse. Therefore, no specific mitigation measures are required. This applies to both the construction (including site preparation and temporary jetty) and operation of HPC.

15.7.2 Since most existing monitoring boreholes will be destroyed during construction, it is intended to install additional groundwater boreholes on the HPC/HPA boundary and to the south-east towards Wick Moor, in order to confirm that significant contaminant migration from HPA site does not occur during the construction phase dewatering. The monitoring will also provide data regarding the extent and magnitude of the dewatering drawdown and is intended to allow confirmation of the predicted impact upon groundwater behaviour particularly in the Wick Moor area.

15.8 Residual Impacts

15.8.1 As there has been no specific mitigation the residual impacts remain the same as the impacts already assessed.

15.9 Summary of Impacts

15.9.1 **Table 15.18** contains a summary of all potential groundwater impacts.

Table 15.18: Overall Summary of Impacts

Project Activity	Receptor	Potential Impact	Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation/ Bes Practices	Residual Impact
Impacts during Preliminary Works, Main Construction Works and Operation								
All	Groundwater	Impact on groundwater quality due to accidental contamination from mechanised plant	Low	Local, indirect, adverse, possible, reversible, temporary	Low	Minor	No mitigation required	Minor
Hardstanding Areas	Groundwater	Impact on groundwater recharge and levels in hardstanding areas due to diversion of run-off into site drainage system	Very low	Local, direct, adverse, possible, reversible, temporary	Very low	Negligible	No mitigation required	Negligible
Impacts during Preliminary Works								
Site Clearance – vegetation removal	Groundwater	Impact on groundwater recharge and levels in hardstanding areas due to diversion of run-off into site drainage system The vegetation removal activity would cause a slight reduction in overall evapotranspiration and consequently a slight increase in groundwater recharge and hence groundwater levels in aquifer outcrop areas.	Very low	Local, direct, adverse, likely, reversible, temporary	Very low	Negligible	No mitigation required	Negligible

Project Activity	Receptor	Potential Impact	Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation/ Bes Practices	Residual Impact
Ground Preparation – stripped areas	Groundwater	Impact on groundwater recharge and levels, source and platform areas In source areas where material is stripped there could be some minor but possibly indiscernible impact on groundwater recharge and levels as recharge is enhanced due to the removal of soil moisture retention characteristics or levels reduced by drainage in platform areas.	Very low to low	Local, direct, adverse, likely, reversible, temporary	Very low	Negligible	No mitigation required	Negligible
Ground Preparation – material stockpiling	Groundwater	Impact on groundwater recharge and levels, stockpile areas Stockpiling may result in a reduction in direct recharge to the stockpile footprint in areas where the Lower Lias aquifer outcrops. This results from the enhanced run-off from the stockpile slope faces.	Very low to low	Local, indirect, adverse, unlikely, reversible, temporary	Very low	Negligible	No mitigation required	Negligible
Ground Preparation – topsoil stripping and stockpiling	Groundwater	Impact on aquifer properties (reduced permeability and storage) due to compression exerted by the stockpile mass. Local modification of groundwater flow regime.	Very low	Local, direct, adverse, very unlikely, irreversible, permanent	Very low	Negligible	No mitigation required	Negligible

Project Activity	Receptor	Potential Impact	Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation/ Bes Practices	Residual Impact
Site levelling/ terracing	Groundwater	Impact from stripped areas on groundwater levels. In some source areas where material would be stripped, notably in the Built Development Area West, the existing groundwater levels are higher than the final platform elevations. These levels would be reduced prior to excavation by the provision of drains to undertake shallow passive (gravity) dewatering, and so the existing groundwater regime would be impacted by having the water table lowered by up to 6m to the level of the drainage inverts at around 9-10m AOD.	Low	Local, direct, adverse, likely, reversible, temporary	Very low	Negligible	No mitigation required	Negligible
Site levelling/ terracing	Groundwater	Impact on groundwater recharge and levels, stockpile areas Topsoil stockpiling may result in a reduction in direct recharge to the stockpile footprint in areas where the Lower Lias aquifer outcrops. This results from the enhanced run-off from the stockpile slope faces.	Very low	Local, indirect, adverse, unlikely, reversible, temporary	Very low	Negligible	No mitigation required	Negligible
Stockpile and Aggregates storage areas	Groundwater	Impact on aquifer properties (reduced hydraulic conductivity and storage) due to the compression exerted by the materials mass locally modifying the subsequent groundwater flow regime.	Very Low	Local, indirect, adverse, very unlikely, irreversible, permanent	Very low	Negligible	N/A	Negligible

Project Activity	Receptor	Potential Impact	Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation/ Bes Practices	Residual Impact
Drainage and dewatering	Groundwater	Impact on groundwater levels due to drainage and dewatering in UK EPR reactor unit areas	Low	Local, direct, adverse, certain, reversible, temporary	Very low	Negligible	No mitigation required but a groundwater monitoring programme will be instigated as part of the EMMP	Negligible
Retaining wall	Groundwater	Impact on groundwater levels	Very low	Local, direct, adverse, possible, reversible, temporary	Very low	Negligible	No mitigation required	Negligible

Project Activity	Receptor	Potential Impact	Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation/ Bes Practices	Residual Impact
Impacts During Main Construction Phase (Including ISFS Construction)								
Construction dewatering	Groundwater	Impact on controlled waters (groundwater levels) The dewatering activity will cause the drawdown of groundwater to create cones of depression. For the main Nuclear Island, this drawdown is assumed to reach a maximum of 29m below platform level, i.e. to -15 to -19mAOD, assumed to represent about 30-40m total drawdown in practice. For the ISFS this drawdown is assumed to reach a level of -12mAOD.	Low-medium	Site specific/local, direct, adverse, certain, reversible, temporary	Very Low	Negligible-Minor	N/A	Negligible-Minor
Construction dewatering	Groundwater	Impact on controlled waters (groundwater quality) The dewatering activity will cause the movement of groundwater in the cones of depression towards the abstraction points, i.e. the deep excavations. If the groundwater contains contaminants then the contaminants will also move.	Low-medium	Site specific/local, direct, adverse, possible, irreversible, permanent	Low	Minor	N/A	Minor

Project Activity	Receptor	Potential Impact	Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation/ Bes Practices	Residual Impact
Construction dewatering	Groundwater	Impact on controlled waters (saline intrusion). Dewatering activity could result in some saline intrusion as far as the deep pumping station excavations and ISFS, but limited by lithology and structure of Blue Lias.	Low-medium	Site specific, direct, adverse, possible, irreversible, permanent	Low	Minor	N/A	Minor
Construction dewatering	Groundwater	Impact on controlled waters (other groundwater abstractions) Dewatering could impact the water levels and yields of any licensed abstractions in the area of influence.	Very low	Local, direct, adverse, very unlikely, reversible, temporary	Very low	Negligible	N/A	Negligible
Construction dewatering	Groundwater	Impact on buildings and infrastructure If groundwater gradients under a structure increase significantly it is possible that stresses can be generated due to the differential hydrostatic pressures under the structures and potentially cause damage to the foundations due to differential settlement.	Very low	Local, indirect, adverse, unlikely, irreversible, permanent	low	Negligible	N/A	Negligible
Impacts during Jetty Dismantling and Restoration								
Removal of constructed features	Groundwater	Same impacts as described for construction phase.				Negligible to Minor		Negligible to Minor

Project Activity	Receptor	Potential Impact	Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation/ Bes Practices	Residual Impact
Impacts during the Operational Phase								
Built sub-water table buildings and structures	Groundwater	Impact on controlled waters (groundwater levels) New impermeable sub-water table structures could potentially cause a rise in groundwater level on their up-gradient side. Offset by reduced recharge and surface drainage system, managed by passive groundwater control system.	Low	Site specific, direct, adverse, certain irreversible, permanent	Very low	Negligible	N/A	Negligible
Built sub-water table buildings and structures	Groundwater	Impact on controlled waters (sea water intrusion) If the baseline groundwater regime is significantly changed, or specifically if the groundwater flux is reduced so that sea water intrusion is facilitated, then sea water could potentially penetrate further inland than it does at present.	Very low	Site specific, direct, adverse, unlikely irreversible, permanent	Low	Negligible	N/A.	Negligible
Built sub-water table buildings and structures	Groundwater	Impact on controlled waters (groundwater quality) Change in the natural groundwater regime resulting in movement and redistribution of contaminated groundwater Possible leakage of contaminants from surface.	Low	Site specific, direct, adverse, possible, irreversible, permanent	Low	Minor	N/A	Minor

CHAPTER 16: SURFACE WATER

CONTENTS

TABLES

FIGURES

APPENDICES

16. SURFACE WATER

16.1 Introduction

16.1.1 This chapter provides an assessment of the potential impacts to the terrestrial surface water environment associated with the construction, operational and land restoration phases of the Hinkley Point C (HPC) development site. Consideration of the current baseline conditions and the potential changes to the hydrological and drainage regime and the water quality status of watercourses within the locality of the HPC development site are presented. Impacts resulting from the potential changes to baseline conditions during the construction, operational and restoration phases identified. Where required, mitigation measures are identified to prevent, reduce and, where possible off-set any potential adverse impacts that are identified to be of significance.

16.1.2 This chapter also assesses the potential impacts that the HPC development will have on the flood regime at the HPC development site and in the surrounding area, during the construction and operational phases. The chapter draws on detailed information and data pertaining to the flood impacts associated with the development of HPC which are to be found in a separate **Flood Risk Assessment (FRA)**.

16.1.3 The **Flood Risk Assessment** has been prepared in accordance with Planning Policy Statement 25: Development and Flood Risk (PPS25) (Ref. 16.1). The **Flood Risk Assessment** considered a number of fluvial, tidal and combined fluvial/tidal/wave overtopping risk scenarios including the anticipated effects of climate changee and sea level rise over the construction and operational phases of the HPC development site. Potential impacts identified through the **Flood Risk Assessment** have been identified in this chapter.

16.2 Scope and Objectives

16.2.1 The scope of the surface water assessment has been determined through specific consultations with statutory consultees and through the Stage 1, Stage 2 and Stage 2 Update consultation processes located elsewhere in the ES.

16.2.2 The assessment of surface water impacts arising from the HPC development site have been undertaken adopting the methodologies described in Section 16.3 of this chapter. This assessment addresses only surface water issues associated with the HPC development. An assessment of potential groundwater impacts is presented in **Chapter 15** and for marine water quality impacts in **Chapter 18**.

16.2.3 The surface water assessment may be divided into two technical areas (hydrology and drainage, and surface water quality), which have merited separate yet complimentary studies. The scope of these two studies is discussed below.

a) Hydrology and Drainage Assessment Scope

16.2.4 The current baseline conditions and the potential changes to the hydrological and drainage regime in the vicinity of the HPC development site have been determined through site walkovers, channel surveys of the local surface water drainage system and through predictive modelling techniques. Baseline conditions and identified existing and future hydrology and drainage receptors are described in Section 16.5. The study area for the hydrology and drainage assessment, as illustrated in **Figure 16.1**, comprises all watercourses (and their associated catchments) that may be affected by the HPC development together with the intertidal area to the north of the HPC development site.

16.2.5 Section 16.6 assesses the potential changes to the baseline hydrology and drainage receptors, which include:

- downstream, on-site, and adjacent watercourses, such as, Hinkley Point C Drainage Ditch (HPC Drainage Ditch), Holford Stream, Bum Brook, West Brook and East Brook, Stogursey Brook, Bayley's Brook, and the watercourses feeding Wick Moor, which lie to the east of the C182, defined as Viewed Rhynes by the Somerset Drainage Board Consortium;
- the intertidal area adjacent to the HPC development site; and
- land adjacent to the HPC development site.

b) Water Quality Assessment Scope

16.2.6 Characterisation of current water quality conditions within the local terrestrial surface waters of relevance to the HPC development site was undertaken in order to establish a baseline against which future potential impacts may be assessed. To define the baseline conditions, a series of terrestrial water monitoring campaigns was undertaken in 2009. Baseline conditions and identified existing and future water quality receptors are described in **Section 16.5.97**. The study area for the water quality assessment includes those surface watercourses within, adjacent to and downstream of the proposed HPC development site, as illustrated in **Figure 16.1**. Section 16.6 assesses the potential changes to the baseline water quality receptors which include:

- HPC Drainage Ditch;
- Holford Stream; and
- Bum Brook.

16.2.7 There is a close relationship between the assessment presented within this chapter and **Chapter 18, Marine Water** and **Sediment Quality**. All potential marine water quality impacts are described and assessed within **Chapter 18**.

16.2.8 In addition to the studies identified above, a number of potential accidents and incidents that may result in surface water-related impacts are assessed.

c) Surface Water Assessment and Objectives

16.2.9 The objectives of this surface water assessment are:

- to identify all surface water receptors within the study area that may be affected by changes to terrestrial water quality or hydrology and drainage, during all phases of the HPC development;
- to characterise the baseline and future baseline surface water characteristics for the study area, including water quality status, watercourse hydraulic characteristics, surface water run-off characteristics and flood risk;

- to assess the impacts from all phases of the HPC development on the identified water quality and hydrology, drainage and flood risk receptors;
- to recommend mitigation measures, if determined necessary, to reduce the impacts on those surface water receptors; and
- to assess the residual impacts of all phases of the HPC development on those identified surface water receptors.

16.2.10 Appropriate mitigation measures aimed at preventing, reducing or off-setting any potential adverse impacts of the HPC development on surface waters that are identified to be of significance are presented in Section 16.7. The assessment of residual impacts following implementation of the mitigation measures is presented in Section 16.8. An assessment of cumulative impacts resulting from the HPC and other planned or reasonably foreseeable projects is provided in **Volume 11** of this ES.

16.3 Legislation, Policy and Guidance

16.3.1 This section identifies and describes legislation, policy and guidance of relevance to the assessment of impacts upon the surface water environment.

16.3.2 As stated in **Volume 1**, **Chapter 4**, the Overarching National Policy Statement (NPS) for Energy (NPS EN-1) when combined with the NPS for Nuclear Power Generation (NPS EN-6) provides the primary basis for decisions by the IPC on applications for nuclear power generation developments that fall within the scope of the NPSs.

16.3.3 Notwithstanding this, the IPC may consider other matters that are both important and relevant to its decision-making. This could include Planning Policy Statements (PPSs), Planning Policy Guidance Notes (PPGs), regional and local policy documents, although, if there is a conflict between these and the NPS, the NPS prevails for the purposes of IPC decision making.

16.3.4 Further, the Planning Act 2008 provides that the IPC must, in making its decision on an application, have regard to any Local Impact Report (LIR) prepared by relevant local authorities. It is anticipated that the LIRs will rely in part on PPSs, PPGs, regional and local policy to provide a context for their assessment. On this basis, regard has been given to these documents (where relevant to the technical assessment) since they are likely to inform the LIRs prepared by the relevant local authorities.

a) International

16.3.5 The scope of the assessment is not affected by international legislation beyond that within the European Union (EU).

16.3.6 Many of the standards and methodologies relating to surface waters are regulated at EU level through a range of environmental directives. The most relevant of these with respect to hydrology and drainage flood risk, and water quality and to the proposed development are the:

- Water Framework Directive (WFD) (2000/60/EC) (Ref. 16.2) (which largely supersedes the Dangerous Substances Directive ((76/464/EEC) (Ref. 16.3));

- Habitats Directive (92/43/EEC) (Ref. 16.4);
- Fish Directive (2006/44/EC) (Ref. 16.5); and
- Floods Directive (2007/60/EC) (Ref. 16.6).

i. Water Framework Directive (Ref. 16.8)

16.3.7 The WFD is a key piece of legislation relating to the protection of water quality and the ecological status of freshwaters and coastal waters.

16.3.8 The WFD provides a mechanism by which disparate regulatory controls on human activities that have the potential to impact on water quality may be managed effectively and consistently. In addition to a range of inland surface waters and groundwater, the WFD covers transitional waters (estuaries and lagoons) and coastal waters up to one nautical mile from mean low water (baseline from which territorial waters are measured). Existing regulations that will eventually be subsumed by the WFD include the Freshwater Fish Directive (78/659/EEC as consolidated in 2006) (Ref. 16.8 and Ref. 16.7) and the Dangerous Substances Directive (76/464/EEC) (Ref. 16.3). The WFD is implemented in England and Wales primarily through the Water Environment (Water Framework Directive) (England and Wales) Regulations 2003 (the Water Framework Regulations) (Ref. 16.8).

16.3.9 UK surface waters have been divided into a number of discrete units termed ‘water bodies’, with meaningful typologies that relate to their physical and ecological characteristics. Based upon ecology and water quality, these water bodies have been classified as falling into different status classes. The WFD requires that all inland and coastal waters must reach at least ‘good’ status by 2015 and that the status of all surface water bodies should not deteriorate. Individual water bodies that have been modified by man to the extent that it will not be possible for them to meet the WFD targets are categorised as Heavily Modified Water Bodies.

16.3.10 Implementation of the WFD is primarily achieved through a system of river basin management planning. The water bodies of England and Wales have been allocated to river basin areas depending on catchment areas and a management plan has been drawn up for each. The plans contain a programme of measures tailored to each catchment and designed to ensure the constituent water bodies achieve and maintain the appropriate status in accordance with the timelines set out in the WFD.

16.3.11 As part of the ongoing implementation of the WFD, the Environment Agency has recently been given the power to apply environmental standards to individually defined WFD water bodies via the ‘River Basin Districts Typology, Standards and Groundwater Threshold Values’ (Water Framework Directive) (England and Wales) Directions 2010 (Ref. 16.9), and the ‘River Basin Districts Surface Water and Groundwater Classification’ (Water Framework Directive) (England and Wales) Direction 2009) (Ref. 16.10).

ii. Dangerous Substances Directive (76/464/EEC) (Ref. 16.3)

16.3.12 The Dangerous Substances Directive (76/464/EEC) (Ref. 16.3) is implemented through the Surface Waters (Dangerous Substances) (Classification) Regulations 1997 (Ref. 16.11) and 1998 (Ref. 16.12). It sets Environmental Quality Standards (EQS) for a range of substances in water. The regulation of ‘Priority Substances’ under the WFD effectively supersedes many of these standards, although standards for some substances remain in force. The 2010 Directions referred to above complete the transposition of the Priority Substances Directive (Ref. 16.13).

16.3.13 The Dangerous Substances Directive and its 'daughter' directives are concerned with controlling the level of discharges that may contain dangerous substances and which may reach inland, coastal and territorial waters. List I substances – Black List, covers substances that are regarded as particularly toxic and persistent and which may accumulate in the environment. Pollution by these substances must be eliminated. List II substances – Grey List, cover substances whose effects are less serious but still toxic. Pollution by Grey List substances should be reduced wherever possible.

iii. Fish Directive (Ref. 16.5)

16.3.14 The Fish Directive (Ref. 16.5) is concerned with protecting and improving the quality of rivers and lakes to encourage self sustaining healthy fish populations. It sets out physical and chemical water quality objectives, and monitoring requirements for designated areas.

16.3.15 The Directive was originally adopted in 1978 and was consolidated in 2006. It will be repealed in 2013 by the WFD (Ref. 16.2).

iv. The Floods Directive 2007 (Ref. 16.6)

16.3.16 The Floods Directive (2007/60/EC) (Ref. 16.6) requires all Member States to determine if watercourses and coastlines are at flood risk, to map flood extent and assets and people at risk from flood, and to take appropriate measures to reduce the flood risk. Delivery of the Floods Directive is coordinated with the Water Framework Directive (Ref. 16.8) through flood risk management plans and river basin management plans. The Floods Directive is transposed into domestic law via the Flood Risk Regulations 2009 (Ref. 16.14).

b) National Legislation

16.3.17 The key pieces of national legislation relevant to the control and mitigation of risks to the surface water environment are:

- Environment Act 1995 (Ref. 16.15);
- Environmental Protection Act 1990 (Ref. 16.16);
- Environmental Permitting (England and Wales) Regulations 2010 (EPR) (Ref. 16.17);
- Water Resources Act 1991 (Ref. 16.18);
- Surface Waters (Dangerous Substances) (Classifications) Regulations 1997 (Ref. 16.11) and 1998 (Ref. 16.12);
- Water Environment (Water Framework Directive) (England and Wales) Regulations 2003 (the Water Framework Regulations) (Ref. 16.8);
- River Basin Districts Typology, Standards and Groundwater Threshold Values (Water Framework Directive) (England and Wales) Directions 2010 (Ref. 16.9);
- River Basin Districts Surface Water and Groundwater Classification (Water Framework Directive) (England and Wales) Direction 2009 (Ref. 16.10);

- Land Drainage Act 1991 (Ref. 16.19);
- Flood Risk Regulations 2009 (Ref. 16.14); and
- Flood and Water Management Act 2010 (Ref. 16.20).

i. **Environment Act 1995** (Ref. 16.15)

16.3.18 This Act established basic terms of reference for the Environment Agency. The Act provides the Environment Agency with a duty to take action as it considers necessary to conserve, enhance and secure the proper use of water resources in England and Wales. In respect of land drainage and flood defence functions, the Act places a duty on the Environment Agency with respect to the conservation of natural beauty and sustainable development.

ii. **Environmental Protection Act (EPA) 1990** (Ref. 16.16)

16.3.19 Part IIA of the Environmental Protection Act 1990 describes a regulatory role for Local Authorities in dealing with contaminated land, including assessment for any resulting pollution of controlled waters.

iii. **Environmental Permitting (England and Wales) Regulations 2010** (Ref. 16.17)

16.3.20 The Environmental Permitting Regulations 2010 (Ref 16.17) provide a consolidated system for environmental permits and exemptions for activities which include discharges to surface waters. It also sets out the powers, functions and duties of the regulators. The Environmental Permitting Regulations repeal parts of the Water Resources Act, 1991 (Ref. 16.18).

iv. **Water Resources Act 1991** (Ref. 16.18)

16.3.21 The Water Resources Act 1991 (Ref 16.18) (as amended by the Water Act, 2003 (Ref. 16.21) sets out the regulatory controls and restrictions that provide protection to the water environment through controls on abstraction, impounding and discharges as well as identifying water quality and drought provisions. This Act set the framework for surface water management over the past two decades in the UK, but elements of the Water Resources Act have now been superseded by the Environmental Permitting (England and Wales) Regulations 2010 (Ref. 16.17).

v. **Surface Waters (Dangerous Substances) (Classifications) Regulations 1997** (Ref. 16.11) **and 1998** (Ref. 16.12)

16.3.22 These Regulations prescribe a system for classifying the quality of inland freshwaters, coastal waters and relevant territorial waters with a view to reducing the pollution of those waters by dangerous substances (as defined by the Dangerous Substances Directive (Ref. 16.12). The Environment Agency is required by the Regulations to monitor the effect of discharges containing dangerous substances.

vi. **Water Environment (Water Framework Directive) (England and Wales) Regulations 2003 (the Water Framework Regulations)** (Ref. 16.8)

16.3.23 These Regulations make provision for the purpose of implementing the WFD (Ref. 16.8). The Environment Agency is required to carry out detailed monitoring and analysis in relation to each river basin district. The results of the Agency's technical work, the environmental objectives and proposals for programmes of measures are brought together in a River Basin Management Plan (RBMP) for each river basin district. The South West RBMP covers the study area for the surface water assessment (see paragraph 16.3.49 below).

vii. River Basin Districts Typology, Standards and Groundwater Threshold Values (Water Framework Directive) (England and Wales) Directions 2010 (Ref. 16.9)

16.3.24 These Directions detail the standards used to classify types of watercourses, stillwaters and presents the WFD Environmental Quality Standards (EQS) for surface and groundwaters in England and Wales.

viii. River Basin Districts Surface Water and Groundwater Classification (Water Framework Directive) (England and Wales) Direction 2009 (Ref. 16.10)

16.3.25 These Directions details the criteria that are used for the classification of surface and groundwaters in England and Wales for the purpose of the Water Framework Directive.

ix. Land Drainage Act 1991 (Ref. 16.19)

16.3.26 This Act consolidates enactments relating to Internal Drainage Boards and the functions of these boards and of Local Authorities in relation to land drainage. Internal Drainage Boards (IDB) exercise general supervision and perform powers relating to the drainage of land within their district.

16.3.27 Sections 23 – 27 of the Act address the requirements associated with obstructing flow in watercourses and culverting watercourses. Internal Drainage Board powers to serve notice on persons with respect to remedying the condition of watercourses are outlined in Section 25. Sections 28 to 31 are also of relevance to hydrology and drainage as they outline the requirements for the restoration and improvement of ditches.

x. Flood Risk Regulations (2009) (Ref. 16.14)

16.3.28 The Flood Risk Regulations 2009 (Ref. 16.14) transposes the EC Floods Directive (Ref. 16.6) into domestic law and implement its provisions. The Flood Risk Regulations (2009) do not impact on the private sector. The impact is on the public sector, in particular Local Authorities, and the Environment Agency, which are required to prepare preliminary **Flood Risk Assessment**s, maps and plans. The Environment Agency also has a duty to quality assure and coordinate the outputs and make them available to the EC. Although the outputs of the Flood Risk Regulations 2009 (Ref. 16.14) process are more strategic in nature, there is also a legislative obligation for relevant authorities to provide information where reasonable to fulfil the requirements of the regulations.

xi. Flood and Water Management Act 2010 (Ref 16.20)

16.3.29 The Flood and Water Management Act 2010 (Ref. 16. 20) sets out proposals for a new framework to help improve flood risk management, manage water more sustainably and improve water related services for the public in England and Wales. The Act received Royal Assent on 8 April 2010 and implementation of the first parts of the Act began on the 1 October 2010.

16.3.30 The Act prescribes a number of changes to the assessment and management of flood risk in England and Wales. These changes include defining new roles and responsibilities for flood risk management (including clarifying the Environment Agency's overview role on flood risk management); continuation of the Environment Agency's role in producing and maintaining the main river map; assignment of lead responsibility for local flood risk management to county and unitary local authorities; encouragement of national design and performance standards for Sustainable Drainage Systems (SuDS); and implementation of the Pitt Review (Ref. 16.22) recommendation to place a duty on relevant organisations to co-operate and share information.

c) National Planning Policy

i. Planning Policy Statement 1: Delivering Sustainable Development (PPS1) (2005) (Ref. 16.23)

16.3.31 PPS1 was published in 2005 and sets out the Government's overarching planning policies on the delivery of sustainable development through the planning system.

16.3.32 Paragraph 22 of PPS1 advises that regional planning authorities and Local Authorities should promote, amongst other things, the sustainable use of water resources; and the use of sustainable drainage systems in the management of runoff.

ii. Planning Policy Statement: Planning and Climate Change – Supplement to PPS1 (2007) (Ref. 16.24)

16.3.33 The supplement to PPS1 sets out how planning should contribute to reducing emissions and stabilising climate change (mitigation) and take into account the unavoidable consequences which result from climate change (adaptation).

16.3.34 Paragraph 42 advises that planning authorities in their consideration of the environmental performance of proposed development, taking particular account of the climatic conditions the development is likely to experience over its lifetime, should expect new development to, amongst other things:

> *"…give priority to the use of sustainable drainage systems, paying attention to the potential contribution to be gained to water harvesting from impermeable surfaces and encourage layouts that accommodate waste water recycling…"*

iii. Planning Policy Statement 23: Planning and Pollution Control (PPS23) (2004) (Ref. 16.25)

16.3.35 PPS23 is intended to complement the pollution control framework under the Pollution Prevention and Control Act 1999 and the Pollution Prevention and Control Regulations 2000 (now replaced by the Environmental Permitting (England and Wales) Regulations 2010 (Ref. 16.17). The statement advises on the importance of the planning system in determining the location of development which may give rise to pollution, either directly or indirectly. The statement also ensures that other uses and developments are not, as far as possible, affected by major existing or potential sources of pollution.

16.3.36 PPS23 advises that, amongst other things, the following matters may be material in the consideration of individual planning applications where pollution considerations arise:

- *"…the possible adverse impacts on water quality and the impact of any possible discharge of effluent or leachates which may pose a threat to surface or underground water resources directly or indirectly through surrounding soils;*
- *the need to make suitable provision for the drainage of surface water;…"* (Page 12).

iv. Planning Policy Statement 25: Development and Flood Risk (PPS25) (2010) (Ref. 16.1)

16.3.37 PPS25 is the principal planning policy statement that regulates new developments with respect to flood risk. PPS25 sets out the Government's policies on development and flood risk. The aim of this PPS is to ensure that flood risk is taken into account at all stages in the planning process, to avoid inappropriate development in areas at risk of flooding. Where development is exceptionally necessary in areas of flood risk, this policy intends to make it safe without increasing flood risk elsewhere and where possible, reducing flood risk overall.

16.3.38 Paragraph 8 (Page 5) states:

"LPAs should in determining planning applications:

- *have regard to the policies in this PPS and, as relevant, in the RSS for their region, as material considerations which may supersede the policies in their existing development plan, when considering planning applications for developments in flood risk areas before that plan can be reviewed to reflect this PPS;*
- *ensure that planning applications are supported by site-specific flood risk assessments (FRAs) as appropriate;*
- *apply the sequential approach (see paras. 14–17) at a site level to minimise risk by directing the most vulnerable development to areas of lowest flood risk, matching vulnerability of land use to flood risk;*
- *give priority to the use of SUDs; and*
- *ensure that all new development in flood risk areas is appropriately flood resilient and resistant, including safe access and escape routes where required, and that any residual risk can be safely managed."*

d) Regional Planning Policy

16.3.39 The Government's revocation of regional strategies was quashed in the High Court on 10 November 2010. However, on that same date the Government reiterated in a letter to Chief Planners its intention to revoke regional strategies through the Localism Bill. This letter was also challenged but, on 7 February 2011, the High Court held that the Government's advice to local authorities that the proposed revocation of regional strategies was to be regarded as a material consideration in their planning development control decisions should stand. The decision of the High Court was upheld by the Court of Appeal on 27 May 2011. Therefore, the regional strategies remain in place but in the case of development control decisions it is for planning decision makers to decide on the weight to attach to the strategies (see **Volume 1**, **Chapter 4** for a full summary of the position regarding the status of regional planning policy).

i. Regional Planning Guidance 10 for the South West 2001 – 2016 (RPG10) (2001) (Ref. 16.26)

16.3.40 RPG10 sets out the broad development strategy for the period to 2016 and beyond. Policy RE 1 (Water Resources and Water Quality) states that to achieve the long term sustainable use of water, water resources need to be used more efficiently. The policy also states that the quality of inland and coastal water environments must be conserved and enhanced.

16.3.41 Policy RE 2 (Flood Risk) states that:

"Local authorities, the Environment Agency, other agencies and developers should seek to:

- *protect land liable to river and coastal flooding from new development, by directing development away from river and coastal floodplains;*
- *promote, recognise and adopt the use of sustainable drainage systems for surface water drainage; and*
- *adopt a sequential approach to the allocation and development of sites, having regard to their flood risk potential in accordance with advice in PPG25 (Development and Flood Risk)."*

ii. The Draft Revised Regional Spatial Strategy for the South West Incorporating the Secretary of State's Proposed Changes 2008 – 2026 (July 2008) (Ref. 16.27)

16.3.42 Chapter 7 deals with Enhancing Distinctive Environments and Cultural Life. Policy F1 (Flood Risk) states that:

"Taking account of climate change and the increasing risk of coastal and river flooding, the priority is to:

- *Defend existing properties and, where possible, locate new development in places with little or no risk of flooding.*
- *Protect flood plains and land liable to tidal or coastal flooding from development.*
- *Follow a sequential approach to development in flood risk areas.*
- *Use development to reduce the risk of flooding through location, layout and design.*
- *Relocate existing development from areas of the coast at risk, which cannot be realistically defended.*
- *Identify areas of opportunity for managed realignment to reduce the risk of flooding and create new wildlife areas."*

16.3.43 Policy RE6 (Water Resources) states that:

"The region's network of ground, surface and coastal waters and associated ecosystems will be protected and enhanced, taking account of the Environment Agency's 'Regional Water Resources Strategy', catchment abstraction management strategies, groundwater vulnerability maps, groundwater source protection zone maps and river basin management plans. Surface and groundwater pollution risks must be minimised so that environmental quality standards are achieved and where possible exceeded. Local planning authorities, through their LDDs must ensure that rates of planned development do not exceed the capacity of existing water supply and wastewater treatment systems and do not proceed ahead of essential planned improvements to these systems."

iii. Somerset and Exmoor National Park Joint Structure Plan Review 1991-2011 (2000) (Policies 'saved' from 27 September 2007) (Ref. 16.28)

16.3.44 The Somerset and Exmoor National Park Joint Structure Plan was adopted in 2000 with relevant policies saved from 27 September 2007. The Plan provides a strategic base for all land use planning within the plan area for the period up to 2011.

16.3.45 Policy 15 (Coastal Development) states that provision for any development along the coast, including the Exmoor Heritage Coast, should be made within towns, rural centres and villages. Where development requires an undeveloped coastal location it should respect the natural beauty, biodiversity and geology of the coast and be essential in that location. New coastal developments should minimise the risk of flooding, erosion and landslip.

16.3.46 Policy 59 (Safeguarding Water Resources) states that protection will be afforded to all surface, underground and marine water resources from development which could harm their quality or quantity.

16.3.47 Policy 60 (Floodplain Protection) states that areas vulnerable to flooding should continue to be protected from development which would cause a net loss of flood storage area or interrupt the free flow of water or adversely affect their environmental or ecological value. In allocating land for development in local plans, consideration must be given to measures to mitigate the impact on the existing land drainage regime to avoid exacerbating flooding problems.

16.3.48 Policy 61 (Development in Areas Liable to Marine Flooding) states that provision should only be made for development in areas vulnerable to marine or tidal flooding where the development is needed in that location, no alternative location exists for the development, and adequate measures exist or can be readily provided to protect the development.

iv. River Basin Management Plan, South West River Basin District (2009) (Ref. 16.29)

16.3.49 The River Basin Management Plan (RBMP) has been prepared for the South West River Basin District's rivers and coastal areas under the requirements of the Water Framework Directive (Ref. 16.8). The plan describes the river basin district, and the pressures that the water environment faces. It shows what this means for the current state of the water environment, and what actions will be taken to address the pressures. It sets out what improvements are possible by 2015 and how the actions will make a difference to the local environment including the catchments, the estuaries, coasts and groundwater.

16.3.50 The plan sets out that development planning plays a key role in sustainable development and that the Environment Agency will continue to work closely with planning authorities to ensure that planners understand the objectives of the Water Framework Directive and are able to translate them into planning policy (page 29).

16.3.51 The plan presents current and future water body status objectives (Annex B) and thus site specific Environmental Quality Standards (EQS) can to be derived.

v. South West Regional Flood Risk Assessment (RFRA) (2007) (Ref. 16.34)

16.3.52 In accordance with PPS25 (Ref. 16.1), the South West Regional Assembly published their Regional Flood Risk Appraisal in February 2007 (Ref. 16.30). The document is a high level review of flood risk and strategy. In this document, concerns over the potential effects of climate change are identified across the South West region.

vi. Severn Estuary Flood Risk Management Strategy (2011) (Ref. 16.31)

16.3.53 The consultation sets out the Environment Agency's strategy to manage flood risk on the Severn Estuary.

16.3.54 Specifically in relation to the Hinkley Point C Project, the consultation explains that the Environment Agency's proposals may be amended to complement other projects planned for this area, including the proposed power station at Hinkley Point which would have some impact on flood defences.

e) Local Planning Policy and Local Strategy

i. West Somerset Local Plan (2006) (Policies 'saved' from 17 April 2009) (Ref. 16.32)

16.3.55 The West Somerset Local Plan forms part of the development plan for West Somerset. The Local Plan was adopted in April 2006 (with relevant policies 'saved' from 17 April 2009). The site is not subject to any specific surface water designations. The site lies outside of the defined Development Boundary.

16.3.56 The following saved policies are considered to be potentially relevant:

16.3.57 Policy W/1 (Waste Water Management, Sewage and Sewage Disposal) states:

> *"Development will only be permitted where adequate drainage, sewerage and sewage treatment facilities are available or where suitable arrangements are made for their provision. In sewered areas, new development will be expected to connect to main drainage. New sewers will be expected to be constructed to a standard adoptable by the appropriate water company."*

16.3.58 Policy W/2 (Surface Water Protection) states:

> *"Development which would adversely affect the quantitative and quality aspects of surface, underground or coastal waters will only be permitted*

where acceptable mitigating works are undertaken as an integral part of that development."

16.3.59 Policy W/3 (Groundwater Source Protection) states:

"Development which would adversely affect Groundwater Source Protection Areas will not be permitted if the risk to the quality and quantity of water in water courses or aquifers could result in the inability of a groundwater source to maintain public supply."

16.3.60 Policy W/5 (Surface Water Runoff Management) states:

"Development which would result in significant additional surface water runoff and result in contributing to an increase in the risk of flooding within the site and elsewhere, particularly in relation to areas liable to flooding will only be permitted where appropriate mitigating measures are taken as a part of the development."

16.3.61 Policy W/6 (Floodplain Protection) states:

"Development on floodplains or that which would result in increased flood risk of water courses, land and property, whether on the site or elsewhere will only be permitted where satisfactory environmentally acceptable measures are undertaken to mitigate these risks."

16.3.62 Policy W/7 (Protection of River Corridors) states:

"Development which would harm the landscape, nature conservation, fisheries or the recreational interest of water courses, wetlands and the surrounding landscape will only be permitted where suitable mitigation measures are undertaken to ensure that any damage is kept to a minimum and compensatory measures, including enhancement and habitat restoration, are secured."

ii. West Somerset District Local Development Framework (LDF) Core Strategy (Options Paper) (January 2010) (Ref. 16.33)

16.3.63 The Core Strategy is at a preliminary stage of preparation and the Options Paper does not include any specific policies relating to surface water impacts. The paper does however identify the types of policy that WSC considers could be included in the Core Strategy, including a requirement that new developments incorporate measures to mitigate against flood risk and manage surface water runoff through appropriate use of SuDS (sustainable drainage systems).

iii. Supplementary Planning Guidance

16.3.64 Sedgemoor District Council and West Somerset Council have jointly prepared draft supplementary planning guidance in relation to the Hinkley Point C Project. Public consultation on the Consultation version of the Draft Hinkley Point C Project Supplementary Planning Document (the draft HPC SPD) commenced on 1 March 2011 and concluded on 12 April 2011. EDF Energy has submitted representations which object to the draft supplementary planning guidance. See **Volume 1**,

Chapter 4 for a full summary of the position regarding the status of the draft HPC SPD.

16.3.65 In relation to climate change adaptation and flood risk, Box 3 in the document sets out the following approach:

> *"In accordance with PPS25, the location of development proposals should be justified through a sequential approach, in combination with relevant local policy relating to preferred locations for housing and employment development (where applicable)…*
>
> *...HPC project development should also be sited and designed to with consideration for other potential effects arising from climate change, such as more frequent summer 'heat waves' and generally warmer summers." (Page 12)*

16.3.66 Further planning policy context is provided in the Legislative Planning Policy Context chapter (**Volume 1**, **Chapter 4**) and the Introduction chapter (**Volume 2**, **Chapter 16**).

iv. West Somerset Council Level 2 Strategic Flood Risk Assessment (SFRA) (Ref 16.34)

16.3.67 The West Somerset Council Level 2 Strategic Flood Risk Assessment (SFRA) was published in October 2010, as a follow up to the Level 1 SFRA. The Level 2 SFRA considers three strategic development areas in West Somerset within the settlements of Minehead, Williton and Watchet. There are no specific requirements for the HPC development site.

v. West Somerset Catchment Flood Management Plan (Ref 16.35)

16.3.68 The HPC development site is within the area covered by the West Somerset Catchment Flood Management Plan, which was completed in December 2009. HPC is located in Sub Area 8, Hills and Cliffs, which has been assigned Policy Option 1: Monitor and Advise, for which no specific actions were identified.

vi. Parrett Catchment Flood Management Plan (Ref. 16.36)

16.3.69 The southern section of the HPC development site is located within the Holford Stream valley, which is within the area covered in the Parrett Catchment Flood Management Plan. Holford Stream valley and the upstream sections of Bum Brook, Bayley's Brook and Stogursey Brook are located within the 'Upper and North West Parrett' sub-area. The downstream sections of these watercourses, including Wick Moor, are located within the 'Shoreline' sub-area. Both of these sub-areas are covered by Policy 3:

> *"Areas of low to moderate flood risk where we are generally managing existing flood risk effectively – This policy will tend to be applied where the risks are currently appropriately managed and where the risk of flooding is not expected to increase significantly in the future. However, we keep our approach under review, looking for improvements and responding to new challenges or information as they emerge. We may review our approach to managing flood defences and other flood risk management actions, to*

ensure that we are managing efficiently and taking the best approach to managing flood risk in the longer term."

vii. Parrett Internal Drainage Board Byelaws (Ref. 16.37)

Byelaw 3 – Control of Introduction of Water and Increase in Flow or Volume of Water

"No person shall, without the previous consent of the Board, for any purpose, by means of any channel, siphon, pipeline or sluice or by any other means whatsoever, introduce any water into the District or, whether directly or indirectly, increase the flow or volume of water in any watercourse in the District."

Byelaw 10 – No Obstructions within 9 Metres of the Edge of the Watercourse

"No person without the previous consent of the Board shall erect any building or structure, whether temporary or permanent, or plant any tree, shrub, willow or other similar growth within 9 metres of the landward toe of the bank where there is an embankment or wall or within 9 metres of the top of the batter where there is no embankment or wall, or where the watercourse is enclosed within 9 metres of the enclosing structure."

f) Best Practice Guidance

16.3.70 A range of best practice guidance is of relevance to this assessment including the following (only those specifically referred to in the assessment of impacts are included in the reference list):

- Environment Agency Policy and Practice for the Protection of Groundwater (Ref. 16.38);
- Environment Agency Pollution Prevention Guidance Notes (PPG) (Ref. 16.39), including:
  - PPG 1 General guide to the prevention of water pollution.
  - PPG 2 Above ground oil storage tanks.
  - PPG 3 Use and design of oil separators in surface water drainage systems.
  - PPG 4 Disposal of sewage where no mains drainage is available.
  - PPG 5 Works in, near or liable to affect watercourses.
  - PPG 6 Working at construction and demolition sites.
  - PPG 8 Safe storage and disposal of used oils.
  - PPG 21 Pollution incident response planning.
- Construction Industry Research and Information Association (CIRIA) Report C532: Control of Water Pollution from Construction Sites (Ref. 16.40).
- CIRIA Report C650: Environmental Good Practice on Site (Ref. 16.41).
- CIRIA Culvert Design and Operation Guide (C689) (Ref. 16.42).
- CIRIA: The SuDS Manual (C697) (Ref. 16.43).

- BS6031:2009 Code of Practice for Earth Works (Ref. 16.44).
- Good Practice Guide for Handling Soils (MAFF, 2000); (Ref. 16.45).
- Designing for Exceedance in Urban Drainage – Good Practice, C635 (2006) (Ref. 16.46). This has been used in the determination of an appropriate drainage strategy for the HPC development site.

g) Regulatory compliance

16.3.71 In accordance with PPS25 (Ref. 16.1), surface water Runoff to controlled waters from a greenfield development site should be controlled to greenfield rates unless an alternative rate is agreed during consultation. However, the Environment Agency have stated in a Discharge Conditionality Report for HPC (Ref. 16.47) that, in terms of discharge rate to the foreshore and Bristol Channel, no constraints will be sought, subject to adequate demonstration that no adverse impacts to foreshore ecological habitats will be incurred (as discussed in the **Chapter 19 Marine Ecology**).

16.4 Methodology

16.4.1 The methodology adopted for assessing potential impacts to the surface water environment has been undertaken in accordance with the requirements for the environmental impact assessment of major projects in the UK (see **Volume 1, Chapter 7**). This approach was adopted across all technical study areas and consists of four clear stages:

- definition of the current baseline;
- impact assessment;
- proposed mitigation measures; and
- assessment of any residual impacts after implementation of mitigation.

16.4.2 The construction, operation and land restoration phases of the proposed HPC development are assessed.

a) Study Area

16.4.3 The geographical extent of the study area for this assessment comprises:

- the area within the HPC development site, together with the catchments of watercourses draining into and around the HPC development site; and
- in relation to the hydrology and drainage assessments only, the Hinkley Point intertidal area which will receive surface water discharges from the HPC development site. The water quality assessment for the intertidal area is addressed in **Chapter 18**.

16.4.4 The study area above is illustrated in **Figure 16.1.** In addition, there are eleven locations constituting the off-site highway, these are presented in the project description in **Volume 1, Chapter 2**.

b) Baseline Assessment

16.4.5 Baseline environmental characteristics for the study area were identified by utilising the following key data sources:

- Ordnance Survey (OS) (2005) Landranger Map 1:50,000 scale ‘Weston-super-Mare, Bridgwater and Wells’ Sheet 182 (Ref. 16.48).
- Ordnance Survey (OS) (2009) Landranger Map 1:50,000 scale ‘Minehead and Brendon Hills’ Sheet 181 (Ref. 16.49).
- Environment Agency “What’s In My Backyard” website in 2010 (Ref. 16.50);
- Aerial photography (Ref. 16.51).
- Walkover survey of the site (August 2009) (see photographs in **Appendix 16A**).
- Topographic channel survey of the downstream watercourses and defences (August 2009) (see **Appendix B of the Flood Risk Assessment** (Modelling Report and Figures).
- Consultation with appropriate Statutory Bodies (i.e. Environment Agency and Somerset Drainage Boards Consortium) (see below).
- The **Flood Risk Assessment** for the HPC site.
- Flood Estimation Handbook (FEH) and accompanying CD-ROM (Version 3.0) (Ref. 16.52).
- Extreme Precipitation Analysis at Hinkley Point – Final Report which was prepared for EDF by the Met Office in June 2010 (Ref. 16.53).
- Institute of Hydrology Report No. 124: Flood Estimation for Small Catchments (June, 1994) (Ref. 16.54).
- Terrestrial surface water quality monitoring campaigns carried out in 2009 (Ref. 16.65).

16.4.6 The assessment of the water quality status for surface watercourses in the vicinity of the HPC development site was undertaken using a combination of approaches. Historical water quality monitoring data were only available for Stogursey Brook, and these data were subject to collation and review. A summary of these data is presented in **Appendix 16B**. Of the surface watercourses within the study area, a WFD waterbody description is only available for Stogursey Brook (provided in **Appendix 16C**) and this was used as an indicative surrogate for the water quality status of Holford Stream and Bum Brook which form part of the same catchment. These data were supplemented with a programme of water sample collection and in-situ monitoring during 2009, to provide further information on the water quality conditions, in relation to WFD EQS (Ref 16.8), for watercourses in the HPC development site. The summary results of the water quality monitoring programme are provided in **Appendix 16D** (see also Ref. 16.65).

16.4.7 The desk-based assessments and walkover surveys listed above identified the need for survey data to carry out modelling studies on the extensive fluvial network surrounding the HPC development site and a tidal breach analysis, and analysis of the surface water quality data on the local watercourses.

16.4.8 As identified above a topographic survey of the local watercourses and defences was carried out by an appointed contractor for the **Flood Risk Assessment** and to aid the assessment of impacts to flood risk in this chapter. Details and drawings of which can be found in **Appendix B of the Flood Risk Assessment**.

16.4.9 A description of the proposed HPC development site and broad baseline conditions is provided in **Chapter 2**. Further details regarding the baseline surface water conditions are presented in Section 16.5**.**

c) Consultation

16.4.10 Extensive consultation has been undertaken throughout the EIA process. Meetings were held with the Environment Agency and West Somerset Council to discuss all stages of the assessment including specific aspects of the development. Details of these consultations are given below. Multiple consultations have been carried out in the preparation of the **Flood Risk Assessment** and these are detailed within the **Flood Risk Assessment** document.

i. Stage 1

16.4.11 A range of informal consultations were undertaken with stakeholders prior to publication of the Stage 1 consultation document and these have been detailed below and summarised in **Table 16.1**.

16.4.12 Prior to the commencement of the terrestrial water quality monitoring programme consultations were undertaken with local Environment Agency personnel in December 2008 to agree the sampling locations and analytical test parameters.

16.4.13 A number of other consultation meetings (in addition to the formal consultation reports produced) have taken place as part of the EIA process and these are summarised in **Table 16.1**.

16.4.14 Meetings were held with the Marine Authorities Liaison Group (MALG), as detailed in **Table 16.1**, to discuss various elements of the Hinkley Point C development, including the proposals for the Holford Stream culvert and the surface drainage strategy i.e. discussions were not limited to marine subjects.

16.4.15 MALG members include the Centre for Environment, Fisheries and Aquaculture Science (Cefas), the Countryside Council for Wales (CCW), Natural England (NE), the Environment Agency (EA), the Marine Management Organisation (MMO), Somerset County Council, the Royal Society for the Protection of Birds (RSPB), the Crown Estate, English Heritage (EH) and West Somerset Council (WSC).

Table 16.1: Summary of Surface Water Consultations

Date of consultation	Consultees attending	Issues discussed relating to surface water
15/12/2008	Environment Agency	Discussion and agreement of water quality monitoring strategy
11/5/2009	Environment Agency	Discussion of discharges and consenting
10/8/2009	Environment Agency and SDBC	Discussions surrounding the **Flood Risk Assessment** and drainage requirements
14/10/2009	Environment Agency	Meeting with the Environment Agency regarding construction activities in Holford Valley and associated drainage issues. Discussion of requirement for hydraulic structures such as bridges and culverts
24/6/2009	MALG	Discussion of application for discharge consents Presentation of terrestrial water quality

Date of consultation	Consultees attending	Issues discussed relating to surface water
		monitoring results Discussion of proposed discharge strategy
2/9/2009	MALG	Discussion of information required on discharge consents during construction Discussion of maintaining flows and water quality in Holford Stream
14/10/2009	Environment Agency	Discussion of drainage strategy and culverting of Holford Stream

Stage 1 Consultation Responses

16.4.16 Following issue of the Stage 1 consultation document a range of comments were received from consultees. The comments were taken account of in the scope of on-going studies for the HPC development site. Responses to these comments and how they were accounted for within the studies are provided in the consultation response document.

ii. Stage 2

16.4.17 Further consultation meetings detailed in **Table 16.2**, where terrestrial water quality was discussed, were carried out prior to issue of the Stage 2 consultation document which are detailed below and summarised in **Table 16.2**.

Table 16.2: Summary of Surface Water Consultations Carried Out at Stage 2.

Date of consultation	Consultees attending	Issues discussed relating to water quality
21/1/2010	Environment Agency	Discussion of Holford Stream culvert Discussion of drainage discharge strategy
14/4/2010	MALG	Discussion of drainage strategy in the area of Holford Stream and the importance of the maintenance quality during works was highlighted A discussion regarding drainage to the intertidal area was also held
24/5/2010	Environment Agency, ISDBC, and Natural England	Discussions of drainage strategy during site preparation including culverting of Holford Stream

16.4.18 During a meeting held in May 2010, it was agreed that the Environment Agency would provide a Discharge Conditionality Report (Ref. 16.47) in association with the HPC development site preliminary works which would stipulate requirements for discharges to the intertidal area. The document provided in 2010 by the Environment Agency and refers to the Site Preparation Works, however, this has been used as guidance for the entire HPC development construction phase.

16.4.19 It was agreed with the Environment Agency that EDF Energy would provide a Holford Stream culvert Justification Report. A Briefing Note was provided in July 2010 (Ref 16.55). Discussions were also held as to the requirement for EDF Energy to demonstrate that intertidal habitats would not be impacted as a result of the drainage outfall options under consideration at that time (see, **Chapter 19** – Marine Ecology).

16.4.20 It was agreed with the Environment Agency during consultation held in April 2010, that both the Institute of Hydrology Report No. 124 method (IH124) (Ref. 16.54) and the ReFH method (Ref. 16.56) would be used to calculate baseline peak discharges depending on catchment area (IH124 for areas less than 2 km^2 and ReFH for areas greater than 2km^2).

16.4.21 Additional meetings with the Environment Agency were held towards the end of 2010 to discuss mitigation options for any potential increase in flood risk to third party properties at Stolford.

Stage 2 Consultation Responses

16.4.22 Stage 2 consultation responses for Hinkley Point C relating to surface water considerations, were provided by the Environment Agency, WSC, all other key consultees and the general public between July and October 2010. These consultation responses have been reviewed and addressed in this chapter. Responses to these comments and how they were accounted for within the studies are provided in the Consultation Report.

iii. Stage 2 Update

16.4.23 A range of informal consultations were undertaken with stakeholders prior to publication of the Stage 2 Update consultation document (see below).

16.4.24 At the end of 2010 and beginning of 2011 meetings were held with the Environment Agency and WSC to discuss the approach to the assessment including the **Flood Risk Assessment** and associated modelling. A meeting was held with the Environment Agency in June 2011 to discuss Environmental Permit applications for the construction phase of works.

Stage 2 Update Consultation Responses

16.4.25 Stage 2 update consultation responses for HPC relating to surface water considerations, have been reviewed and addressed in this chapter. Responses to these comments and how they were accounted for within the studies are provided in the Consultation Report.

d) Assessment Methodology

16.4.26 The methodology adopted for assessing the potential environmental impacts to surface waters is outlined in **Volume 1**, **Chapter 7**. In addition, specific information is provided below on the determination of receptor value and sensitivity and of impact magnitudes for surface waters.

i. Value and Sensitivity

16.4.27 All of the surface water receptors that have the potential to be impacted by the proposed HPC development were assigned a level of importance in accordance with those definitions set out in **Volume 1**, **Chapter 7,** and with the surface water specific definitions given in **Table 16.3**.

16.4.28 Where a receptor could reasonably be placed within more than one value and sensitivity rating in **Table 16.3**, conservative professional judgement has been used to determine which rating would be applicable.

Table 16.3: Criteria Used to Determine the Value and Sensitivity of Surface Water Receptors

Importance and Sensitivity	Description
High	*Hydrology and drainage specific definition:* Controlled waters receptor located in area of significant social/community and economic value and considered of high amenity and economic value. Receptors shown on Environment Agency flood maps as being located in designated flood risk zones 2 and 3 and/or all designated Critical Ordinary watercourses. Controlled waters receptor identified is of significant UK or European value in terms of its hydrological status such that designated habitats and/or species are sensitive to change in hydrological regime. Receptor identified as having no capacity to adapt to, or recover from, proposed form of change, i.e. fluvial watercourse will not naturally realign and erode to optimise flow conveyance such that impact will persist. *Water quality specific definition:* Water quality of receptor supports or contributes towards the designation of a feature of national (or international) importance. Very low capacity to accommodate any change to current water quality status, compared to baseline conditions. Water quality of receptor waterbody classified under the WFD as high or good ecological status/potential. The receptor environment is likely to have natural ecosystems and make very good salmonid and cyprinid fisheries. The receptor may be used for any type of water abstraction including potable supply.
Medium	*Hydrology and drainage specific definition:* Controlled waters receptor located in area of moderate social/community and economic value and economic value and considered of medium amenity benefit and economic value. All watercourses defined as Main River. Receptors not located in designated Environment Agency flood risk zones 2 and 3 and are not designated Critical Ordinary watercourses. Controlled waters receptor identified is of moderate UK value or of moderate regional or local value in terms of its hydrological status such that selected designated habitats and/or species are potentially sensitive to change in hydrological regime. Receptor identified as having low capacity to accommodate proposed form of change i.e. fluvial watercourse will only partially reconfigure to optimise flow conveyance such that impact may persist or will be transposed to another location. *Water quality specific definition:* Water quality of receptor supports high biodiversity (not designated). Receptor has low capacity to accommodate change to water quality status. Water quality of receptor waterbody classified under WFD as good ecological status/potential. Receptor environment considered suitable for support of coarse fisheries.

Importance and Sensitivity	Description
Low	*Hydrology and drainage specific definition:* Controlled waters receptor located in area of no social/community and economic value and considered of low amenity benefit and economic value. All controlled waters and designated Ordinary Watercourses that are not designated Main Rivers. Receptors not located in designated Environment Agency flood risk zones 2 and 3 and are not designated Critical Ordinary watercourses. Controlled waters receptor is of only moderate local value in terms of its hydrological status. Receptor identified as having moderate capacity to accommodate proposed form of change i.e. fluvial watercourse will reconfigure to optimise flow conveyance such that change will, after time, return to approaching baseline conditions. *Water quality specific definition:* Baseline conditions define an environment that has a high capacity to accommodate proposed change to water quality status due, for example, to the large relative size of receiving water feature and effect of dilution. Baseline water quality status generally poor. Water quality of receptor could be expected to be classified under the WFD as moderate ecological status/potential. Receptor is likely to be capable of supporting only limited fish populations.
Very Low	*Hydrology and drainage specific definition:* Controlled waters receptor is of poor hydrological value with negligible amenity benefits and economic value. Receptor identified as being generally tolerant to the proposed change. *Water quality specific definition:* Specific water quality conditions of receptor water feature likely to be able to tolerate proposed change with very little or no impact upon the baseline conditions. Water quality of receptor waterbody could be expected to be classified under the WFD as poor or bad ecological status/potential. Poor or bad status waterbodies have severely restricted ecosystems and are very polluted.

ii. Magnitude

16.4.29 The assessment of magnitude of impact has been based on the effects that the HPC development would have upon the local surface water features and has been considered in terms of high, medium, low and very low magnitude ratings.

16.4.30 All of the surface water impacts identified as a result of the HPC development have been assigned a level of magnitude in accordance with those definitions set out in **Volume 1**, **Chapter 7**, and with the surface water specific definitions given in **Table 16.4** below. Potential impacts have been considered in terms of permanent or temporary, adverse (negative) or beneficial (positive) and cumulative.

16.4.31 The assessment of impact magnitude takes into account those elements which form part of the HPC development design, in particular the details of the drainage strategy.

16.4.32 Where a receptor could reasonably be placed within more than one magnitude rating in **Table 16.4**, conservative professional judgement has been used to determine which rating would be applicable.

Table 16.4: Criteria Used to Determine the Magnitude of Surface Water Receptors

Magnitude	Description
High	*Hydrology and drainage specific definition:* Very significant change to key hydrological/hydraulic characteristics of the receiving water feature to the extent that UK and European legislation is contravened. Chronic occurrence of change and/or changes are prolonged, lasting significantly longer than the duration of the hydrological event that initiated the change (i.e. normal period of time over which water levels in watercourse receptors would be expected to rise and fall). Changes are spatially extensive beyond the local area where the impact was incurred. Receptor waterbody impacted to the extent that permanent change in hydrological/hydraulic characteristics of the receptor waterbody significantly contravenes regulatory standards with respect to flood risk or low flow in accordance with statutory legislative requirements. *Water quality specific definition:* Very significant change to key characteristics of the water quality status of the receiving water feature. For example, water quality status degraded to the extent that a permanent change and inability to meet EQS is likely.
Medium	*Hydrology and drainage specific definition:* Significant changes to key run-off characteristics such that hydrological/hydraulic characteristics of the controlled water feature are impacted to the extent that UK and European legislation is contravened. Changes are limited in time to the duration of the hydrological event that initiated the change (i.e. normal period of time over which water levels in watercourse receptors would be expected to rise and fall). Changes are spatially extensive beyond the local area where the impact was incurred. Receptor waterbody impacted to the extent that permanent change in hydrological/hydraulic characteristics render receptor water body unable to meet regulatory standards with respect to flood risk and low flow in accordance with statutory legislative requirements. *Water quality specific definition:* Significant changes to key characteristics of the water quality status taking account of the receptor volume, mixing capacity, flow rate, etc. Water quality status likely to take considerable time to recover to baseline conditions. Changes are limited in time to the duration of the hydrological event that initiated the change (i.e. normal period of time over which water levels in watercourse receptors would be expected to rise and fall).
Low	*Hydrology and drainage specific definition:* Noticeable but insignificant changes to key run-off characteristics such that hydrological/hydraulic characteristics of receptor controlled water features would not contravene UK and European legislation. *Water quality specific definition:* Noticeable but not considered significant changes to water quality status of receptor water feature. Activity not likely to alter local status to the extent that water quality characteristics change considerably or EQS are compromised. Activities are likely to have an impact for a short time scale (e.g. relative to turnover of water feature) and baseline water quality conditions are maintained.

Magnitude	Description
Very low	*Hydrology and drainage specific definition:* Occasional but insignificant impact to key run-off characteristics with changes to hydrological/hydraulic characteristics of receptor controlled water features predicted to occur over a short period of time. Any change to hydrological/hydraulic characteristics will be quickly reversed once activity ceases. *Water quality specific definition:* Although there may be some impact upon water quality status, activities predicted to occur over a short period. Any change to water quality status will be quickly reversed once activity ceases.

iii. Significance of Impacts

16.4.33 The significance of the impact is judged on the relationship of the magnitude of impact to the assessed sensitivity and/or value of the receptor. The methodology for the assessment of the predicted significance of impacts, is outlined in **Volume 1, Chapter 7**.

iv. Cumulative Impacts

16.4.34 **Volume 1**, **Chapter 7** of this ES sets out the methodology used to assess cumulative impacts. Additive and interactive effects between site-specific impacts are considered within this chapter. The assessment of cumulative impacts with other elements of the HPC Project and other proposed and reasonably foreseeable projects are considered in **Volume 11** of this ES.

e) Limitations, Assumptions and Uncertainties

16.4.35 Limitations, assumptions and uncertainties identified and made for the assessments are listed below:

Limitations

- Annual mean and percentile concentration values calculated for water chemistry parameters have been derived from a limited number of sampling campaigns. The survey data are considered sufficient in order to undertake the impact assessment.
- The extent of flood risk has primarily been based on available historical data and hydrological and hydraulic modelling carried out for the **Flood Risk Assessment**. There is no available fluvial gauge data for the HPC development site. However, such data would not be expected given the relatively small size of catchment and the type of watercourses (ditches and rhynes) in the vicinity of the HPC development site.

Assumptions

- Consent for culverting Holford Stream and for any works within 9m of the watercourse will be sought from the Parrett Internal Drainage Board under the Land Drainage Act 1991 (Ref. 16.19).
- The impact assessment (specifically the determination of magnitude score) takes into account those elements of the HPC development site design relevant to surface water (e.g. provision of water management zones (WMZs)) before the

determination of impact significance is made (as project design is not considered to be a form of additional mitigation for the purposes of this assessment).

- It is assumed that no deterioration of the individual component elements of the water quality WFD waterbody designation is acceptable (e.g. a good current status for dissolved oxygen should be protected, even if the overall WFD waterbody status is moderate).
- Surface water discharge to Holford Stream will be managed so it does not exceed the predetermined greenfield run-off rates in accordance with PPS25 (Ref. 16.1).
- Suspended solid concentrations in water discharged into Holford Stream will be controlled as prescribed in the Environment Agency Hinkley Point C Site Preparation Drainage Design Discharge Conditionality Report (Ref. 16.47). Surface water and sediment discharge to the intertidal area and Bristol Channel will be at a rate and concentration as agreed with the Environment Agency and in line with the Hinkley Point C Site Preparation Drainage Design Discharge Conditionality Report (Ref. 16.47).
- Environmental Quality Standards (EQS) which are prescribed for downstream designated WFD waterbodies have been adopted for upstream watercourses for the purpose of the assessment.
- The construction surface water drainage system will be designed to the 3.33% Annual Exceedance Probability (AEP) event such that the system will not surcharge. The designs will ensure that surface run-off from the HPC development is controlled and managed for all events that exceed the design standard of the drainage system up to and including the 1% AEP event plus allowance for climate change.
- The operational drainage system will be designed to a 1% AEP storm event plus climate change allowances with no flooding with a 95% confidence limit (Jacobs, 2010 (Ref. 16.57)). The HPC development will also be designed to accommodate the 0.01% AEP storm event to ensure that the station operational safety is not compromised.
- The assessment assumes that all surface water discharges, during all phases of the development, will be subject to Environmental Permit, under the Environmental Permitting Regulations (Ref. 16.17). The Environment Permits will be applied individually to different waste streams i.e. surface water, groundwater and treated sanitary effluent.
- It has been assumed that consent for discharge to controlled waters will be required from the Environment Agency (and from Somerset Drainage Board Consortium where discharges could potentially be made to watercourses in any of their catchments) prior to constructing the temporary drainage system for the construction site and the permanent drainage system for the operational site. This is in accordance with legislation (including the Land Drainage Act 1991 (Ref. 16.19)) to ensure that the drainage methods, construction methods and proposed method of discharge to controlled waters would not result in adverse hydrological (including flooding), geomorphological and ecological impacts.

Uncertainties

- The current nutrient status of Holford Stream is unknown as this parameter was not included within the monitoring analytical suite that was agreed with the

Environment Agency. Historical phosphorus monitoring data is available for Storgursey Brook and it is assumed that Holford Stream will have a similar phosphorus status given that both watercourses are within the same catchment and have similar surrounding agricultural land use.

16.5 Baseline Environmental Characteristics

a) Introduction

16.5.1 This section describes the baseline environmental characteristics for the HPC development site and surrounding areas with specific reference to hydrology and drainage, including flood risk, and water quality. A definition of the baseline characteristics has allowed the potential effects of the HPC development to be determined and appropriate mitigation to be identified as necessary.

16.5.2 A brief overview of environmental conditions with respect to topography, soils, geology and hydrogeology is also presented in order to provide sufficient context for the specific surface water related baseline conditions.

b) Study Area Description

16.5.3 The HPC development site can be divided into two main drainage areas, north and south. The divide is delineated by a ridge (occupied by Green Lane) that runs east-to-west through the central part of the site (see **Figure 16.2)**.

16.5.4 The flood risk study area extends east of the HPC development site to include Wick Moor and residential properties in and around Stolford, the Steart to the south-east and contributing catchments upstream of the HPC development site which contribute to Bum Brook, Holford Stream and the HPC Drainage Ditch (see **Figure 16.3**).

16.5.5 Eleven off-site highway improvement schemes will be included in the HPC Project DCO application. They are described in **Volume 2**, **Chapter 2** of this ES. The schemes concern land that is presently within the highway, on highway land, verges, limited areas of hard surfacing and urban green space. Only schemes increasing the area of hardstanding compared to the baseline situation and/or in an area of flood risk have the potential to impact surface water. There are six such schemes which are discussed in Section 16.6. The study areas for each of these schemes comprise the land within the flow path of any surface run-off.

i. Environmental Overview

16.5.6 A general overview of the baseline setting for the study area is provided in the following sections. This provides background information relevant to the surface water assessment i.e. both water quality and hydrology and drainage/flood risk technical studies.

Topography

16.5.7 The following should be read in conjunction with the Light Detection and Ranging (LiDAR) data relief map presented in **Figure 16.2**.

16.5.8 The topography of the study area is characterised by undulating countryside, terminating at Bridgwater Bay to the north at a natural cliff line. An east-west trending ridge (occupied by Green Lane) which peaks at a maximum elevation of

35.3m AOD provides a topographical divide within the Hinkley Point C development site between the permanent development areas to the north and the SCPA to the south.

16.5.9 To the north of the ridge, ground levels generally range between 14m AOD and 31m AOD. An east-west depression associated with the valley of an unnamed watercourse (hereafter referred to as the HPC Drainage Ditch) passes through the centre of this area. The HPC Drainage Ditch flows west to east through the BDAW, before turning to the north (at an elevation of 8.6m AOD) at the boundary between the BDAW and BDAE and finally discharging to the Hinkley Point foreshore at an elevation of 8.5m AOD. Elevations along the top of the cliff range from 10.7m AOD to 16.6m AOD.

16.5.10 To the south of the ridge, ground levels range from approximately 14m AOD to 22m AOD. The gently undulating relief continues from the depression referred to above with the land gently rising to 5.8m AOD and then sloping more steeply to a maximum of between 21.1 and 24.8m AOD. The land then gently falls towards the southern boundary of the HPC development site where elevations typically range between 15m AOD and 16m AOD adjacent to Bum Brook. A small hillock is located towards the south-west corner of the site where the land crests at an elevation of 28.7m AOD.

Geology and Hydrogeology

16.5.11 The geology of the HPC development site and of the wider environment is presented within **Volume 2**, **Chapter 14** of the ES and within the Geological Survey and Mapping report (Ref. 16.58). A description of the hydrogeology of the HPC development site is presented in **Chapter 15** on Groundwater.

Soils

16.5.12 Soils throughout the HPC development site are identified as Soil Class 1 (Ref. 16.59) (soils of intermediate leaching potential) with the exception of an area comprising soils of high leaching potential, which extends along the site's southern boundary and corresponds to the extent of alluvial material shown on the GroundSure Superficial Deposits and Landslips map (Ref. 16.59).

16.5.13 Particle size distribution tests undertaken on samples of the superficial clay indicate a spread of classifications between slightly gravelly sandy silty clay and slightly gravelly sandy clayey silt. The main soil type on the HPC development site may be described as silty clay loam. Further details regarding the HPC development site soils are provided in **Volume 2**, **Chapter 13**.

16.5.14 The Standard Percentage Runoff derived using the Hydrology of Soil Types (SPRHOST) was obtained from the Flood Estimation Handbook (FEH) CD-ROM (Version 3.0) (Ref. 16.52) for the Holford Stream catchment, west of the upstream limit of the channel. This catchment was selected as the HPC Drainage Ditch is not covered by the FEH CD-ROM. The value varies slightly across the study area, however an average SPRHOST value of 53% was obtained for the site, indicating that approximately 53% of rainfall runs off as surface water in this catchment.

ii. Hydrological Baseline Overview

Greenfield Run-off

16.5.15 The greenfield run-off rate for the HPC development site is defined as the pre-development natural run-off rate, as given in the IH124 (Ref. 16.54). To clarify the impact assessment process, the HPC development site has been divided into seven zones as shown in **Figure 16.4** and described below:

- Zone 1: The area to the north of the Holford Stream catchment, draining to the HPC intertidal area. It should be noted that the majority of this area lies within HPC Drainage Ditch catchment which is marked on **Figure 16.4**.
- Zone 2: The area falling within the natural catchment area of Wick Moor.
- Zone 3: The area falling within the natural catchment area of Bum Brook.
- Zone 4: The area of the HPC Drainage Ditch to the west of the HPC development site boundary.
- Zone 5: The area of Holford Stream to the west of the HPC development site boundary.

16.5.16 The corresponding greenfield run-off rates for each zone have been calculated using the methodology given in IH124 (Ref. 16.54). The site-specific input parameters and output from the greenfield run-off analysis up to 2115 (as per PPS25 guidance) are presented in **Table 16.5**, as calculated using the IH124 method (Ref. 16.54). These rates are indicative of the HPC development site natural drainage areas. At present, estimates for climate change allowances are only available until 2100 (UKCP09) or 2115 (PPS25), however the uncertainty surrounding climate change predictions beyond 2100 is referred to several times in EN-6 and the need for additional safeguards is mentioned. Additional safeguards for the HPC development to withstand the potential impacts of climate change have been taken into account in the **Flood Risk Assessment** through a managed adaptive approach for the period beyond 2100. Zones 4 and 5 represent greenfield run-off upstream of the HPC development site boundary.

Table 16.5: Indicative Greenfield Run-off Rates for the Catchment Zones Identified in Figure 16.4

IH Parameters and output	Catchment Zones				
	Zone 1	Zone 2	Zone 3	Zone 4	Zone 5
AREA (ha)	73.77*	77.17	19.79	24.32	51.88
SAAR (mm)	753	753	753	753	753
SOIL (dimensionless)	0.530	0.530	0.530	0.53	0.530
Q_1 (m^3/s)	0.425*	0.442	0.119	0.146	0.310
Q_{BAR} (m^3/s)	0.482.*	0.502	0.135	0.166	0.353
Q_5 (m^3/s)	0.593*	0.618	0.166	0.204	0.434
Q_{10} (m^3/s)	0.719*	0.748	0.201	0.247	0.525
Q_{30} (m^3/s)	0.912*	0.949	0.255	0.314	0.667
Q_{50} (m^3/s)	1.023*	1.064	0.286	0.352	0.748

IH Parameters and output	Catchment Zones				
	Zone 1	Zone 2	Zone 3	Zone 4	Zone 5
Q_{100} (m^3/s)	1.167*	1.215	0.327	0.402	0.853
Q_{100} + 10% climate change up to 2025 (m^3/s)	1.284*	1.337	0.360	0.442	0.938
Q_{100} + 20% climate change from 2025 to 2115 (m^3/s)	1.400*	1.458	0.392	0.482	1.024

*The area of Zone 1 incorporates land that does not natural drainage to HPC Drainage Ditch catchment (see **Figure 16.4**)

Surface Watercourses

16.5.17 The definitions of controlled waters and other watercourse designations are given below, as taken from the Somerset Drainage Board Consortium's website (Ref 16.60) (August 2011):

- *"Main Rivers are normally the principle or arterial watercourses in an area and are designated as such on maps held by the Department for Environment, Food and Rural Affairs and the Environment Agency. The term also includes any structures in the bed or bank for controlling or regulating the flow of these watercourses".*
- *"Ordinary Watercourses comprise all watercourses that are not Main Rivers. These include all tributaries, streams, rhynes, ditches, and those watercourses that have been culverted or piped".*
- *"Viewed Rhynes are Ordinary Watercourses (either open or culverted) that provide a significant function in the drainage or irrigation of an area. Viewed Rhynes are maintained by the Board on a regular or infrequent basis as necessary. The Board undertakes its consenting and enforcement powers on all Viewed Rhynes. The term also includes any structures in the bed or banks for controlling or regulating the flow of these watercourses".*

16.5.18 Controlled waters include virtually all freshwaters, public supply reservoirs, underground waters, tidal waters, and coastal waters up to three nautical miles out to sea. Exceptions include small ponds and reservoirs that do not supply water to other watercourses.

16.5.19 There are a number of watercourses in the Hinkley Point study area which are both controlled waters and ordinary watercourses. These are illustrated in **Figure 16.1** and **Figure 16.3**. The controlled waters of interest to this assessment are sub-categorised as follows:

- an interconnected series of intermittently flowing (ephemeral) agricultural ditches that drain the northern area of the HPC development site: these watercourses ultimately discharge water to the intertidal area via the HPC Drainage Ditch; and
- perennial streams in and around the HPC development site and to the west of the C182, comprising Holford Stream, Bum Brook, Bayley's Brook and Stogursey Brook.

16.5.20 The watercourses feeding Wick Moor, which lie to the east of the C182, are defined as Viewed Rhynes by the Somerset Drainage Board Consortium (see definitions above). The levels and flows within these watercourses are controlled by the Parrett Internal Drainage Board by a series of sluices.

16.5.21 To the east of the C182, Holford Stream continues to flow to the east through Wick Moor and converges with West Brook at Sharpham Sluice. West Brook converges with East Brook immediately upstream of Great Arch Sluice, through which the watercourse discharges via an 80m long culvert to the intertidal area.

16.5.22 Stogursey Brook converges with Bum Brook and then Bum Brook diverges into West Brook and East Brook which are within the Parrett Internal Drainage Board boundary.

16.5.23 Each watercourse of interest to this assessment is described in the following paragraphs. The catchment areas that correspond to each of the watercourses discussed are highlighted in **Figure 16.1** and **Figure 16.4.**

Hinkley Point C Drainage Ditch

16.5.24 The HPC Drainage Ditch flows through the centre of the northern part of the HPC development site (see **Figure 16.1** and **Appendix 16A**, **Plates 16.1** and **16.2**). Its contributing catchment is undulating with generally shallow slopes. It runs from west to east with its source at 14.5m AOD. At NGR 320310, 145840, the HPC Drainage Ditch changes route to the north where it discharges onto the intertidal area at NGR 320290, 146150. The maximum elevation of the catchment is 37.4m AOD and the lowest point where it discharges to the intertidal area is at an elevation of 8.3m AOD.

16.5.25 **Table 16.6** displays the catchment and flow parameters for the HPC Drainage Ditch's existing catchment: this shows the predicted greenfield run-off rates for events of various AEPs, as calculated using the IH124 method (Ref. 16.54).

Table 16.6: Catchment and Flow Parameters for the HPC Drainage Ditch's Catchment (Catchment ID1, see Figure 16.3) Using IH124 Method (Ref. 16.54)

ID1 HPC Drainage Ditch	
AREA (km^2)	0.783
SAAR (mm)	753
SOIL (dimensionless)	0.530
Q_{1yr}	0.448m^3/s
Q_{BAR}	0.509m^3/s
Q_{5yr}	0.626m^3/s
Q_{10yr}	0.758m^3/s
Q_{30yr}	0.961m^3/s
Q_{50yr}	1.078m^3/s
Q_{100yr}	1.231m^3/s
Q_{100yr} (including 20% for climate change)	1.477m^3/s

Holford Stream

16.5.26 The source of Holford Stream is to the west of the HPC development site (see **Figure 16.1**). The stream's flow path is from west to east across the northern part of the SCPA to where it is culverted under the C182. Flow parameters for the watercourse at this location are given in **Table 16.7**. Downstream of the C182 culvert, the stream flows for a further 10m prior to entering a culvert under a track.

16.5.27 To the east of the C182 the catchment is characterised by an interconnected series of rhynes. Holford Stream flows through Wick Moor and converges with West Brook (note: flow parameters at this location are given in **Table 16.7**). An old sluice is located at the confluence of Holford Stream with West Brook (see **Appendix 16A, Plates 16.3** and **16.4**).

16.5.28 To the west of the C182 the catchment slopes are steeper, while to the east the catchment is characterised by low lying flat pasture land (see **Figure 16.1** and **Figure 16.2**). At present, land use for the catchment is rural with no urbanisation. In general, the riparian vegetation is dense, comprising long grasses, thistles and reeds (see **Appendix 16A, Plates 16.5 and 16.6**).

Bayley's Brook

16.5.29 Bayley's Brook flows from south-west to north-east through the village of Shurton and converges with Bum Brook at NGR 320320, 144530 to the south of the HPC development site.

Bum Brook

16.5.30 Bum Brook flows from west to east along the majority of the southern boundary of the HPC development site prior to flowing under the C182 to the south-east of the site (see **Figure 16.1**). Flow parameters at the C182 Bum Brook crossing are presented in **Table 16.7**. Bum Brook has two tributaries: Bayley's Brook and Stogursey Brook, which are described below. To the east of the village of Wick, Bum Brook bifurcates into East Brook and West Brook. The stream has several hydraulic structures along its course, including bridges, culverts, a weir and a ford. Bum Brook, at a location immediately downstream of its confluence with Bayley's Brook, is shown in **Appendix 16A**, **Plates 16.7** and **16.8**.

16.5.31 Between the confluence with Bayley's Brook and the C182, Bum Brook flows through farmland and gardens. The watercourse is culverted under the C182 and under the lane to and from Wick. Downstream of this lane the river is forded twice, primarily for use by agricultural vehicles. **Appendix 16A**, **Plates 16.7** and **16.8** show the first ford and the C182 crossing at NGR 321600, 144440.

16.5.32 The photographs presented in **Appendix 16A** were taken in August 2009 and thus the vegetation was denser than would be expected during the winter months. The riparian vegetation along the course of Bum Brook upstream of the C182 is characterised by grasses, wheat and reeds (see **Appendix 16A**, **Plates 16.9** and **16.10**). Downstream of the C182, the riparian vegetation comprises long grasses, nettles, hawthorn and brambles.

Stogursey Brook

16.5.33 Stogursey Brook flows south-west to north-east through the settlement of Stogursey, then through farmland, the hamlet of Newnham and then once again through farmland (see **Figure 16.1**). The stream then turns to the east at NGR 320760, 144540 and passes under the C182 before changing direction to the north-east where it converges with Bum Brook 130m downstream of the C182 at NGR 320910, 144590. Flow parameters are given in **Table 16.7**.

16.5.34 At the time of observation (August, 2009) the vegetation along Stogursey Brook was dense. **Appendix 16A**, **Plates 16.11** and **16.12** shows the vegetation upstream of the C182. The dense vegetation continues downstream of the road until it turns north-east where the riparian zone is more sparsely vegetated with trees and brambles.

East Brook and West Brook

16.5.35 To the east of Wick, Bum Brook (having converged with Stogursey Brook to the west) bifurcates into East Brook and West Brook at NGR 321687 144515 (see **Figure 16.1** and **Appendix 16A**, **Plates 16.13** and **16.14** for views downstream of West Brook from this location). East Brook and West Brook then flow parallel with each other for 1.52km before converging immediately upstream of Great Arch Sluice (see **Appendix 16A**, **Plates 16.13** and **16.14**). East Brook and West Brook flow through flat, low-lying farmland used primarily as pasture. **Appendix 16A**, **Plates 16.15** and **16.16** illustrate the riparian vegetation upstream of Sharpham Sluice. The channel banks are overgrown with grasses, reeds and thistles. The flow parameters for the fluvial network upstream of Sharpham Sluice and upstream of Great Arch Sluice are given in **Table 16.7**.

Table 16.7: Summary of Flow Characteristics at Key Points of Interest throughout the Study Area (for ID Locations see Figure 16.3).

ID	Catchment	Catchment descriptions	Design flow (m³/s)		
		Area (km²)	Q_{BAR} (m³/s)	Q_{30yr} (m³/s)	Q_{100yr} (m³/s)
			ReFH	ReFH	ReFH
2	Holford Stream (west of start of channel)	0.52	0.23	0.80	1.08
3	Holford Stream (upstream of the C182)	1.32	0.54	1.38	1.82
4	Holford Stream upstream of Sharpham Sluice	2.90	1.08	2.39	2.61
5	Bum Brook (upstream of the C182)	13.36	3.28	7.05	9.03
6	Stogursey Brook (upstream of the C182)	11.42	3.40	7.29	9.34
7	Fluvial network upstream of West/East Brook confluence (excluding Holford Stream	26.54	7.86	14.90	19.02
8	Fluvial network upstream of Great Arch Sluice	29.46	8.57	16.20	20.75

Note: for ID1 see **Table 16.6**

Surface Water Outfalls

16.5.36 With the exclusion of HPC Drainage Ditch, which discharges to the Hinkley Point intertidal area, the fluvial network in the area is served by two outfalls, both of which are illustrated on **Figure 16.1**. The largest outfall is Great Arch Sluice, which is located immediately downstream of East Brook and West Brook and includes the Holford Stream catchment, with a collective catchment area in excess of approximately 30km². A secondary outfall known as Cole Lane Sluice is located to the immediate east of the Hinkley Point B power station. Both of these are described in more detail in the following paragraphs.

Great Arch Sluice

16.5.37 Great Arch Sluice is located at NGR 322717, 145947 (see **Figure 16.1**). **Appendix 16A, Plates 16.17** and **16.18** show the upstream face of the sluice where a trash screen is evident. The water flows through a culvert under the flood embankment and under the crest of the embankment enters a large inspection chamber (see **Appendix 16A**, **Plates 16.19** and **16.20**). This chamber contains the flap that prevents tidal flow upstream. **Appendix 16A**, **Plates 16.19** and **16.20** show the chamber during both low and high tides.

Cole Lane Sluice

16.5.38 Cole Lane Sluice is located at NGR 312781, 141607 (see **Figure 16.1**) and **Appendix 16A**, **Plates 16.21** and **16.22**). Here the stream flows under the flood defence embankment and into the Bristol Channel, draining the series of rhynes located to the south of the existing Hinkley Point Power Station Complex. Rhyne East is a ditch that flows around an area of farmland to the west of the Hinkley Point sewage treatment works and connects to West Brook at Sharpham Sluice. **Appendix 16A**, **Plates 16.21** and **16.22** illustrate Rhyne East with the flood defence embankment in the distance, together with a close-up view of Cole Lane Sluice.

Bristol Channel Tidal Levels

16.5.39 The Bristol Channel has one of the highest tidal ranges in the world, with a maximum predicted tidal range of over 13m at Hinkley Point between 2005 and 2025 (Ref. 16.61). Water levels can rise by more than 2m above predicted levels during adverse weather conditions. **Table 16.8** and **Table 16.9** show the design event still water levels for Hinkley Point and Stolford based on extreme tide levels provided by the Environment Agency (Ref. 16.62) and adjusted to 2017, 2100 and 2115 as per Defra 2006 prediction in PPS25 (Ref. 16.1). Estimates for climate change allowances are only available until 2115 in PPS25, as beyond this date there is much uncertainty surrounding climate change predictions, Tidal modelling has been carried out for the **Flood Risk Assessment** using these values for the 2100 baseline scenario.

Table 16.8: Environment Agency Extreme Still Water Levels for the Bristol Channel at HPC with Defra 2006 Climate Change Allowances (m AOD)

AEP %	Peak still water level (mAOD)			
	Baseline Environment Agency extreme water levels*	2017	2100	2115
1	7.74	7.77	8.60	8.82
0.5	7.84	7.87	8.70	8.92
0.1	8.09	8.12	8.95	9.17

*EA 2008 data relates to chainage location 326, off the coast of HPC.

Table 16.9: Environment Agency Extreme Still Water Levels for the Bristol Channel at Stolford with Defra 2006 Climate Change Allowances (m AOD)

AEP %	Peak still water level (mAOD)			
	Baseline Environment Agency extreme water levels*	2017	2100	2115
1	7.78	7.81	8.64	8.86
0.5	7.89	7.92	8.75	8.97
0.1	8.14	8.17	9.00	9.22

*EA 2008 data relates to chainage location 328, off the coast of the Stolford defences

Evapotranspiration

16.5.40 Evapotranspiration was determined from the Met Office Surface Exchange System (MOSES) database (Ref. 16.63). Potential and Actual Evapotranspiration, Effective Precipitation and Soil Moisture Deficit are calculated for grass and averaged land use categories for a 40km cell. The cell used for this study is centred on NGR 320000 140000, approximately 6km due south of the HPC development site. Parameters were calculated using meteorological data observed between 1961 and 2001. Over this period, the average annual Actual Evapotranspiration was 460.5mm/yr for the averaged land use class compared with an average annual Potential Evapotranspiration of 545.5mm/yr.

Rainfall

16.5.41 Average annual rainfall in the HPC development site area has been derived from a number of sources. It is generally accepted throughout the UK that, in the absence of long-term rainfall records, the catchment information provided by the Flood Estimation Handbook (FEH) CD-ROM Version 3.0 (Ref. 16.52) provides the most current information with respect to mean annual rainfall, however, this is for the period 1960 to 1990.

16.5.42 The FEH CD-ROM (Ref. 16.52) gives values for the annual average rainfall (also known as ‘Standard-period Average Annual Rainfall – SAAR) for the period 1960 to 1990 and these data are shown in **Table 16.10** for the surface water catchments illustrated in **Figure 16.3**.

16.5.43 It is shown in **Table 16.10** that annual average rainfall generally increases with distance inland, the likely result of increasing topography and associated orographic effects. A SAAR value in the range 747 – 753 mm/yr is considered to be the most applicable for the HPC development site.

Table 16.10: Standard-period Average Annual Rainfall (SAAR) for all the Catchments of Interest in the Hinkley Point Area (Based on FEH DDF Model)

Catchment Name	Catchment ID	SAAR (mm)
HPC Drainage Ditch	1	753*
Holford Stream west of the start of the channel	2	753
Holford Stream upstream of C182	3	752
Holford Stream upstream of Sharpham Sluice	4	748
Bum Brook upstream of C182	5	812
Stogursey Brook upstream of C182	6	854
Fluvial network upstream of Sharpham Sluice (with exception of Holford Stream and rhynes to south of Hinkley Point A and B)	7	825
Fluvial network upstream of Great Arch Sluice	8	817

**This catchment is not identifiable on the FEH CD-ROM and SAAR is assumed to be the same as that for Holford Stream catchment upstream of source*

16.5.44 A study into extreme precipitation events in the Hinkley Point area has been prepared for EDF Energy by the Meteorological Office in June 2010 (Ref 16.53) (see **Table 16.11**). This study provides both current day and climate change extreme rainfall estimates at Hinkley Point using a combination of observed and modelled rainfall amounts. The Met Office study sourced the current day extreme rainfall estimates from the FEH CD-ROM DDF rainfall model (Ref.16.52); these are reproduced in **Table 16.10**.

Table 16.11: Current day (2010) Extreme Rainfall Estimates at Hinkley Point (mm) for Different Storm Durations

% AEP	Duration		
	15 minute	1 hour	Daily
20	12.8	18.6	50.4
10	15.7	23	58.4
1	33.3	44.6	92.6
0.01	145.1	163.7	228.8

16.5.45 **Table 16.12** displays the rainfall depths for different storm durations for the HPC development site. These were derived from the FEH CD-ROM DDF rainfall model and were multiplied by 1.30 for the upper limit of confidence interval of 95% and then by 1.33 for climate change for winter 2070-2099 (Jacobs, 2010 (Ref. 16.57). These data were sourced from the report prepared for EDF Energy by the Met Office (Ref. 16.53).

Table 16.12: Rainfall Depths (mm) for Different Storm Durations for Hinkley Point C for 2070-2099 with a 95% Confidence Limit

% AEP plus climate change	Duration		
	15 minute	1 hour	Daily
20	22.1	32.2	87.1
10	27.1	39.8	101.0
1	57.6	77.1	160.1
0.01	250.9	283.0	395.6

16.5.46 It is also important to consider rainfall characteristics at a larger scale, such as those storm durations that influence flood events. A range of rainfall depths for storms of varying magnitude was derived from the FEH CD-ROM DDF rainfall model (Ref. 16.52). This is the recommended method for determining rainfall depth in the UK and has largely superseded the Flood Studies Report (FSR) method although the FSR (Ref. 16.64) is still widely used, not least because it is able to provide rainfall depths for event magnitudes with a 0.01% AEP whereas the DDF model is not recommended for events with an AEP less than 0.1% AEP.

Groundwater Recharge

16.5.47 Rainfall recharge provides the driving mechanism for groundwater flow at certain areas across the HPC development site. Groundwater springs out at outcrops of lower permeability strata and also provides baseflow to surface watercourses. It is likely that the watercourses are structurally controlled, with those flowing west to east following the trends of the strike faults and fold axes, and those flowing south-west to north-east following structures parallel to the Hinkley Point Fault (as well as following the topography to the Bristol Channel).

16.5.48 Given the topography and likely groundwater flow regime it is considered that the surface watercourses are, at least, in partial hydraulic continuity with the groundwater, probably with significant groundwater contributions to baseflow and possible groundwater recharge in places. However, in broad terms, in the north of the HPC development site and across Wick Moor conceptual modelling (described in detail in **Chapter 15**) shows that there is no significant hydraulic connectivity between surface waters and groundwater due to the presence of low permeability alluvium. Further details are provided within the groundwater discussions in **Chapter 15**.

iii. Flood Risk Overview

16.5.49 There are areas of the HPC development site that are located within Environment Agency Flood Risk Map Zones 2 and 3. Flood Zone 3 is characterised as having greater than a 1% AEP of river flooding or greater than a 0.5% AEP of tidally influenced river flooding or flooding directly from the sea. Flood Zone 2 is characterised as having greater than a 0.1% AEP of river flooding or tidal flooding. The Environment Agency tidal, fluvial and combined tidal and fluvial Flood Zones are illustrated in **Figures 16.5**, **16.6** and **16.7**.

Tidal Flood Risk

16.5.50 The Environment Agency flood zone map shows a section of the Holford Stream Valley in the Southern Construction Phase Area (SCPA) as lying within Flood Zone 3 based on the 0.5% AEP tide inundating the land to the west of the HPC development site, assuming no flood defences to be present. However, the area benefits from a flood defence embankment located between Hinkley Point and Stolford Point which provides protection to the valley from coastal flooding. A topographical survey carried out for the purposes of the **Flood Risk Assessment** found a minimum effective crest level of 8.23m AOD on the western section of the defence near to Hinkley Point, while higher levels, up to a maximum crest level of 9.39m AOD, were found near Stolford on the eastern end of the defence.

16.5.51 Modelling of the baseline 2017 and 2100 overtopping and breach events was carried out for the **Flood Risk Assessment**, the results of which are presented in **Figures 25**, **27**, **30** and **33** of the **Flood Risk Assessment**. The results indicate that flooding of Wick Moor, a cluster of houses near Fisheries Cottage and Chapel Cottages would occur during the overtopping of the coastal defences (**Figure 25** of the **Flood Risk Assessment**), with increased flood depths and extents should a breach of the defences occur (**Figure 27** of the **Flood Risk Assessment**). The modelling also indicates flooding at or near Little Dowden's Farm, Swallowcliffe, Fisherman's Cottage, Stolford Farm and some properties north of Croft Farm. The predicted depths and extents increase further during the 2100 events, affecting a further third party property in Stolford (Seaview), the C182 and the existing Sewage Treatment Works and national grid towers (pylons).

Fluvial Flood Risk

16.5.52 The **Flood Risk Assessment** provides a detailed assessment of the fluvial flood risk for the study area. The Environment Agency fluvial Flood Zone Map (**Figure 16.6**) shows there to be a small area of fluvial floodplain within Flood Zone 3 along the very southern boundary of the HPC development site, bordering Bum Brook.

16.5.53 The Environment Agency fluvial Flood Zone Maps only indicate flood risk for catchments greater than 3km^2. Therefore, this information cannot be relied upon to give a complete view of the baseline fluvial flood risk. As part of the **Flood Risk Assessment** modelling of the fluvial network of the local watercourses has been undertaken to establish the baseline flood risk zoning. The modelling carried out for the **Flood Risk Assessment** used 2017 as the baseline year.

16.5.54 The **Flood Risk Assessment** modelling indicates that some areas of the Holford Stream floodplain within the HPC development site area would be categorised as functional floodplain (Flood Zone 3b). The **Flood Risk Assessment** modelling also indicates a small area of flooding under the 5% AEP event near to the proposed Bum Brook emergency access road bridge that would be categorised as Flood Zone 3b.

16.5.55 The modelling showed that some off-site residential properties at Stolford (near Little Dowden's Farm) may have their gardens flooded to shallow depths for the 0.1% AEP event in 2017, defined as Flood Zone 2, see **Figure 50** of the **Flood Risk Assessment** which is a close match to the Environment Agency Flood Zone map (see **Figure 16.6**).

Groundwater Flood Risk

16.5.56 Groundwater flooding occurs when groundwater levels rise above surface elevations. This is most likely to occur in low-lying areas, such as the Holford Stream Valley at an elevation of 4 to 5m AOD and alongside the HPC Drainage Ditch at an elevation of 8 to 9m AOD. Modelling carried out for **Chapter 15** has shown that the groundwater bodies in the northern (BDAW and BDAE) and southern (SCPA) areas of the site are not linked. Impacts relating to groundwater have been assessed in **Chapter 15** and are not consider further in this chapter.

Surface Water (Pluvial) Flood Risk

16.5.57 Surface water (pluvial) flooding arises from intense rainfall that is unable to soak into the ground or exceeds the capacity of drainage systems, therefore running quickly off the land and resulting in localised flooding. The acceptance potential of the soil affects the run-off rates, which are displayed in **Table 16.5**. The aforementioned paragraph and **Table 16.5** show that the soils on the HPC development site have a very low rainfall acceptance which in turn results in high run-off rates.

Sewer Flood Risk

16.5.58 Localised flash flooding from blocked or overloaded sewer systems can occur at times of heavy rainfall. At present, there is only a small amount of drainage infrastructure on site and the potential to flood the HPC development site would be very limited.

Flood Risk from Reservoirs and Other Artificial Sources

16.5.59 Flooding from artificial sources includes reservoirs, canals and lakes where water is retained above the natural ground level. There are no existing artificial sources in the vicinity of the study area.

iv. Water Quality Baseline Overview

16.5.60 The surface watercourses that drain the proposed HPC development site which have been examined for the purpose of freshwater quality assessment are:

- The series of interconnected agricultural ditches that drain the BDAW and which ultimately discharge to the Hinkley intertidal area through HPC Drainage Ditch.
- Holford Stream that flows in an easterly direction across the Southern Construction Phase Area (SCPA).
- Bum Brook that flows in an easterly direction along the southern perimeter of the SCPA.
- Stogursey Brook which forms part of a catchment that includes Holford Stream and Bum Brook.

16.5.61 The locations of the surface watercourses on the HPC development site are presented in **Figure 16.1**.

16.5.62 There are no historical water quality data available for the surface watercourses draining any part of the HPC development site. The most relevant surface water quality data which is available is Environment Agency data for Stogursey Brook which is located to the south of the site. Stogursey Brook forms a confluence with

Bum Brook, which itself flows along the southern perimeter of the SCPA. Given that both watercourses and Holford Stream are within the same catchment with similar surrounding agricultural land use, their water quality characteristics may be expected to be similar. Data were sourced from the Environment Agency website (www.environment-agency.gov.uk) for the period 2002 to 2007 for a 4.4km reach of the Stogursey Brook with a grid reference for the upstream limit of the reach at NGR 317800, 142400. A summary of this limited data set is presented in **Appendix 16C**. Bum Brook and Holford Stream discharge into the WFD waterbody named as ‘Stogursey Brook’ (see **Appendix 16D** for the WFD waterbody table for Stogursey Brook, taken from Annex B of the South West River Basin District Management Plan (Ref 16.29)). The Stogursey Brook waterbody is currently at overall ‘Poor’ WFD standard with the objective of reaching ‘Good Ecological Status’ by 2015. A number of water chemistry elements are specifically listed in the Stogursey Brook waterbody table as supporting elements to the status description (where data has allowed specific characterisation). The existing ‘Poor’ WFD status is a result of elevated phosphorus conditions which is detailed as a supporting element that is very certain and is recorded in the historical EA dataset.

16.5.63 To augment the limited baseline data, a terrestrial surface water quality monitoring programme was carried out for EDF Energy in 2009, following consultations with the Environment Agency. Full details of the sampling programme and methodologies may be found within the ‘Summary of Terrestrial Surface Water Quality Non-Radiochemical Analysis Results (Campaigns 1-6 including WFD)’ (Ref 16.65). A summary of the monitoring programme is provided below.

16.5.64 Terrestrial surface water quality monitoring was undertaken on surface freshwater features (field ditches and streams) on the area proposed for the Built Development (BDAW and BDAE) between January and July 2009. Following campaign 3 (of the water quality monitoring programme) in April 2009, the geographical scope of the monitoring area was increased, to cover the SCPA. In order to gather a sufficiently comprehensive baseline of the water quality conditions on the SCPA, three additional sample locations were added during campaigns four, five and six. The locations of the freshwater surface monitoring points are shown in **Figure 16.8**. The additional monitoring points within the Southern Construction Phase Area are identified as SWA (Bum Brook), SWB (Holford Stream) and SWC (unnamed watercourse).

16.5.65 Water sample collection and recording of *in-situ* water quality parameters such as pH, dissolved oxygen and temperature was undertaken on an approximate monthly basis; six campaigns were undertaken in total, as discussed with the Environment Agency during the December 2008 consultation meeting. *In-situ* measurements were recorded using pre-calibrated field meters. The sample collection methodology and handling of samples was undertaken according to the methods described in the British Standard for Water Quality Sampling (BS EN ISO 5667: 2006) (Ref 16.66). Prior to collection, water samples were subject to *in-situ* radiological screening to identify any potential hazards for sampling staff and the testing laboratories receiving the samples. No samples were found to be above the threshold values for alpha and beta particles and gamma emissions throughout the sampling programme.

16.5.66 The main anticipated discharges to freshwater surface features during the construction phase are suspended solids, BOD and petroleum hydrocarbons. The expected BOD discharges are associated with grey and black waste water generated from contractor facilities. The baseline monitoring campaigns of the existing surface watercourses employed a wider range of chemical parameters to assist in assessing their water quality status. The suite of chemical analysis testing for terrestrial surface water samples, which was agreed in consultation with the Environment Agency included:

- suspended solids;
- Biochemical Oxygen Demand (BOD);
- Total Petroleum Hydrocarbons (TPH);
- total zinc;
- dissolved and total boron;
- chloride;
- ammoniacal nitrogen;
- nitrate; and
- total hardness.

Freshwater Environmental Quality Standards

16.5.67 The water quality guidance values that have been used to access the data from the terrestrial surface water monitoring campaign are detailed in **Table 16.13** and are based on freshwater Environmental Quality Standards (EQS) values and Drinking Water Standards (DWS). Directions have recently been issued (Ref. 16.9) by the UK Government to the Environment Agency which allow revised water quality environmental standards developed by UKTAG (United Kingdom Technical Advisory Group) for the WFD (Ref. 16.8) and Priority Substances Directive (Ref. 16.13) to be implemented. The WFD EQS values are presented in **Table 16.13** alongside previous standards. The references for the range of water quality standards used to examine the data are provided as notes to **Table 16.13.**

16.5.68 A number of water chemistry parameters are specifically listed in the Stogursey Brook WFD waterbody classification table as supporting elements to the status description (where data has allowed specific characterisation) and these have been used, together with the target status of 'Good' to define appropriate EQSs (see **Appendix 16D** and **Table 16.13**). In each case, the highest available status score has been chosen, given that the WFD (Ref. 16.8) dictates no deterioration of any component water quality parameter should occur. Thus the EQS most likely to be used as a regulatory threshold (by the Environment Agency) has been selected for monitoring data assessment purposes. For this assessment all surface watercourses have been compared to the Stogursey Brook WFD EQS standards (see **Appendix 16D**) because in some cases this is the relevant WFD freshwater waterbody downstream of the HPC development site and for the case of the agricultural ditches in the northern part of the HPC development site, it is the closest freshwater WFD waterbody. The locations of WFD designated waterbodies in the locality of the HPC development site are presented in **Figure 16.9**.

16.5.69 The determination of WFD EQSs for total ammonia, Biochemical Oxygen Demand (BOD) and Dissolved Oxygen (DO) are linked to the alkalinity status of a watercourse. In order to allow comparison with the WFD standards alkalinity has been retrospectively calculated as it has not been determined by sample analysis during the monitoring programme. It should also be noted that many of the EQS values listed relate to annual mean values or percentile values. Comparison of the freshwater monitoring data collected during 2009 with EQS values has been performed using calculated annual mean and percentile concentrations that have been derived from a limited number of sampling campaigns.

.

Table 16.13 Guideline Freshwater Quality Standards used to Assess the Water Quality of Terrestrial Surface Water Features at Hinkley Point.

Determinand	Units	Minimum Reporting Value	Screening Value				
			Pre-WFD		WFD		
			DWS	Fresh-water EQS	WFD Type	Water-body and Status	WFD Standard
Total Zinc	(µg/l)	5	5,000[5]	75-500[2 AT9] (300-2000)[P]	Hardness related	Stogursey Brook – High[CPr] Note only 'good' standard presented in WFD directions.	125 [AT9]

Ammonium, NH_4	(mg/l)	0.01	0.5[1]	1[12]	-	-	-
Total Ammonia as N	(mg/l)	0.1	-	1.3[4]	Alkalinity related	Stogursey Brook – Good[CPrP]	0.6[10]
Un-ionised Ammonia as NH_3	(mg/l)	-	-	0.025[7I]	-	-	-
Un-ionised Ammonia as N	(mg/l)	-	-	-	('Specific Pollutant' – Annex 8)	Stogursey Brook – Good[CPrA]	n/a
BOD	(mg/l)	2	-	6 [4]	Alkalinity related	Stogursey Brook – Good[PrP]	5 (90%)[10]
Chloride	(mg/l)	1	250[18]	250[3 A]	-	-	-
Nitrate	(mg/l)	1	50[1]	-	-	-	-
Suspended Solids	(mg/l)	5	-	25[7]	-	-	-
Total Hardness	(mg/l as $CaCO_3$)	10	-	-	-	-	-
Total Petroleum Hydrocarbons (C_8-C_{35})	(µg/l)	10	10[5]	50[6]	-	-	-
pH	pH units	0 (*In-situ*)	6.5-10[1]	6-9[I]	n/a	Stogursey Brook – High[CPrP]	6 (5%) 9 (95%)
Temperature	°C	n/a	-	-	Cyprinid	Stogursey Brook – High[CPrP A]	25 (98%)
Dissolved Oxygen	% saturation	0 (*In-situ*)	-	-	Alkalinity related	Stogursey Brook – High[CPrP]	70 (10%)[10]
Dissolved Oxygen	mg/l	0 (*In-situ*)	-	50%>8[G7] 100%>5[G7] 50%>7[I7]	-	-	-

Table notes:

- Derived Ammonia values are based upon calculations as presented in: Canadian Council of Ministers of the Environment (2010) (Ref. 16.67).
- WFD Standards are derived from 'The River Basin Districts Typology, Standards and Groundwater Threshold Values (Water Framework Directive)(England and Wales) Directions 2010 (Ref. 16.9).
- Drinking Water Standards (DWS) are not used as environmental thresholds where other EQS values are available.

A Annual Average

T Total

P 90% of results

I Imperative value

G Guideline Value

C Current WFD status;

Pr- Predicted WFD status by 2015;

\- Analysis not undertaken or not relevant;

1 The Water Supply (Water Quality) Regulations 2000 (Ref. 16.68).

2 National Environmental Quality Standards (EQS) – For List II substances. Source DoE Circular 7/89 (Ref. 16.69).

3 Environment Agency Non-Statutory (Operational) Environmental Quality Standards – source Table B11 (Ref.16.70).

4 River Ecosystem Classification (RE3) – (90^{th} percentile) (Ref. 16.71).

5 The Water Supply (Water Quality) Regulations 1989 (Ref. 16.72). N.B. These Regulations were superseded by the 2000 regulations therefore there is currently no UK DWS for zinc and/or Total Petroleum Hydrocarbons.

6 The Surface Waters (Abstraction) for Drinking Water (Classification) Regulations 1996 (Ref. 16.73). DW1 treatment (i.e. simple physical treatment and disinfection) limit.

7 2006/44/ EC Fish Directive, Cyprinid Fish Guideline. (Ref. 16.5).

8 Point of Monitoring/Compliance may be at samples leaving treatment works or at other supply point, e.g. consumer's taps.

9 Hardness related (Zinc toxicity is influenced by hardness. Specific EQS values (mg/l zinc) are given for different hardness ranges within the legislation. By comparing to the hardness value, the appropriate EQS concentration has been selected).

10 Alkalinity related. By comparing to the alkalinity value, the appropriate EQS concentration has been determined. Note that alkalinity has been calculated for the purposes of this report.

11 Non statutory/proposed EQS, but EQS never adopted in UK. Therefore value quoted is for guidance only.

12 No statutory EQS for dissolved Boron – adopted Total Boron value

16.5.70 All test parameters have corresponding EQS values, with the exception of nitrate for which comparison could only be made to the Drinking Water Standard. It should be noted that although reference is made to Drinking Water Standards (DWS) in **Table 16.13,** the watercourses located within the vicinity of the HPC development site, and which therefore may potentially receive discharges during the construction and operational phases, are not used for potable water abstraction.

2009 Freshwater Quality Monitoring Results

16.5.71 A summary of the findings of the terrestrial water quality monitoring campaigns has been reported in 'Summary of Terrestrial Surface Water Quality Non-Radiochemical Analysis Results August 2010' (Ref. 16.65). The summary report is presented in **Appendix 16E**. The conclusions from the monitoring programme are as follows:

- The water quality results are representative of what would be expected for shallow, turbid slow flowing watercourses and ditches draining agricultural land that typically show wide variation in water quality and flow characteristics which may depend, for example, on rainfall intensity and associated surface drainage from surrounding fields.
- The drainage ditches in the BDAW are ephemeral in nature and a number of sites were found to be dry on different sampling visits. The drainage ditches, Holford Stream and Bum Brook are not described as WFD waterbody units and therefore WFD EQS standards' are not applicable and are used for information purposes only.
- The threshold level exceedences with respect to adopted water quality assessment criteria that have been found for various parameters are considered typical for the type of watercourse present in these areas of the HPC development site (i.e. small agricultural drainage ditches).
- Baseline dissolved oxygen concentrations are low within both Holford Stream and Bum Brook, the only two watercourses that are considered to be able to support fish populations (due to the ephemeral nature of the other drainage ditches on the Built Development Area land).
- Elevated concentrations of BOD and suspended solids were a regular occurrence across the monitoring programme. Elevated concentrations of these parameters commonly occur in shallow, heavily sedimented surface waters, particularly in field drainage ditches associated with agricultural land. Temporal variation in BOD, in watercourses of this type may be attributable to a range of factors including prevailing weather conditions (e.g. rainfall) and inputs of organic matter (e.g. cut vegetation). Temporal variation in suspended solids concentrations may be attributable to re-suspension of fine bed sediments.

16.5.72 **Appendix 16B** presents a graphical summary of the terrestrial surface water data (and a comparison to relevant environmental thresholds) for:

- suspended solids;
- ammonia; and
- BOD.

In-Situ Water Quality Monitoring Results

16.5.73 The pH results across all sampling campaigns ranged from 6.8 to 8.3 pH units, which represented a range of conditions from close to neutral to slightly alkaline (basic). All pH readings across the HPC development site fall within a relatively restricted range and are typical of lowland freshwater watercourses. EQS values recently introduced for pH and temperature under the WFD have allowed the *in situ* results to be compared against revised statutory limits. The pH and temperature values at all monitoring sites were found to fall within the normal range specified under the WFD EQS.

16.5.74 A wide range of dissolved oxygen concentrations, ranging from 21.2% saturation (2.4mg/l at 11.3^{o}C) to 96.3% saturation (11.3mg/l at 8.5^{o}C) was recorded across the six campaigns. This is to be expected in shallow, slow flowing, freshwater watercourses. The drainage watercourses within the BDAW are not considered suitable to support fish populations due to the ephemeral nature of the flows within them and comparisons to dissolved oxygen environmental quality standards for the protection of fish are therefore not considered to be appropriate.

16.5.75 The concentration of dissolved oxygen from all locations was found to be below the EQS values set by the WFD (Ref 16.8). A comparison of the dissolved oxygen data from Holford Stream and Bum Brook with the WFD EQS is presented in **Table 16.14**. Comparison of dissolved oxygen monitoring results with EQS percentile values (WFD EQS is a 10 percentile value) should be made with caution, given that the results for Holford Stream and Bum Brook are based on a limited data set i.e. only three *in situ* measurements. The comparison with the WFD EQS values, which is consistent with the discussions above, suggests that baseline dissolved oxygen concentrations are low within both Holford Stream and Bum Brook. Dissolved oxygen concentrations within all other watercourses that were not monitored may be expected to be similarly low, given the shallow depths and the ephemeral nature of flows within this surface agricultural drainage system.

Table 16.14: Comparison of *in-situ* Dissolved Oxygen (DO) Concentrations for Holford Stream and Bum Brook with Standards Specified in the Water Framework Directive.

DO EQS (% saturation)	Holford Stream (% saturation)	Bum Brook (% saturation)
70[1]	36 [1,2]	51.4 [1,2]

Table notes:

1 10 percentile value.

2 Based upon 3 in situ measurements.

c) Potential Receptor Value and Sensitivity

i. Hydrology and Drainage Receptors

16.5.76 The hydrology and drainage receptors include the HPC Drainage Ditch, (plus a network of smaller agricultural ditches), the Hinkley Point intertidal area, Holford Stream, Bum Brook and Wick Moor. The value and sensitivity rating for the hydrological conditions of the Bristol Channel is considered to be negligible as the Bristol Channel has a very high assimilative capacity for additional discharges at the volumes which would be generated from the HPC development site areas.

Therefore, the Bristol Channel is not considered further as a receptor in this assessment.

16.5.77 The flood risk receptors include the HPC development site, areas of agricultural land to the west of the HPC development site, Wick Moor and third party properties (such as those in Stolford and the existing sewage treatment works south of the HPA and B complex). The value and sensitivity of the receptors are based on the information given in **Table 16.3** and are discussed in more detail in the sections that follow.

Hinkley Point C Drainage Ditch

16.5.78 HPC Drainage Ditch has a low value and sensitivity rating as it is a controlled water of moderate hydrological status with a moderate capacity to accommodate the proposed form of change. It has no social/community and economic value and is not a main river.

16.5.79 Its hydrological status is only of low value as it does not contribute to a licensed water abstraction point, a surface water reservoir, any hydropower scheme or any other water reliant industry such as a mill, a power station or a fish farm, and does not comprise an upstream catchment that contributes to an area served by a strategic flood alleviation scheme.

Hinkley Point Intertidal Area

16.5.80 Run-off draining from the northern part of the HPC development site discharges to the intertidal area. Any increase in surface water run-off rates would result in elevated volumes of water flowing across the intertidal area before entering the Bristol Channel, except during very high tides, when it would discharge directly into the sea water which reaches the base of the cliff under such tidal conditions. The run-off is therefore discharging either directly onto the intertidal area or into the sea.

16.5.81 The value and sensitivity of the receptors is assessed to be very low as neither receptor would be adversely impacted hydrologically by the discharge (as detailed in **Chapter 17**) and both would be tolerant to the proposed change.

Holford Stream

16.5.82 Holford Stream has a high value and sensitivity rating as it is a controlled, ordinary watercourse with a high local value in terms of its hydrological status such that selected designated habitats and/or species are potentially sensitive to change in hydrological regime.

16.5.83 Holford Stream discharges to Wick Moor which is part of the designated Bridgwater Bay SSSI, and forms part of a network of rhynes that are maintained and controlled by the Parrett Internal Drainage Board, which forms part of the SDBC. As such, Holford Stream is classified as a Viewed Rhyne.

16.5.84 It should be noted that this chapter is only concerned with the hydrological impacts on Holford Stream within Wick Moor and the impact on water quality. Any potential impacts on the ecological features of Wick Moor as a result of changes to the hydrology and water quality condition are considered in **Chapter 20** on **Terrestrial Ecology & Ornithology**.

Bum Brook

16.5.85 Bum Brook has a high value and sensitivity rating as it is a controlled, ordinary watercourse with a high local value in terms of its hydrological status such that selected designated habitats and/or species are potentially sensitive to change in hydrological regime.

16.5.86 Bum Brook bifurcates into West and East Brook which flow through Wick Moor, which is part of the designated Bridgwater Bay SSSI.

Wick Moor

16.5.87 Wick Moor comprises part of the designated Bridgwater Bay SSSI and Severn Estuary SPA and Ramsar site and is within the area controlled by the Somerset Drainage Board Consortium (SDBC). It should be noted that the ecological value of Wick Moor is high for terrestrial ecological receptors. Indirect impacts on marine or terrestrial ecological receptors are addressed in **Chapters 19** and **20**, respectively.

16.5.88 During low flows Wick Moor requires enough water throughout the year to maintain a high water table level to support its nature conservation interests, therefore it is sensitive to the low flow regime and the value and sensitivity of Wick Moor is assessed to be high.

16.5.89 During high flows Wick Moor lies within Flood Zone 2 and 3. During high flows or a flood event the area is moderately tolerant to changes in water levels and is classed as a 'less vulnerable' receptor in PPS25 (Ref. 16.1). Therefore it has been given a value and sensitivity rating of medium during these events.

Agricultural Land Off-site to the West of the HPC development site and Holford Stream

16.5.90 This area of land is located within Flood Zone 2 with a small section in Flood Zone 3 and is classified as a 'less vulnerable' receptor in PPS25 (Ref. 16.1). The Environment Agency Flood Zone maps do not take the presence of flood defences into account, therefore the flood risk is only residual as it would only occur as a result of a breach of the coastal defences (see **Figure 16.5**). Therefore, the hydrology and drainage value and sensitivity is assessed to be medium.

Agricultural Land Off-site to the West of the HPC development site and Hinkley Point C Drainage Ditch

16.5.91 The value and sensitivity of land in this area is determined by its hydrological status. This land is within Flood Zone 1 (see **Figure 16.5**) and is classified as a 'less vulnerable' receptor in PPS25 (Ref. 16.1), and thus is assessed as being of low hydrological value and sensitivity.

Land Off-Site Adjacent to Bum Brook

16.5.92 This land is located in the fluvial Flood Zones 2 and 3 and is classified as a 'less vulnerable' receptor in PPS25 (Ref. 16.1). Therefore the hydrology and drainage value and sensitivity is assessed to be medium as (see **Figure 16.6**).

Third Party Properties

16.5.93 There are a number of third party properties in the study area. There are several residential properties in the Stolford and Wick Moor area; in addition the existing HPB Sewage Treatment Works (STW) is located in Wick Moor as are several national grid towers (pylons). These receptors are potentially affected by the displacement of flood storage resulting from the placement of materials arising from excavations for the HPC construction works to provide platforms upon which construction activities will occur within the Holford Stream Valley.

Residential Third Party Properties

16.5.94 The third party residential properties have a high value/sensitivity due to their social and economic value and also because of their location in Flood Zones 2 and 3 (see **Figure 16.7**) and their 'more vulnerable' classification in PPS25 (Ref. 16.1).

16.5.95 The off-site highway improvement works may also result in an impact to third party residential properties and/or land. Six of the schemes are located in Flood Zone 2 and/or 3. These third party properties also have a high value/sensitivity due to their social and economic value and their 'more vulnerable' classification in PPS25 (Ref. 16.1).

Non Residential Third Party Properties

16.5.96 The non-residential third party receptors will have a medium value and sensitivity as the STW are classed as 'less vulnerable' and towers (pylons) as 'essential infrastructure' in PPS25 (Ref. 16.1).

ii. Water Quality Receptors

16.5.97 The terrestrial surface water quality receptors are the HPC Drainage Ditch (which is the principle receiving watercourse for the field drainage network in the BDAW), Holford Stream and Bum Brook. Wick Moor is not considered as a receptor for water quality impacts as any potential effects will be negated by affording protection to water quality in Holford Stream and Bum Brook which form part of the upstream catchment. Freshwater discharges to the intertidal area and marine environment are not examined within this chapter and have been assessed within **Chapter 18** on **Marine Water and Sediment Quality**. A summary of the value and sensitivity of freshwater quality receptors is presented in **Table 16.15**.

Hinkley Point C Drainage Ditch

16.5.98 The proposed HPC construction works may impact upon the water quality conditions in the series of interconnecting agricultural drainage ditches that drain the Built Development Area West. These ditches discharge into the HPC Drainage Ditch that ultimately discharges to the Hinkley Point intertidal area. These watercourses are supplied with water from surface drainage running off surrounding agricultural land. The water quality status is characterised by highly variable water quality conditions, including elevated concentrations of suspended solids. The watercourses are ephemeral in nature, drying out during prolonged periods without rainfall. Given the current baseline conditions, the value and sensitivity of these watercourses has been assigned as low.

Holford Stream and Bum Brook

16.5.99 The freshwater watercourses that drain the Southern Construction Phase Area, (Holford Stream and Bum Brook) may be described as having a moderate water quality status, based on the available water quality monitoring data and historical information for Stogursey Brook which forms part of the same catchment.

16.5.100 Bum Brook, and in particular Holford Stream, are important water supply streams to the Bridgwater Bay SSSI which lies downstream and to the east of the HPC development site. The designation of the Bridgwater Bay SSSI relates to the mosaic of habitats present, such as coastal grazing marsh, saltmarsh and mudflat that are intersected by a network of brackish and freshwater ditches. The communities of plants and invertebrates that are associated with this complex water dependent ecosystem are listed within the SSSI citation. Due to the water dependent nature of this SSSI, Holford Stream and Bum Brook are considered to be sensitive to any potential water quality or flow changes and have therefore been assigned a high sensitivity and value.

Summary of Receptor Value and Sensitivity

16.5.101 The value and sensitivity of the various receptors is summarised in **Table 16.15**. **Table 16.3** should also be read in conjunction with this section.

Table 16.15: Summary of Receptor Water Quality and Hydrological Value and Sensitivity

Receptor	Value and Sensitivity	
	Rating	Summary Explanation
HPC Drainage Ditch	Low	*Hydrology* The land adjacent to the ditch is located in Flood Zone 1, therefore is not sensitive to flooding impacts Not Main River No social or economic dependents
	Low	*Water Quality* Highly variable water quality conditions with elevated suspended solids Open agricultural surface drainage system Ephemeral nature
Hinkley Point intertidal area	Very Low	*Hydrology* Receptor identified as being tolerant to the proposed change
	Not applicable	*Water Quality* Not assessed within **Chapter 16** (see **Chapter 18**)
Holford Stream	High	*Hydrology* The land adjacent to the stream is located in Flood Zone 2 and 3, therefore is sensitive to flooding impacts Somerset Drainage Board Consortium Viewed Rhyne
	High	*Water Quality* Moderate water quality status Important water supply to freshwater wetland habitats of Wick Moor and Bridgwater Bay SSSI

Receptor	Value and Sensitivity	
	Rating	Summary Explanation
Bum Brook	High	*Hydrology* The land adjacent to the stream is located in Flood Zones 2 and 3, therefore is sensitive to flooding impacts
	High	*Water Quality* Moderate water quality status Important water supply to freshwater wetland habitats of Wick Moor and Bridgwater Bay SSSI
Wick Moor	High	*Hydrology- During low flows* High sensitivity to low flows due to the sensitivity of the water table Located in SDBC area
	Medium	*Hydrology- During high flows* Some tolerance to high flows and flood events. Classed as a ‘less vulnerable’ receptor in PPS25 (Ref. 16.1) Located in SDBC area
	Not applicable	*Water Quality* Not assessed as protection provided to water quality in upstream catchment
Agricultural land off-site of the HPC development site west of Holford Stream	Medium	*Hydrology* Located in residual tidal Flood Zone 2 and 3 Classed as a ‘less vulnerable’ receptor in PPS25 (Ref. 16.1)
	Not applicable	*Water Quality* Not applicable
Agricultural land off-site from the HPC development site west of HPC Drainage Ditch	Low	*Hydrology* Located in Flood Zone 1 Classed as a ‘less vulnerable’ receptor in PPS25 (Ref. 16.1)
	Not applicable	*Water Quality* Not applicable
Land off-site adjacent to Bum Brook	Medium	*Hydrology* Located in fluvial Flood Zones 2 and 3 Classed as a ‘less vulnerable’ receptor in PPS25 (Ref. 16.1)
	Not applicable	*Water Quality* Not applicable
Residential third party properties	High	*Hydrology* High social value Classed as a ‘more vulnerable’ receptor in PPS25 (Ref. 16.1) Located in Flood Zones 2 and 3
	Not applicable	*Water Quality* Not applicable

Receptor	Value and Sensitivity	
	Rating	Summary Explanation
Non residential third party properties	Medium	*Hydrology* Classed as a 'less vulnerable' or 'essential infrastructure' receptor in PPS25 (Ref. 16.1) Located in Flood Zones 2 and 3
	Not applicable	*Water Quality* Not applicable

d) Statutory Constraints

16.5.102 There are no statutory constraints which have restricted the collection of baseline data, analysis and interpretation of information or the assessment of impacts within the environmental impact assessment of the HPC development with regards to surface water quality or quantity.

16.5.103 Statutory constraints in terms of flood risk are discussed within the **Flood Risk Assessment**.

16.6 Assessment of Impacts

16.6.1 This section of the chapter assesses the identified potential impacts on surface drainage and water quality receptors both within the HPC development site and for any off-site associated receptors that may be affected from changes to the hydrology or water quality status of local watercourses. An outline description is provided of the proposed surface and foul water drainage strategy to demonstrate how these systems will evolve and be managed through all phases of the development. The description of the drainage system provides identification of the discharge locations for surface drainage and waste water from the site during site preparation, construction, operation and restoration phases.

16.6.2 The key design feature of the drainage system is the provision of Water Management Zones (WMZs) to treat to a suitable quality and attenuate, where necessary, water requiring discharge from the HPC development site into the local surface water features. A full assessment of all identified potential impacts in terms of hydrology, flooding and water quality are provided in this chapter. This includes an assessment of risks from accidents and incidents and the approach that has been adopted to minimise their probability of occurrence and incident management. Cumulative impacts are also assessed for interactive impacts that may occur as a result of the different activities taking place on the site simultaneously.

16.6.3 Legislative compliance dictates that an Environmental Permit (which includes discharge consents) will be required by the site operator for water discharges to be released. By definition of compliance with a consent to discharge (under the Environmental Permitting Regulations 2010 (Ref. 16.17)), a legal discharge will not significantly adversely affect the receiving environment. The drainage system incorporates design features such as WMZs that have been developed to ensure compliance with the requirements of Environmental Permits in terms of discharge water quality and rate. The assessment of impact magnitude takes into account this range of design measures, which have been developed to reduce the potential for hydrological and surface water quality impacts to occur (and are therefore not considered to be additional mitigation measures for the purposes of this assessment).

a) Surface Water Drainage System

16.6.4 A summary description of the Surface Water Drainage Strategy through all phases of the HPC development is outlined below and is presented in **Chapters 2** and **3** of this volume. The assessment of the potential water quality, hydrology and drainage impacts has taken into account the evolution of the drainage systems throughout the lifetime of HPC.

16.6.5 In terms of the drainage strategy, the site is divided into two areas which are the combined area of the BDAW (Build Development Area West) and BDAE (Build Development Area East) and the SCPA (Southern Construction Phase Area) which is considered separately. The proposed earthworks will result in infilling of the existing agricultural drainage ditch system in the BDAW and BDAE areas including the HPC Drainage Ditch.

16.6.6 The construction drainage system will be fully compliant with applicable current legislation, regulations and guidance, ensuring that water is discharged to the identified receptors at rates and of a chemical quality that ensure that discharge conditions are met. Discharges to Holford Stream and Bum Brook will be at controlled greenfield rates to minimise downstream impacts.

16.6.7 A site-specific **Water Management Plan** will provide details of the manner in which the preliminary works and main construction works phases should be undertaken (by earthworks contractors for example) to ensure Environmental Permit requirements in relation to protection of the local surface water features, are met.

i. Drainage Strategy Phases

16.6.8 There are five main phases of the drainage system strategy:

- Phase 1: site preparation;
- Phase 2: construction;
- Phase 3: transition from construction to operational phase drainage system;
- Phase 4: landscaping and restoration works (only on SCPA);
- Phase 5: operation; and
- Phase 6: BDAE and BDAW decommissioning.

Phase 1: Site Preparation Drainage System Strategy

16.6.9 During the site preparation works phase, surface drainage collected in the BDAE and BDAW will initially be directed towards the HPC Drainage Ditch having been routed through a WMZ. The HPC Drainage Ditch will initially retain its existing discharge to the Hinkley Point intertidal area at the northern boundary of the site. The discharge point will move to the new Foreshore Construction Outfall structure once it is constructed and commissioned. As the site preparation works progress the agricultural drainage ditches including the HPC Drainage Ditch will be backfilled and the surface drainage system for the main construction phase installed. It will be necessary through all drainage phases to provide a connection for draining the part of the HPC Drainage Ditch which is located outside and to the west of the BDAW, through the drainage system in the northern part of the site. This construction phase system for drainage of the northern part of the HPC development site will discharge via a single new outfall to the upper foreshore area. Additional WMZs will be developed to manage discharges into the installed construction phase drainage system within the BDAW and BDAE.

16.6.10 The spine drains, which will form the principal drainage pathways during the construction phase (see below) will be constructed during the site preparation phase.

16.6.11 During this phase the Holford Stream culvert will be constructed. There will be two surface water discharge points established into Holford Stream at the eastern and western ends of the culvert. A temporary surface drainage system will be developed for the stockpiling and platform areas in the SCPA that will collect run-off and direct it to WMZs for management and treatment prior to discharge into Holford Stream.

Phase 2: Construction Drainage System Strategy

16.6.12 The main elements of the construction drainage system will already have been installed during the site preparation works. Within the BDAE and BDAW surface drainage and dewatering discharges will continue to be directed to one of three WMZs. The WMZs will provide treatment of discharges to ensure that quality conditions of Environmental Permits are met. There are no greenfield run-off attenuation requirements since all surface water, groundwater and treated effluent will discharge via the Foreshore Construction Outfall.

16.6.13 WMZs will be located in the north, east, west and south of the site to control the discharge of water from run-off and dewatering activities. This phase will also see the ongoing operation of Holford Stream culvert. During this phase of works surface drainage and other wastewaters from the BDAW and BDAE areas will discharge through the construction phase drainage system to the Foreshore Construction Outfall.

16.6.14 Surface drainage from the SCPA will continue to be directed through WMZ to two discharge points into Holford Stream. The WMZs will provide treatment of surface drainage to ensure that quality conditions of Environmental Permits are met and that discharges are made at greenfield run-off rates.

16.6.15 The construction drainage systems will be designed such that no flooding to third party receptors will result from rainfall events up to the 1% AEP event plus allowance for climate change.

Phase 3: Transition from Construction to Operational Phase Drainage System

16.6.16 During the construction phase there will be a periodic evolution from the construction phase drainage system described above to the operational phase permanent drainage system as elements of the permanent infrastructure are progressively installed. In some areas, the permanent systems may use parts of the construction drainage infrastructure. In these cases, the connections will be arranged to ensure that the drainage is managed throughout the transition from temporary to permanent systems. It may be that some elements of the construction phase drainage will form part of the permanent drainage system. Parts of the temporary drainage systems within the permanent power station site will be in use until relatively late in the construction works when the cooling water outfall tunnel has been commissioned.

16.6.17 The part of the construction phase drainage system, not incorporated into the permanent operational system to the north of Green Lane within the permanent development area will be made redundant. Some elements of the construction phase drainage system may be left in position for the operational phase but will effectively be redundant.

Phase 4: Landscaping and Restoration Works in SCPA

16.6.18 During and following the landscaping works on surrounding areas the gradual removal of elements of construction phase drainage system will be undertaken. This will include elements of the WMZs, SuDS features including ditches and swales, and outfall structures. The Holford Stream culvert will be retained together with all the associated features, such as energy dissipation measures and the adjacent drains. Further details on the Holford Stream culvert are provided below.

16.6.19 During the landscape restoration activities, the WMZs will be retained and are likely to be resized appropriately to accommodate the expected lower surface water run-off during this phase and thereafter. An additional WMZ will be developed for works associated with early landscaping of southern areas of the SCPA to manage surface drainage within this area, prior to a discharge into Bum Brook. In addition a network of ditches throughout the SCPA area is also proposed; these ditches will provide some attenuation of surface water flows and encourage biodiversity.

Phase 5: Operational Drainage System Strategy

16.6.20 The permanent drainage system will be designed to cope with rainfall events up to the 1% AEP standard without surface flooding due to overloading of the drainage network. The drainage system in combination with the final restored landscape and sea wall design, will also be designed to discharge any wave overtopping of the sea wall up to a rate of 10 litres/ linear m/s. This is far in excess of the estimated peak overtopping discharge of approximately 1.5 litres/linear m/s during the 0.01% AEP event (Ref. 16.74). Additionally, the operational drainage design will ensure that surface water flooding that might arise during events that exceed the design standard will be effectively managed such that the consequences will be minimised up to the 0.01% AEP event.

16.6.21 The permanent drainage will include a groundwater drainage system, designed to maintain groundwater levels to no higher than about six metres below the power station platform level (which will be at 14m AOD), in order to limit the flotation forces which might otherwise be caused by groundwater pressure on deep building foundations and sub-surface structures.

16.6.22 As described in **Chapter 2** of this volume, the surface and groundwater drainage systems will be routed into the attenuation pond before being discharged to the Severn Estuary via the cooling water outfall tunnel.

Phase 6: Decommissioning Operational Drainage System Strategy

16.6.23 Following secession of generation the use of the cooling water outfall tunnel will no longer be available. It will be necessary to disconnect the outfall pipe, which passes all surface water flows, from the attenuation pond and provide an alternative outfall.

16.6.24 The existing surface water drainage network will be abandoned in a staged process as demolition of buildings and structures proceeds.

16.6.25 At the appropriate stage, a ditch will be provided to link the existing HPC Drainage Ditch through the site to the Foreshore Construction Outfall. This will provide for continuity of discharge and a facility for draining the BDAE and BDAW when restored to a greenfield site.

ii. Foul Water Drainage Systems

Phase 1: Site Preparation Phase

16.6.26 During the site preparation works phase, grey and black water generated by contractors facilities will either be sent to sealed underground tanks for off-site disposal. Package wastewater treatment works will be installed during this phase of works but will not be operated until the main site construction phase commences in 2013.

Phase 2: Main Site Construction Phase

16.6.27 Grey water (e.g. from wash basins) and black water (e.g. from toilets) arising during this phase will be collected by a temporary foul drainage network and directed towards the three package treatments plants located in the BDAW and BDAE. Treated waste water effluent from package treatment works, will discharge to the intertidal area via the spine drain system and the Foreshore Construction Outfall (see **Chapter 18**).

16.6.28 Grey and black water generated from the accommodation campus will be discharged via temporary foulwater drains to a dedicated temporary package sewage treatment plant. Treated final effluent will towards a WMZ associated with the discharge into Holford Stream at the eastern end of the culverted reach. This is the only treated effluent that will be directed towards a terrestrial surface watercourse and the discharge will be subject to volume and quality controls under an Environmental Permit.

Phase 3: Operational Phase

16.6.29 Grey water (e.g. from wash basins) and black water (e.g. from toilets) that is generated during the operation of the power station will be collected and discharged through a permanent foulwater drainage network to the permanent wastewater treatment works. Treated final effluent will be discharged to the attenuation pond for discharge via the cooling water outflow tunnel. The assessment of these discharges to the marine environment is presented in **Chapter 18**.

Phase 4: Decommissioning Operational Foulwater Drainage System

16.6.30 At some time after secession of generation the use of the cooling water outfall tunnel as a wastewater disposal route will no longer be available. It will be necessary to disconnect the final effluent pipe from the attenuation pond and provide an alternative outfall. It is intended that the Foreshore Construction Outfall will be used for this purpose.

16.6.31 The wastewater treatment facility can continue to be used during decommissioning of the main operational site and to serve the Interim Spent Fuel Storage Facility which will remain in use until 2140. However, it may be necessary to modify the treatment plant in order that it can maintain final effluent standards whilst treating reduced wastewater volumes. Alternatively a new treatment plant may be required.

16.6.32 The existing foulwater drainage network will be abandoned in a staged process as demolition of buildings and structures proceeds.

iii. Holford Stream Culvert

16.6.33 During the construction phase, Holford Stream will be culverted from a point close to the western boundary of the HPC development site across to the eastern boundary of the site, where it will discharge water into the existing open Holford Stream watercourse. At the upstream face of the culvert, flow from Holford Stream will be diverted into a prefabricated box culvert, approximately 2.5m wide by 2.5m high (see Holford Stream Culvert Justification Report Ref 16.55), which will run parallel to the existing watercourse alignment at a distance of approximately 50m to the north. The culvert will run almost the entire width of the site, with a total length of approximately 690m. The culvert has been sized to enable access for small plant such as a bobcat for maintenance and inspection purposes. The culvert fall in a west to east direction will be approximately 1m, dropping from 6m AOD to 5m AOD. Energy dissipation measures will be implemented at the outfall of the culvert to reduce flow velocities.

16.6.34 The base of the culvert will be impermeable to prevent transmission losses through the channel bed when groundwater levels are low. However, adjacent to and along the length of the culvert, two 500mm drains will be installed and backfilled with sand/gravel to allow groundwater to be collected and discharged at the eastern end of the culvert (when groundwater levels are high enough).

iv. Water Management Zones

16.6.35 Surface water discharges to the HPC Drainage Ditch (during the site preparation phase), the intertidal area, Holford Stream and Bum Brook will be routed via respective WMZs. Sufficient surface water storage capacity is provided within the WMZs for pre-discharge treatment in order that conditions of Environmental Permits for discharges are met and, where necessary, to control discharge rates.

16.6.36 The WMZs discharging to Holford Stream and Bum Brook will be designed to store water up to the 3.33% AEP storm with discharge limited to greenfield discharge rates. To prevent inundation in times of flooding, bunds will be built around the two Holford Stream WMZs. The **Flood Risk Assessment** states that the height of bund around the eastern WMZ determined by modelling for the 1% AEP fluvial flood level in the watercourse, should be no less than 6.1m AOD, which includes a freeboard of 300mm. The bund is intended to prevent potential pollutants and sediments stored within the WMZs from being washed into the watercourses in the event of a fluvial flood.

v. Soil Retaining Wall

16.6.37 A temporary soil retaining wall will be constructed during the site preparation works phase at a location inland of the existing cliff edge as detailed in **Volume 1**, **Chapter 6**. This will be set back at least 10m from the cliff edge. Any construction drainage from around the working area for this structure would be collected and discharged following routing through a WMZ into the site preparation drainage system (either the HPC Drainage Ditch or the spine drains) and ultimately to the intertidal area. The retaining wall will become redundant and effectively replaced by the sea wall following its construction (during the construction phase).

vi. Sustainable Drainage Systems

16.6.38 Good practice measures will be adopted to reduce, where possible, the volume of surface drainage being collected and requiring disposal through discharge. By restricting drainage run-off rates, the erosion of bare soils would be reduced leading to a reduction in potential sediment generation. The use of the Sustainable Drainage System (SuDS) principle of porous surface is not deemed practical within the BDAW and BDAE for two principle reasons:

- There is no requirement for attenuation given that discharges of surface drainage are made directly to sea.
- There will be an on-going requirement for groundwater dewatering in order to avoid the risk of flotation to buildings due to groundwater pressure. Therefore the ground infiltration of surface drainage through SuDs would effectively contribute to a requirement for increased dewatering efforts.

16.6.39 SuDS principles will be adopted where practical within the SCPA. These would include the use of porous hard surface areas and, where soil conditions allow, the adoption of soakaway systems for disposal of uncontaminated surface drainage water.

16.6.40 The groundwater that has been recharged from the SuDS system would be low in suspended solids as the soakaway system would effectively remove solids through soil filtration.

vii.Provision for Emergency Run-off During the Construction Phase

Construction Phase

16.6.41 Provision would be made for rainfall events that exceed the normal design criteria for drainage systems in order to minimise the consequences associated with inundation of systems and potential failure/breach of water storage infrastructure. For example, the construction phase drainage system will be designed to a 3.33% AEP standard and any excess water will be controlled and temporarily stored on site up to and including the 1% AEP rainfall event plus allowance for climate change. Guidance with respect to designing for exceedence is given in CIRIA Manual 635 (Ref. 16.46). Such contingencies might include, but not be limited to:

- Locating water management infrastructure such that any flooding will be channelled to designated areas in which water can be contained by natural topographic features or by constructed bunds that would comprise a secondary line of defence. These provisions should minimise the risk of accidental discharges to controlled waters that would breach planning conditions or Environmental Permit conditions, with the exception of very low probability events.

- Allowing excess water to be channelled into excavations making sure that no damage is incurred to infrastructure already constructed within them. Under these circumstances sufficient pumping capacity would be made available to allow post-event dewatering of the excavations and agreed routes of disposal of water made with the regulator.

16.6.42 Run-off management during the operational phase is discussed above.

b) Off-site highway improvements

16.6.43 In addition to the main HPC development site, consideration has been given to the eleven off-site highway improvement works. The highway improvement schemes apply to existing roads and junctions and details and locations of each improvement scheme may be found in **Volume 2**, **Chapter 2** of this ES. Details of those schemes for which surface water interactions are notable are provided below.

16.6.44 The scope of each scheme has been investigated in relation to the surrounding surface water environment. The limited nature of the works (primarily road traffic management changes and existing junction widening) dictates that the existing road drainage will be sufficient to mitigate against any significant impacts to the water quality status of the nearby watercourses. Good construction practices will be sufficient to prevent any additional potential water quality impacts during the construction of the schemes.

16.6.45 Two schemes were not included in the highway improvements works **Flood Risk Assessment** as they were within Flood Risk Zone 1 and less than one hectare in size; therefore a **Flood Risk Assessment** was not required. These were the Claylands Corner Junction scheme and the Cannington Traffic Calming Measures scheme.

16.6.46 The **Flood Risk Assessment** concluded that six of the schemes would result in a net increase in impermeable surface area, four of which are located within Flood Risk Zone 2 or 3. The schemes would not result in a decrease in flood plain storage. Any increase in flood risk would arise from a very limited increase in surface water run-off.

Table 16.16: Off-site Highway Improvements that will Result in Increases in Impermeable Areas (Source: Highway Improvement Works **Flood Risk Assessment**) and Environment Agency Flood Risk Zone

Site	Site Area (ha)	Net Increase in Impermeable Area (m^2)	EA Flood Risk Zone
A39 Broadway/A38 Taunton Road Junction	0.9	0	3
Wylds Road/ The Drove Junction	0.5	352	3
A38 Bristol Road/Wylds Road Junction	0.4	404	3
A38 Bristol Road/The Drove Junction	0.3	0	3
A39 New Road/B3339 Sandford Hill Roundabout	0.6	376	3
M5 Junction 23 Roundabout	4.1	587	3

Site	Site Area (ha)	Net Increase in Impermeable Area (m^2)	EA Flood Risk Zone
Washford Cross Roundabout	1.5	782	1
C182/Farringdon Hill Lane, Horse Crossing	1.2	117	1

16.6.47 Six schemes have the potential to impact the surface water run-off, these are.

- Wylds Road/The Drove Junction – increasing width of road.
- A38 Bristol Road/Wylds Road Junction – increasing width of road.
- A39 New Road/ B3339 Sandford Hill Roundabout – new roundabout.
- M5 Junction 23 – increasing width of road.
- Washford Cross – new roundabout.
- C182/Farringdon Hill Lane, horse crossing – new crossing point.

16.6.48 Third party residential properties/land adjacent to highway improvement works may have an increased risk of flooding as a result of larger run-off due to greater impermeable areas (Wylds Road/ The Drove Junction; A38 Bristol Road/Wylds Road Junction; A39 New Road/B3339 Sandford Hill Roundabout; M5 Junction 23 Roundabout; Washford Cross Roundabout; and C182/Farringdon Hill Lane, Horse Crossing). However, any potential increase in run-off will either be managed within the existing highway drainage system, or the improvement works will include measures to improve the highway drainage system to reduce the surface water flood risk. Therefore the potential impact magnitude associated with elevated surface water run-off to the third party property/land is assessed to be very low and of minor significance and as a result the schemes are not given any further consideration within this chapter.

c) Construction Impacts

i. Hydrology and Drainage Construction Impacts

16.6.49 A full description of the construction phase activities is provided in **Volume 2**, **Chapter 3**. This element of works includes the site preparation works and the temporary jetty development. However, the key elements of the construction phase works which may impact the hydrology and drainage, are:

- creation of bare earth surfaces due to the stripping of topsoil and vegetation;
- changes to topography due to site levelling and terracing, stockpiling, deep excavations for the two UK EPR units; and the early landscaping works south of the 144750mN grid line;
- construction of semi-permeable and impermeable surfaces, such as the site entrances, roundabouts, site internal roads, site compounds areas, accommodation campus, substation, Nuclear Island, Conventional Island, ancillary buildings, sea wall and off-site highway improvements works;
- construction of an emergency access road including the bridge crossing over Bum Brook;

- installation of the construction phase drainage system and implementation of the surface water and sediment management system to include the following;
  - infilling of agricultural ditches and construction of a drain to intercept the upstream area of the HPC Drainage Ditch catchment at the western boundary of the HPC development site;
  - construction of three main spine drains and associated WMZs within the northern part of the site;
  - construction of a single outfall to the Hinkley Point foreshore;
  - culverting of a section of Holford Stream;
  - construction of two WMZs and two outfalls draining the southern part of the site to Holford Stream to facilitate discharge conditions; and
  - construction of one temporary WMZ and outfall to Bum Brook during the early landscaping works.

16.6.50 Common hydrology and drainage impacts, resulting from construction activities, will not occur in isolation and therefore have been grouped and are considered cumulatively.

16.6.51 A number of the works elements are likely to require some dewatering of excavated areas. Impacts to the groundwater regime as a result of dewatering are assessed within **Chapter 15** of this volume. As the lower section of HPC Drainage Ditch catchment including the ditch itself is to be removed during the deep excavations and replaced with new drainage infrastructure, there would be no further impact to the ditch catchment and drainage ditch once the relevant works are completed and therefore this drainage feature is not assessed beyond the construction phase of works.

16.6.52 Potential impacts common to the above activities include:

- elevated surface water run-off volume and run-off rates;
- pluvial flooding as a result of elevated surface water run-off;
- fluvial flooding due to a reduced channel capacity as a result of elevated sediment deposition in channels;
- fluvial flooding as a result of blockages in culverts and/or bridges;
- reduced flood storage capacity for flood waters resulting in:
  - increased flood risk to off-site receptors due to fluvial flooding; and
  - increased flood risk to off-site receptors due to tidal flooding;
- changes to Holford Stream hydraulic conditions.

16.6.53 The land-based elements of the construction phase works that have the potential to have an impact on surface water run-off (and which have been considered herein) include:

- the creation of bare earth surfaces (vegetation removal and topsoil stripping and stockpiling);

- changes to topography (cut and fill operations and the levelling and creation of construction and development platform areas); and
- creation of impermeable and semi-permeable surfaces (impermeable surfaces such as the access road, roundabouts, car parks, buildings and off-site highways improvements and semi-permeable surfaces such as the internal haul roads).

Creation of Bare Earth Surface

16.6.54 The creation of bare earth surfaces during the construction activities could increase the surface water run-off rate for the following reasons:

- reduced near-surface water retention due to the removal of the vegetated layer and compaction by vehicles and plant;
- reduced soil moisture deficit causing a potential increase in the propensity for saturation excess overland flow;
- increased propensity for infiltration excess overland flow resulting from the compaction of the bare earth surface;
- compounding effects of reduced surface roughness increasing the overland flow rate; and
- increased overland flow leading to channelisation via rills which would further enhance run-off rates.

16.6.55 Assuming that a storm event is preceded by a period of dry weather and that the soil moisture deficit (SMD) is relatively high, if the rainfall does not exceed the infiltration rate of the soil under these conditions then water would normally be stored within the vegetated layer. Vegetation removal would cause a reduction in average SMDs due to reduced evapotranspiration, with the result that saturation excess overland flow would be initiated more quickly, relative to the baseline greenfield condition.

16.6.56 If the rainfall rate exceeds the maximum infiltration rate of the soil then the portion of rainfall volume that is unable to infiltrate would remain at the surface and initiate infiltration excess overland flow. The propensity for such overland flow would be affected by the following:

- the capacity for infiltration would be reduced as a result of the compacted bare earth surface and loss of plant root system that provides preferential infiltration pathways;
- the infiltration capacity may reduce over time as a result of soil pore space and preferential infiltration flow paths being blocked by fine soil particles that would be more readily mobilised during the bare-earth condition; and
- compaction of the bare earth surface due to rainfall energy during intense rainfall events would exacerbate the reduction in infiltration.

16.6.57 If soil saturation and infiltration conditions are such that saturation excess and/or infiltration excess overland flow is initiated, the flow rate would be primarily influenced by vegetation roughness characteristics, the surface gradient, and the volume/depth of water. As such, by removing vegetation and increasing the steepness of slopes in certain areas (for example at the edges of the construction and development platforms), some areas of the site would be more prone to the risks associated with overland flow than others.

16.6.58 Over time and if left unmitigated, water that is allowed to flow over bare surfaces would potentially form preferential flow pathways that, over the duration of a storm event, would be subject to erosion action by flow such that the preferential pathways incise and become channelised; firstly in the form of rills and then evolving into gullies. Whilst further exacerbating run-off rates, these processes would result in the erosion and mobilisation of fine sediments which can potentially be delivered to receiving watercourses and suspended sediments subsequently deposited on the channel bed, potentially reducing the channel capacity.

16.6.59 The surfaces of relatively steep slope batters would, if left bare, give rise to relatively higher overland flow velocity which, in turn, would increase the capacity for erosion and transporting suspended sediments to surface watercourses. The entry of sediment-laden water into surface watercourses may potentially impact on both water quality status (increases in suspended solids concentrations) and the hydraulic regime (through siltation).

Change to Natural Topography

16.6.60 The changes to the natural baseline topography arising from the construction of the platforms and stockpiles, will result in a number of slope batters being located across the development area which could give rise to the following potential impacts:

- elevated surface water run-off;
- elevated discharge to controlled waters;
- more rapid run-off response to rainfall;
- increased soil erosion on-site; and
- in some areas, reduced surface water run-off where slopes have been reduced.

16.6.61 A number of terraces and new platforms are to be created that vary in elevation. The construction of the platform in Flood Zones 2 and 3 (see **Figures 16.7** and the construction phasing plans presented in the **Construction Method Statement**) would comprise a substantial batter to the east that would slope down at a relatively steep angle to the Holford Stream Valley floor from a level of 22m AOD to approximately 5.50m AOD.

16.6.62 The creation of platforms and terraces in the north of the site (BDAW and BDAE) will result in the removal of the lower section of the HPC Drainage Ditch catchment and infilling of HPC Drainage Ditch. Run-off generated in the upper catchment area will be intercepted by a drain at the west boundary of the HPC development site and incorporated and managed by the construction phase surface water drainage system. The removal of the catchment may result in a more rapid Run-off response and consequently elevated surface water run-off rates.

16.6.63 There will be one main stockpile area, with a limited maximum elevation, the creation of which would cause localised changes in catchment relief (i.e. from stockpile batters). Furthermore the development and evolution of stockpiles throughout the construction phase would lead to continual changes to topography.

16.6.64 The land to the south of the 144750mN grid line will undergo early landscaping works to be complete by early 2013 (see **Figure 4.1** in the **Construction Method Statement**). The land in the north-west of this area will be re-profiled and raised from an existing peak elevation of 28.8m AOD to an elevation of 35m AOD, with new slopes created to the south to blend in with the existing contours at around 20m AOD adjacent to Bum Brook. The land in the north-east will be raised from 23.5m AOD to 30m AOD. The early landscaping works will result in increased surface water run-off rates and increased run-off response to rainfall. It should be noted that some run-off which would naturally drain to Bum Brook will be diverted to Holford Stream by this stage of the development; therefore only limited potential additional surface water run-off to Bum Brook is expected relative to baseline conditions. During these earthworks, sediment-laden run-off may be generated which could be deposited within Bum Brook. The entry of sediment-laden water into Bum Brook may potentially impact on both water quality status (increase in suspended solids concentration) and hydraulic regime (through siltation), of this small watercourse.

Creation of Impermeable and Semi-Permeable Surfaces

16.6.65 The conversion of permeable greenfield land to impermeable and semi-permeable surfaces would result in the following potential impacts:

- elevated surface water run-off rates;
- elevated discharge rates to controlled waters; and
- more rapid run-off response to rainfall events.

16.6.66 A summary of the drainage system and the evolution of the drainage system throughout the site preparation works, subsequent construction phase and operational and removal/reinstatement phases is provided at the start of this section. Surfaces would typically comprise compacted Type 1 granular fill for the internal haul roads, together with areas of impermeable roofing and tarmac. Rain falling on these areas will ultimately be routed to the spine drain network via a network of piped and open drains. Therefore, discharge from the proposed outfall to the intertidal area will be at a greater flow rate than for the existing baseline condition. Discharges in the area of the outfall are currently diffuse land drainage rather than the point discharge associated with the proposed outfall and therefore this represents a change from baseline conditions.

16.6.67 The specification of appropriate discharge mechanisms to the intertidal area and subsequently offshore into the Severn Estuary via the cooling water outfall has given consideration to marine water quality standards, ecological sensitivities, and health and safety considerations. Further details on the impacts associated with the discharges via the cooling water outfall are provided in **Chapters 18** and **19** of this volume, respectively.

16.6.68 Any potential increase in run-off, due to the six highway improvement schemes, will be managed within the existing highway drainage system, given the limited nature of the scope of the works in most cases. In areas which may-be currently vulnerable to surface water ponding/flooding or where the existing drainage system would be unable to cope with the additional run-off, the improvement works will include additional measures to improve the highway drainage system to reduce the surface water flood risk.

Change to Flood Storage Capacity of Holford Stream Valley and Wick Moor

16.6.69 The site preparation works include the major earthworks activities associated with the creation of the platforms upon which construction activities will be carried out. The earthworks will include the infilling of a ditch in the northern section of the site (HPC Drainage Ditch) and the culverting and valley infilling of a watercourse (Holford Stream) in the southern section of the site. This infilling of Holford Stream valley is located within Flood Zone 1, 2 and 3 and therefore could result in off-site impacts. Fluvial and tidal modelling was carried out for the **Flood Risk Assessment** in order to quantify the impact of this activity on off-site receptors, such as third party properties. A summary of the **Flood Risk Assessment** findings is presented below.

16.6.70 The fluvial modelling carried out for the **Flood Risk Assessment** has indicated that for the 1% AEP 2017 and 2100 events the development would increase water levels downstream of the platform due to increased conveyance of Holford Stream culvert. However fluvial floods water are not predicted to reach third party properties. In addition, no impact upstream of the site boundary at Holford Stream is predicted.

16.6.71 The tidal modelling carried out for the **Flood Risk Assessment** indicates that, during the 2017 0.5% AEP flood event, there would be no increase in tidal flood risk to third party off-site receptors due to the infilling of Holford Stream valley caused by overtopping or breach of the existing sea defences. There is a very small predicted increase in flood depth (0.01m) at Wick Moor during the overtopping (2017) 0.5% AEP event. There is no impact during the equivalent breach event.

16.6.72 During a 0.5% AEP future (2100) flood event caused by overtopping the modelling showed an increase in flood depth of around 0.03m at the C182, HPA and HPB Sewage Treatment Works (STW) and some residential properties near Stolford. In all cases there would be no change in hazard rating. Under a 2100 0.5% AEP event breach scenario there would be an increased impact (up to 0.11m increase in flood depth) at the C182 and STW. There is no predicted impact to the third party properties during this breach event. There is no predicted change in hazard rating at off-site receptors apart from at the national grid tower (pylons) to the west of the existing HPA and HPB STWs.

16.6.73 In addition to the above scenario runs, the 1% AEP 2100 overtopping scenario was simulated. This showed an impact of 0.09m (increase in flood depth) to third party receptors southwest of Sharpham Embankment (these include the C182, Wick Moor, the national grid tower (pylons), the HPA and HPC STWs, and properties near to Little Dowden's Farm, and Fisheries Cottage. There is no impact to other properties in the Stolford area.

16.6.74 The Shoreline Management Plan (SMP) (Ref. 16.75) discusses the potential for managed realignment of the defence immediately to the east of the existing Hinkley Point B power station to Stolford further to the east. The preferred policy in the short-term (to 2025) is to continue to maintain the existing embankment defences under a hold the line policy and investigate opportunities for managed realignment. In the medium-term (2025 to 2055) the preferred policy is to implement managed realignment of the defences and in the long-term (2055 to 2105) to hold the line of the realigned defence. Therefore after 2025 it is the current policy that the defences should be improved and possibly realigned.

Changes to the Flood Regime of Bum Brook

16.6.75 A small area of the Bum Brook catchment and stream falls within the HPC development site boundary. Changes to the topography include raising the elevation of the slope to the north of the stream, and the provision of a bridge to carry the emergency access road over Bum Brook (see **Figure 4.2** in the **Construction Method Statement**).

16.6.76 Modelling carried out as part of the **Flood Risk Assessment** indicates that the proposed bridge over Bum Brook would increase flood levels in the watercourse immediately upstream and decrease flood levels downstream of the bridge. There would be no effect on third party residential receptors. The potential impact of a blockage under the bridge is assessed later in this section.

Change to Holford Stream Hydraulic Conditions

16.6.77 Currently, greenfield run-off from catchment Zones 2 and 5 (see **Figure 16.4**) is via Holford Stream. This will generally remain the case during the construction phase; however, there will be run-off from a small additional area from Zone 3 from which run-off will be routed from Bum Brook to Holford Stream and the loss of a section in the north which will be routed to the intertidal area.

16.6.78 The presence of impermeable surfaces and the operation of the Holford Stream culvert will potentially cause elevated water flow velocity in Holford Stream to the immediate east of the culvert outfall. Currently, the section of Holford Stream upstream of the C182 access road is densely vegetated (see paragraph 16.5.28). As such, the roughness of the stream channel is considerably greater (a Manning's n value of 0.07 is used in the modelling carried out for the **Flood Risk Assessment**) in comparison to a concrete culvert for which a Manning's n value of 0.015 is used in the modelling, therefore the flow velocities within the culvert may be greater than for the baseline condition.

16.6.79 Flooding upstream of the Holford Stream culvert could potentially arise as a result of the culvert being blocked by debris. The risk of potential blockage of the Holford Stream culvert is very low due to the large cross sectional area combined with the proposed proactive operational maintenance regime (that will be set out in an operation and maintenance manual for the Holford Stream culvert).

16.6.80 It is proposed that prior to the culvert becoming operational, the WMZs will be constructed upstream of the existing Holford Stream culvert under the C182. Here the water will be attenuated to discharge at the baseline greenfield run-off rates displayed in **Table 16.5** (see **Figure 16.4**).

16.6.81 An assessment of the fluvial impacts of culverting Holford Stream is presented in the **Flood Risk Assessment**. The **Flood Risk Assessment** has been prepared to be consistent with the requirements stipulated by the Environment Agency for consent for works affecting controlled waters under the Land Drainage Act 1991 (Ref. 16.19). As part of the discharge consent that will be required and in accordance with PPS25 (Ref. 16.1), discharge leaving the site via Holford Stream will be limited to greenfield rates, therefore no significant impacts would occur downstream of the Holford Stream culvert. This has been taken into account in the fluvial modelling carried out for the **Flood Risk Assessment**.

16.6.82 Prior to constructing the surface water drainage system, consent from the Environment Agency is required in accordance with the Land Drainage Act 1991 (Ref. 16.19). Holford Stream and the Wick Moor Rhynes are under the jurisdiction of the Parrett Internal Drainage Board (part of the Somerset Drainage Board Consortium). Therefore, Land Drainage Consent under the Land Drainage Act 1991 needs to be obtained from the Parrett Internal Drainage Board for the construction of the Holford Stream culvert and any modifications or for any works within 9m of an existing channel (see section 16.3).

Assessment of Construction Impacts

IMPACT: Effect of Elevated Surface Water Run-off Rate

16.6.83 Increased surface water run-off would result in elevated discharge to controlled waters and more rapid run-off response to rainfall potentially increasing the surface water flood risk. Six hydrological receptors have been identified which may be adversely impacted by elevated surface water run-off, the sensitivity of each of these receptors is presented in **Table 16.15**:

- HPC Drainage Ditch (during the initial stages of construction only, after which the HPC Drainage Ditch will be removed).
- Hinkley Point intertidal area (following the removal of HPC Drainage Ditch).
- Holford Stream.
- Wick Moor (via Holford Stream).
- Bum Brook (during the early landscaping works).
- Residential third party properties adjacent to the highway improvement works.

16.6.84 Discharges to HPC Drainage Ditch will be managed via attenuation in the WMZs in the north of the HPC development site to ensure that discharges do not exceed the capacity of the ditch. Therefore the potential impact magnitude associated with elevated surface water discharges to HPC Drainage Ditch is considered to be very low. Run-off to the intertidal area will not be attenuated however will still discharge via WMZs. The potential impact magnitude associated with elevated surface water discharges to the intertidal area is considered to be medium.

16.6.85 Provided that discharge to Holford Stream and Bum Brook is controlled to greenfield rates the impact magnitude associated to these receptors is assessed to be very low.

16.6.86 Based upon the value and sensitivity ratings of these receptors (**Table 16.15**) the resultant significance of potential impacts related to elevated surface water run-off has been assessed to have the following significance:

- HPC Drainage Ditch: very low impact magnitude; low value/sensitivity; leading to a **negligible** impact.
- Hinkley Point intertidal area (following the removal of HPC Drainage Ditch): medium impact magnitude; very low value sensitivity; leading to a **minor adverse** impact.
- Holford Stream (and ultimately Wick Moor): very low impact magnitude; high value/sensitivity; leading to a **minor adverse** impact.

- Wick Moor (via of Holford Stream): very low impact magnitude; high value/sensitivity (worst case value/sensitivity assumed in the instance of a low flow event); leading to a **minor adverse** impact.
- Bum Brook: very low impact magnitude; high value/sensitivity; leading to a **minor adverse** impact.
- Residential third party properties/land: very low impact magnitude; high value/sensitivity; leading to a **minor adverse** impact.

IMPACT: Effect of Elevated Sediment Delivery and Deposition in Watercourses

16.6.87 The Water Quality impact section below identifies increased sediment-laden run-off reaching the watercourses as an impact. In the following text the indirect impact presented from this potential source of impact is assessed with respect to the reduction in channel capacity and hence increased flood risk.

16.6.88 Three hydrological receptors have been identified which may be impacted by elevated sediment delivery and deposition, namely:

- HPC Drainage Ditch;
- Holford Stream; and
- Bum Brook.

16.6.89 The Water Quality section assesses the impact magnitude associated with delivery of sediment-laden run-off to watercourses to be low or very low due to the presence of the WMZs which will control discharge in line with conditions imposed by the Environment Agency (Ref. 16.47). Discharges to Holford Stream and Bum Brook are likely to be more strictly controlled (in relation to suspended solids concentrations) than discharges to the HPC Drainage Ditch. Therefore sediment-laden run-off is very unlikely to reach the watercourses in quantities large enough to deposit sufficient sediment to reduce the channel capacity and alter the watercourse hydraulics. Based upon the value and sensitivity ratings of these receptors (**Table 16.15**) the resultant significance of potential impacts has been assessed to have been found to have the following significance:

- HPC Drainage Ditch: low impact magnitude; low value/sensitivity; leading to a **minor adverse** impact.
- Holford Stream: very low impact magnitude; high value/sensitivity; leading to a **minor adverse** impact.
- Bum Brook: very low impact magnitude; high value/sensitivity; leading to a **minor adverse** impact.

IMPACT: Effect of Increased Flood Risk of Land Outside the HPC development site from Pluvial Sources of Flooding

16.6.90 Localised flooding off-site could result indirectly from elevated surface water run-off causing overland flow to flood land off-site. The assessment of these impacts follows that carried out for the assessment of elevated surface water run-off impacts.

16.6.91 Five hydrological receptors have been identified which may be impacted by pluvial flooding, namely:

- Hinkley Point intertidal area;
- agricultural land to the west of the BDAW;
- agricultural land to the west of the SCPA;
- Wick Moor; and
- Land adjacent to Bum Brook.

16.6.92 The sensitivity of these identified receptors to this potential impact ranges from very low to high (see **Table 16.3**).

16.6.93 Due to the implementation of the construction phase drainage strategy including elements such as the WMZs, the impact magnitude of pluvial flooding to these receptors as a result of elevated surface water run-off from the HPC development site is assessed to be very low to low. The likelihood of flooding is unlikely, only potentially occurring during low probability extreme rainfall events and over very short durations, and the consequences of flooding are likely to be insignificant due to the probable shallow depth of flood waters and short lived event durations. Based upon the value and sensitivity ratings of these receptors (**Table 16.15**) the resultant significance of potential impacts has been assessed to have the following significance:

- Hinkley Point intertidal area: low impact magnitude; very low value/sensitivity; leading to a **negligible** impact.
- agricultural land off-site from the HPC development site west of HPC Drainage Ditch: very low impact magnitude; low value/sensitivity; leading to a **negligible** impact.
- agricultural land off-site from the HPC development site west of Holford Stream to: very low impact magnitude; medium value/sensitivity; leading to a **minor adverse** impact.
- Wick Moor: very low impact magnitude; medium value/sensitivity; leading to a **minor adverse** impact.
- Land off-site adjacent to Bum Brook: very low impact magnitude; medium value/sensitivity; leading to a **minor adverse** impact.

IMPACT: Increased Fluvial Flood Risk to Land Outside of the HPC development site

16.6.94 Four hydrological receptor groups have been identified which may be impacted by increased fluvial flood risk during construction:

- Agricultural land to the west of the SCPA;
- Wick Moor;
- Residential third party properties (Doggett’s Farm and Little Dowden’s farm area); and
- Land adjacent to Bum Brook (upstream of the emergency access bridge).

16.6.95 Elevated off-site fluvial flood risk may arise due to the following mechanisms:

- Reduced channel capacity due to sediment deposition within the receiving watercourse.
- Reduced flood storage capacity of Holford Stream Valley due to platform and WMZs.
- Flow restriction or blockage under the emergency access bridge crossing Bum Brook.
- Flow restriction or blockage in Holford Stream culvert.

16.6.96 Flooding of Wick Moor and the land adjacent to Bum Brook may occur due to elevated sediment deposition in the Holford Stream and Bum Brook respectively which could cause a reduction in channel capacity. The impact on magnitude of flooding due to reduced channel capacity is assessed to be very low because the suspended sediment concentration of water discharging to Holford Stream will be controlled within the construction phase drainage system and associated WMZs in line with consents issued under the Environmental Permitting Regulations (Ref. 16.17) and therefore the volume of sediment reaching the watercourses will be minimal.

Table 16.17: Summary of Fluvial Flood Risk Impacts to Receptors as a Result of Infilling and Culverting Holford Stream Valley and the Emergency Access Road Bridge over Bum Brook

Receptor	Value/ Sensitivity	Scenario	Increase in flood levels	Impact magnitude	Impact rating
Wick Moor (CS4.13)	Medium	1.0% 2017	+0.05	Very low	**Minor**
		0.5% 2017	+0.03	Very low	**Minor**
		0.1% 2017	+0.03	Very low	**Minor**
		1.0% 2100	+0.06	Very low	**Minor**
		0.5% 2100	+0.06	Very low	**Minor**
		0.1% 2100*	+0.07	Very low	**Minor**
Agricultural land off-site, west of the HPC development site of Holford Stream	Medium	1.0% 2017	0.00	No impact	
		0.5% 2017	0.00	No impact	
		0.1% 2017	0.00	No impact	
		1.0% 2100	0.00	No impact	
		0.5% 2100	0.00	No impact	
		0.1% 2100*	0.00	No impact	
Land off-site adjacent to Bum Brook	Medium	1.0% 2017	+0.11**	Low	**Minor**
		0.5% 2017	+0.16**	Low	**Minor**
		0.1% 2100	+0.28**	Low	**Minor**
		1.0% 2100	+0.16**	Low	**Minor**

		0.1% 2100*	0.00	No impact	

* These results are only indicative due to model instabilities during simulation.

** Adverse impact located upstream of Bum Brook emergency access road bridge (ISIS node CS2.42).

*** Low magnitude due to low probability event and future scenario (2100),

**** During the 1% AEP 2017 event a positive impact is experienced at Wick Village receptor, with a reduction in flood level of 0.02m.

***** During the 0.1% 2017, 1% and 0.5% 2100 events a **positive** impact is experienced at Doggetts Farm and Wick Village receptors, with a reduction in flood levels of 0.01m at each location.

16.6.97 The fluvial modelling reported within the **Flood Risk Assessment** predicts that the infilling and culverting of the Holford Stream Valley would cause a small increase in maximum water levels both upstream of the culvert and downstream across Wick Moor. Attenuation provided in the WMZs and in SuDS features, minimises the fluvial impact downstream of the platform as it attenuates run-off generated on the platform and discharges to Q_{BAR} greenfield rates under all scenarios. The 0.1% AEP 2100 results are only indicative due to model instabilities during simulation. **Table 16.17** shows the increase to flood depths off-site in Wick Moor is up to 0.06m (barring the 0.1% AEP event), but does not impact third party properties, therefore the impact magnitude for this event downstream of the platform is assessed to be very low.

16.6.98 The increase in maximum water levels upstream of the Holford Stream culvert is largely contained within the HPC development site boundary, with only a minimal increase (less than 0.01m) contained within the ditch west of Benhole Lane (see **Table 16.17 –** Agricultural land off-site, west of the HPC development site of Holford Stream), therefore it is assessed to have **no impact**.

16.6.99 The modelling of the proposed emergency road crossing bridge at Bum Brook has been based upon preliminary designs, with modifications, to suit local topography. The bridge has been represented by a three arch bridge, which slopes gently to the south with a deck level of 21m AOD at the southern end, rising to 24m AOD at the northern end.

16.6.100 The **Flood Risk Assessment** shows that the emergency access bridge would cause a limited throttling of flows during extreme flood events, however, this would only impact water levels immediately upstream and downstream of the bridge. **Table 16.17** summarises the impact for each model scenarios run. For the 1% AEP 2100 event the maximum increase in flood levels immediately upstream of the bridge of 0.28m. Off-site the impact is less severe with increases of up to approximately 0.2m (for this scenario) immediately west of the boundary and decreasing further west. The impact upstream does not affect any third parties properties. The impact magnitude is therefore assessed to be low. In addition a blockage under the bridge is very unlikely due to the size of the bridge arch openings and as the modelling will be used to inform the final design. As such, the impact magnitude of a blockage is assessed to be very low.

16.6.101 Downstream the bridge shows is a positive impact with slightly reduce water levels, see **Table 16.17 –** Third party properties footnotes, therefore **no adverse impact** is found and a positive impact with a magnitude of very low is assessed.

16.6.102 A blockage of Holford Stream is extremely unlikely due to the large size of the culvert, the WMZ upstream of the Holford Stream culvert entrance and the small upstream catchment area. Therefore the impact magnitude is assessed to be very low.

16.6.103 The C182 main route to Hinkley Point has not been assessed as an individual receptor. However it is assessed in the **Flood Risk Assessment**, which indicates the route would currently remain clear during all events apart from the 0.1% 2100 event (however these results are only indicative), where the crossing at Bum Brook would flood to depths of 0.13m, and Holford Stream crossing to depths of 0.10m. Post infilling of Holford Stream valley the depth at Bum Brook would decrease slightly though not significantly (-0.01m), due to the effect of the Bum Brook bridge. Whereas, at the Holford Stream crossing the depth would increase by 0.06m (to a total of 0.16m). If these depths were deemed to be unsafe, access/egress would still be possible via the emergency access bridge across Bum Brook, which the model results indicate will not flood during this event.

16.6.104 Based upon the value and sensitivity ratings of these receptors (**Table 16.15**) the resultant significance of potential impacts relating to increased fluvial flood risk has been assessed to have the following significance:

- Wick Moor (reduced channel capacity due to sediment deposition within Holford Stream): very low impact magnitude; medium value sensitivity; leading to a **minor adverse** impact.
- Land off-site adjacent to Bum Brook (as a result of reduced channel capacity due to sediment deposition within Bum Brook); very low impact magnitude; high value/sensitivity; leading to a **minor adverse** impact.
- Wick Moor (as a result of reduced flood storage capacity of Holford Valley): very low impact magnitude; medium value sensitivity; leading to a **minor adverse** impact.
- Land off-site adjacent to Bum Brook (due to restricted flow under the emergency access road bridge crossing Bum Brook); low impact magnitude; medium value/sensitivity; leading to a **minor adverse** impact.
- Residential third party properties (due to restricted flow under the emergency access bridge crossing Bum Brook): very low impact magnitude; high value/sensitivity; leading to a **minor positive** impact.
- Agricultural land off-site from the HPC development site west of Holford Stream (due to a blockage in the culvert): very low impact magnitude; medium value/sensitivity; leading to a **minor adverse** impact.

- Land off-site adjacent to Bum Brook (due to blockage under the emergency access bridge crossing Bum Brook); low impact magnitude; medium value/sensitivity; leading to a **minor adverse** impact.

IMPACT: Effect of Increased Tidal Flood Risk to Land Outside of the HPC development site

16.6.105 Four hydrological receptors have been identified which may be impacted by increased tidal flood risk:

- Wick Moor;
- residential third party properties;
- non-residential third party properties; and
- agricultural land to the west of the SCPA.

16.6.106 Elevated off-site tidal flood risk may arise due to reduced flood storage capacity of Holford Stream Valley due to infilling of the valley for the creation of platforms and materials stockpiling.

16.6.107 The area of land to the west and east of C182 falls within Flood Zone 2 and 3 of the Environment Agency's tidal flood risk map (see **Figure 16.5**). The Environment Agency flood maps are precautionary in that they do not account for the presence of the defences between Hinkley Point and Stolford Point.

16.6.108 The impact magnitude and rating to each receptor as a results of reduce floodplain storage is summarised in **Table 16.18**. It should be noted that the impact magnitude of a breach event is assessed to be less likely to occur than an overtopping event and therefore often has a lower magnitude rating.

Table 16.18: Summary of Tidal Flood Risk Impacts to Receptors as a Result of infilling Holford Stream Valley

Receptor	Value/ Sensitivity	Scenario	Increase in Flood Level	Impact Magnitude	Impact Rating
Wick Moor	Medium	0.5% 2017 overtopping	0.01m increase	Very low	**Minor**
		0.5% 2017 breach	No impact		
		0.5% 2100 overtopping	0.03m increase	Very low	**Minor**
		0.5% 2100 breach	0.11 increase	Very low	**Minor**
		1.0% 2100 overtopping	0.094 increase	Low	**Minor**
Agricultural land off-site, west of the HPC development site of Holford Stream	Medium	0.5% 2017 overtopping	No impact		
		0.5% 2017 breach	No impact		
		0.5% 2100 overtopping	0.013m decrease	No adverse impact	
		0.5% 2100 breach	No impact		
		1.0% 2100 overtopping	No impact		

Receptor	Value/ Sensitivity	Scenario	Increase in Flood Level	Impact Magnitude	Impact Rating
Residential third party properties	High	0.5% 2017 overtopping	No impact		
		0.5% 2017 breach	No impact		
		0.5% 2100 overtopping	0.03m increase*	Very low	**Minor**
		0.5% 2100 breach	No impact		
		1.0% 2100 overtopping	0.09m increase***	Low	**Moderate**
Non residential third party properties	Medium	0.5% 2017 overtopping	No impact		
		0.5% 2017 breach	No impact		
		0.5% 2100 overtopping	0.03m increase*	Very Low	**Minor**
		0.5% 2100 breach	0.11m increase**	Very Low	**Minor**
		1.0% 2100 overtopping	0.09m increase***	Low	**Minor**

* Impact to C182, the STW, national grid towers (pylons), Little Dowden's Farm, Fisheries Cottage, North of Croft Farm, Swallowcliffe, and Fisherman's Cottage (see Figure 32 of the **Flood Risk Assessment**).

** 0.11m increase in flood depth at C182, the STW and national grid tower (pylons) (see Figure 35 of the **Flood Risk Assessment**).

*** Impact to C182, the STW, national grid tower (pylons), Little Dowden's Farm and Fisheries Cottage.

16.6.109 It should be noted that all impacts, with the exception of a minor increase in flood depth to Wick Moor, are for future scenarios (2100) where allowance has been made for climate change. A breach event is very unlikely to occur and therefore the overall impact magnitude for these events is assessed to be very low. The impact magnitude of the 0.5% 2100 overtopping event has also assessed to be very low due to the minor increase in flood level. The impact magnitude for the 1% 2100 overtopping event is assessed to be low as the return period is AEP is higher and therefore is slightly more likely to occur and is as a result of overtopping rather than a breach event. The impact magnitude is low as it is a future event only predicted to occur in 2100. In addition, the preferred policy set out in Shoreline Management Plan (Ref. 16.75) is for managed realignment of this stretch of defence from 2025, which would potentially alleviate the impact to these receptors, this however is not presented as mitigation only context to the situation.

16.6.110 The C182 main route to Hinkley Point has not been assessed as an individual receptor. However it is assessed in the **Flood Risk Assessment**, and mitigation is presented in Section 16.7 of this chapter.

16.6.111 Based upon the value and sensitivity ratings of these receptors the resultant significance of potential impacts relating to increased tidal flood risk has been summarised in **Table 16.18**, showing a **moderate adverse** impact to residential third party properties (Little Dowden's Farm and Fisheries Cottage) during the 1% AEP 2100 overtopping event.

IMPACT: Change to Holford Stream Hydraulic Characteristics

16.6.112 Two hydrological receptors have been identified which may be impacted by a change to the baseline hydraulic conditions:

- Holford Stream; and
- Wick Moor.

16.6.113 The Holford Stream culvert will be constructed during the site preparation works phase and will be operational during the construction phase and might potentially result in increased flow velocities immediately downstream due to reduced channel roughness and the linear nature of the culvert. Increased flow velocities could potentially lead to flood and scour problems downstream.

16.6.114 Due to the energy dissipation measures implemented at the outfall of the culvert the impact magnitude of increased flow velocities is considered to be very low.

16.6.115 As the culvert would be constructed off-line and flow re-routed to the culvert, interruption to flow should be minimal and this impact magnitude is considered to be very low.

16.6.116 Given the size of the culvert, there will be an increased provision of in-channel water storage such that water levels in Wick Moor could be reduced. However, as the base of the culvert will be impermeable no transmission losses through the channel bed will occur when flows are not controlled by groundwater. The two adjacent groundwater interceptor drains will ensure that all available groundwater is transmitted to Wick Moor. Ponds created at either end of the culvert will also assist in providing a more consistent base flow in the stream. Water levels in Wick Moor may therefore be augmented as a result of reduced losses through the stream bed. The impact magnitude associated with reduced water levels in the Wick Moor SSSI due to the presence of the culvert is assessed to be very low as water levels in Wick Moor may be increased by the reduced losses through the stream bed along the length of the culvert. However, as this has not been quantified, the impact is still assessed as adverse.

16.6.117 Based upon the value and sensitivity ratings of these receptors (**Table 16.15)** the resultant significance of potential impacts has been assessed to have the following significance:

- Holford Stream (due to increased flow velocities): very low impact magnitude; high value/sensitivity; leading to a **minor adverse** impact.
- Holford Stream (due to interruption to flow): very low impact magnitude; high value/sensitivity; leading to a **minor adverse** impact.
- Wick Moor: very low impact magnitude; high value/sensitivity (during assessment of low flows); leading to a **minor adverse** impact.

ii. Water Quality Construction Impacts

16.6.118 Many of the potential impacts on the water quality status of freshwater receptors derive from the large scale earthworks that would necessitate major changes to existing surface water drainage patterns. These works would give rise to increased rates of run-off that are likely to contain elevated concentrations of suspended solids and, potentially, hydrocarbons from use of plant and equipment.

16.6.119 Increased suspended sediment concentrations can have a negative impact on water quality. Impacts are generally related to:

- changes in water temperature regime resulting from shallowing of the waterbody caused by siltation;
- physical disturbance effects; or
- mobilisation of sediments that are contaminated or are rich in organic matter or nutrients.

16.6.120 Run-off of hydrocarbons particularly from road drainage and compounds, may have a deleterious effect on the water quality status of receiving surface water features.

16.6.121 Concrete would be used throughout the construction works. The culvert for Holford Stream would be constructed from pre-cast concrete to avoid concrete leachate issues that could otherwise arise from the pouring of in-situ concrete. There is no intention to concrete hardstanding areas; these areas would instead be surfaced with aggregate and highly trafficked areas would be tarmacked. Where use of wet concrete is required, high pH leachate may be generated. Such leachate may potentially impact on the water quality status of receiving watercourses and in particular the freshwater systems such as Holford Stream.

16.6.122 All identified impacts on surface water quality are presented in **Table 16.19** below. Those impacts on surface water quality from sediment-laden run-off, hydrocarbon contaminated run-off and concrete leachate, i.e. those impacts related to commonly occurring activities, together with any potential impacts that have been found to be significant i.e. of moderate or major significance prior to mitigation are discussed below.

IMPACT: Sediment-Laden Run-off

16.6.123 During the site construction phase, there is the potential for the generation of sediment-laden run-off water. Activities that have been identified that could potentially produce sediment-laden run-off include:

- excavations, including dewatering of excavated areas;
- stockpiling of materials (particularly soil and rock);
- mobilisation of stream bed sediments due to increased water flows, resulting from surface compaction from plant movements for example; and
- general earthworks, which may include:
  - topsoil stripping;
  - vegetation stripping;
  - fencing;
  - construction of Holford Stream culvert;
  - construction of WMZs;
  - installation of the surface drainage system;

- construction of site compound and construction/upgrade of internal roads;
- construction of the soil retaining wall; and
- creation of development platforms.

16.6.124 Three water quality receptors have been identified which may be impacted by sediment-laden run-off, namely the HPC Drainage Ditch, Holford Stream and Bum Brook. The value/sensitivity of each of these receptors is presented in **Table 16.15**.

16.6.125 All surface waters would be directed to the surface water drainage system and the concentration of suspended sediments would be reduced, where necessary, prior to controlled discharge to the watercourses. Design measures that are incorporated into the surface water drainage system which will minimise sediment generation include:

- provision of WMZs;
- compliance with a site-specific **Water Management Plan** and best practice guidelines; and
- control of surface water run-off to greenfield rates from any WMZ to an existing watercourse.

16.6.126 As a result of these measures that will ensure the conditions set out within an Environmental Permit are met, many of the sediment-laden discharge impacts have a magnitude score that is assessed as low or very low (see **Table 16.19**).

16.6.127 It should be noted, as set out in **Table 16.15**, that Holford Stream is considered to have a high sensitivity, due to the dependence of the downstream wetland conditions in Wick Moor, which is part of the Bridgwater Bay SSSI.

16.6.128 Due to the sensitive nature of Holford Stream, inputs of sediment-laden surface run-off, in the absence of mitigation, could potentially have an impact greater than minor significance. These include:

- installation and removal of temporary drainage systems including WMZs, in the SCPA (low magnitude; high sensitivity; **moderate adverse** significance);
- earthworks activities in the SCPA (medium magnitude; high sensitivity; **major adverse** significance); and
- sediment-laden run-off water from stockpiling in the SCPA (low magnitude; high sensitivity; **moderate adverse** significance).

IMPACT: Hydrocarbon Contaminated Run-off

16.6.129 During the construction phase, there is the potential for the generation of run-off water contaminated with hydrocarbons.

16.6.130 There are two primary sources of potential hydrocarbons during the construction phase including the use of plant and equipment (construction type plant such as bulldozers) and run-off from hard surfaced areas such as compounds and plant/vehicle parking and maintenance areas. All run-off will pass through oil interceptors which form part of the WMZs prior to discharge to surface water receptors.

16.6.131 Potential adverse impacts upon water quality status would be local, temporary in nature and are considered to have a likelihood of possible occurrence. The magnitude of all potential adverse impacts associated with hydrocarbon contaminated run-off, taking into account design measures such as oil interceptors, is considered to be very low. Hydrocarbon contaminated run-off has the potential to impact the HPC Drainage Ditch and Holford Stream during the construction phase.

16.6.132 Taking into account the design measures such as the use of oil interceptors as an integral part of the drainage system (which incorporate best practice on management of fuels, oils and lubricants) that will ensure the conditions set out within an Environmental Permit are met, all potential impacts associated with potential hydrocarbon contaminated run-off are assessed to be of **negligible** to **minor adverse** significance (see **Table 16.19**).

IMPACT: Concrete Leachate

16.6.133 A number of construction phase works elements include the pouring of concrete in-situ, during which there is the potential for surface water quality impacts resulting from concrete leachate. Construction activities which may include the use of concrete in-situ include:

- construction of the foundations (note: all foundation pours will take place within excavations and therefore there will be no direct run-off pathway to surface water receptors);
- construction of headwall structures for the Holford Stream culvert (offline from the existing Holford Stream channel);
- construction of the chain-link perimeter fence threshold;
- construction of footings and foundations associated with the site compound and other temporary buildings and workshops in SCPA; and
- road construction for kerb areas on site access roads.

16.6.134 Further leachate will result from washout of concrete delivery lorries and equipment and routine cleaning maintenance of the concrete batching works. The wastewater from these sources is expected to be of low volume but with elevated pH and will be collected and passed through a proprietary treatment system prior to discharge in to the surface drainage system and receiving WMZ. The treatment system will recover solids and adjust the pH of the wastewater as required.

16.6.135 These potential impacts are considered to be local (spatial scale) and temporary (temporal scale) in nature. The likelihood of potential impacts is considered to be possible, although this is considered a conservative assumption given that these activities would be controlled through the measures described in the **Water Management Plan.** These measures will ensure that the discharge conditions set out within an Environmental Permit are met. The assessment magnitude for potential concrete leachate impacts is assessed as very low. The value/sensitivity of those water quality receptors that may be affected by concrete leachate impacts are presented in **Table 16.15**. All concrete leachate impacts have been assessed to have a **negligible** to **minor adverse** significance (see **Table 16.19).**

IMPACT: Run-off Containing Elevated Concentrations of Nutrients

16.6.136 During the earthworks activities including the installation of drainage infrastructure, there is a potential for nutrient mobilisation via disturbed sediment to occur. Since surface waters are draining former agricultural land, run-off is likely to contain raised levels of nutrients. Elevated nutrient concentrations (phosphorus being the key limiting nutrient in freshwater systems) may have an adverse impact upon water quality status and the functioning of the receiving watercourses, through increased growth of aquatic vegetation for example.

16.6.137 Baseline conditions within the surface water receptors have been considered in the assessment of potential nutrient additions arising from activities related to the construction phase and the general sensitivity classifications of each receptor are presented in **Table 16.15**. The potential changes in nutrient status are not likely to alter the conditions in the receiving watercourses and therefore the magnitude in each individual impact case has been assessed to be low. The nature of these potential impacts may also be described as local, temporary and direct. Potential impacts associated with the HPC Drainage Ditch have been assessed to be of **minor adverse** significance. In any event the ditch will be removed once the Foreshore Construction Outfall structure is available for use. However, due to the additional sensitivity that is afforded to Holford Stream and Bum Brook, the same potential impact on these receptors is considered to be of **moderate adverse** significance prior to mitigation (see **Table 16.19**).

IMPACT: Surface Run-off from Rock Stockpile Areas

16.6.138 The generation of acid rock drainage (ARD) from stockpiles of excavated mudstones (in the Southern Construction Phase Area), should it occur, may reduce the pH of surface water run-off that would be discharged from this area into Holford Stream. The discharge of low pH water directly into Holford Stream could impact on water quality status as the stream is currently characterised by neutral pH conditions. Given that any surface drainage discharged to Holford Stream would be subject to treatment and attenuation within the proposed WMZs that will ensure the conditions set out within an Environmental Permit are met, the impact magnitude is assessed as low. This impact would be local, adverse, temporary, direct and may possibly occur. Holford Stream provides an important water supply to support the downstream freshwater wetland features in Wick Moor, which is part of Bridgwater Bay SSSI, therefore the maintenance of good water quality conditions in the SSSI area is important and the value and sensitivity of the receptor has been assigned a high status (**Table 16.15**). The potential significance of this impact has therefore been assessed as **moderate adverse** without mitigation.

iii. Surface Water Construction Risks

16.6.139 There is a risk of potential impacts occurring as a result of accidents or incidents. It is not likely that accidents and incidents will arise under normal circumstances hence these scenarios are presented as risks rather than as impacts. The risks and their likelihood of occurrence can be managed, and minimised through the use of good practice management measures. Such measures are outlined in the **Water Management Plan**. These management measures may not influence the significance of an incident should it occur but will reduce the risk of an incident to a very low level of probability.

16.6.140 In combination with the subject specific management plans, an **Environmental Incident Control Plan** is being developed by EDF Energy that sets out the response and management techniques that will be applied for a range of different incident types, should they occur. The implementation of this plan effectively acts as the mitigation to any incident through providing measures to reduce impact magnitude primarily through containment.

16.6.141 The **Environmental Incident Control Plan** would be instigated through an issue identified from routine monitoring and inspection and more importantly through a system of efficient incident reporting. For the **Environmental Incident Control Plan** to be effective then rapid implementation of the containment or other mitigation measures is required to reduce the potential impact to a non-significant level. The **Environmental Incident Control Plan** therefore acts as the overarching mitigation measure for managing incidents and accidents and reducing impact significance.

16.6.142 In respect of surface water, the following risks have been identified during the construction phase as being of potential concern:

- failure of water management infrastructure such as pipe collapse, balancing pond breach, pump failure etc. due to an extreme rainfall event;
- accidental spillage relating to operation of water bowsers (e.g. for concrete water/dust suppression), operative error;
- blockages of drainage infrastructure;
- accidental release of suspended sediments generated by collapse of banks, failure of silt settlement systems, deposition of soils into a watercourse, collapse of a stockpile into a watercourse;
- accidental spills of fuels or oils;
- emergency discharges associated with firewater; and
- accidental spillage of wet concrete and/or cement.

d) Cumulative Construction Impacts

16.6.143 Surface water drainage, groundwater and other wastewater will be collected from across the site during the construction phase and passed through WMZ prior to discharge into the identified surface water receptors. The different wastewater streams will be subject to individual Environmental Permits that will set conditions on each discharge in terms of volume rate and chemical quality. In setting the discharge conditions for each Environmental Permit, the regulator takes into account any other discharges to the watercourse, in addition to those from the HPC development site, and any downstream uses of the watercourse (i.e. abstractions) to ensure there is no significant deterioration in water quality status.

16.6.144 Discharges to Holford Stream and Bum Brook (during the landscape restoration phase only) will also be managed at greenfield runoff rates to ensure the current hydraulic regime is maintained to provide protection to downstream reaches from flooding issues.

16.6.145 Given that all discharges to surface watercourses during the construction phase will be subject to the conditions of Environmental Permit, applied to each of a limited number of outfall locations, there is not expected to be any significant cumulative impact on either water quality status or hydraulic regime in the receptor watercourses.

16.6.146 A summary of the overall combined water quality and hydrology impacts on each of the receptors during the construction phase is detailed below:

Hinkley Point C Drainage Ditch

16.6.147 This watercourse will be used as a conduit for the discharge of surface drainage and groundwater to the intertidal area during the initial construction phase in the northern area of the site. Surface water and groundwater will be collected from across the BDAW and BDAE and routed to a WMZ (described above) prior to discharge into the HPC Drainage Ditch.

16.6.148 The surface water drainage to the ditch will come from the BDAW and BDAE and is expected to be characterised by elevated suspended solids concentrations and potential contamination by residual hydrocarbons and concrete leachate.

16.6.149 In addition, groundwater pumped from the excavation dewatering borehole system as a result of the dewatering of the nuclear islands may be characterised by elevated mineral content and a degree of metal contamination (see **Volume 2, Chapter 15**).

16.6.150 Within the WMZ, facilities will be provided in order to attenuate flows and treat the water to the necessary standard to meet the conditions of the Environmental Permit. As a minimum this is likely to include a lagoon for the settlement of suspended solids and flow attenuation and oil inceptors to remove residual hydrocarbons. Other facilities will also be provided as required, depending on the quality of the water received by the WMZ, in order for achieving the necessary level of treatment to the conditions of discharge in to the HPC Drainage Ditch. Groundwater routed to the WMZ will be maintained as a separate waste stream from the surface water drainage and will be subject to an individual Environmental Permit. Measures to ameliorate any groundwater contaminants may include chemical treatment for elevated metal concentrations, if present.

16.6.151 The measures above (and others, as required by the Environment Agency) will ensure there is no significant deterioration in the quality of water of the HPC Drainage Ditch, as compared with its baseline characteristics, and there is no alteration in its flow characteristics.

16.6.152 Further, the impacts considered above will be temporary in that following completion of the temporary construction drainage system and Foreshore Construction Outfall the HPC Drainage Ditch will be in-filled and form part of the development platform.

16.6.153 In conclusion, for the reasons set out above (in particular the measures to ensure no deterioration in quality and impact on flow) as detailed in **Table 16.19**, the overall impact on this receptor, up to point where it is in-filled, is assessed to be of **minor adverse** significance. This ditch will be permanently removed during the construction phase.

Holford Stream and Wick Moor

16.6.154 The reach of Holford Stream the SCPA will be permanently diverted through an offline culvert. The existing stream channel and valley within the HPC development site will then be used for materials stockpiling and construction platforms. The culvert has been designed as an oversized structure, for routine maintenance purposes, and therefore is not expected to present a flood risk. The infilling of Holford Valley will lead to some loss of flood storage capacity for low probability tidal flooding events that will lead to small increases in the normal flood water level to a small number of third party properties.

16.6.155 Discharges in to Holford Stream will be made through two WMZs located at each end of the culvert. The WMZs will receive surface water drainage, groundwater pumped from shallow excavations with the SCPA and treated sewage effluent from the accommodation campus during the construction phase.

16.6.156 The surface water drainage to Holford Stream will come from the SCPA and is expected to be characterised by elevated suspended solids concentrations and potential contamination by residual hydrocarbons, concrete leachate, elevated nutrient concentrations and reduced pH from acid rock drainage from rock stockpiles.

16.6.157 Discharges of treated sanitary effluent from the accommodation campus will also be directed towards the WMZ at the western end of the Holford Stream culvert. Package treatment works effluent will be subject to a specific Environmental Permit that will that will set conditions for flow rate and chemical and microbiological quality at the discharge point into the drainage system upstream of the WMZ.

16.6.158 Within the WMZs associated with Holford Stream, facilities will be provided in order to attenuate flows and treat the water to the necessary standard to meet the conditions of the Environmental Permit. As a minimum this is likely to include a lagoon for the settlement of suspended solids and flow attenuation (to greenfield rates) and oil inceptors to remove residual hydrocarbons. Other facilities will also be provided as required, depending on the quality of the water received by the WMZ, in order for achieving the necessary level of treatment to the conditions of discharge into Holford Stream. Treatment of low pH drainage from rock stockpiles is likely to be undertaken within the drainage system upstream of the WMZs.

16.6.159 The measures above (and others, as required by the Environment Agency) will ensure there is no significant deterioration in the quality of water and change to flow characteristics of Holford Stream and consequently the downstream Wick Moor area, when compared with the baseline characteristics.

16.6.160 In conclusion, for the reasons set out above (in particular the measures to ensure no deterioration in quality and impact on flow) as detailed in **Table 16.19**, the overall impact on this receptor, is assessed to be of **minor adverse** significance.

Bum Brook

16.6.161 A road bridge will be constructed across Bum Brook. The design of this spanning crossing point will not require in-channel works to be undertaken. The design has also taken into account the conveyance of flood flows and has been developed to not increase the risk of local flooding. At the end of the construction phase landscaping of the SCPA will be undertaken. During this period an additional WMZ will be developed to which surface drainage will be routed for discharge into Bum Brook.

16.6.162 The surface water drainage to Bum Brook will come from SCPA landscaping works at the end of the construction phase to be characterised by elevated suspended solids concentrations and potential contamination by residual hydrocarbons.

16.6.163 Within the WMZs associated with Bum Brook, facilities will be provided in order to attenuate flows and treat the water to the necessary standard to meet the conditions of the Environmental Permit. As a minimum this is likely to include a lagoon for the settlement of suspended solids and flow attenuation (to greenfield rates) and oil inceptors to remove residual hydrocarbons. Other facilities will also be provided as required, depending on the quality of the water received by the WMZ, in order for achieving the necessary level of treatment to the conditions of discharge into Bum Brook.

16.6.164 The measures above (and others, as required by the Environment Agency) will ensure there is no significant deterioration in the quality of water and change to flow characteristics of Bum Brook as compared with the baseline characteristics.

16.6.165 In conclusion, for the reasons set out above (in particular the measures to ensure no deterioration in quality and impact on flow) as detailed in **Table 16.19**, the overall impact on this receptor, is assessed to be of **minor adverse** significance.

16.6.166 Cumulative effects with elements of the HPC project and with other planned or reasonably foreseeable projects are considered in **Volume 11** of this ES.

e) Operational Impacts

16.6.167 The only activity to take place during the operational phase of HPC that may result in an impact to the baseline surface water conditions is the operation of the operational phase surface water drainage system. No significant impacts (i.e. greater than minor in significance) were identified in relation to surface waters during the operational phase of the development (see **Table 16.19**).

16.6.168 It is proposed that surface waters (from the restored landscaped areas of the HPC development site) will primarily drain to ground during the operational phase. Surface water run-off generated from the built elements of the operational site will be collected and discharged into the building known as the HXO, for discharge to the marine environment via the cooling water outfall tunnel. Groundwater generated from the passive groundwater level management system and treated sanitary effluent will also be discharged via this route. The operational site will effectively be isolated from the local terrestrial surface water environment.

16.6.169 All other areas used during the construction phase, will be restored to a greenfield state in the latter stages of construction and early stages of the operational phase. After these restoration works are complete this area of land will not undergo any further changes during the operational phase. The impact on future flood risk during the operational phase has been considered within the construction phase impacts section, and therefore is not repeated within this section.

16.6.170 The landscaped areas to the south of the development site will continue to drain at greenfield rates to either Holford Stream or Bum Brook.

i. Operational Risks

16.6.171 During the site operation phase the risks of incidents and accidents occurring will be reduced by measures that are incorporated into the design of the plant infrastructure and drainage systems and through appropriate management procedures.

16.6.172 The risk of water quality incidents occurring during the operational phase to the retained surface water receptors of Holford Stream and Bum Brook, the HPC Drainage Ditch having been abandoned, is extremely low due to an absence of operational activities within their catchments. This area of the site will be re-landscaped during the restoration phase to restore greenfield conditions.

16.6.173 The HPC operational site topography and landform will be designed in such a way to manage excess overland flow under very extreme exceedence events (up to and including the 0.01% AEP storm event). This will include designing surface features to convey (and temporarily store) excess run-off.

16.6.174 As with the construction phase the **Environmental Incident Control Plan** will form part of the operational phase design measures. The implementation of this plan will effectively act as mitigation to reduce the magnitude of any incidents to a non-significant level.

f) Cumulative Operational Impacts

16.6.175 No significant flood risk or change to hydraulic regime is expected in the receptor watercourses of Holford Stream and Bum Brook during the operational phase. Surface water drainage and operational groundwater dewatering will be collected across the northern area of the site (BDAW and BDAE) by the permanent drainage system and discharged to the marine environment, following any necessary treatment, through the cooling water discharge (see **Chapter 18**). During the operational phase there are no proposed discharges to surface watercourses other than permanent greenfield land drainage from the restored landscaped areas in the SCPA (see Removal and Restoration Impacts section below). The Holford Stream culvert and Bum Brook bridge crossing will be retained as permanent features throughout the operational phase of the development. No cumulative impacts as a result of on-site operational activities have been identified with respect to all surface freshwater receptors.

16.6.176 Taking into account of the range of potential impacts on the water quality status and hydraulic regime of Holford and Bum Brook Stream during the operational phase and detailed in **Table 16.19,** the overall impact on these receptors is assessed as **negligible.**

16.6.177 Cumulative effects with other elements of the HPC project and with other planned or reasonably foreseeable projects are addressed in **Volume 11** of this ES.

g) Removal/Restoration Impacts

16.6.178 The removal/restoration phase of the development includes the dismantling and removal of the jetty structure and the restoration of land surrounding the built elements of the Hinkley Point C Power Station.

Hydrology and Drainage Removal/Restoration Impacts

16.6.179 Activities that may result in change to the baseline hydrology and drainage environment are listed below:

- removal of impermeable and semi-permeable surfaces such as the access roads and roundabouts;
- removal of temporary aggregates storage area;
- removal of any redundant construction phase drainage systems, not including Holford Stream culvert which is to be retained;
- restoration of topography; and
- restoration of vegetated surfaces.

16.6.180 These activities will contribute to returning the restored areas of the site to a greenfield drainage regime.

16.6.181 Elements of the WMZs will be retained beyond the construction phase and the restoration works will be carried out to prevent any additional adverse hydrological or drainage impacts beyond those already identified within the construction phase (discussed above). Discharges to Holford Stream and Bum Brook for example, during the restoration phase may still be subject to discharge under Environmental Permit and are therefore restricted in terms of discharge rate. Best practice measures and management controls required under the **Water Management Plan** will still operate during this phase of works.

16.6.182 There will be no restoration works to the area of site draining to Bum Brook during this phase of works. All work on this area will have been completed during the early part of the construction phase. The removal of the drainage system infrastructure will reverse the effects of installing the system, removing the pathway by which accidental on-site discharges can reach surface water receptors.

Water Quality Removal/Restoration Impacts

16.6.183 With respect to terrestrial water quality, the assessment process has identified that similar potential impacts may be expected during the removal/restoration phase as for those identified in relation to the construction phase. Typically, the magnitude of potential impacts arising during the restoration phase may be expected to be less than similar impacts during the construction phase. For example, the earth movements that are required during the restoration phase will be reduced in scale when compared to the construction phase, with associated reduction in the potential for sediment-laden run-off to be generated.

16.6.184 Given that the same standard of working practice and Environmental Permit discharge standards applied during the construction phases will apply during the restoration phase, it is not considered necessary to present the impacts to surface water quality that will occur during this latter stage because similar activities and impacts of greater magnitude are already taken account of and provided for.

h) Cumulative Removal/Restoration Impacts

16.6.185 No cumulative impacts as a result of removal and restoration activities have been identified with respect to all surface water receptors.

16.6.186 Cumulative effects with other elements of the HPC project and with other planned or reasonably foreseeable projects are addressed in **Volume 11** of this ES.

16.7 Mitigation of Impacts

16.7.1 The impact assessment has identified that there is the potential for surface watercourses to be adversely affected as a result of a range of activities associated with the construction and landscape restoration phases of the development if appropriate mitigation measures are not put in place. During these phases a range of potential impacts were identified that had a significance rating of greater than minor which requires mitigation measures to be implemented. For the hydrology and drainage assessment these identified impacts relate to:

- An increase in tidal flooding to Wick Moor, the C182, the STW, national grid tower (pylons), and the areas around Little Dowden's Farm and Fisheries Cottage during the 1% AEP 2100 overtopping event; and
- increased risk of flooding due to reduced channel capacity of Holford Stream/Bum Brook as a result of accidental release of sediments.

16.7.2 For the water quality assessment these identified impacts may be broadly divided into:

- the generation of sediment-laden surface drainage water from a range of construction and earth working activities;
- surface drainage discharges with elevated concentrations of nutrients (phosphates) being discharged into Holford Stream;
- discharges of low pH (acidic) drainage from rock stock piles into Holford Stream; and
- accidental spillages of chemicals, including hydrocarbons during construction activities on the site.

16.7.3 The Impact and Mitigation Table presented as **Table 16.19** details mitigation proposals for each of the identified impacts.

a) Hydrology and Drainage

i. Drainage System Monitoring and Maintenance

16.7.4 All drainage systems employed during the construction and operation of Hinkley Point C would be frequently monitored and maintained to ensure their capacity for storage and/or flow conveyance is kept at the maximum for which they were originally designed. For open surface ditches, the monitoring process would ensure that:

- no flow obstructions are present in open ditches such as general litter, general construction works waste, construction materials, plant and leaf litter, wood debris and dead wildlife;

- any sediment deposits are not restricting the flow along any sections of watercourse. Sediment deposits might take the form of particles that have settled out of suspension during transportation through the network or at localised points where the ditch banks may have failed, thus causing a more significant obstruction to flow;
- ditch linings remain effective and damage is repaired in a timely manner; and
- where sediment control measures (e.g. sediment tubes) are employed, channel margins are not eroded at the deployment locations.

16.7.5 Monitoring will also include regular inspection of Bum Brook in the vicinity of the emergency access road bridge to prevent and/or remove any loss debris from the channel.

16.7.6 The condition of deep stone-filled drains would be less easy to monitor, although by implementing the measures at the drain surface highlighted above, the transportation of sediment into the drain should be minimised. Stone drains can be maintained by building access sumps at sufficiently spaced intervals such that pressure washers are able to effectively wash sediment between sections. Deposits can then be removed from individual sumps, either manually or by gully suckers. Equally, drains can be excavated and reinstated.

16.7.7 Where weirs are employed throughout the temporary drainage network, the effective crest levels will be periodically checked to ensure that the weir is still hydraulically functional in terms of flow control.

16.7.8 The **Water Management Plan** would be prepared by the operations maintenance team, however examples of methods which could be included in the plan are:

- annual CCTV inspections of pipe network to check structural integrity and for potential sources of blockage;
- frequent cleaning of road gullies, channel and kerb drains and Holford Stream culvert to ensure no blockage from leaf litter, general litter, etc.; and
- periodic consultation with professional drainage consultants or engineers throughout the operational phase to ensure that current guidance with respect to hydrological assessment is maintained, e.g. to allow for any potential changes in the severity of climate change predictions with respect to increasing rainfall intensity.

16.7.9 The implementation of the above mitigation (or proposals of a similar scope) will result in the impact magnitude, associated with increased fluvial flood risk at Bum Brook due to a blockage at the bridge, being as the likelihood of an incident would be very much reduced.

ii. Increased Flood Risk

16.7.10 A moderate adverse impact to the C182, the STW, national grid tower (pylons), and the areas around Little Dowden's Farm and Fisheries Cottage was determined during the tidal 1% AEP 2100 climate change tidal overtopping event, For further detail of the flood risk management strategies and options see Section 10 of the **Flood Risk Assessment**. No adverse impacts to the fluvial flood risk at third party properties were found.

Third Party Off-Site Receptors

16.7.11 A moderate impact to residential third party properties has been assessed during a tidal 1% AEP 2100 tidal overtopping event, with a minor impact assessed during 0.5% AEP 2100 events. These properties would be subject to flooding under tidal overtopping events despite the HPC development. The effect of the development will be to cause a minor increase in flood level under these low probability events. This assessment needs to be placed in the context of predictions in sea level rise and maintenance of the existing sea defence configuration in 2100. EDF Energy is proposing an agreement in the form of a compensatory scheme to be put in place to cover the potential increased risk to property owners in Stolford. This would involve entering into a Section 106 type agreement with the local planning authority to:

- continue to monitor sea levels and climate change with reference to Hinkley Point; and
- inform local residents if an agreed “trigger point” is reached based on monitoring of sea levels (which would not be expected to occur, if at all, until towards the end of this century).

16.7.12 In these circumstances EDF Energy would:assess the likely flood impact to each identified property;

- enter into a covenant with each property owner based on an appropriate contribution to the cost of repairs related to flood damage, proportionate to the impact caused by the Hinkley Point C development; and
- agree to pay the appropriate contribution should a flood event actually occur.

16.7.13 Further details are provided within the **Flood Risk Assessment**.

C182 main route

16.7.14 Access/egress to and from the site via the primary access route (C182) is not impacted during fluvial 2017 flood events, the 0.1% AEP 2100 event is covered below. However the Holford Stream crossing may be affected during tidal flooding via breaching and/or overtopping of the defences to the east of the existing Hinkley Point Power Station Complex. Should this crossing become impassable, access to the site would continue to be possible via the southern site access route to 2140, without the need to use the emergency access road during tidal flood events. Therefore no additional mitigation to protect this section of the C182 is considered necessary at this time.

16.7.15 EDF Energy will monitor the frequency of any future partial restriction to access which may be caused by tidal flooding, and may implement adaptive mitigation measures to limit the inconvenience such flooding may cause. Adaptive mitigation measures could include:

- raising the sections of the C182 access road; or
- enhancement of site access via the southern access route.

16.7.16 During the 0.1% AEP 2100 fluvial event modelling indicates that the C182 at the existing Holford Stream crossing and Bum Brook crossing would flood, with the greatest depths at the Bum Brook crossing of 0.22m. Although there is a small reduction in flood level downstream of the new emergency access road bridge (-0.01m), it would still be necessary to provide an alternative route in the event the bridge becomes impassable. Under these circumstances access/egress would still be possible via the emergency access bridge across Bum Brook, which the model results indicate would not flood during this event.

iii. Contingency Discharge

16.7.17 Contingencies for pumped emergency discharges or surface water following high rainfall events would be identified such that consents/permit conditions for discharge would be agreed with the contractor(s) and with the appropriate authorities prior to the commencement of the relevant works on-site.

iv. Accidents and incidents

16.7.18 Mitigation measures will be put in place to ensure that impacts are minimised in the case of accidents or incidents on site. The proposed measures will include:

- identification, at the earliest possible stage, of possible sources and locations of accidents that could potentially lead to on-site discharge of water;
- assessment of the likely extent of the area that could potentially be inundated should an accident occur;
- assessment of potential risks to infrastructure; and
- development of procedures to:
  - enable prompt isolation of the inundation area with respect to the safety of site operatives;
  - ensure prompt recovery and clean-up of the area of potential inundation; and
  - allow assessment of incidents to inform the need for updates to the emergency procedure.

b) Water Quality

16.7.19 Water quality mitigation measures are presented within this section. Mitigation measures are considered necessary to manage to acceptable levels any identified significant impacts on water quality (i.e. moderate and major adverse impacts).

16.7.20 The main anticipated impact (associated with all phases of the proposed development) was found to be the generation of sediment-laden water which may impact upon the water quality status of surface watercourse receptors. Therefore, the majority of the mitigation is directed towards the reduction of sediment-laden surface drainage. A **Water Management Plan** will be implemented for the construction of HPC. Subsequent sections of this chapter describe mitigation measures for sediment control which form part of the **Water Management Plan**.

16.7.21 Further potential impacts may be anticipated from oils and fuels (hydrocarbons) related to the use of construction plant and equipment and leachate from the use of fresh concrete and cement. Both of these impact types have been assessed as being negligible or minor adverse; and it is assumed that best working practice procedures would be adopted during construction practices to effectively manage the impacts.

16.7.22 An **Environmental Incident Control Plan** will also be developed for the site. A full suite of equipment will be made available by the contractors for managing the range and magnitude of potential spillages. This will include emergency spill kits and equipment for containment and clean-up.

i. Surface Water Drainage Environmental Permits

16.7.23 The key mitigation for protection of the freshwater quality status in local watercourses will be treatment and attenuation to discharges into Hinkley C Drainage Ditch, Holford Stream and Bum Brook (the latter during the early landscaping works only). The requirements of the permit(s) in terms of chemical quality and flow volume will be met through the use of (a) WMZs, where attenuation and any required treatment of water quality will be undertaken, and (b) the adoption of appropriate working practices.

16.7.24 Environmental Permits (which set out discharge consent requirements) are set by the Environment Agency under the Environmental Permitting Regulations (2010) (Ref. 16.17). Based on the range of expected potential contaminants that may be present in surface drainage as a result of activities during the construction phases for HPC key discharge specifications for water quality are proposed below. These proposals will be subject to detailed discussion and agreement with the Environment Agency.

ii. Discharges to Holford Stream and Bum Brook

16.7.25 Discharges to Holford Stream and Bum Brook will be made following attenuation to greenfield run-off rates and treatment within the WMZs. The proposed basic chemical quality of the discharges is based on WFD EQS values for 'Good' Status for pH (Ref. 16.8) and the Fish Directive (Ref. 16.5) guideline value for suspended solids. In proposing these values, consideration has been given to the small size of these watercourses and the sensitivity of downstream aquatic habitats. Basic proposed criteria for discharges to these watercourses are as follows:

- suspended solids : 25mg/l;
- pH : 6 (5 percentile) to 9 (95 percentile) pH units; and
- no visible oils.

16.7.26 In addition to these basic parameters further additional water quality conditions may be applied to the permit for the eastern discharge into Holford Stream in relation to treated sanitary effluent from the accommodation campus. Further conditions may also be applied to the Environmental Permits for the two proposed discharges into Holford Stream in terms of nutrient concentrations (phosphate) due to the potential sensitivity of downstream wetland habitats to eutrophication.

iii. Discharges to Hinkley C Drainage Ditch

16.7.27 Surface drainage discharges to the Hinkley C Drainage Ditch during the early part of the construction phase will ultimately discharge to the Hinkley intertidal area. As part of the drainage design, discharges will be subject to attenuation and treatment in WMZs. Given that that HPC Drainage Ditch has a low sensitivity and value and will be backfilled during installation of the construction drainage system, the value proposed for suspended solids is a higher value based on the mean concentration recorded in the marine surface water sampling campaign (Ref. 16.76) of 264mg/l.

The following values have been proposed for the HPC Drainage Ditch discharges to the Hinkley intertidal area:

- suspended solids: 250mg/l;
- pH : 6 (5 percentile) to 9 (95 percentile) pH units; and
- no visible oils.

16.7.28 Surface water discharges will transfer to the intertidal area once the Hinkley Foreshore Construction Outfall has been constructed and commissioned, at which time the HPC Drainage Ditch will be abandoned. The proposed discharge quality values will remain the same.

iv. Disposal of Groundwater

16.7.29 During the construction phase, there will be a requirement to dewater accumulations of ground and surface water within excavated areas. If the water is deemed to be of suitable quality, following monitoring, it will be pumped from the excavated area into the surface drainage system for disposal either to Holford Stream or the Hinkley Foreshore Construction Outfall. In the BDAE and BDAW, the wastewater stream from the dewatering of excavations will be maintained separately from the active dewatering system proposed for the lowering of groundwater levels across the northern area of the site.

16.7.30 During the initial excavations required for construction of the Holford Stream culvert, the SCPA WMZs will still be in preparation and therefore unavailable. Excavation dewatering discharges from this area will be routed, though suitable treatment, directly in to Holford Stream via a series of discharge locations that will be subject to individual Environmental Permits.

16.7.31 Mitigation measures will be implemented to ensure that any encountered contaminated groundwater is not disposed of in to the drainage systems so that there will be no resultant impact upon the quality or status of the local watercourse receptors. The chemical quality characteristics of the groundwater suitability for disposal will be agreed with the Environment Agency, together with an appropriate monitoring and management regime.

16.7.32 Groundwater that is found to be contaminated and to exceed discharge chemical or radiochemical quality parameters set by the Environment Agency will be managed in two ways:

- use of on-site techniques to treat the water to a suitable discharge standard such as removal of sediments by settlement or mechanical methods; and
- for chemically or radiochemically contaminated water that is found to be unsuitable for in-situ treatment then off-site disposal to a suitable facility will be implemented.

v. Sediment-Laden Run-off

Reducing Sediment Generation: Introduction

16.7.33 A range of techniques will be adopted to reduce sediment generation from the relevant activities which may act as a source of sediment. A **Water Management**

Plan will be in place to ensure that surface water run-off and sediments generated during earthworks activities are properly managed and controlled and this plan will be provided for approval by the appropriate bodies (principally the Environment Agency) prior to the commencement of the relevant works on-site. This **Water Management Plan** incorporates the techniques described below to reduce sediment generation.

16.7.34 Sediment generation is normally associated with surface drainage and de-watering operations from earth working areas where soils are exposed. The main sources are drainage from exposed soil in working areas which have been recently excavated or landscaped; excavated or imported materials which have been temporarily stockpiled; and exposure and erosion of surface soils associated with movements of construction plant. The key requirement is to prevent uncontrolled and untreated surface drainage from these areas reaching surface water features.

Reducing Sediment Generation: Exposed Soils

16.7.35 A range of techniques will be employed to reduce erosion and generation of sediment-laden surface drainage from newly excavated areas. These include the placement of sediment fencing or tubes at intervals up the face of a slope which has a dual effect in reducing the speed of water flow down the excavated slope face, which causes the erosion, and the trapping of sediment behind these barriers. Other techniques that will be used, as appropriate, include: placement of hessian netting and geo-grid soil stabilisation systems to assist in soil retention and therefore reduce sediment generation.

16.7.36 These techniques are most suited for exposed soils prior to the establishment of soil-stabilising vegetation. Seeding of the slopes and the topsoil and subsoil stockpiles will be undertaken at the earliest opportunity to allow rapid establishment of plants and consolidation of the soils.

16.7.37 Such approaches are not usually practical in areas where continued earthworks activities are being undertaken due to a requirement for continued movement of the sediment barriers for construction plant access and movements. In these areas the development of a temporary drain at the foot of the slope to collect drainage water is often more practical.

16.7.38 Sediment fencing and sediment tubes may also be deployed at strategic locations as appropriate around working areas to retain sediments within that area and close to the source of generation.

Reducing Sediment Generation: Dewatering of Excavated Areas

16.7.39 During the dewatering of excavated areas, for example after periods of heavy rain or through groundwater ingress, a temporary area for collection of water will be allocated within the excavated zone. This will involve excavation of a sump area in the lowest part of the excavation into which temporary ditches flow from around the excavation area. Water is then pumped from this area for discharge into soakaway areas or to the drainage system, for attenuation and settlement of solids within WMZs prior to discharge. Settlement of solids may occur within the sump area and therefore pumping of water will occur from the surface layers to reduce the movement of sediments outside the working area.

Reducing Sediment Generation: Stockpile Areas

16.7.40 Stockpiled soils and materials would be sited away from floodplains of surface watercourses to prevent the entry into watercourses of sediment-laden surface drainage and to ensure that the flood storage capacity of the fluvial floodplain is not compromised where possible. A number of approaches will be adopted to reduce the generation of sediment-laden drainage water from stockpiled areas. These techniques will include ring fencing the stockpile with either sediment fencing or sediment tubes to retain sediment run-off. If stockpiles are to be left for an extended period prior to re-use of the material then seeding with fast growing vegetation would be carried out in order to reduce surface erosion from rainfall. Perimeter drainage ditches will be established around stockpiles as necessary to collect surface drainage which would then either be discharged into the surface drainage system for treatment in the WMZ, or to a soakaway area.

Reducing Sediment Generation: Construction Plant Movements

16.7.41 The movement of heavy construction plant across exposed soils can lead to erosion and rutting that can generate sediment-laden surface drainage water. Haul roads will be constructed for areas and routes of frequent plant movement and restrictions on traffic movements enforced so that there is no unnecessary access for vehicles or plant to areas of soft soils. Where plant access is required across soft soils, then movements would be restricted to pre-defined corridors and suitable lateral or perimeter drainage ditches employed to collect surface drainage run-off.

Reducing Suspended Solids Concentrations in Surface Drainage Water: Introduction

16.7.42 There is a requirement to ensure high concentrations of suspended solids are not discharged into surface watercourses. There is the potential that surface water drainage collected during construction phases may have a higher concentration of suspended solids than the consented discharge level that has been detailed in the Environment Agency discharge conditionality report. Therefore, techniques will be employed to reduce the suspended solids concentration to an acceptable level prior to discharge. Large sediment particles will readily settle out under reduced flow velocity conditions (e.g. settlement lagoon). However, the finer fractions (such as clays) may tend to persist as a colloidal suspension and require more intensive physical or chemical intervention for effective removal (e.g. chemical flocculation).

Reducing Suspended Solids Concentrations in Surface Drainage Water: Sediment Removal within Temporary Surface Drainage Systems

16.7.43 Temporary drainage ditches used to collect water from construction areas across the site will incorporate a number of features to reduce further sediment treatment requirements prior to discharge. Main collection ditches that feed into settlement lagoons in the WMZs will be stone or geotextile lined to prevent bed erosion during periods of high flows. They will incorporate stepped weirs to encourage sediment settlement within the ditch and may also incorporate sediment trapping barriers (e.g. sediment tubes) to further retain silt and sediments within the ditch. Surface drainage may also be diverted through small silt trap areas constructed within the drainage system for the removal of suspended solids.

Reducing Suspended Solids Concentrations in Surface Drainage Water in the Water Management Zones

16.7.44 There will be a need to construct temporary settlement lagoons into which water from the construction phase surface drainage system and water from dewatering of excavations will be passed to allow the settlement of solids. The lagoons within the WMZs will serve an additional function of attenuating flows. To be as effective as possible, such lagoons require as long a retention time as possible to promote effective settlement. Residence time within the lagoons would be increased, if necessary, by the use of geo-textile baffles.

Reducing Suspended Solids Concentrations in Surface Drainage Water: Mechanical Recovery of Suspended Solids

16.7.45 A range of commercial systems are available that may be employed to mechanically separate solids from water. These include technology such as ‘silt busters’ and wedge wire screen drum filters. These systems will likely form part of a ‘tool box’ of techniques necessary to ensure discharges to terrestrial surface water systems meet the Environmental Permit discharge consent conditions.

Reducing Suspended Solids Concentrations in Surface Drainage Water: Chemical Recovery of Suspended Solids

16.7.46 Suspended solids may also be removed from surface drainage water through the use of chemical flocculants in treatment lagoons. These are particularly effective for removal of the finer particles (e.g. clay) that may not settle out in settlement facilities due to colloidal effects. Alum is routinely used in the wastewater industry for flocculation, however there are noted pH reduction effects associated with its application. Other available chemical flocculants that may be applied are usually synthetic organic polymers. Agreement would be sought from the Environment Agency on the potential need for and use of chemical flocculants if necessary. However, it is not envisaged that the use of chemical flocculants would be required.

vi. Sustainable Drainage Systems

16.7.47 Good practice measures would be adopted to reduce, where possible, the volume of surface drainage that may have elevated suspended solids concentrations, being collected and requiring disposal through discharge. By restricting drainage run-off rates, the erosion of bare soils would be reduced leading to a reduction in potential sediment generation. Where practical during the construction phase, Sustainable Drainage System (SuDS) principles would be adopted for the surface drainage system in the SCPA This would include techniques such as the use of porous hard surface areas, the adoption of soakaway systems for disposal of uncontaminated surface drainage water where practicable. There are no opportunities for use of SuDs techniques within the BDAW and BDAE during either the construction or operational phases as disposal of surface drainage will be made directly to the sea and the use of infiltration techniques will conflict with the requirement to actively maintain groundwater levels at reduced level to prevent damage to buildings.

16.7.48 Currently it is proposed that a green roof system will be developed on some of the HPC buildings.

vii. Management of Site Areas

16.7.49 Stockpiled materials will need to be placed outside the area of flood zones for surface watercourses. This will ensure that there is limited potential for increased risk of localised flooding from the use of floodplain storage capacity or sediment generation resulting from floodwater inundation of stockpiles.

16.7.50 To ensure protection of Holford Stream, a buffer zone would be created during the pre-culverting phase along the stretch of stream parallel to the culvert alignment. The buffer zone would be demarked with sediment fencing. This physical barrier will serve several purposes:

- to prevent heavy plant accessing the riparian zone and causing bank erosion and potential bank collapse;
- to ensure materials are not deposited within areas that have the potential to flood; and
- to reduce the potential for sediment-laden water from the stockpiling areas and haul routes entering Holford Stream.

viii. Monitoring

16.7.51 An environmental monitoring strategy will be set out within the EMMP for all elements of the terrestrial surface drainage system to ensure the conditions of Environmental Permits for discharges to terrestrial surface watercourses are met on all occasions. Specific additional details will be provided in the supporting **Water Management Plan**. The monitoring strategy will extend to routine inspection, assessment of system performance, maintenance, and monitoring of all elements of the surface drainage system across the entire HPC development site. The deployment of mitigation measures will be dictated by the results of the monitoring programme in combination with the status of the construction works programme and prevailing weather conditions. This will require a flexible and pro-active approach to provide protection to retained surface water features within and local to the site.

ix. Nutrient Concentrations in Surface Drainage

16.7.52 Phosphorus is the key nutrient associated with the eutrophication of freshwater systems. Disturbance of the existing agricultural soils during construction works may increase the mobilisation of phosphorus and discharge of this substance within surface drainage to Holford Stream and Bum Brook. This may negatively impact both water quality and ecological conditions. The majority of phosphorus is likely to be associated with suspended solids and therefore the removal of suspended solids prior to discharge, would be a likely requirement of conditions under an Environmental Permit. Removal of suspended solids would be achieved through the implementation of control measures within the surface drainage system and treatment of surface drainage prior to discharge from the WMZs. The requirement to reduce suspended solids to acceptable concentrations would assist in limiting nutrient inputs into Holford Stream and Bum Brook.

16.7.53 It may be deemed appropriate to routinely monitor the nutrient status of drainage water being discharged to watercourses. If nutrient concentrations are present that are significantly above existing baseline concentrations then additional remedial measures may be required such as treatment within attenuation basins provided in the WMZs with a phosphorus binding agent such as 'Phoslock'.

x. Acid Rock Drainage (ARD)

16.7.54 The potential impact of acid rock drainage discharges to Holford Stream, from stockpiled areas of mudstone in the SCPA, has been assessed to be of moderate significance and therefore requires mitigation measures to be adopted. The mitigation for this impact would involve use of appropriate stockpiling techniques to minimise ARD generation and monitoring of surface run-off from stockpiles and treatment, if required.

16.7.55 Monitoring of the drainage collected from areas of stockpile material will include measurement of pH. If low pH conditions are recorded then further testing may be required to determine if leaching of other trace elements is taking place. Example mitigation approaches that may be adopted which are:

- reducing the generation of ARD from the stockpile using techniques such as compaction or prevention of water ingress; and
- treatment of the low pH surface drainage within the WMZs using techniques such as Anoxic Limestone Ditches (ALDs) to ameliorate the acidic conditions prior to discharge.

xi. Spillages Including Soils, Hydrocarbons and Concrete

16.7.56 Best practice measures will be adopted for the maintenance of plant and equipment, storage of fuel and other chemicals and refuelling of construction plant and equipment. These activities will be located at distance from the surface watercourses. Biodegradable greases and lubricants would be used where possible on mobile construction plant. Oil separators/interceptors will be incorporated into the surface drainage system to prevent discharge of hydrocarbons to the HPC Drainage Ditch and Holford Stream.

16.7.57 To mitigate against potential impacts of leaching from fresh concrete, Environment Agency guidance detailed in PPG 5 and 6 (Ref. 16.39) would be followed. Quick setting concrete formulas would be used where possible and any spillages would be contained immediately. Where possible, concreting would be carried out in dry conditions.

xii.Mitigation of Impacts during Removal and Restoration

16.7.58 The same range of impacts are expected for removal/reinstatement (if required) and, therefore, the same range of mitigation measures as proposed for the construction phase works would be applied.

16.8 Residual Impacts

16.8.1 Residual impacts for all identified impacts including those which were not at a level of significance that required mitigation have been detailed in the summary impact assessment table (see **Table 16.19**).

a) Construction Impacts

16.8.2 A **moderate adverse** impact remains during a during 1% AEP 2100 overtopping event for the residential third party receptors at Little Dowden's Farm and Fisheries Cottage, with more widespread minor impacts to residential and non-residential third party receptors during other tidal events. The managed adaptive approach to mitigation discussed in section 16.7.11 and 16.7.12 recognises that impacts are only predicted as a result of sea level rise and do not impact immediately In addition, the hazard rating to these residential third party receptors does not increase. The **Flood Risk Assessment** shows that the receptors would flood with or without the HPC development.

16.8.3 No other (greater than minor) residual impacts on surface water receptors have been identified, in relation to the construction phase.

b) Operational Impacts

16.8.4 No significant (greater than minor) residual impacts on surface water receptors have been identified, in relation to the operational phase.

c) Removal/Restoration Impacts

16.8.5 No significant (greater than minor) residual impacts on surface water receptors have been identified, in relation to the removal/restoration works.

16.9 Summary of Impacts

Table 16.19: Surface Water Impact and Mitigation Table

Potential Impact	Receptor	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Construction Impacts – Hydrology and Drainage							
Elevated surface water run-off							
Elevated surface water run-off.	HPC Drainage Ditch	Very low (Due to WMZs controlling discharge to greenfield rates)	Local Adverse Temporary Direct Possible	Low	Negligible	No mitigation required	Minor
Elevated surface water run-off.	Hinkley Point intertidal area	Medium (Due to WMZs)	Local Adverse Temporary Direct Possible	Very low	Minor	No mitigation required	Negligible
Elevated surface water run-off.	Holford Stream (and Wick Moor)	Very low (Due to WMZs controlling discharge to greenfield rates)	Local Adverse Temporary Direct Unlikely	High	Minor	No mitigation required	Minor
Elevated surface water run-off.	Wick Moor (via Holford Stream)	Very low (Due to WMZs controlling discharge to greenfield rates)	Local Adverse Temporary Indirect Unlikely	High	Minor	No mitigation required	Minor

Potential Impact	Receptor	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Elevated surface water run-off.	Bum Brook	Very low (Due to WMZs controlling discharge to greenfield rates)	Local Adverse Temporary Indirect Unlikely	High	Minor	No mitigation required	Minor
Elevated surface water run-off from the highway improvement works.	Residential third party properties/land	Very low	Local Adverse Temporary Indirect Unlikely	High	Minor	No mitigation required	Minor
Elevated sediment delivery and deposition in watercourses							
Elevated sediment delivery and deposition in watercourses.	HPC Drainage Ditch	Low (Practices to follow PPG and discharges under Environmental Permit)	Local Adverse Temporary Indirect Possible	Low	Minor	No mitigation required	Minor
Elevated sediment delivery and deposition in watercourses.	Holford Stream	Very low (Practices to follow PPG and discharges under Environmental Permit)	Local Adverse Temporary Indirect Unlikely	High	Minor	No mitigation required	Minor
Elevated sediment delivery and deposition in watercourses.	Bum Brook	Very low (Practices to follow PPG and discharges under Environmental Permit)	Local Adverse Temporary Indirect Unlikely	High	Minor	No mitigation required	Minor

Potential Impact	Receptor	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Increased flood risk of land outside the HPC development site from pluvial sources of flooding							
Increased flood risk due to elevated surface water run-off from the proposed HPC development site.	Hinkley Point intertidal area	Low	Local Adverse Temporary Indirect Possible	Very Low	Negligible	No mitigation required	Minor
Increased flood risk due to elevated surface water run-off from the proposed HPC development site.	Agricultural land off-site from the HPC development site west of HPC Drainage Ditch	Very low	Local Adverse Temporary Indirect Unlikely	Low	Negligible	No mitigation required	Minor
Increased flood risk due to elevated surface water run-off from the proposed HPC development site.	Agricultural land off-site from the HPC development site west of Holford Stream	Very low	Local Adverse Temporary Indirect Unlikely	Medium	Minor	No mitigation required	Minor
Increased flood risk due to elevated surface water run-off from the proposed HPC development site.	Wick Moor	Very low	Local Adverse Temporary Indirect Unlikely	Medium	Minor	No mitigation required	Minor
Increased flood risk due to elevated surface water run-off from the proposed HPC development site.	Land off-site adjacent to Bum Brook	Very low	Local Adverse Temporary Indirect Unlikely	Medium	Minor	No mitigation required	Minor

Potential Impact	Receptor	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Fluvial flood risk							
Increased fluvial flood risk due to reduced channel capacity as a result of sediment deposition within Holford Stream.	Wick Moor	Very low	Local Adverse Temporary Indirect Unlikely	Medium	Minor	No mitigation required	Minor
Increased fluvial flood risk due to reduced channel capacity as a result of sediment deposition within Bum Brook.	Land off-site adjacent to Bum Brook	Low	Local Adverse Temporary Indirect Unlikely	Medium	Minor	No mitigation required	Minor
Increased fluvial flood risk due to reduced flood storage capacity of Holford stream valley as a results of the platform and WMZs.	Wick Moor	Very low	Local Positive Temporary Direct Likely	Medium	Minor	No mitigation required	Minor
Increased fluvial flood risk due to a blockage in Holford stream culvert.	Agricultural land off-site from the HPC development site west of Holford Stream	Very low	Local Adverse Temporary Direct Unlikely	Medium	Minor	No mitigation required (however regular monitoring of the culvert will be carried out to ensure that lose debris does not build up)	Minor
Increased fluvial flood risk due restricted flow under bum brook emergency access bridge during a flood event.	Land off-site adjacent to Bum Brook	Very low	Local Adverse Temporary Direct Possible	Medium	Minor	No mitigation required	Minor

Potential Impact	Receptor	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Increased fluvial flood risk due restricted flow under Bum brook emergency access bridge during a flood event.	Residential third party properties	Very low	Local Positive Temporary Direct Possible	High	Minor	No mitigation required	Minor
Increased fluvial flood risk due a blockage under Bum brook emergency access bridge.	Land off-site adjacent to Bum Brook	Low	Local Adverse Temporary Direct Possible	Medium	Minor	No mitigation required (however regular monitoring of Bum Brook will be carried out to ensure that lose debris does not build up)	Minor
Tidal flood risk							
Increased tidal flood risk during 0.5% AEP 2017 overtopping event due to reduced flood storage capacity of Holford stream valley due to infilling of the valley for the platform.	Wick Moor	Very low	Local Adverse Temporary Direct Unlikely	Medium	Minor	No mitigation required	Minor
Increased tidal flood risk during 0.5% AEP 2100 overtopping event due to reduced flood storage capacity of Holford stream valley due to infilling of the valley for the platform.	Wick Moor	Very low	Local Adverse Temporary Direct Unlikely	Medium	Minor	No mitigation required	Minor

Potential Impact	Receptor	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Increased tidal flood risk during 0.5% AEP 2100 breach event due to reduced flood storage capacity of Holford stream valley due to infilling of the valley for the platform.	Wick Moor	Very low	Local Adverse Temporary Direct Unlikely	Medium	Minor	No mitigation required	Minor
Increased tidal flood risk during 1% AEP 2100 overtopping event due to reduced flood storage capacity of Holford stream valley due to infilling of the valley for the platform.	Wick Moor	Low	Local Adverse Temporary Direct Unlikely	Medium	Minor	No mitigation required	Minor
Increased tidal flood risk during 0.5% AEP 2100 overtopping event due to reduced flood storage capacity of Holford stream valley due to infilling of the valley for the platform.	Residential third party properties (Little Dowden's Farm, Fisheries Cottage, North of Croft Farm, Swallowcliffe, and Fisherman's Cottage)	Very low	Local Adverse Temporary Direct Unlikely	High	Minor	EDF Energy will monitor sea levels and climate change and should a "trigger point" be reached, EDF Energy would assess the likely flood impact to each identified property, enter into a covenant with each property owner based on an appropriate contribution to the cost of repairs related to flood damage, proportionate to the impact caused by the Hinkley Point C development and agree to pay the appropriate contribution should a flood event actually occur.	Minor

Potential Impact	Receptor	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Increased tidal flood risk during 0.5% AEP 2100 overtopping event due to reduced flood storage capacity of Holford stream valley due to infilling of the valley for the platform.	Non-residential third party properties (C182, the STW, and the national grid tower (pylons))	Very low	Local Adverse Temporary Direct Unlikely	Medium	Minor	No mitigation required	Minor
Increased tidal flood risk during 0.5% AEP 2100 breach event due to reduced flood storage capacity of Holford stream valley due to infilling of the valley for the platform.	Non-residential third party properties (0.11m increase in flood depth at C182, the STW and national grid tower (pylons))	Very low	Local Adverse Temporary Direct Unlikely	Medium	Minor	No mitigation required	Minor
Increased tidal flood risk during 1% AEP 2100 overtopping event due to reduced flood storage capacity of Holford stream valley due to infilling of the valley for the platform.	Residential third party properties (Little Dowden's Farm and Fisheries Cottage)	Low	Local Adverse Temporary Direct Unlikely	High	Moderate	EDF Energy will monitor sea levels and climate change and should a "trigger point" be reached, EDF Energy would assess the likely flood impact to each identified property, enter into a covenant with each property owner based on an appropriate contribution to the cost of repairs related to flood damage, proportionate to the impact caused by the Hinkley Point C development and agree to pay the appropriate contribution should a flood event actually occur.	Moderate

Potential Impact	Receptor	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Increased tidal flood risk during 1% AEP 2100 overtopping event due to reduced flood storage capacity of Holford stream valley due to infilling of the valley for the platform.	Non-residential third party properties (C182, the STW, and the national grid tower (pylons))	Low	Local Adverse Temporary Direct Unlikely	Medium	Minor	No mitigation required	Minor
Change to Holford Stream Hydraulic Characteristics due to the construction of Holford Stream culvert							
Increased flow velocities due to Holford stream culvert.	Holford Stream	Very low (Due to energy dissipation measures)	Local Adverse Permanent Direct Unlikely	High	Minor	No mitigation required	Minor
Interruption of flows in Holford Stream due to construction of culvert.	Holford Stream	Very low (Due to offline construction)	Local Adverse Temporary Direct Unlikely	High	Minor	No mitigation required	Minor
Influence on water levels in the wick moor SSSI due to Holford stream culvert.	Wick Moor	Very low (Due to impermeable culvert base and adjacent groundwater collector drains)	Local Positive Permanent Direct Unlikely	High	Minor	No mitigation required	Minor

Potential Impact	Receptor	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Construction Impacts – Water Quality							
Installation and removal of Temporary Surface Water Drainage System including Water Management Zones in the Built Development Areas East and West							
Sediment-laden run-off associated with topsoil stripping, excavations and excavation dewatering.	Freshwater Quality Status – HPC Drainage Ditch	Low	Local Adverse Temporary Direct Certain	Low	Minor	No mitigation required, however, assessment of magnitude assumes good practice measures adopted.	Minor
Hydrocarbon contaminated run-off deriving from plant activities.	Freshwater Quality Status – HPC Drainage Ditch.	Very low	Local Adverse Temporary Direct Possible	Low	Negligible	No mitigation required, however, assessment of magnitude assumes good practice measures adopted.	Negligible
Mobilisation of stream bed sediments as a result of increased flows.	Freshwater Quality Status – HPC drainage ditch.	Very low	Local Adverse Temporary Direct Possible	Low	Negligible	No mitigation required, however assessment of magnitude assumes attenuation of discharges to greenfield run-off rates.	Negligible
Installation and removal of Temporary Surface Water Drainage Systems including Water Management Zones in Southern Construction Phase Area							
Sediment-laden run-off associated with topsoil stripping, excavations and excavation dewatering.	Freshwater Quality Status – Holford Stream	Low	Local Adverse Temporary Direct Certain	High	Moderate	Mitigation measures required to reduce sediment generation at source and removal prior to discharge into Holford Stream under Environment Agency consent.	Minor

Potential Impact	Receptor	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Hydrocarbon contaminated run-off deriving from plant activities.	Freshwater Quality Status – Holford Stream	Very low	Local Adverse Temporary Direct Possible	High	Minor	Ensure oil interceptors are present in drainage systems. Use biodegradable oils and lubricants on construction plant.	Minor
Mobilisation of stream bed sediments as a result of increased flows.	Freshwater Quality Status – Holford Stream	Very low	Local Adverse Temporary Direct Possible	High	Minor	Attenuation of flows to allow discharges to be made at greenfield run-off rates	Minor
Construction of culvert for Holford Stream							
Sediment-laden run-off associated with topsoil stripping, excavations and excavation dewatering.	Freshwater Quality Status – Holford Stream	Very low (culvert to be constructed offline)	Local Adverse Temporary Direct Certain	High	Minor	Mitigation measures required to reduce sediment generation at source and removal prior to discharge into Holford Stream under Environment Agency consent.	Minor
Hydrocarbon contaminated run-off deriving from plant activities.	Freshwater Quality Status – Holford Stream	Very low (culvert to be constructed offline)	Local Adverse Temporary Direct Possible	High	Minor	Ensure oil interceptors are present in drainage systems. Use biodegradable oils and lubricants on construction plant.	Minor
Mobilisation of stream bed sediments as a result of increased flows.	Freshwater Quality Status – Holford Stream	Very low (culvert to be constructed offline)	Local Adverse Temporary Direct Possible	High	Minor	Attenuation of flows to allow discharges to be made at greenfield run-off rates.	Minor

Potential Impact	Receptor	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Concrete leachate from construction of culvert.	Freshwater Quality Status – Holford Stream	Very low (culvert to be constructed offline and use of best practice)	Local Adverse Temporary Direct Possible	High	Minor	Minimise in-situ concrete use using pre-cast components.	Minor
Construction phase earthworks							
Sediment-laden surface drainage from earthworks activities, including vegetation removal, topsoil stripping, creation of development platform levels, creation of temporary aggregates storage area, landscaping, fence erection and dewatering of excavations.	Freshwater Quality Status – HPC Drainage Ditch.	Medium	Local Adverse Temporary Direct Certain	Low	Minor	No mitigation required, however assessment of magnitude assumes good practice measures adopted.	Minor
Sediment-laden surface drainage from earthworks activities, including vegetation removal, topsoil stripping, creation of development platform levels, landscaping, fence erection and dewatering of excavations.	Freshwater Quality Status – Holford Stream	Medium	Local Adverse Temporary Direct Certain	High	Major	Adopted best practice measures to reduce sediment generation at source. Collection and treatment of sediment-laden surface drainage and treatment to reduce suspended solids concentrations to levels of discharge consent.	Minor

Potential Impact	Receptor	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Sediment-laden run-off from short-term stockpiling areas in Built Development Areas East and West.	Freshwater Quality Status – HPC Drainage Ditch.	Low	Local Adverse Temporary Direct Possible	Low	Minor	No mitigation required, however, assessment of magnitude assumes good practice measures adopted such as ring-fencing of stockpiles with sediment fencing.	Minor
Sediment-laden run-off from short-term and long-term stockpiling areas in Southern Construction Phase Area.	Freshwater Quality Status – Holford Stream	Low	Local Adverse Temporary Direct Possible	High	Moderate	Mitigation measures to be adopted to minimise sediment generation by stockpiles. Collection of surface drainage water from stockpiling area and treatment in WMZ prior to discharge under consent	Minor
Concrete leachate from foundation works e.g. fence erection works, workshop footings, etc.	Freshwater Quality Status – HPC Drainage Ditch.	Very low (highly localised and use of best practice guidance)	Local Adverse Temporary Direct Possible	Low	Negligible	No mitigation required	Negligible
Concrete leachate from foundation works e.g. fence erection works, workshop footings, etc.	Freshwater Quality Status – Holford Stream	Very low (highly localised and use of best practice guidance)	Local Adverse Temporary Direct Possible	High	Minor	No mitigation required	Minor
Run-off containing elevated concentrations of nutrients following sediment disturbance.	Freshwater Quality Status – HPC Drainage Ditch.	Low	Local Adverse Temporary Direct Possible	Low	Minor	No mitigation required, however, assessment of magnitude assumes good practice measures adopted.	Minor

Potential Impact	Receptor	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Run-off containing elevated concentrations of nutrients following sediment disturbance.	Freshwater Quality Status – Holford Stream	Low	Local Adverse Temporary Direct Possible	High	Moderate	Removal of sediments in surface drainage system and WMZ prior to discharges to reduce nutrient inputs in to watercourse.	Minor
Run-off containing elevated concentrations of nutrients following sediment disturbance (during landscape restoration works).	Freshwater Quality Status – Bum Brook	Very low	Local Adverse Temporary Direct Possible	High	Minor	No mitigation required. Removal of sediments in surface drainage system and WMZ prior to discharges to reduce nutrient inputs in to watercourse.	Minor
Surface water run-off containing elevated concentrations of hydrocarbons from temporary plant.	Freshwater Quality Status – HPC Drainage Ditch.	Very low	Local Adverse Temporary Direct Possible	Low	Negligible	No mitigation required, however, assessment of magnitude assumes good practice measures adopted such as use of oil interceptors in drainage system.	Negligible
Surface water run-off containing elevated concentrations of hydrocarbons from temporary plant.	Freshwater Quality Status – Holford Stream	Very low	Local Adverse Temporary Direct Possible	High	Minor	No mitigation required, however, assessment of magnitude assumes good practice measures adopted such as use of oil interceptors in drainage system.	Minor
Groundwater pumped into surface drainage system.	Freshwater Quality Status – HPC drainage ditch.	Low	Local Adverse Temporary Direct Possible	Low	Minor	No mitigation required. Assessment of magnitude assumes good practice measures adopted such as routine quality monitoring of pumped groundwater.	Minor

Potential Impact	Receptor	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Surface run-off from rock stockpile areas, of potentially low pH.	Freshwater Quality Status – Holford Stream	Low	Local Adverse Temporary Direct Possible	High	Moderate	Stockpiling techniques to minimise percolation. Monitoring of surface drainage from rock stockpiling area. Treatment of any low pH using techniques with Water Managements Zones such as anoxic limestone ditches.	Minor
Construction of site compound, development site roads (access and haul roads)							
Surface run-off containing elevated concentrations of suspended sediment.	Freshwater Quality Status – HPC Drainage Ditch.	Low	Local Adverse Temporary Direct Certain	Low	Minor	No mitigation required, however, assessment of magnitude assumes good practice measures adopted.	Minor
Concrete leachate from in-situ construction of footings and foundations.	Freshwater Quality Status – HPC Drainage Ditch.	Very low (highly localised and use of best practice guidance)	Local Adverse Temporary Direct Possible	Low	Negligible	No mitigation required, however, assessment of magnitude assumes good practice measures adopted.	Negligible
Surface run-off containing elevated concentrations of hydrocarbons from temporary plant and vehicle parking areas.	Freshwater Quality Status – HPC Drainage Ditch.	Very low	Local Adverse Temporary Direct Possible	Low	Negligible	No mitigation required, however, assessment of magnitude assumes good practice measures adopted.	Negligible

Potential Impact	Receptor	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Surface run-off containing elevated concentrations of suspended sediment.	Freshwater Quality Status – Holford Stream	Very low (On basis of culvert already installed isolating receptor)	Local Adverse Temporary Direct Certain	High	Minor	No mitigation required, however, assessment of magnitude assumes good practice measures adopted.	Minor
Concrete leachate from in-situ construction of footings and foundations.	Freshwater Quality Status – Holford Stream	Very low (highly localised and use of best practice guidance)	Local Adverse Temporary Direct Possible	High	Minor	No mitigation required, however, assessment of magnitude assumes good practice measures adopted.	Minor
Surface run-off containing elevated concentrations of hydrocarbons from temporary plant and vehicle parking areas.	Freshwater Quality Status – Holford Stream	Very low	Local Adverse Temporary Direct Possible	High	Minor	No mitigation required, however, assessment of magnitude assumes good practice measures adopted.	Minor
Surface run-off containing elevated concentrations of suspended sediment during construction of emergency access route crossing Bum Brook.	Freshwater Quality Status – Bum Brook	Very low (Single span bridge crossing watercourse avoiding need for in-river works)	Local Adverse Temporary Direct Possible	High	Minor	No mitigation required, however, assessment of magnitude assumes good practice measures adopted.	Minor
Concrete leachate from in-situ construction of footings and foundations during construction of emergency access route crossing Bum Brook.	Freshwater Quality Status – Bum Brook	Very low (Single span bridge crossing watercourse avoiding need for in-river works)	Local Adverse Temporary Direct Possible	High	Minor	No mitigation required, however, assessment of magnitude assumes good practice measures adopted.	Minor

Potential Impact	Receptor	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Surface run-off containing elevated concentrations of hydrocarbons from temporary plant and vehicle parking areas during construction of emergency access route crossing Bum Brook.	Freshwater Quality Status – Bum Brook	Very low (Single span bridge crossing watercourse avoiding need for in-river works)	Local Adverse Temporary Direct Possible	High	Minor	No mitigation required, however, assessment of magnitude assumes good practice measures adopted.	Minor
Construction of Soil Retaining Wall (during site preparation)							
Surface run-off containing elevated concentrations of suspended sediment.	Freshwater Quality Status – HPC Drainage Ditch.	Low	Local Adverse Temporary Direct Certain	Low	Minor	No mitigation required, however, assessment of magnitude assumes good practice measures adopted.	Minor
Surface run-off containing elevated concentrations of hydrocarbons from temporary plant.	Freshwater Quality Status – HPC Drainage Ditch.	Very low	Local Adverse Temporary Direct Possible	Low	Negligible	No mitigation required, however, assessment of magnitude assumes good practice measures adopted.	Negligible
Discharges from Water Management Zones							
Discharges into surface water feature, including treated sanitary effluent discharges from accommodation campus.	Freshwater Quality Status – Holford Stream	Very low (subject to WMZ configured to meet environmental permit conditions)	Local Neutral Temporary Direct Certain	High	Minor	No mitigation required.	Minor

Potential Impact	Receptor	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Discharges into surface water feature prior to installation of subsequent drainage infrastructure.	Freshwater Quality Status – Hinkley C Drainage Ditch	Very low (subject to WMZ configured to meet environmental permit conditions)	Local Neutral Temporary Direct Certain	Low	Negligible	No mitigation required.	Negligible
Discharges into surface water feature at end of construction phase during landscape restoration.	Freshwater Quality Status – Bum Brook	Very low (subject to WMZ configured to meet environmental permit conditions)	Local Neutral Temporary Direct Certain	High	Minor	No mitigation required.	Minor
Reconfiguration of Water Management Zones (WMZs) during landscape restorations							
Sediment laden run-off associated with reconfiguration of WMZs.	Freshwater Quality Status – Holford Stream	Very low (subject to WMZ configured to meet environmental permit conditions until works complete)	Local Adverse Temporary Direct Possible	High	Minor	No mitigation required. Schedule should ensure that sediment mitigation measures are in place during all phases of reconfiguration, or alternatively that no pathway exists for surface drainage to reach receptor.	Minor
Sediment laden run-off associated with reconfiguration of WMZs.	Freshwater Quality Status – Bum Brook	Very low (subject to WMZ configured to meet environmental permit conditions until works complete)	Local Adverse Temporary Direct Possible	High	Minor	No mitigation required. Schedule should ensure that sediment mitigation measures are in place during all phases of reconfiguration, or alternatively that no pathway exists for surface drainage to reach receptor.	Minor

Potential Impact	Receptor	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Hydrocarbon contaminated run-off from plant during reconfiguration of WMZs.	Freshwater Quality Status – Holford Stream	Very low (subject to WMZ configured to meet environmental permit conditions until works complete)	Local Adverse Temporary Direct Possible	High	Minor	No mitigation required	Minor
Hydrocarbon contaminated run-off from plant during reconfiguration of WMZs.	Freshwater Quality Status – Bum Brook	Very low (subject to WMZ configured to meet environmental permit conditions until works complete)	Local Adverse Temporary Direct Possible	High	Minor	No mitigation required	Minor
Operational Impacts							
Hydrology and Drainage							
Risk: Elevated surface water run-off due to an extreme rainfall event (greater than 0.1% AEP).	Hinkley Point intertidal area	Very low	Local Adverse Temporary Direct Unlikely	Low	Negligible	No mitigation required	Minor
Water Quality							
Site drainage discharges to Holford Stream.	Freshwater quality status – Holford Stream	Very low (Run-off from landscaped areas)	Local Neutral Permanent Direct Certain	High	Minor	No mitigation required	Minor

Potential Impact	Receptor	Potential Magnitude	Description	Value/ Sensitivity	Significance	Proposed Mitigation	Residual Impact Assessment
Removal/Restoration Impacts							
Hydrology and Drainage							
Assessed above within construction impacts because a similar suite of construction type activities (but generally of lesser magnitude).	n/a	n/a	n/a	n/a	n/a	n/a	n/a
Water Quality							
Assessed above within construction impacts because a similar suite of construction type activities (but generally of lesser magnitude).	n/a	n/a	n/a	n/a	n/a	n/a	n/a

CHAPTER 17: COASTAL HYDRODYNAMICS AND GEOMORPHOLOGY

CONTENTS

TABLES

FIGURES

17. COASTAL HYDRODYNAMICS AND GEOMORPHOLOGY

17.1 Introduction

17.1.1 This chapter of the Environmental Statement (ES) provides an assessment of the potential effects on coastal hydrodynamics and geomorphology associated with the construction and operational phase of Hinkley Point C (HPC) (see **Chapters 2**, **3**, and **4** of this volume of the ES for details).

17.1.2 The site for the proposed new power station is on the southern shore of the Inner Bristol Channel. As part of the proposed works there will be a need to establish a series of structures at the head of the shore, across that shore and on the local seabed. There will be a consequential degree of interaction between these structures and their operation and marine and estuarine hydrodynamic and sedimentary processes.

17.1.3 This chapter describes the existing hydrodynamic regime and sediment transport processes operating in the Inner Bristol Channel, with an emphasis on the Hinkley Point area where these processes could potentially interact with the proposed development. The predicted effects to these processes during the construction and operational phases of the proposed development are then described.

17.1.4 While the development of HPC may alter hydrodynamic and sedimentary processes (both locally and potentially more widely), the significance of such a change or effect has not been defined in this chapter as an impact. This is because coastal processes themselves are not considered to be a receptor sensitive to change. Hence, while a change to a process can be predicted and described with respect to the known baseline in terms of its magnitude, it is not appropriate to predict the significance of an impact on the process. The significance of this change is nevertheless assessed with respect to those environmental receptors that could be influenced, such as marine ecological interests, within the other relevant technical chapters of this ES.

17.1.5 Where required, mitigation measures are identified to prevent, reduce and, where possible, off-set any potentially adverse effects that could have a significant impact on another receptor. In some instances, mitigation measures are an integral aspect of the initial project design (e.g. the temporary aggregate jetty design or cooling water outfall location).

17.1.6 Consultation has been undertaken throughout the EIA process and further information may be found in the **Consultation Report**. Of particular relevance to coastal issues, regular meetings of the Marine Authorities Liaison Group (MALG) were held in 2009 and 2010 (after which they were replaced by topic specific meetings). The MALG comprised a technical forum attended by representatives of regulatory and advisory agencies with a particular interest in the HPC Project from a marine and coastal perspective.

a) Scope of Assessment

17.1.7 The following development components have been identified as having the potential to influence coastal hydrodynamics and/or coastal geomorphology:

- During construction:
  - the emplacement of the new sea wall fronting the HPC site;
  - drainage from the construction site across the shore;
  - the construction, operation and subsequent dismantling of the temporary jetty;
  - the drilling of vertical shafts offshore for the cooling water intake and outfall structures;
  - the establishment of a discharge point for the Fish Recovery and Return system; and
  - the capital and any subsequent maintenance dredging of the berthing pocket for the temporary jetty.
- During operation:
  - the presence of the new sea wall;
  - the abstraction and discharge of cooling water; and
  - the presence of cooling water intake and outfall headworks and any other structures on the seabed, including those associated with the Fish Recovery and Return and Acoustic Fish Deterrence systems.

17.1.8 The assessment presented in the following sections addresses the potential effects of the activities and structures described above on processes operating within the littoral and offshore zones and, where relevant, the geomorphological features present. For the purposes of this chapter the littoral zone is regarded as the area between the seaward limit of terrestrial plants (i.e. the splash-zone, above Mean High Water Mark) and the subtidal location where seabed sediment is not disturbed by waves. In this area, both tidally-driven and wave-driven sediment transport processes are active, although the relative significance of these will vary both through the tidal cycle and according to wave conditions at any specific location.

17.1.9 Current best estimates of future trends in sea level, driven in part by climate change, are considered where appropriate.

17.1.10 In the offshore zone of the Inner Bristol Channel, tidal currents are dominant. The effects of the proposed development on both bedload processes (sediment particles transported in contact with the bed) and suspended sediment processes (sediment particles transported in suspension) are considered where these are relevant to overall sediment transport processes. The effects of the proposed development with regard to suspended sediment concentrations as an attribute of water quality are covered in **Chapter 18** (Marine Water and Sediment Quality) of **Volume 2**.

17.2 Legislation, Policy and Guidance

17.2.1 The legislative, policy and guidance context for coastal hydrodynamics and geomorphology is addressed below.

a) International Legislation

17.2.2 The two key international legislative instruments associated with disposal of dredged material at sea are the London Convention (LC), 1972 and OSPAR Convention, 1992. The licensing of disposal of dredged material from the jetty development and its maintenance will be subject to these requirements.

b) European Legislation

17.2.3 Given that coastal hydrodynamic or geomorphological effects may affect designated European coastal and marine sites, the EC Habitats Directive (92/43/EC) is relevant to this assessment. Under the Habitats Directive it is necessary to take into account whether an activity is likely to have a significant effect on the interest features of relevant European sites alone or in combination with other plans / projects and activities. A report to inform the relevant Habitats Regulations Assessment (HRA) is being submitted in parallel to this ES as part of the DCO application.

17.2.4 The Water Framework Directive (WFD) requires that all inland and coastal waters within defined river basin districts must reach at least ‘good status’ (or 'good potential’, if considering a heavily modified water body) by 2015 and defines how this should be achieved through the establishment of environmental objectives and ecological targets for surface waters. Under the requirements of the Directive, the present water quality status must be assessed and any significant water quality issues identified. The overall aim is to enhance water resource quality, reduce pollution and promote sustainable use of water resources.

17.2.5 The WFD is implemented in the UK under The Water Environment (England and Wales) Regulations 2003. Coastal and estuarine waters have been split up into water bodies by the “competent authority” (Environment Agency for England and Wales) and these bodies are assessed individually. Bodies are grouped according to a type defined by hydromorphological assessment, physico-chemical criteria and are designated as coastal or transitional. The area of the Inner Bristol Channel under consideration is regarded as a coastal water from the English shore across to the Welsh shore and the Parrett is a transitional (estuarine) water.

17.2.6 WFD prioritises ecological assessment as a way of classifying water bodies but also includes physico-chemical assessment and the use of environmental chemical standards for priority substances and specific pollutants, as well as an assessment of defined hydromorphological criteria. A WFD assessment is provided in Appendix 18B.

c) UK Legislation

17.2.7 The Environment Agency, the Marine Management Organisation (MMO), the Welsh Assembly Government’s (WAG) Marine Licensing Unit (with regards to Welsh waters) and the statutory port and harbour authorities also have important roles in managing some aspects of the marine and coastal environment.

i. Water Resources Act (as amended)

17.2.8 The Water Resources Act 1991 (as amended by the Water Act 2003) controls the abstraction and impounding of water. It is relevant here because a number of waste streams will be discharged from the site. Discharge consents have recently been superseded by Environmental Permits issued under the Environmental Permitting Regulations 2010.

ii. UK Marine and Coastal Access Act

17.2.9 The UK Marine and Coastal Access Act 2009 (Marine Act) provides the legal mechanism to help ensure clean, healthy, safe, productive and biologically diverse oceans and seas by putting in place new systems for improved management and protection of the marine and coastal environment. Of particular interest in the context of this EIA, is that the Act has superseded the two existing Acts which set the framework for the current marine licensing system (i.e. the Food and Environment Protection Act 1985 (FEPA) and the Coast Protection Act 1949).

iii. Food and Environment Protection Act / Marine and Coastal Access Act

17.2.10 FEPA licences both permit construction within the marine environment and the deposition of materials at sea following an assessment of whether the specific activities are likely to cause harm to the food chain, thus impacting on human and environmental health. FEPA licences have recently been replaced by Marine Licences under the Marine and Coastal Access Act. However the requirements of the licensing process in terms of sampling and environmental assessment have not changed significantly. The dredging and construction activities (below MHWS) that are proposed as part of the HPC Project will require Marine Licences. Assessment of the contaminant status of offshore silts is presented as part of the Marine Water and Sediment Chapter in **Volume 2**, **Chapter 18**.

d) National Policy

17.2.11 There are no national policies relevant to the proposals for the HPC development in terms of effects on the local hydrodynamic regime or geomorphological processes. Coastal change, however, is covered in the supplement to Planning Policy Statement 25: Development and Coastal Change (which largely replaces PPG20).

e) Regional Policy

17.2.12 Within England and Wales flood and coastal defence proposals that affect the intertidal zone are regulated by the Environment Agency in accordance with Shoreline Management Plans. Further regulatory influence is also extended to Natural England and CCW as statutory consultees, particularly where development proposals concern designated European Marine Sites.

17.2.13 A Shoreline Management Plan (SMP) is a large-scale assessment of the risks associated with coastal processes which sets out measures to reduce these risks to people and the developed, historic and natural environments. The second generation of SMP is currently being developed by the North Devon and Somerset Coastal Advisory Group. An Issues and Objectives document has recently been produced.

17.2.14 The draft North Devon & Somerset SMP (www.ndascag.org/ of October 2010, marked on that site as 'final') divides the coastline into eight sections. Hinkley Point features in two of these sections: 'Minehead to Hinkley Point' and 'Hinkley Point to Brean Down'. The section of the coast along the length of the application site is identified as having nationally important geological features, where the SMP objective is to avoid adverse impacts. A key objective of the SMP document is to ensure critical services remain operational at the Hinkley Point Power Station Complex.

17.2.15 Part 5 of the SMP report, published as 'final' in October 2010, (www.ndascag.org/) describes the policies that have been established for the site and its neighbouring frontages.

17.2.16 For 'Lilstock to Hinkley Point', policy unit 7d30, being the frontage to the West of the proposed Hinkley Point C site (taken, within the SMP, as having its Eastern boundary at Benhole Point), the policy is 'to allow the natural coastal evolution to continue' in the short, medium and longer terms.

17.2.17 For 'Hinkley Point', policy unit 7d31, being the frontage of the existing Hinkley Point A and Hinkley Point B sites, and the proposed Hinkley Point C site frontage as far as Benhole Point to the West, the short and medium term policies are to 'hold the line', with this policy being applied for the longer term if the Hinkley Point power station site is extended, as proposed here.

17.2.18 For 'Hinkley Point to Stolford', policy units 7d32 and 7d33, being immediately to the east of the Hinkley Point power stations, the short term policy is to 'hold the line', the medium term policy is 'managed realignment', and the longer term policy is 'hold the line at the set back defences'.

f) Local Policy

17.2.19 There are no local policies relevant to the proposals for the construction and maintenance of works and structures in terms of effects on the local hydrodynamic regime or geomorphological processes.

17.3 Assessment Methodology

a) Study Area

17.3.1 The geographical extent of the area of interest for this assessment is dependent upon an understanding of the highly dynamic physical processes that govern the form, function and ecology of the Severn Estuary and Bristol Channel and the potential reach of effects, particularly those associated with thermal plume dynamics. Due to the extreme tidal regime, tidal excursions local to the Hinkley Point site are substantial and, as a result, the area within which dedicated surveys were completed extended across the local sea area from Watchet in the West to Brean Down in the North, including the whole of Bridgwater Bay and the lower Parrett Estuary and associated shores. Where information was necessary to secure a baseline or boundary condition beyond the immediate bounds of that area, this was also obtained.

b) Assessment Methodology

17.3.2 As noted in 17.1 above, the methods adopted in this chapter to understand and assess changes to coastal processes inevitably differ from those adopted for other chapters of this ES. That is, while the development of HPC may alter hydrodynamic and sedimentary processes, the significance of such a change or effect in terms of its impact cannot be readily measured (i.e. they are not considered to be a receptor sensitive to change). Hence, while a change to a process can be predicted and described with respect to the known baseline, it is not appropriate to predict the significance of an impact on the process (see Ref. 17.55). For example, a local change in current speed that may result from the construction of a solid structure in the path of a current can be described with reference to known current speed in the affected area and the nature and magnitude of this 'change' determined in relation to natural variability. However, in the context of the process an 'impact' will not have arisen, (for example, an estuarine current is not a receptor).

17.3.3 The commentary in this chapter therefore focuses on describing the potential magnitude of change in process variables rather than on defining an impact. This magnitude of change, or the extent to which the natural variables of the process are affected, is classified as high, medium, low or negligible and justification is provided in Sections 17.8 and 17.9. Potential impacts on marine resources caused by changes in hydrodynamic and sedimentary processes are described in **Volume 2**, **Chapter 19** (Marine Ecology) of this ES.

c) Limitations, Constraints and Assumptions

17.3.4 Due to the extremely large (hypertidal) tidal range and tidal currents off Hinkley Point, the local subtidal and intertidal sedimentary environment is highly dynamic. As a result the marine surface sediments are kept in a state of almost constant flux.

17.3.5 Many years of study of this particularly dynamic environment have permitted the development of a high level of consensus on its key features. A reflection of this understanding, directly pertinent to the topics covered within this chapter as well as those on marine ecology and marine water quality and the design and operation of the engineering plant itself, is provided below.

17.4 Baseline Assessment

17.4.1 A wide range of studies have been undertaken in order to better understand the coastal processes operating in the Bristol Channel and Severn Estuary. Much of this work was carried out in the 1970s and 1980s and, although there has been relatively little field based data collection and re-interpretation of this data undertaken since then, much of this earlier work remains of direct relevance to the current proposed development.

17.4.2 Much of that historical effort is summarised and reviewed for this application within the Hinkley Point Physical Science Report (Ref. 17.1). The material presented in this chapter is based both upon that Physical Science Report and a number of other relevant sources, referenced where appropriate.

17.4.3 The published studies have been supplemented by specifically commissioned marine surveys undertaken in support of this particular development application as a component of the British EDF Estuarine & Marine Studies project (BEEMS). Extensive measurements of bathymetry, sediment type and distribution, waves, tidal currents and suspended sediment concentrations have been taken and, where pertinent, continue. The results of these surveys are described in the references listed below. On the basis of these findings a series of numerical hydrodynamic models have been developed and validated. Outputs from that modelling effort are summarised in **Volume 2**, **Chapters 18** and **19** and supporting appendices.

17.4.4 The following studies and assessments were carried out as part of the BEEMS program and are referred to within this chapter:

- wide field bathymetry and habitat mapping via sidescan and swath sonar and associated ground truthing (Ref. 17.2);
- expert assessments of potential scour around proposed structures (Ref. 17.3);
- a range of surveys (Ref. 17.15) to monitor oceanographic processes (including tidal excursion; current flows and spatial variation; wave measurements; turbidity; water quality and meteorological conditions) was undertaken between August and October 2008 covering four Spring-Neap cycles; see **Figure 17.1**. The work used both mobile and fixed instrumentation. The sampling sites included three subtidal moorings (H1, H5 and H6), three intertidal moorings (H2, H3 and H4), three Acoustic Doppler Current Profile (ADCP) sections (A, B and C), a short ADCP anchor station at H1, and the deployment of a series of drogues and a thermal-plume monitoring survey (the locations are shown in **Figure 17.2**) designed to calibrate the numerical hydrodynamic models described in **Volume 2**, **Chapters 18** and **19** and allied appendices:
- additional seabed instrument deployments (Ref. 17.4);
- additional sea surface instrument deployments (Ref. 17.5);
- expert workshops on potential future geomorphological scenarios (Ref. 17.6);
- mineralogy assessment (Ref. 17.7);
- analyses of oceanographic extremes (Ref. 17.8); and
- analyses of coastal extremes (Ref. 17.9).

17.4.5 In addition, a series of engineering design studies have been carried out in association with the HPC development proposal that are relevant to this chapter:

- rate of infill study for temporary jetty berthing pocket (Ref. 17.10);
- sea wall design report (Ref. 17.11);
- jetty design report (Ref. 17.12); and
- cooling water intake and outfall design (Ref. 17.13).

17.5 Baseline Environmental Characteristics

a) Setting

17.5.1 For the purpose of descriptions in both this chapter and **Chapters 18** and **19**, the Hinkley Point site is located on a rocky section (**Figure 17.8**) of the southern shore of the Inner Bristol Channel, and marks the western limit of Bridgwater Bay, itself bound to the north and east by the promontory of Brean Down. Within Bridgwater Bay, a substantial intertidal area is split into two parts by the estuarine channel of the River Parrett, with Stert Flats and the outer Gore Sands to the south and Berrow Flats to the north. The Inner Bristol Channel extends from a line between Hurlestone Point (west of Minehead, Somerset) and Nash Point (Glamorgan) to the west, and Brean Down (Somerset) and Lavernock Point (Glamorgan) to the east, upstream of which lies the Severn estuary. The Bristol Channel as a whole is taken to extend as far seaward as a line running approximately between Hartland Point on the Cornish coast and Old Castle Head on the Pembrokeshire coast.

b) Key Features

17.5.2 A consideration of the key features of the physical environment is directly relevant to both the design of engineering plant and its management within a dynamic environment.

17.5.3 A current understanding of the key physical features of the Inner Bristol Channel and Severn Estuary (after Ref. 17.14) is summarised in **Table 17.1**.

17.5.4 The bathymetry and dynamics of the Inner Bristol Channel and the immediately associated Severn Estuary make it unique in the UK. It is a highly turbid system although much of the seabed itself is bare of soft sediment. There appears to be no modern source of sand and gravel within the system (Ref. 17.34) and small grain fractions of sediment are constantly reworked in suspension. What sediment there is on the seabed is strongly affected by the Spring/Neap cycle and it is highly mobile. Where subtidal sediment is found, its depth and composition will change significantly over time.

17.5.5 The vast majority of the seabed in the Inner Bristol Channel and Severn Estuary system is rock or coarse gravel; there is relatively little sand and most (though not all) of the mud is in suspension or is intermittently mobilised. The sediments are not related to the hypertidal (i.e. > 6 m tidal range) nature of the system, but rather to the geological and indeed comparatively recent industrial history. The suspended material off Hinkley Point contains a very high proportion of coal and slag-derived particulates (see Ref. 17.7).

Table 17.1: Key Physical Features of the Bristol Channel and Severn Estuary, derived from Reference 17.14

Key Physical Features	Comment
Large funnel shaped Estuary facing the Atlantic	Influences physical features, particularly tidal regime.
Large branching Estuary	The sub-estuaries within the Bristol Channel and Severn Estuary absorb energy at tidal frequencies, but input energy at longer frequencies because of river flow variation. The Parrett, Usk and other sub-estuaries are not insignificant regarding freshwater influx into the system.
High salinity variation	There is a high salinity variation as a result of the seasonal and tidal variation. The discharge from the Parrett significantly adds to this variation in the Hinkley Point area.
Estuary controlled by geological constriction	The geological constriction in the area of the Holm Islands, between Cardiff and Brean Down (constraining the Estuary in terms of both width and depth) is the key large scale physical feature. To landwards, the waters of the Severn Estuary are generally vertically mixed (in terms of salinity). To seawards, the waters of the Inner Bristol Channel are less uniform and may at times be density (by salinity) stratified. The constriction also acts to divide different suites of physical sedimentary processes, regarding waves, currents and sediment transport.

Key Physical Features	Comment
Hypertidal	This area experiences one of the highest tidal ranges in the world and is classified as hypertidal, being > 6 m. The range at Hinkley Point, between mean high and low water Spring tides, is 10.7m. This regime has direct consequences for physical sedimentary processes and sediment transport.
Periodic energy inputs	Spring to Neap changes are very large, with Spring tides having a mean value of 10.7m and Neaps 4.8m, resulting in a system with a major component of fortnightly change (as well as other tidal periods). Long periods of low winds reduce the suspended solids concentrations, at least in surface waters. The sedimentary system is thus periodic, directly impacting upon the light regime (hence production), the benthic habitats and the benthos.
Waves dominant in shallow water	In shallow areas, waves are dominant over the effects of tidal currents. Most important in the Hinkley Point area are the intertidal and shallow 'flats' where it is waves that are mostly responsible in terms of mobilising and/or changing the physical environment and thus affecting the biota.
Surprisingly sediment starved	The vast majority of the seabed in the Bristol Channel and Severn Estuary system is rock or coarse gravel; there is relatively little sand, and most (though not all) of the mud is in suspension or is intermittently mobilised.
Not in morphological equilibrium	For the Severn Estuary and Bristol Channel, the geological constriction at the Holm Islands means that the Estuary is compartmentalised.
No new significant sources of sediment	The limited supply of 'new' sediments makes the Severn Estuary and Inner Bristol Channel susceptible to change, e.g. from developments such as the Bristol Port and the various proposed tidal power schemes. Because of the preponderance of hard surfaces on the seabed, and the relatively thin nature of sands and muds where present, a small change in the sedimentary regime might cause major changes in the nature of the seabed habitats – i.e. significant change can happen relatively easily.
Physics makes change in subtidal habitats the norm, not the exception	Changes to the sediment transport system have the potential to induce major changes in habitat. Changes in sediment distribution (natural and man made) are likely and these will affect habitats.
Highly turbid environment (unique in UK)	High concentrations of sediment are present within the water column (in both permanent and temporary suspension and is intermittently deposited) but there is relatively little contribution from the rivers or from the outer Bristol Channel.
Entrance to the Parrett – mobile banks	The mouth of the Parrett has a variety of intertidal and subtidal banks, which consist of layered sediments and are extremely mobile; as such they tend to have low density biota.
Influence of existing Parrett plume on the intertidal area	Existing freshwater runoff peaks are significant in that they affect the extent of the plume across Bridgwater Bay.
Periodic major changes in bed elevation	Erosion/deposition cycles occur naturally and periodically, especially in outer Bridgwater Bay.
Coastline and seabed near the Parrett susceptible to change	The Steart Flats peninsula is susceptible to breaching in the longer term (century scale), and breaching would significantly affect cooling water flows across the (greatly changed) intertidal habitats.

Key Physical Features	Comment
Residual circulation	Tidal averaging of flows shows strong outward residual flow from Flat Holm to the south side of the Channel off Kilve. Recirculation cells occur to north and south. This could both trap persistent contaminants or effluent, and provides routes for fish migration. Crudely summarised as: 'fish in north, out south'. This feature persists to Holm Island. Given the small magnitude of any residual circulation compared to the regular tidal flows the significance of this feature is uncertain.

c) Hydrodynamic Regime

i. Tides

17.5.6 **Table 17.2** illustrates the tidal levels currently associated with the Hinkley Point site (from Ref. 17.9) on the basis of UK National Tidal Sea Level Facility (NTSLF) predictions for the 2008-2026 period and their field observations from the Hinkley Point tide gauge (part of the UK Tide Gauge Network managed by the National Oceanographic Centre) for the period 1990-2008. This shows that the Mean High Water Spring and Mean Low Water Spring elevations at Hinkley Point are 5.64m Ordnance Datum Newlyn (ODN) and -5.10m ODN, respectively. The mean Spring tide range is therefore 10.74m. The highest tidal elevation recorded over the period 1993-2008 by the Proudman tide gauge at Hinkley was 7.36m ODN (see Ref. 17.9) (ODN, frequently abbreviated to 'OD', with 'AOD' meaning 'above Ordnance Datum', is the vertical reference level in national use across the UK against which land based mapping is set). This particular level of 7.36m represented an instance of Highest Astronomical Tide combined with a surge.

Table 17.2: NTSLF Predicted Tidal Levels to ODN at Hinkley Point from Reference 17.9

Tidal Condition or Range		Elevation Relative to Ordnance Datum Newlyn (m)
Lowest Astronomical Tide	LAT	-6.10
Mean Low Water Springs	MLWS	-5.10
Mean Low Water Neaps	MLWN	-2.30
Mean Sea Level	MSL	0.10
Mean High Water Neaps	MHWN	2.50
Mean High Water Springs	MHWS	5.64
Highest Astronomical Tide	HAT	7.12
Mean Spring Tidal Range	MSTR	10.74
Mean Neap Tidal Range	MNTR	4.80

***Note**: Local Chart Datum (CD) is -5.9m ODN*

17.5.7 Tidal currents in the Inner Bristol Channel and Severn Estuary flow from west to east on the flood tide and east to west on the ebb tide. Maximum tidal current velocities increase upstream, from approximately 0.7m.s^{-1} at Lundy to 2.4m.s^{-1} off Avonmouth. Data from two Admiralty tidal diamonds, one 6km north of Watchet and the other between Steep Holm and Brean Down, show that peak ebb current velocities are slightly higher than flood velocities (**Table 17.3**); a typical range of tidal variation over Spring/Neap cycles is shown in **Figure 17.1**.

Table 17.3: Peak Ebb and Current Velocities at two Locations in the Bristol Channel (from Admiralty Chart: Bristol Channel: Nash Point to Sand Point)

	6 km North of Watchet		Between Steep Holm and Brean Down	
	Neaps ($m.s^{-1}$)	Springs ($m.s^{-1}$)	Neaps ($m.s^{-1}$)	Springs ($m.s^{-1}$)
Flood	0.75	1.45	0.85	1.6
Ebb	0.80	1.5	0.80	1.5

17.5.8 The marine surveys undertaken to gather site-specific tidal current data (**Figure 17.2**) are described in Ref. 17.4 and 17.15. The data arising from these studies show that tidal currents flow approximately parallel with the shoreline. In the subtidal zone adjacent to Hinkley Point, current velocities reached a maximum of $1.5m.s^{-1}$ on Spring tides and $1.0m.s^{-1}$ on Neap tides. Further offshore, the maximum velocities increased to $1.7m.s^{-1}$ on Spring tides and $1.4m.s^{-1}$ on Neap tides. At Gore Buoy, where a 'Waverider' buoy was established for long term use (see 17.5.12), peak surface velocities were approximately $2.0m.s^{-1}$. At all locations the ebb currents were faster than the flood currents. Typical currents at the intertidal zone moorings were approximately 1.0m/s on Spring tides, but did reach a maximum of $1.3m.s^{-1}$ during a strong wind event.

ii. Wind and Wave Climate

17.5.9 Due to its geographical location, winds at Hinkley Point are dominated by those arriving from the west-north-west (**Figure 17.3**). These wind directions occur around one third of the time and there is an effective fetch (the extent of open water) for wave generation of 400km. 50% of the winds of force 5 and above come from this direction (Ref. 17.17). Winds from the north-west to north-east occur for around 10% of the time; the fetch in this direction is 23km. Winds are least frequent and are weakest from the north-east to south sector, where fetch is also minimal. In combination with the regional bathymetry and coastal configuration, the result is that Hinkley Point is mostly subjected to waves from the west-north-west. The shoaling effects of the near-shore bathymetry are highly significant in determining the actual wave field experienced on the Hinkley Point frontage.

17.5.10 Reference 17.18 describes a significant swell component within the wave climate of the Bristol Channel, dominated by the open fetch to the North Atlantic. Wave energy is focused at headlands, although the offshore banks do dissipate energy.

17.5.11 Waves are understood to play a significant role in sediment transport at the coast itself (Ref. 17.18). As noted above, tidal circulation within the Bristol Channel is complex but is considered to be ebb-dominant with large volumes of sand and mud being transported westward in the Channel's centre. Conversely, the dominant waves from the west and south-west are held to drive the littoral drift, predominantly eastward, and flood-dominant sediment transport occurs for limited periods throughout the year along the coastal fringe.

17.5.12 Additional wave data was obtained between December 2008 and July 2009 (over a period of 225 days) using the Waverider at Gore Buoy, offshore and north-west of Hinkley Point in about 10m of water (Ref. 17.5). The data collected from the Waverider show that the dominant wave approach was from the west to north-west with less frequent waves from the west. Significant wave heights (the mean height of the highest third of waves) were mostly less than 1m, but did reach over 2m at times, with a peak of 2.3m recorded in early March. The highest energy waves with periods greater than five seconds approached from the west-north-west with less frequent shorter period waves from the west. **Figure 17.3** summarises the wind direction, speed and frequency and **Figure 17.4** the analogous wave distribution in terms of wave height and **Figure 17.5** in terms of wave period.

iii. Extreme Water Levels

17.5.13 The astronomical tidal elevations can be raised significantly by interaction with surge events influenced by global weather systems. Positive surges, causing higher tidal elevations in the Bristol Channel, are associated with low pressure systems crossing the Atlantic and approaching from the west. Small surges are frequent (Ref. 17.19), with positive surges of about 1m occurring every one to two years, and those of 2m or more occurring on a decadal time scale (Ref. 17.20). There is also a potential response to meteorological forcing at frequencies similar to the tide, resulting in intense surges which are generated and then decay during a single semi-diurnal tidal cycle.

17.5.14 The baseline extreme water levels and storm surge profile used in the **Flood Risk Assessment** that accompanies this ES have been taken from the recently published Environment Agency study into extreme water levels which covered the whole UK, including Hinkley Point (Ref. 17.60).

17.5.15 The Environment Agency data includes extreme water levels at 2km chainages/nodes along the coastline. Node location 326 is located directly offshore of HPC. Node location 328 is located offshore of Stolford. Therefore, different baseline extreme water levels are applicable dependent upon the area being considered.

17.5.16 The Environment Agency extreme water levels were published in 2011, subsequent to EDF Energy's Stage 2 consultation on the HPC Project proposals, and subsequent to several flood related studies commissioned by EDF Energy to demonstrate the nuclear safety case, including a physical modelling study for the new sea wall. The nuclear safety case studies are based upon a HR Wallingford study into the joint probability of extreme water levels and wave heights, which was commissioned by EDF Energy specifically for the HPC development (Ref.17.61). This study provided lower, best and upper estimates for extreme still water levels relative to Ordnance Datum for 2080 using Defra 2006 climate change allowances (although the nuclear safety case will rely upon the HR Wallingford extreme water levels with UKCP09 allowances as opposed to the Defra allowances). The HR Wallingford Study did not provide values for the 100%, 5% and 0.5% Annual Exceedance Probability (AEP – the chance of an event of given size occurring in any one year) events, as these were not required for the nuclear safety case studies.

17.5.17 Comparison of the Environment Agency and HR Wallingford extreme water levels for 2008 (which were back calculated using the Defra 2006 climate change allowances) is provided in **Table 17.4**. The datasets are generally comparable, with the Environment Agency levels generally lying between the HR Wallingford 'best' and 'upper' estimates. The use of the HR Wallingford upper estimates is considered appropriate to provide the precautionary approach required to demonstrate the nuclear safety case. However, following discussions with the Environment Agency, the modelling carried out specifically for the **Flood Risk Assessment** has used the latest Environment Agency extreme levels.

17.5.18 The predicted pattern of waves modelled (seasonal mean and extreme waves etc.) around the UK is one of high variability, although there is a suggestion of a slight decrease in the Bristol Channel area. Observations in the north-east Atlantic and south-west approaches show considerable variability on a decadal timescale (Ref. 17.9).

Table 17.4: Comparison of baseline (2008) extreme still water levels for the Bristol Channel at HPC and Stolford (m AOD)

AEP Event	HR Wallingford (at HPC) (m AOD)			Environment Agency (m AOD)	
	Lower Estimate	Best Estimate	Upper Estimate	HPC (Node 326)	Stolford (Node 328)
100	-	-	-	7.10	7.14
5				7.31	7.35
2	7.55	7.61	7.67	7.64	7.68
1	7.69	7.76	7.83	7.74	7.78
0.5	-	-	-	7.84	7.89
0.2	7.889	7.98	8.07	7.98	8.03
0.1	7.98	8.09	8.20	8.09	8.14
0.01	8.26	8.44	8.62	8.45	8.52

17.5.19 Reference 17.9 has calculated return water levels for 2100 based on estimated joint probability of predicted astronomical tides, observed storm surges at Hinkley Point over 1990 to 2008 and waves recorded off Hinkley Point in 2008 to 2009 – see **Table 17.5**.

Table 17.5: Estimation of Return Periods of Extremely High Water Levels (in m ODN) at Hinkley Point, using Joint Probability Analysis of Predicted Tides, Surges and Waves in the Year 2100, after Reference 17.9

Return Period (years)	Joint Probabilities of Tides and Surges Predicted for 2100			Probabilities of Tides, Surges and Waves Predicted for 2100		
	Predicted tides + surge residuals	Predicted tides + skew surges	Predicted tides + surges at high water	Predicted tides + surge residuals + waves	Predicted tides + skew surges + waves	Predicted tides + surges at high water + waves
1	8.12	8.10	8.10	8.52	8.51	8.51
2	8.22	8.19	8.19	8.65	8.63	8.63
5	8.37	8.30	8.31	8.82	8.79	8.79
10	8.49	8.40	8.41	8.95	8.91	8.91
20	8.63	8.51	8.53	9.08	9.02	9.03
50	8.82	8.69	8.71	9.26	9.18	9.19
100	8.98	8.83	8.85	9.40	9.29	9.30

	Joint Probabilities of Tides and Surges Predicted for 2100			Probabilities of Tides, Surges and Waves Predicted for 2100		
200	9.16	8.98	8.99	9.54	9.41	9.42
500	9.38	9.16	9.16	9.74	9.56	9.57
1000	9.53	9.27	9.27	9.90	9.67	9.68
5000	9.84	9.46	9.46	10.12	9.92	9.93
10000	9.94	9.53	9.53	10.34	10.02	10.03
100000	10.18	9.65	9.65	10.70	10.35	10.35

17.5.20 A number of increases are assumed in the calculations, e.g. high water increase, skew surge increase (the difference between the elevation of the projected astronomical high tide and the nearest (in time) simulated high water), and significant wave height increase. The results of this study are illustrative only, but indicate that by 2100 a 1:10,000 year event combination of high water levels, surge and waves could produce resultant water levels marginally in excess of 12m ODN. This level may be compared to the proposed sea wall crest height of 13.5m ODN and development platform height of 14m ODN, as seen in **Figures 17.6** and **17.7**.

17.5.21 Occurrences of extreme water levels associated with the coincidence of high tides, surges and even large waves are not necessarily of great importance from the viewpoint of coastal morphological change (erosion or accretion). Morphological changes, such as changing patterns of coastal erosion/accretion or changes in the pattern of estuarine banks and channels, are brought about by coastal processes over extended periods; seasonal storms will tend to have a predominant influence (Ref. 17.1).

17.5.22 The effect of storm waves on the shoreline during a single storm is dependent on the duration, as well as the elevation, of high water levels. The dissipation of wave energy at various levels across the intertidal and supra-tidal zones is strongly dependent on the time interval over which higher water levels are maintained (Ref. 17.9). In areas of very large tidal range, such as Bridgwater Bay, the wave energy is spread over a large vertical range during any single tide. An increase in average wave energy conditions, or the occurrence of several severe storm surge events within a short period of time, is likely to result in lowered foreshore levels. If sustained for a significant period of time, greater wave energy may be expected to enhance the break-up and erosion of the limestone intertidal platform which fronts the existing Hinkley Point power station and neighbouring cliffs; however, this is likely to be a progressive rather than a catastrophic process. These potential changes are as a result of predicted future change in coastal processes, they are not changes as a result of the power station development.

iv. Observed Sea-level Rise and Climate Change

17.5.23 Hinkley Point has a tide-gauge station operated by the Proudman Oceanographic Laboratory as part of a national network, and this particular gauge has recorded local levels at high resolution for the past 15 years. The data shows a rise of 4.65mm/yr for Mean High Water Spring over this time period (Ref. 17.22). This rate is considered likely to increase in the future due to climate change.

17.5.24 Relevant sources of historical data on the range of marine hazards that could potentially be influenced by climate change, together with the most recent advice available (e.g. Ref. 17.23, Ref. 17.24 and Ref. 17.25) and the 2009 outputs of the UK Climate Impacts Programme (UKCIP) (primarily Ref. 17.26 and Ref. 17.27) have been taken into account in considering the engineering design requirements for HPC. The detailed analysis is provided in the **Flood Risk Assessment** accompanying this ES.

17.5.25 **Figures 17.6** and **17.7** (after Ref. 17.9) provide a profile of the planned sea wall and platform level set against historical, current and potential future extremes in sea level, incorporating both surge and wave.

17.5.26 The sea wall has been designed to allow for adaptation in the future, if necessary, should future trends in climate change differ from those currently predicted. The potential means of adaptation include:

- the rock armour toe could be extended to protect against an increased period of beach lowering;
- the sea wall and return walls could be raised to accommodate potential increases in water level and wave height;
- further rock armour could be added to the east and west sea wall boundaries to protect against the effects of coastal erosion and to prevent outflanking of the structure; and
- the return walls could be extended further inland to protect against the effects of coastal erosion and outflanking.

17.5.27 As with the sea wall, the cooling water pumping stations have been designed based on a current understanding of climate change. In this instance, however, consideration of the relevant H++ scenarios (Ref. 17.26 and Ref. 17.27) has also been taken into account in that initial design.

17.5.28 Further information on sea level rise and climate change scenarios considered in relation to potential flood risk associated with the HPC development proposals are detailed within the Flood Risk Assessment (FRA) associated with this ES.

17.6 Sedimentary Processes and Geomorphology

a) Introduction

17.6.1 This section provides details on the existing geomorphology at HPC, present distribution of sediments and the nature of sedimentary processes operating in the Severn Estuary and Inner Bristol Channel. Consideration is also given to potential future geomorphological scenarios for the area and changes that might be expected in relation to the distribution and transport of sediments.

17.6.2 The importance of understanding and identifying potential geomorphological and sedimentary change has been highlighted by recent guidance on best practice from the Environment Agency (Ref. 17.28). That report notes that, given the long life-cycle of nuclear power stations, coastal processes in some dynamic locations could lead to shifts in bathymetry that have the potential to effect the cooling water supply. Some sedimentation can be dealt with by dredging, but the movement of offshore banks can cut off or limit flow around intake and outfall zones, which will reduce coastal water exchange. Understanding the potential for such coastal process and geomorphological change at the design stage for a nuclear power station is therefore of critical importance in order that the dynamics of these processes can be accommodated within the design philosophy and measures are implemented to monitor and manage the potential change.

17.6.3 Studies of sediment distribution and landforms can provide clear evidence for the nature and magnitude of some past environmental changes and trends, and thus give a robust basis for the development of clear indicators of possible future geomorphological scenarios. However, it is apparent that when dealing with a wide variety of physical oceanographic and sedimentary processes, significant uncertainty may exist in our knowledge and hence in the assessment process. For example, models of sediment transport simply do not exist at the levels of sophistication and reliability which will be required to sensibly predict the sedimentary future of the Inner Bristol Channel and Severn Estuary system. In dealing with this uncertainty, the role of expert opinion in reviewing available information and evidence is an essential approach to address areas of complexity and increase confidence in the conclusions reached.

17.6.4 The work described in this chapter has used the advice of an expert group to consider the potential future scenarios that this development might be subject to in the longer term. They reviewed and assessed available information and determined likely geomorphological and coastal process responses to the proposed development. This ‘future geoscenarios’ process and its detailed outcome is described in Reference 17.6.

b) Geological and Geomorphological Setting of the Inner Bristol Channel

17.6.5 Reference 17.29 describes the geology and superficial sediments of the Inner Bristol Channel and Severn Estuary. The area is floored by a gently folded and faulted succession of limestones, mudstones and siltstones. Over much of the western part of the area, bedrock is exposed at the seabed. In the Inner Bristol Channel this bedrock comprises gently folded interbedded limestones and shales.

17.6.6 Overlying the bedrock is a series of superficial sediment, divided by Reference 17.29 into: glacial till; post-glacial valley infill; thick recent accumulations and surface sediments. These sediments lie atop an incised valley drainage system, whose overall axial profile drops from -20 to -30m OD in the east to approximately -40m north of Minehead, in the extreme west. This system represents the net effect of drainage and erosion during the last glacial period combined with the erosive effects of postglacial marine inundation and estuarine erosion.

17.6.7 The post-glacial marine transgression associated with melting of the continental ice sheets and glaciers led to the sedimentary infilling of many areas around the valley margins, such as the Somerset Levels. Elsewhere, superficial sediments form a variety of sedimentary features, including mudflats, linear sand ridges, sand banks and sandwave fields, which partly overlie older valley infill or glacial till (Ref. 17.29).

17.6.8 Close to Hinkley Point, sedimentation is strongly influenced by that of Bridgwater Bay. The bay comprises an extensive area of coastal lowland bounded in the north by Brean Down and the south by Hinkley Point. On the coast south of Brean there are a set of coastal aeolian dunes overlying post-glacial estuarine deposits and freshwater peats, whilst between the estuary of the River Parrett and Hinkley Point, Holocene deposits are mainly overlain by storm shingle ridges which reach elevations of +6m OD, which are in turn backed by relict aeolian sand dunes near Steart (Ref. 17.30).

17.6.9 Reference 17.30 defines coastline changes as either small scale (over decades to centuries and one to two kilometres) or large scale (occurring over thousands of years and tens of kilometres). The large-scale changes have involved major inundations of the Somerset Levels during the early and late Holocene. The main factor to note is that this is a sedimentary system which has largely adapted to the past few thousand years of coastal change. Whilst it is not liable to undergo major changes, there is greater potential for small scale change, particularly in terms of the structure of and sedimentary processes in Bridgwater Bay.

17.6.10 Hinkley Point forms a natural boundary between two lengths of shoreline along which the behaviour of physical and sedimentary processes are essentially consistent and relatively independent from each other.

17.6.11 The shoreline to the west of Hinkley Point as far as Lilstock is characterised by a cliff fronted by a cross-shore rock platform (**Figure 17.8**). The cliffs are approximately 3m high immediately to the west of the existing power stations and rise up to 25m high at Lilstock, and are composed of friable limestones and shales interbedded with mudstones of the Blue Lias series (see **Volume 2**, **Chapter 14** of this ES for a detailed description of this geology). Fronting the cliffs is a shore platform, up to 500m wide, composed of limestones and shales dipping to the north, partially covered by a veneer of limestone and shale cobbles. A narrow storm beach is present at the junction between the platform and the cliff consisting of shingle derived from erosion of the cliffs and platform. Immediately offshore from the platform is a narrow discontinuous zone of subtidal sand and gravel, followed by large areas of mud that extend towards the centre of the Inner Bristol Channel.

17.6.12 To the east of Hinkley Point, the shoreline forms part of the outer Parrett Estuary and is characterised by post-glacial saltmarsh and mudflat deposits. These deposits have, historically, been largely reclaimed for agricultural purposes. At Stolford, this extensive reclaimed area is interrupted by a ridge of head deposits that project into the nearshore. East of Stolford, the shoreline comprises a complex series of shingle ridges with some sand dunes fronted by a narrow strip of saltmarsh. Offshore, the sediments comprise a wide expanse of intertidal mudflat (and some sandflat) up to 3 km wide extending into Bridgwater Bay. **Figure 17.9** illustrates the distribution of intertidal sediments around Hinkley Point (Refs. 17.58 and 17.59) and **Figure 17.10** the distribution of seabed sediments (Ref. 17.2).

17.6.13 Coastal erosion along the Hinkley frontage is predominantly of two types: cliff erosion (where no sea wall already exists) and shore platform down-cutting. Cliff erosion occurs largely by undercutting at the cliff base (a wave-cut notch may develop particularly where shale is exposed) followed by collapse of the overlying strata. In addition to wave undercutting, it is likely that the cliffs also fail due to excess groundwater pressures just behind their face as well as weathering by rain and frost for example. Based on measurements over a period of 30 months, Reference 17.17 shows that the rate of cliff recession was approximately 0.1 to 0.5 $m.yr^{-1}$. A longer-term recession rate, since 1888 (Ref. 17.21), for the cliff section along the proposed development site has been estimated as approximately 0.13 $m.yr^{-1}$. The rate of cliff erosion may increase in the future as a result of higher sea levels and enhanced wave attack linked to climate change.

17.6.14 Erosion of the Blue Lias shore platform is caused by subaerial weathering and marine erosion processes, including abrasion by tidally-driven sediments. Weathering of the platform takes place along planes of weakness, joints and bedding planes in the limestone and bedding planes in the shales. Marine processes, particularly mechanical wave erosion, leads to the detachment of cobble-sized blocks from the platform which are then scattered across the surface. During storms, some of these detached pieces are transported by waves to form a shingle beach at the base of the cliffs.

17.6.15 There is no information relating to the down wearing of the Blue Lias rock shore platform at Hinkley Point, however a study carried out (Ref. 17.32) on the Blue Lias platform on the Glamorgan Coast provides an analogous site with very similar environmental characteristics. Erosion measurements of the Blue Lias platform were carried out using laser scanning and mirco-erosion measurements (MEM). The laser scanner showed net erosion rates of approximately 0.04 $mm.yr^{-1}$ and the MEM showed swelling of the shore platform surface by, again, approximately 0.04 $mm.yr^{-1}$; however more recent studies have shown that measurements based on these techniques are difficult to extrapolate over large timescales. Evidence suggests that ‘joint-block removal’ will be the main method of platform development on this coastline caused by high magnitude low frequency events (Ref. 17.33). It is therefore not appropriate to extrapolate local micro-scales erosion rates to the whole platform. In the absence of site specific information, a conservative estimate of platform down wearing of 1.5m over the next 100 years is predicted based upon available evidence (Ref. 17.11).

c) Sediment Distribution – Bristol Channel and Hinkley

17.6.16 Due to the large tidal range and strong currents operating in the Bristol Channel and Severn Estuary the sedimentary regime is very dynamic. Deposits of fine sediments in the Bristol Channel are highly mobile and a large amount of mobile fine sediment (Ref. 17.34) is present in the system at any one time. Suspended sediment concentrations are relatively high and the process of bedload sediment erosion, transport and deposition is complex, with many areas subject to continual or periodic reworking. The majority of fine sediment in the Severn Estuary and Bristol Channel is material eroded originally from the surrounding catchments and supplied via rivers. The hard bedrock and coastal cliffs are not a major source of fine sediment (Ref. 17.35).

17.6.17 There is a large variation in the type and distribution of sediment within the Bristol Channel and along the Hinkley Point frontage. Exposed bedrock covers extensive sections of the bottom of the Bristol Channel, particularly across the central Bristol Channel (Refs. 17.36 and Ref. 17.37). The tidal velocity is an important factor influencing the distribution of seabed sediment and respective grain size within the Bristol Channel and large areas of the Bristol Channel are characterised by thin veneers of sand and gravel that are mobile on the bed.

17.6.18 Regionally, the seabed is dominated by mud with significant areas of mega-rippled sand at the Parrett Estuary confluence and around Gore Sand. Coarse sediment comprising gravel and cobble substrates occurs throughout the area, with the most extensive deposits to the north-west of the site, as illustrated in **Figure 17.10**. In some areas the underlying bedrock is close to the surface beneath the mud. Locally, the intertidal and subtidal areas are dominated by the bedrock shore platform. As demonstrated by high resolution sidescan and swathe, this platform is fronted offshore by narrow strips of gravel and mega-rippled sand (Ref. 17.2), followed further seaward by mud with sand (**Figure 17.10**).

17.6.19 Generally, sediments range from finer sediment in the east (around Bridgwater Bay) to coarser material in the west. The seabed sediments immediately offshore of Hinkley Point are muds (Ref. 17.36) and described in Reference 17.38 as a thin muddy veneer overlaying the bedrock.

17.6.20 The superficial sedimentary succession and spatial distribution of sediments in the sea area immediately off Hinkley Point is detailed in Reference 17.39, which draws upon a total of 50 vibrocores and a variety of geophysical and oceanographic techniques. The study found that most vibrocores penetrated through soft sediments to a stiff clay which lay immediately above the rockhead. In general, there was a thin topmost layer of about 10 cm thickness, consisting of a brown, very soft, silty clay (representing oxidised sediments changed over the last few tides), which was underlain by dark grey, very soft, silty clay. These soft sediments were underlain in many cores by a soft, medium grey, silty clay, which in turn was underlain by a thin, firm layer or layers of peat of about 10cm thickness at depths of 3-4 m. These organic layers finally graded into the stiff, bottom clay layer in which the vibrocores refused. Sand and gravels were also found at various levels throughout most of the cores, interpreted by as representing storm events (Ref 17.39).

17.6.21 Subsequent work used the presence and absence of radionuclides (e.g. ^{137}Cs) to investigate past changes in bed elevation offshore of Hinkley Point. At a location 1.4 km west-north-west of the existing Hinkley Point B (HPB) cooling water intake, Reference 17.17 interpreted vertical changes in radionuclides and past bathymetric survey data to indicate approximately 2 m of sediment accumulation since the 1950s.

17.6.22 More recent analysis has been undertaken on vibrocore data from Bridgwater Bay (Ref 17.30). Of particular relevance to HPC are the detailed results from cores taken in 2001 close to Hinkley Point (BWB11, approx 1 km NW and BWB15, 2.5 km NW of Hinkley Point respectively – see **Figure 17.11**). Based on the assumed introduction of the radionuclide ^{137}Cs into the system during atomic weapons testing in the 1950s, a maximum estimated net sediment accumulation rate of 4 mm.yr^{--1} was determined for the location at BWB11 and a maximum accumulation rate at BWB15 of 18 mm.yr^{-1}. For further details, see Reference 17.30.

17.6.23 Both on the basis of these studies and the side scan sonar survey data (Ref. 17.2), the area around the proposed cooling water intake and outfall locations may be described as one of sediment accumulation.

d) Sediment Distribution - Bridgwater Bay

17.6.24 To the east of Hinkley Point, Bridgwater Bay is characterised by a large (18 km^2) subtidal and intertidal expanse of muddy silts. The sublittoral substrate is described as highly mobile, nearly liquid mud with some areas of sand waves and isolated reefs of agglomerated *Sabellaria* worm tubes (Ref 17.40).

17.6.25 The sediment cover over the intertidal area of Bridgwater Bay is also mobile, both in terms of movements within the bay and changes to the height of these flats over short time scales (Ref. 17.41).

17.6.26 Over most of the Bristol Channel and Severn Estuary superficial sediments are a few metres thick, but in Bridgwater Bay, the present 'mud belt' (or patch) sediments (shown as 'mud' in **Figure 17.10**) are over 6m thick in places. These sediments are dark grey to black, soft, plastic, silty sandy muds with sand laminae (Ref. 17.29). The seaward extent of the mud belt is clearly defined on side-scan sonar records (Ref. 17.2), but thin mud drapes and mud pebbles are common outside this limit.

17.6.27 Based on extensive datasets from geophysical surveys, water column samples and bed samples, the authors of Reference 17.42 have proposed that the mud belt comprises three distinct regions of mobile and stationary suspensions, and of settled mud (see **Figure 17.12**). There is strong evidence supporting long term sediment accumulation in the western part of this 'mud patch' (Ref 17.30).

e) Sediment Transport

17.6.28 At a relatively simple level, it is considered that the distribution of sediment within the Bristol Channel correlates with maximum bed shear stress and that this explains the existence of fine sediment around the margins of the Bristol Channel and sand, gravel and rocky areas in axial regions.

17.6.29 There is no major modern source of sand fraction sediment (0.05-2.0mm) currently present for the Inner Bristol Channel and Severn Estuary (Ref. 17.34). Bedrock, subtidal rock and coastal cliffs are made of material that would not principally produce sand grade materials and supply from rivers is likely to be minimal given the various weirs along their length (Ref. 17.43). The most mobile sediments present are generally fine sands and muds.

17.6.30 A wide range of sandy bedforms can be found in the subtidal off Bridgwater Bay, e.g. megaripples, sand waves and sand ribbons (Ref. 17.2). The distribution of these bedforms is highly variable and studies of these features have been used to aid understanding of this complex sediment transport system.

17.6.31 Many studies have described an apparent net eastward (up-Estuary) movement of sand from an approximate line between Bridgwater Bay and Barry, and a net westward (seaward) movement to the west of this line. The presence of this 'sediment transport divide' is based upon various observations of sediment distributions, movements, bedforms and grain size studies (e.g. see **Figure 17.13**) together with 1-D tidal modelling. The sediments that are transported eastwards are thought to accumulate within the Severn Estuary, on the Cardiff Grounds and Middle Grounds for example. Sediments that are swept westwards are transported into the Outer Bristol Channel. This model of sand transport may be an oversimplification of the situation, and study of the bedforms in particular indicates local transport pathways and upstream coastal sand transport (flood dominated), contrasting with downstream mid-Channel movement (ebb dominated) (Refs. 17.44 and 17.45).

17.6.32 Interpretation of the available wave data indicates that in the region offshore of Hinkley Point, waves will tend to enhance the tidally-driven transport by increasing bed shear stresses (Ref. 17.1). Waves are thus likely to enhance the magnitude of transport rather than greatly influence its direction. In contrast, at the coast, waves are likely to drive and dominate sediment transport to the east. On the intertidal platform this will enhance along-shore transport of any packets of sand arriving from the west, and also of gravel, pebbles and cobbles (which tend to be generated on the platform itself and at the cliff face) during storm events. The short period, height and occurrence of waves from the north north-east would not appear to provide a significant mechanism to move cobble and pebbles to the west along the shoreline.

17.6.33 A pattern has been suggested (Ref. 17.16) of periodic (spring tides) and episodic (storms) erosion of material from the intertidal flats and its transport seawards as pulses of fluid mud, along the seabed seaward of the wave-cut platform, to accumulate there temporarily, especially at neap tides.

17.6.34 Large sand deposits occur outside the mouth of the River Parrett and along Gore Sand (Refs. 17.1 and 17.2). Many small gravelly-sand patches are located across the Bristol Channel, which includes the Culver Sand, a 'wake feature' created in the lee of the island of Steep Holm (Ref. 17.37). Culver Sand is a mobile sandbank (overlying rocky seabed) and is steadily moving westwards, as shown from historic charts. It is considered highly unlikely that Culver Sand will migrate inshore and pose a significant risk to the proposed intake structures as the evidence indicates that Culver Sand is migrating away from the proposed intake location, and is likely to continue to do so (Ref. 17.38).

17.6.35 The distribution of sediments within Bridgwater Bay is influenced by the presence of the River Parrett. The channel of the River Parrett turns to an east-west orientation below the low water mark and meets the Bridgwater Bar offshore of Hinkley Point. This low water channel bisects the pattern of muddy sediments within Bridgwater Bay and the low water channel exhibits an area of sand, which overlays the mudflats.

f) Suspended Sediments

17.6.36 The dynamic processes operating in the Bristol Channel and Severn Estuary, in particular the strong tidal currents, lead to erosion of intertidal and shallow subtidal deposits and active re-suspension of muddy seabed sediments. The suspended sediment levels in the Inner Bristol Channel can be exceptionally high. A field campaign, recorded suspended sediment concentrations in the Inner Bristol Channel within the range of less than 100 $mg.l^{-1}$ to approaching 200,000 $mg.l^{-1}$ (fluid mud) (Ref 17.38).

17.6.37 The Institute of Ocean Sciences (IOS) undertook five years of vertical sediment profiling covering an area between Watchet and The Shoots. This data was built up into representative Spring and Neap tide distributions of suspended concentration and is presented in Reference 17.43, Reference 17.46 and Reference 17.47. A summary plot of the survey results for observed average suspended concentrations from Reference 17.47 is shown in **Figure 17.14** and illustrates the strong variation in surface to bed values for Spring and Neap tides.

17.6.38 The greatest suspended sediment concentrations found during the marine water quality sampling campaigns (see **Volume 2**, **Chapter 18**) were recorded close to the seabed, which is consistent with data recorded from previous studies, and is what one would expect. Turbidity measurements at the three subtidal stations (H1, H5 and H6 – see **Figure 17.2**) recorded suspended sediment concentrations in excess of 1 $g.l^{-1}$ on both flood and ebb Spring tides (Ref. 17.15). Suspended sediment concentrations are strongly linked to tidal current velocity (**Figure 17.15**).

17.6.39 Studies, supported by remote sensing, have recorded a contrast in suspended sediment concentrations indicating the presence of a sediment front running down the centre of the Inner Bristol Channel, with the highest concentrations occurring on the English side and clearer water on the Welsh side of the Channel (Ref. 17.48). To the south of that front the main control on suspended sediment concentration is tidal velocity, levels of suspended sediments being greater on the flood than the ebb, greater during Spring tides when compared to Neaps and generally proportional to tidal range.

17.6.40 The bedrock and coastal cliffs are not likely to be a major source of fine sediment. Regionally, suspended sediment concentrations are highest between Avonmouth and Bridgwater Bay, including the waters fronting Hinkley Point (Ref. 17.49). A mineralogical analysis of suspended material collected off Hinkley Point (Ref. 17.7) found that 57% of particles within the modal size of the >63 µm fraction of 152.2 µm were composed either of coal or heavy iron-rich minerals, probably industrial slag remnants. The remainder of material was predominantly made up of quartz grains.

g) Longshore Sediment Transport

17.6.41 Reference 17.21 defines a series of coastal units around Hinkley Point, and notes historic evidence for and magnitudes of coastal change. Halcrow's 'Unit 4' covers the frontage of the proposed development site, where evidence indicates that the interbedded limestones and shales of the Blue Lias cliff top has retreated at around 0.13 $m.yr^{-1}$ since 1888. Material arising from this retreating frontage and from the rocky intertidal shore itself will be moved by wind, wave and tide driven processes and as the dominant waves pattern suggests a trend of transport to the east, the geomorphological characteristics of the shoreline to the east of Hinkley Point are discussed in more detail here.

17.6.42 Studies of the pebble ridges between Stolford and Steart (which, with Environment Agency management, form the primary beach defence along that particular area of shore) have been undertaken (Refs. 17.50, 17.51 and 17.17). These are the Catsford, County Wall and Wall Common complexes comprising modern active ridges seaward of older 'fossil' ridges. The coast at Hinkley Point forms part of an intertidal pebble and cobble transport pathway to the east which supplies these features. This transport system is most active in the upper intertidal zone, around the Mean High Water Mark and above. The pebble ridges were perhaps emplaced at the same time as the dune belt at Brean, around 3-4 thousand years ago (Ref. 17.1). The planform morphology, mapped location and mineralogy of these shingle ridges indicate long-term migration to the east, possibly accompanied by a temporal change in the sediment source.

17.6.43 Reference 17.52 provides evidence for the West-East transport pathway: "The overall pebble size in the complexes decreases from west to east, although all sizes are present throughout the length. In the west a half of all large material and most of the total is limestone, with other lithologies only in the smallest shingle. At the extreme eastern end only 10-20% limestone remains, the 80-90% fraction of Fenning Island gravel (near Stert Point) being ORS [Old Red Sandstone] sandstone pebbles.[Reference 17.50 attributes this longshore gradation in lithology to destruction of the limestone along the transport path. He notes that older ridges inshore have a much greater abundance of sandstone pebbles than their offshore equivalents and attributes this to source variations with time. Possibly the Lias

Limestone bedrock has only recently become exposed following erosion of the intertidal sand and later underlying mud deposits?"

17.6.44 Reference 17.52 also notes that: *"It is clear that little new material currently reaches the shingle complexes from the west".* This is supported by a study involving the injection and tracking of shingle across a number of intertidal transects for three or six months over the winter period, including one gale which included gusts of gale Force 10 (48 knots). This work, reported in Reference 17.17, led these authors to conclude that shingle does not leave the spit in front of Catsford Common *"in significant quantities"*. They thus stated that the Wall Common Complex and areas to the east may therefore be *"considered as isolated from any influence on littoral drift by the power station"*. They also stated that: *"The power station is not acting as a barrier to the transport of the pebbles and cobbles around the Hinkley Point itself"*.

17.6.45 Long term erosion on the intertidal mud flats is indicated by the exposure of peat beds (e.g. on the upper intertidal of Wall Common) and 'submerged forests', (e.g. immediately to the east of Hinkley Point). A transect line at Catsford Common (east of Hinkley Point and Stolford), surveyed across a 20 year period, revealed a loss of sediment at all levels, with the beach crest having retreated some 12 m and the upper intertidal area retreating at approximately the same pace (Ref. 17.57).

17.6.46 Erosion on the frontage to the east of Stolford has been a chronic problem for many years, so much so that the Environment Agency has actively maintained the ridges by artificial heightening and re-profiling to prevent flooding of the low-lying land behind. The current intent is to abandon this activity and engage in managed realignment. The Parrett Estuary Flood Risk Management Strategy (Ref. 17.53) described four scenarios for managed realignment of the area to the east of Hinkley Point, with a breach located through the shingle complex in all four cases.

h) Sediment Budget

17.6.47 Such is the dominance of tidally-driven sediment transport processes within the Severn Estuary and Bristol Channel, summaries of sediment budgets for the entire system (i.e. the balance of sediment volumes entering, residing in and leaving the Estuary) are generally presented in terms of suspended sediments alone. Suspended sediments include fine sediments, as discussed above, but also sand grade sediment fractions. **Figure 17.16**, from Reference 17.54, summarises the estimated sediment budget. Reference 17.54 reports a long residence time for suspended solids material in the Severn Estuary and Inner Bristol Channel area, with little gain or loss from the system.

17.6.48 The intertidal zones are composed largely of relict sediments (Ref. 17.48), although short term deposits will occur during calm conditions; as such, intertidal mudflats will act as localised small capacity sinks. The subtidal zone is the most important sediment sink (Ref. 17.48) and probably receives as much as two million tonnes annually. Conversely, erosion of intertidal flats represents a major source of sediment to the Bristol Channel. To put these values in context, Reference 17.48 describes the combined total of fine sediment present in the subtidal mudflats, wetlands and in the water body as amounting to 1.16×10^{10} tonnes.

17.7 Assessment of Effects

17.7.1 In the sections that follow, potential effects on hydrodynamic and sedimentary processes associated with the construction and operational phases of the proposed development are assessed. Unlike many other environmental parameters, specific impact significance ratings are not provided. This is because essentially these processes have no attributable value or sensitivity and the effects resulting from the development are limited to a potential alteration in a physical parameter (e.g. current velocity), that may be of a certain magnitude, rather than an actual 'impact' upon it. For the purposes of assessment, therefore, an indication of the magnitude (or extent) of change from observed values is provided. Where possible, the assessment is quantified through comparison of predictions with known values. The implications of any predicted changes in hydrodynamic and sedimentary processes on environmental parameters that are inherently linked to these processes (e.g. marine water quality and marine ecology) are presented in the relevant chapters of this ES.

17.7.2 Potential effects during the proposed construction and operation phases are considered separately below and assessed in the context of the baseline description provided above. Further information about the construction and operational programmes is provided in **Chapters 2**, **3** and **4**, **Volume 2**.

17.7.3 As set out in Section 17.1 above, the key construction elements for HPC that could affect the hydrodynamic and sedimentary regime are works associated with:

- the emplacement of the new sea wall fronting the HPC site;
- drainage from the construction site across the shore;
- the construction, operation and subsequent dismantling of the temporary jetty;
- the drilling of vertical shafts for the cooling water intake and outfall structures;
- the establishment of a discharge point for the Fish Recovery and Return (FRR) system; and
- the capital and any subsequent maintenance dredging of the berthing pocket for the temporary jetty.

17.7.4 The key elements of the development during the operational phase that could affect the hydrodynamic and sedimentary regime are:

- the presence of the new sea wall;
- the abstraction and discharge of cooling water; and
- the presence of cooling water intake and outfall headworks and any other structures on the seabed, including those associated with the Fish Recovery and Return (FRR) and Acoustic Fish Deterrence (AFD) systems.

17.7.5 These activities and structures may lead to changes in:

- bathymetry;
- hydrodynamic (tidal) regime;
- wave regime;

- sediment transport and turbidity regime; and
- water quality.

17.7.6 Any change to the local hydrodynamic regime (e.g. through the emplacement of structures in the Bristol Channel) may also have an influence upon sedimentary processes and, consequently, the geomorphology.

17.7.7 Given the very high suspended sediment concentration of the Inner Bristol Channel, the marine waters and the physical habitats associated with them have a particularly low sensitivity to potential releases of sediment-laden water during the construction and operational phases.

17.7.8 Similarly, the extremely dynamic nature of the Inner Bristol Channel (i.e. an exceptionally large tidal range on a global scale, associated with high current speeds), its physical scale and the level of temporal and spatial variance that are already the norm, due primarily to tidal processes, strongly suggest that in order for any observable change to occur a human intervention in the system would, itself, have to be very large indeed, e.g. on the scale of a tidal barrage. In this context, the main marine infrastructure components considered as a part of this development are, in comparison, either of a very small scale (e.g. the intake-outfall structures) or designed so as to limit hindrance to coastal processes (e.g. the temporary jetty). These factors are reflected in the following assessment of the likely effects of the works on estuarine hydrodynamics and geomorphology.

17.7.9 Where the assessment has led to an understanding that mitigation measures will be required, these are discussed in Sections 19.10 and 19.11 below.

17.7.10 Issues relating to water quality are assessed within **Volume 2**, **Chapter 18**.

17.8 Construction Effects

17.8.1 Construction by its very nature is temporary and, therefore, any effect that the construction works have on hydrodynamic and sedimentary processes, even in a very much less dynamic system than the one involved here, will tend also to be of a temporary nature. Additionally, as construction is defined as the actual process of building (rather than the built structure itself), effects tend to be largely related to the disturbance to the system that construction generates. In dynamic, large-scale systems, such as the Bristol Channel and Severn Estuary (Ref. 17.14), construction related disturbance events (e.g. sediment released during excavation on the foreshore) are likely to be localised and transient, and thus small scale in magnitude. Overall, therefore, it is generally the case that construction causes very limited change to hydrodynamic and sedimentary properties within this system, unless it is either prolonged or undertaken at a very significant scale (e.g. large-scale dredging). For HPC, generally, construction of the coastal/marine located infrastructure can be viewed as of relatively short duration and localised with respect to the scale of the system.

17.8.2 As the temporary jetty will be constructed and operated during the construction phase for HPC, the effects of its construction, operation and dismantling phases are considered within this section.

b) Land Based Drainage Works

i. Increase in Suspended Sediment Concentrations

17.8.3 During onshore construction activities (tunnel boring, dewatering, earthworks and site drainage) it is anticipated that existing watercourses will be removed and a series of three interconnected spine drains will be installed. These drains will take most of the surface water run-off from the construction site via a dedicated drainage system, incorporating means of treatment as appropriate, and then discharge water to the foreshore.

17.8.4 Discharges of suspended sediment of less than 50 $mg.l^{-1}$ are anticipated and a limit value of 250 $mg.l^{-1}$ has been proposed, which is identical to the median value of suspended solids observed through the local water quality surveys (see **Volume 2, Chapter 18**). As described above, background suspended sediment concentrations within the Inner Bristol Channel are generally extremely high, in the order of 1 $g.l^{-1}$ near bed within 5 m water depth. Hence they are significantly higher than the discharge predicted. The effect of such a limited suspended solids loading will be discernible within only a few metres of the discharge itself and, therefore, the magnitude of this effect is predicted to be negligible.

c) Influence of the Temporary Jetty

17.8.5 The key build elements of the jetty are summarised below:

- It is a temporary structure with an expected operational lifespan of approximately seven years, after which it will be dismantled and the site restored.
- The temporary jetty is located to the north-west of the development site.
- It will comprise a piled bridge structure of 500m in length that terminates in a jetty head in order to accommodate berthed vessels and off loading plant.
- Construction will be undertaken from both land and sea (e.g. using a jack-up barge or platform).
- Steel tubular piles of the order of 0.9m diameter will be installed into the bedrock layer at intervals across the intertidal shore and near sublittoral, in order to support the bridge structure; the jetty head and associated dolphins will also be supported upon piles likewise installed into the bedrock.
- The operating face of the jetty head will be aligned with the direction of ebb/flood tidal currents in the vicinity. A berthing pocket immediately associated with that operational area will be dredged in order to allow safe delivery of materials across a range of tidal conditions. This dredged area is planned to be 160m in length and 27m in width with sediments removed to a uniform depth of around 3.5m below the existing seabed.
- Delivery of materials from the jetty head to the shore will be by covered conveyor for aggregates and a closed pipe delivery system for cement.

17.8.6 The route chosen for the jetty, following a consideration of engineering practicability, navigational safety and environmental sensitivities, crosses a gently sloping section of the shore dominated by an exposed rock platform before extending into the near sublittoral, where it first crosses a relatively steep exposed rock slope and then extends onto the edge of the extensive muddy plain habitat that dominates the local seabed (Ref. 17.2).

i. Construction of the Jetty

17.8.7 During construction of the temporary jetty one or more jack-up platforms may be required. For example piling works may be conducted from a jack-up barge. The presence of these structures / vessels in the water column may cause a localized and temporary disturbance to current flow, much in the same way as the piled legs of the jetty. Given the extremely small spatial scale of the footprint of any plant in relation to the total foreshore platform and subtidal area, and the existing dynamic and energetic conditions of the study area, any change in flow conditions will be extremely localised and not discernible beyond the space of a few metres. Given this minor influence on hydrodynamic conditions and the temporal duration of the construction period (12-18 months), the magnitude of the effect on sediment transport processes will be negligible.

17.8.8 Installation of the piles for the jetty, through either a 'drill and drive' or a 'pre-drilled and socket' technique, will cause some release of sediment and disturbance of seabed sediments at and around each pile location. This disturbance will be very localised in extent and sediment redistribution by tidal processes, both during the construction period and following the cessation of construction, will be rapid.

17.8.9 The construction of the temporary jetty across the upper intertidal area will involve the use of heavy vehicles. Where access across the natural rocky intertidal area occurs, extensive damage may ensue. If such works were to extend to the wider rock platform that dominates the middle and lower intertidal area locally this will tend to dislocate limestone blocks from their settings, crush that material and macerate the associated shale. Erosion could rapidly occur, equivalent to several decades of natural surface degradation. Any such tracks will then form a channel for downshore drainage and sediment transport, potentially compromising the local ecological interest over a wider area of shore to the west – see Marine Ecology, **Chapter 19,**, **Volume 2**.

17.8.10 The use of jack-up rigs over the lower shore could cause similar damage to the rock surface, though over a much reduced area.

17.8.11 The proposed means for mitigation of these effects are discussed in Section 17.10 below.

ii. The Jetty Structure

17.8.12 The location of the jetty both on the foreshore and within the shallow sublittoral means that it has the potential to have a localised influence on the hydrodynamic regime and, in turn, on sediment transport.

17.8.13 The existing hydrodynamic regime as described in Section 17.5 is characterised by an extremely high tidal range (classified as 'hypertidal' – having a mean spring tidal range in excess of 6 m, in this instance of 10.7 m) and very strong tidal currents.

Local hydrodynamic conditions are thus highly energetic. The dominant influence of the tidal regime will decline in shallower water and as one moves up the shore, and the length of the jetty, wave driven processes will tend to dominate instead. This high energy system is responsible for the scouring of the rock platform across which the jetty will run. It is solely the presence of the piles supporting the proposed jetty that will have the potential to influence the currents and waves that cross its path.

17.8.14 As the jetty has been designed as an open structure, potential effects on hydrodynamic processes, notably tidal current flow, will be very much more limited in comparison to a solid structure. The main effect on hydrodynamics therefore relates to any resistance that the piles will have on tidal flow together with any consequential scour of sediments due to turbulent flows at their base (see Ref. 17.3). The pile diameters and spacings represent less than a 4% obstruction of the cross section, across the tide. While small-scale local eddies will shed off these piles, these will tend to extend for only a few radii (3-4 m) downstream and, consequently, changes to the flow regime will be localised and not extend more than 50 m from the side of the structure.

17.8.15 Given the proposed position and length of the jetty, the majority of the supports will be founded in the limestone/shale bedrock foreshore platform. Due to the relatively hard nature of the rock forming the platform, any scour that might occur will be negligible. However, at the seaward end of the jetty the bridge supports will be driven through several metres of unconsolidated sediment which is more likely to erode.

17.8.16 An expert assessment utilising both existing information on tidal bed shear forces, sediment characteristics and a knowledge of the proposed engineering design has been completed (Ref. 17.3). The scour depth predicted to occur in these relatively soft sediments is 1.3 m. This depth presumes a side to side placement of piles but for a single pile this reduces to 1.1 m where there are no group effects. The lateral extent of scour may be calculated from the angle of repose for different sediment types. For loose non-cohesive fine sand and an angle of repose of 26º, this equates to radial scour extent of 2.7 m for a paired jetty pile. For the soft mud typical of the area around the jetty head, the angle of repose would be 5-10º after slumping (or 1 in 5, as assumed for the marginal slopes of the berthing pocket, see below) and the extent of radial scour approximately 6.5 m.

17.8.17 Any eroded material will quickly be transported and incorporated into either the overall suspended sediment load or bed load. The total volume of sediment that could be eroded and transported in this manner will be extremely small and will form a negligible addition to the large volume of transported bed load and suspended sediment already present within the system.

17.8.18 There is a potential for the jetty supports located in the upper part of the foreshore to partially impede any longshore wave driven sediment transport to the east. The height at which predominantly cobble and shingle deposits are found on this length of shore suggests that they are mobilised only during episodes of severe weather and heavy seas. The jetty structure is intentionally designed to limit the hindrance to any waves, allowing them to pass between the widely spaced piles. In addition, the historical data reviewed above indicates that very little shingle from the western side of Hinkley Point is transported eastwards. Hence, the presence of the jetty supports across the intertidal area will have a negligible magnitude of effect on sediment transport to the east of Hinkley Point.

17.8.19 As the jetty will bridge across the existing cliff line there will be no direct disturbance to the cliff face itself.

17.8.20 A temporary service road will be constructed at the foot of the cliff, joining the construction corridor that will run down the flank of the jetty line itself. The increase in elevation associated with that roadbed will result in a decrease in wave energy reaching the cliff line and thus marginally reduce rates of erosion from the cliff face over the construction period.

iii. Capital Dredging of the Berthing Pocket for the Jetty

17.8.21 A berthing pocket will extend off the end of the jetty, allowing ships to maintain their berth at the jetty across the full range of tidal conditions whilst delivering construction materials for HPC.

17.8.22 The berthing pocket will be aligned with the main tidal flows. The capital dredge required to form this berthing pocket (assuming dimensions of 160 m x 27 m x 3.5 m; inclusive of a nominal 0.5 m over dredge and assuming 1 in 5 sloped sides) will generate an estimated 25,140 m^3 of material.

17.8.23 The capital dredge will have two effects: a release of suspended sediment during the dredging operation itself, and changes to local hydrodynamics caused by the localised increase in water depth.

17.8.24 The alteration in bathymetry will affect hydrodynamics (local tidal current velocities and wave climate) and in turn the local sediment transport regime. Although the increase in water depth generated by the berth will represent a significant change locally, within the scale of the wider dynamic processes operating in the Inner Bristol Channel, such a small scale change will be expected to have a negligible effect elsewhere. A small-scale decrease in current velocities over the depth of the water column facing the berth might be expected and this will tend to be greater in the lower half of the tidal cycle than the upper. This influence will be limited, predominately, to the lateral and longitudinal extent of the berthing pocket itself. There will be no consequence for the tidal regime at a wider scale.

17.8.25 It is assumed that the bulk of the sediments that will be removed from the dredge berth, to be either deposited locally (if the relevant criteria are met) or to an existing licensed disposal site (e.g. Cardiff Grounds), will be comprised of relatively recent deposits of soft mud.

17.8.26 Depending on the dredging method used, it is possible that a proportion of the sediment could be maintained within the system (i.e. through losses during dredging, or if a form of hydraulic dredging were to be utilised) and entrained into the local and potentially wider sediment transport system. Given that the volume of sediment to be dredged is relatively small (approximately 25,140m^3), when considered in the context of the Inner Bristol Channel sediment budget and the prevailing turbidity regime, these works will not have any significant effect on that budget or regime. In addition, given the volumes concerned, the potential loss from the system should the dredged material be removed elsewhere would not be significant.

17.8.27 During dredging, suspended sediment released into the water column will generate a sediment plume that will extend out from the dredge area. The extent of this plume will vary according to a number of factors, chief amongst which will be: the composition of the sediment being dredged (e.g. fine or coarse grained), the dredging technique employed and the tidal / wave conditions at the time of dredging.

17.8.28 It is expected, given the hyper-tidal and associated extreme turbidity regime, that material within the plume will become subject to the tidally driven transport, deposition and resuspension processes and thus be continuously reworked until deposited in an area of accretion. Again, given the relatively small volume involved it is not considered likely that the local or wider deposition of sediment from the plume will have any significant effect on existing bathymetry, transport processes or depositional bedforms. The potential effects on marine water quality of the suspended sediment generated during the dredging are considered in **Chapter 18**, **Volume 2**.

iv. Maintenance Dredging of the Berthing Pocket

17.8.29 The area of the berthing pocket is within a zone of mud deposition which on average appears to be accumulating at about 2 cm a year, and is thought to have a mud source to the east. There may be large variations in the magnitude and continuity of this rate, and there is little information about the resulting mud density. It is anticipated that the present thickness of mud is 1 to 2 m. High concentrations of suspended solids settle towards the bed in this area during Neap tides (Ref. 17.1), which are then wholly or partially remobilised during Spring tides when shear forces increase.

17.8.30 High concentrations of near-bed suspended sediment develop because of the gradual diminution of velocities from Spring to Neap tides, with that near-bed suspension eventually becoming stationary when the peak tidal velocity diminishes below a critical value. Because of the depth increase locally due to the dredged berth, this critical velocity will be achieved earlier in the tidal sequence within the berthing pocket than on the seabed area around it. The result of this will be that a suspension will stop moving within the pocket before it does elsewhere, providing more time for consolidation. In other words, the berthing pocket will tend to trap some material that would otherwise travel further. Similarly, the lower velocities in the pocket will delay the remobilisation of the mud as velocities increase towards Spring tides.

17.8.31 In practice, it is not possible to provide a firm estimate of the balance of the differing settlement and remobilisation rates likely to occur, as the operation of the berth itself will add a further dimension. The berth will be used frequently whilst sea conditions permit and the movement of the vessels will influence the rates of both settlement and resuspension. Untoward sea conditions, when the berth cannot be used, will generally involve larger waves and, especially over low tidal periods, will also have an influence on these sediment transport processes. There will thus be a chronic level of disturbance throughout the period of jetty operation which is likely to affect sedimentary processes in the berthing pocket itself.

17.8.32 The implication is that, with frequent vessel usage alternating with periods of bad weather, the need for any maintenance dredging will be limited. Ignoring the additional complexities associated with the operational regime described above, Reference 17.10 provides a worst case estimate of berthing pocket settlement in the range 60,000 to 200,000 $m^3.yr^{-1}$. In practice, the operator will monitor sediment densities in the berthing pocket in order to trigger a maintenance dredge, should this prove necessary.

17.8.33 Should maintenance dredging be required the nature of the sediments involved will limit the means of dredging that are practical. Of the techniques available, whilst the more conventional means will be best suited to the capital dredge (grab or bucket, backhoe or a trailing suction hopper), one or other of the hydraulic methods are likely to be better suited to the maintenance need (ploughing/bed levelling, agitation and water injection) (Ref. 17.6). Good practice will be employed to manage the dredging requirements in order to limit resultant effects.

17.8.34 Whether this material is removed to a licensed disposal point or moved aside into areas of higher tidal shear, there will be benefit in retaining it within the local sediment transport system. Any disturbance associated with this activity will be almost identical to the effects of the tidally driven semi-diurnal and Spring/Neap cycles of widespread mobilisation/deposition/remobilisation of superficial finer sediments in the locality and will, thus, be of very little consequence.

17.8.35 One of the consequences of sediment accumulation within the pocket is likely to be a limited degree of starvation of material flowing downstream along the sediment transport pathway, which is presumed to be towards the west. This could lead to a zone of reduced sedimentation to the west of the berth. This downstream effect may produce a linear disturbance in the local flow regime. The presence of a wide series of linear furrows in this area (Ref. 17.2) suggests that such a feature may propagate in an identical manner and persist for many years.

17.8.36 The jetty operator will, throughout, consult the MMO on the appropriate maintenance dredging protocol and seek licenses for any maintenance dredging activity that might become necessary in a timely and appropriate manner.

v. Jetty Dismantling

17.8.37 During the dismantling of the jetty structure, temporary plant and vessels will be present which may impede flows and cause changes to local hydrodynamic processes and associated sediment transport. The magnitude of this potential effect is assessed as negligible given the small spatial scale of the vessels. Any effects are expected to be highly localised and temporary in nature. The sensitivity of the local hydrodynamic regime is low in this context and the potential significance of any effect is, therefore, predicted to be negligible.

17.8.38 It is not considered feasible to pull out the steel tubular piles, hence they will be cut at rock head / seabed level and the main section of the pile shaft removed. In the intertidal area, where the pile locations could pose a risk to people walking and falling into holes, the remaining section of pile and internal void will be in-filled with grout. At locations on the intertidal where the holes are/restoration is visible, a natural stone slab will be placed into the concrete plug. If, in the future, exposure of pile remnants occurs on the intertidal area, a further cut to the rock head level may be required (this will be monitored). The voids left within the sea bed beyond the intertidal area will not be plugged with concrete but allowed to infill naturally with marine deposits.

17.8.39 The removal of piles and jetty uprights will remove any impedance to flows and those factors with the potential to cause scour (discussed above). Following these works it is anticipated that (within a relatively short timeframe) the sea bed sediments and geomorphology will return to conditions similar to those prior to the construction of the jetty.

17.8.40 The removal of the temporary jetty will also involve vehicle access from landward and marine operations from seaward. Where access across the natural rocky intertidal area occurs, extensive damage to the cross shore rock platform may again ensue.

d) Sea Wall Construction

17.8.41 The design specification and drawings of the proposed sea wall are provided in **Chapter 2** of this volume and Reference 17.11. The sea wall will rise to 13.5 m ODN and be constructed immediately landward of the current cliff line, replacing the existing cliff face along the 760m frontage of the HPC development site itself. The wall will incorporate a layer of toe armouring to counter wave scour with the pre-existing beach profile being replaced. The armour layer is to be 2.5 m thick and 5 m wide, inset into the beach by about 1 m, and based on a geotextile layer. The rocks filling the layer are to be of a mean size of 1.35 m diameter, each weighing 6.54 tonnes. There will thus be two layers of rocks. Following installation, the original beach profile will be reinstated over that defence toe. This is essential in order to minimize potential scouring by currents running along the bottom of the structure at the front face of the protection.

17.8.42 The base of the scour protection is at 1.5 m below the rockhead; the engineering design incorporates a precautionary estimate of beach lowering of 0.015 $m.yr^{-1}$. Further measures will be applied should routine monitoring over station life reveal a more untoward trend.

17.8.43 The porosity of the two layers of rocks will lead to pebbles and shingle penetrating into the matrix, thereby helping to stabilize the layers. However, once the tops of the rocks underlying the replaced beach become exposed to the waves, a trough is likely to develop at the junction because of water flowing through the matrix and the action of waves reflected from the rocks.

17.8.44 Additionally, the wall could produce clapotis (the localised reinforcement of incident and reflected waves) at times, and strong vertical velocities and erosion at set distances from the reflection (Ref. 17.56). It will be desirable that such waves do not occur beyond the protected zone, to avoid accelerated erosion of the beach face close to the scour protection; however this may be difficult to prevent because of their intermittent nature.

17.8.45 In front of the proposed defences, approximately 300 m west of the boundary with Hinkley Point A (HPA), there is a large infilled excavated area. This was originally the graving dock for construction of the HPA and HPB cooling water intake headworks, now positioned offshore. If beach lowering were to make this a prominent feature, exacerbated erosion between it and the wall might occur (Ref. 17.6). The shore surface associated with this feature will thus be monitored throughout the life of HPC.

17.8.46 At the western end of the HPC site the sea wall will be terminated with an element of the coastal protection system extending landward. This will permit natural cliffline erosional process to persist to the west of the site over the life of HPC without risking the integrity of that site.

17.8.47 To the east end of the site the sea wall will abut the existing sea wall of the HPA and HPB stations. A vehicular access ramp to the foreshore will be included at the extreme western end of the sea wall. Additional scour protection will be provided around the base of the access ramp area.

17.8.48 The construction of the sea wall will typically involve the following sequence of events:

- construction of a temporary haul road and foreshore access;
- establishment of a 30m wide working corridor or 'construction zone' at the top of the intertidal area fronting the existing cliff face;
- excavation of the cliff face material for sea wall alignment;
- construction of a sea wall footing and base;
- excavation of material for the toe;
- rock importation by barge to a dedicated area of the foreshore and subsequent rock placement;
- installation of a drainage system behind the sea wall;
- construction of individual sea wall sections in turn along site frontage;
- the placement of backfill behind each new concrete sea wall section in turn;
- the construction of access steps and ramps; and
- the reinstatement of footpaths and fencing.

17.8.49 The construction and installation of the sea wall have the potential to release sediment into near-shore waters due to runoff from the works, excavation of the cliff face and other allied activities. The implications of this for marine water quality and marine ecology are considered in **Chapters 18** and **19**, **Volume 2**.

17.8.50 Excavated material will be sorted for potential re-use in the construction of the sea wall itself and the associated toe, drainage system and backfill.

17.8.51 Rock armour material awaiting placement is likely to be stored along the outer perimeter of the intertidal construction zone, both demarcating that boundary and providing some shelter for the working area behind. Given this limited degree of shelter it is possible that, while present, the area will tend to trap storm-driven sediments moving in to it, or retard the loss of any such materials already present. Given the need to re-establish pre-existing cross-shore profiles in this upper intertidal area on the cessation of works, there will be a need to actively manage the sediment volumes concerned throughout. The related marine ecological assessment of the use of this intertidal sea wall construction zone is provided in **Volume 2**, **Chapter 19** and the zone itself illustrated by **Figure 19.35**.

17.8.52 A suitable area of the intertidal has been identified for the landing and unloading of barges (based on an understanding of local marine ecological sensitivities (see **Volume 2**, **Chapter 19** and **Figure 19.36**)). This area is largely coincident with the historical graving dock developed during construction of the Hinkley Point A and B Station cooling water intake headworks. Any such barges would be brought towards the shore during a high water period and allowed to ground as the tide falls; their rock armour cargo would then be unloaded by mobile crane to trucks and placed within the construction zone as described above. Given the flat-bottomed design of such vessels and the very temporary nature of their mooring, no effect on coastal geomorphological or hydrodynamic processes is anticipated.

17.8.53 The discharge of sediment loads from onshore to the adjacent littoral area will depend on site activities and will be variable throughout the construction period. The volumes involved are not expected to be significant within the context of existing sediment loads present across that littoral area. The works could result in additional volumes of sediment being introduced to the upper shore, and thus available for wave-driven transport. Fine grained sediment will be expected to be rapidly lost due to tidal action, while blocks of limestone and shale (unless removed from the site) will be expected to remain in situ or potentially be entrained and gradually transported locally (eastwards and down shore) by storm events over time.

e) Drilling of Horizontal Intake/Discharge Tunnels

17.8.54 Horizontal tunnels associated with the proposed power station cooling water system will be excavated from onshore. The construction process for the drilling of these tunnels is described in **Chapter 2** of this volume. Wastewater arising from this process will be discharged across the foreshore following appropriate treatment. This will contain suspended solid concentrations of at most 250 $mg.l^{-1}$ (equivalent to the median suspended solids level encountered in the receiving water locally – see **Volume 2**, **Chapter 18**) and be discharged at a rate of about 60 m^3 per hour.

17.8.55 Given that the concentrations estimated to be discharged through the mud-assisted drilling process are similar to the background suspended sediment concentrations recorded in the area, and that the volume and rate of discharge will be very small compared to the volume and suspended sediment load already present in the receiving water body, the effect on sedimentary processes is predicted to be insignificant. The additional loading to the Bristol Channel's sediment budget locally will simply contribute to existing trends in deposition, adding to these to a very minor degree, across a very wide area (Refs. 17.1 and 17.54).

f) Establishing the Fish Recovery and Return discharge line

17.8.56 The discharge line for the FRR system will be established by either directional drilling or 'microtunneling' from landward, under the sea wall and intertidal shore, to a point on the exposed rocky seabed below the level of the Lowest Astronomical Tide (LAT, -6.10 ODN). The tunnel diameter will be less than 1 m and its length approximately 600 m. Waste arisings will be similar in kind to those associated with the cooling water tunnelling operation (primarily water and some solids) but very much more limited in scale. The outfall structure will have minimal profile above the sea bed and thus have a negligible effect on both the sea bed itself and associated sediment and tidal dynamics.

17.8.57 One of the criteria for the outfall location is that it be placed on an area of subtidal scoured rock where no sedimentation is anticipated in the longer term, avoiding the nearby muddy bed and thus limiting the risk of blockage.

g) Drilling of Offshore Vertical Shafts

17.8.58 Six vertical wells will be drilled using a wet drill technique in the offshore zone. Four of these will be excavated with an aperture diameter of 5 m to a depth of 30 m below seabed, approximately 3.3 km offshore, and will be associated with the two horizontal intake tunnels. The two other vertical shafts, associated with the outfall tunnel, will be excavated to 2 m below the seabed, with an aperture diameter of 8.3 m.

17.8.59 Wet drilling will be undertaken from a rig platform fixed to the seabed with piles and anchors. Waste materials from the operation will be contained and transported from the working face below to the platform itself where solids and water will be separated. The processed water will be discharged back into the Bristol Channel, and solids will be transported away for disposal by barge. At the water discharge point, some suspended sediment will be released into the water column. However, the concentration of sediment in the discharge water will be constrained to a level comparable to that found in suspension locally and any effect thus rendered negligible.

17.8.60 Preparatory dredging will be required in the immediate vicinity of these six offshore locations in order to gain access to the rock head itself. As with the dredging proposals allied with the temporary jetty, both the dredging technique utilised and the means of disposal will depend on the nature of the material involved and will be subject to separate agreement with the Marine Management Organisation (MMO). Given the prevailing turbidity regime at these offshore locations and the degree of tidal mobilisation/deposition and remobilisation of superficial sediments in this environment, no significant effect is considered likely on either geomorphological or hydrodynamic processes due to these operations.

17.8.61 The presence of the rig platforms will locally alter the hydrodynamics due to change in flows around the piles and anchors. Given the negligible size of the structures relative to the extent of the surrounding seabed and the Inner Bristol Channel, the changes to the hydrodynamic processes and hence changes in sediment distribution (erosion and accretion patterns) will be limited, and within the range of natural variability. In addition, the works will be of a temporary nature and after the removal of the rig the sea bed will be expected to revert to its pre-construction condition.

17.9 Operational Effects

17.9.1 This section focuses upon those elements of the operation of HPC that will have the greatest potential to affect hydrodynamic and sedimentary processes. These elements comprise the engineered infrastructure that will be established at the top of the shore and on the seabed, being the sea wall and cooling water (CW) intake and outfall structures, together with processes of abstraction and discharge of cooling water.

17.9.2 Following construction, no new structures will be introduced to the intertidal area fronting the station site, nor will there be any modification to the intertidal area except to continue any mitigation effort (site restoration) necessary further to jetty removal.

a) Shoreline Structures: the Presence of the Sea Wall

i. Design Intent

17.9.3 As described in **Chapter 2** of this volume the purpose of the sea wall is coastal protection. Its primary function is to prevent erosion to the seaward boundary of the HPC permanent development site. Flood defence will be secured by the platform height of 14m above ODN, a height that will be attained above a slope some 50m behind the crest of the sea wall itself.

17.9.4 In anticipation of unexpected overtopping during storm events, an extensive drainage system will be incorporated into the design of the sea wall.

17.9.5 As mentioned elsewhere in this chapter, whilst the sea wall is designed to be resilient in the face of low probability external hazards over the length of station life, it is also designed to permit further modification should a trend towards more extreme climate change driven sea levels be observed.

ii. Hydrodynamic Processes

17.9.6 As both the current cliff and the proposed sea wall stand on the upper shore well above mean high tides, it is only in more extreme conditions of either tidal level or storm that there will be any hydrodynamic interaction with this structure. As the structure will simply replace the existing upper shore boundary with a very similar plan form and steepness, there will be no effect on the existing tidal regime.

17.9.7 However, the near vertical concrete face to the sea wall will present a different surface to that of the existing cliff. Although the vertical profile of the existing cliff is similar to that planned for the sea wall, the natural small-scale variations in slope and aspect along its current length present a more energy-absorbing surface than that which will be provided by the smooth concrete face of a sea wall. As a result a greater degree of wave reflection will occur during the more extreme conditions when waves interact with this structure. The engineered scour protection that will be introduced at the base of that wall will serve to mitigate this effect. The predicted effect on sediment transport of both the sea wall and the associated scour protection is discussed below.

iii. Sediment Supply and Transport

17.9.8 The sea wall will eliminate any further contribution of sediment (via erosion and weathering) from the length of cliff that it will replace. Erosional trends on this frontage are estimated, at worst, to have been 0.2 $m.yr^{-1}$ over the last century (Refs. 17.9 and 17.21). If this same trend were presumed to continue this would suggest a retreat of this cliff line of 20 m over the next 100 years. Assuming an erosion rate of an 8 m high cliff at a rate of 0.2 $m.yr^{-1}$ over a length of 760 m, and a proportion of limestone to shale of 25%, this would release 300 $m^3.yr^{-1}$ of pebbles. Assuming a rate of dissolution of 1 $mm.yr^{-1}$, an attrition rate of 10% per yr, and a travel time of five years around Hinkley Point to the east, this suggests only about 150 $m^3.yr^{-1}$ of supply to the gravel complexes of Catsford and Wall Commons (Ref. 17.56).

17.9.9 Thus the fixing of the shoreline will prevent the erosion of sediment from the cliff face. The material that would otherwise have been eroded consists mostly of limestone and marly shale, which would normally degrade relatively quickly. The effect of the establishment of the sea wall and any associated loss of input to the sediment regime is thus predicted to be of low magnitude.

17.9.10 Cliff exposures of potential coarse sediment sources (again largely shales and limestone) to the marine sediment transport regime extend for approximately 20 km to the west, with cliff heights reaching 30 m. On the basis of section length alone, the 760 m cliff section that will be lost on the development site frontage represents a small proportion of the total cliff length within this coastal area. When taking into account the greater height of many of the cliff sections to the west of the site and the extensive rocky foreshore platform fronting this length of coast, which will also provide very similar material to littoral sediment transport pathways, this would suggest that the significance of the loss of potential sediment input from this 760 m cliff section will be even smaller.

17.9.11 As discussed previously, and (for example) in References 17.1, 17.17 and 17.56, studies suggest that although the existing HPA and HPB sea walls are not acting as a barrier to longshore shingle transport, very little new sediment reaches the shingle complexes from the west. This suggests that even if a small reduction in available coarse sediment were to occur, as a result of the sea wall to HPC this will be unlikely to have implications for the integrity of coastal landforms to the east.

17.9.12 The scour protection that will form the toe of the new sea wall will tend to absorb and retard the movement of materials along the top of the shore during more extreme conditions.

17.9.13 There are no cross-shore structures associated with the sea wall that could interfere with long-shore sediment transport processes.

iv. Coastal Squeeze Associated with the Establishment of the Sea Wall

17.9.14 The fixing of the shoreline along the HPC frontage, which might otherwise retreat, together with relative sea level rise and down-cutting of the Blue Lias rock shore platform, will result in a narrowing of the intertidal area over time.

17.9.15 As noted above, the sea wall will be fixed within the existing line of the cliffs bordering the upper shore and no other engineering structures will extend across the shore itself during the operational phase. In addition, the scour protection element that will be introduced at the toe of the sea wall will be finished to match the pre-existing cross shore profiles. Thus, the sea wall and associated scour protection will not themselves, when completed, themselves cause an immediate narrowing of the intertidal area.

17.9.16 The precautionary estimate of cross-shore platform down-cutting employed in developing the sea wall design (Ref. 17.11) is 1.5 m over 100 years. Likely Relative Sea Level (RSL) rise in the Bristol Channel will be 1 m or less by 2100 (Ref. 17.22).

17.9.17 A typical cross section of the intertidal frontage of the development site has a width, between Mean High and Low Water Spring tide levels, of 256 m (Profile P9, Ref. 17.9). A simple graphical analysis shows that adding a RSL rise of 1 m will reduce this width to ~190 m. If the entire profile is then dropped by 1.5 m to simulate cross-shore platform down-cutting, this reduces that width further to ~170 m.

17.9.18 A consequence of the continuing downcutting of the tidal flats will be a lowering of the whole beach profile. However, the rate is unlikely to be uniform. The new sea defences and the scour prevention close to high water will prevent recession of the high water line, but increasing water depth over the mid and lower shore will increase wave height and move the wave break-point towards the upper shore. This will ensure that the highest erosion will occur on the upper shore – with the mid and lower shores undergoing reduced erosion. Thus, although the width of the shore will decrease through downcutting, it will be at a lower narrowing rate than if the profile were uniformly lowered.

17.9.19 A range of estimates of cliff line erosion exist, varying from 0.1-0.5 $m.yr^{-1}$ (Ref. 17.17, on the basis of 30 months data) to 0.13 $m.yr^{-1}$ (Ref. 17.21, on the basis of a GIS analysis of historical records from 1888-2009) and 0.06 $m.yr^{-1}$ (Ref. 17.9, on a similar basis). Given the length of the baseline involved, a rate of 0.2 $m.yr^{-1}$ may be selected as a reasonable worst case, although this does not take account of the possibility of higher rates of erosion that might develop due to wave attack following sea level rise.

17.9.20 As the sea wall will be introduced at a height on the shore above Mean High Water Spring tide level along the full length of the HPC frontage, the imposition of that structure will not contribute directly to the foreshortening of the width of shore described above, but it will inevitably prevent any landward progression of that cross-shore profile with time.

17.9.21 As noted previously, the reflection of storm waves from the sea wall may accentuate erosional trends in the upper shore area and this may, by locally increasing the level of downcutting, cause an alteration in the cross-shore profile itself. The consequence of this potential effect and of the foreshortening of the intertidal area as a result of cross-shore platform down-cutting and RSL rise are discussed further in **Chapter 19**, **Volume 2**.

b) Seabed Structures: The Cooling Water Intake and Outfall Headworks

17.9.22 Due to their location on the seabed, the intake and discharge headworks will have the potential to affect hydrodynamic and sediment transport properties.

17.9.23 Four separate intake structures will be established on the seabed and two outfall structures.

17.9.24 As noted earlier, the connections between these headworks and the power station itself will be a series of vertical shafts connected to tunnels bored under the shore and seabed from landward. Apart from the headworks themselves and the very much smaller outfall structure associated with the FRR System, there will be no other structures introduced to the seabed or shore that will either disturb that seabed or, potentially, cause any impediment to flow.

17.9.25 The four seabed intake structures, each of which will be approximately 10 m x 40 m in plan view, will occupy an area of 1200 m^2 of the seabed; the two outfall structures will occupy some 200 m^2. As the Inner Bristol Channel in the vicinity of the structures is approximately 20 km wide, the footprint that will be occupied by these structures will be negligible. Similarly, in terms of any potential impediment to tidal flows, the cross section presented by these structures in relation to that of the Inner Bristol Channel will have a negligible effect. While the structures will inevitably, in their immediate vicinity, be associated with alterations in tidal flow, any such change will not be discernible beyond a few tens of metres from the structures themselves.

17.9.26 An expert assessment of the level of scour that will be associated with these structures has been completed (Ref. 17.3). This assessment assumed a worst-case approach, where the structures are presumed to occupy the majority of the water column, which would be the case for the two outfall structures alone but only during extreme low tidal periods.

17.9.27 For the outfall headworks the total scour depth associated with the structures themselves (as opposed to the high volume effluent streams) is predicted to be 2.2 m. In practice, as the depth of mud locally is variably 2 m to 4 m over bedrock, that depth could be curtailed and the bedrock itself exposed immediately around each structure. Assuming an angle of 26° for a loose non-cohesive fine sand this equates to a (precautionary) radial extent of scour of 4.3 m. Mud would have an angle of repose in the range 5-10º after slumping, suggesting a radial extent of scour in the range 12-25 m. In other words, the bedrock could be exposed immediately around the structure and beyond this there would be a shallow upward slope of mud.

17.9.28 The flow of water around the proposed heads will be complex (see below). Some local field measurements of water velocity have been higher than the locally averaged values predicted from modelling studies. These higher observed values of 1.89 m/s were adopted for the scour assessment (Ref. 17.3). The predicted total scour depth around the intake head is 0.6 m, leaving approximately 1.4 m depth of soft silts overlying the bedrock. This translates into a lateral extent of scour of 1.2 m to 4.1 m, with the higher figure assuming 2 m of overlying silt.

17.9.29 Given that the propagation of these alterations in hydrodynamic and sediment transport conditions will be highly localised, the overall effect of these structures on physical processes is predicted to be negligible.

c) Seabed structures: the FRR outfall

17.9.30 As noted above for the construction phase, the FRR discharge headworks will be positioned within an area of tidally scoured rock below the level of Lowest Astronomical Tide (-6.10 m ODN). The outfall structure itself will be minimal and of low profile. No interruption to either the local hydrodynamics or the sediment transport regime is predicted and there will be no localised scour as the surrounding sea bed will be rock. As a result, the effect of this structure on physical processes is predicted to be negligible.

d) Intake and Discharge of Cooling Water

17.9.31 The power station’s cooling water supply will be abstracted from the Bristol Channel via a series of intake headworks that will be placed atop the vertical shafts described above, approximately 3.4 and 3.5 km offshore and at a depth of 9.2 m below ODN. The intakes headworks will stand proud of that depth by about 3 m.

17.9.32 Whilst HPC is operating, precisely the same volume will be discharged as abstracted. No suspended solids will be removed. There will thus be no effect upon the tidal prism of the Inner Bristol Channel and no loss of sediment from the system as a result of this process.

17.9.33 The intakes at Hinkley Point are described as following the Low Velocity Side Entry (LVSE) model, designed to maintain a low intake port velocity of approximately 0.3 $m.sec^{-1}$ across all tidal conditions for fish protection purposes. In order to secure this LVSE design for HPC, the detail of these structures has been driven by the use of detailed numerical hydrodynamic models of both the surrounding tidal current regime and internal flow patterns. As noted above, each LVSE intake structure will be approximately 10m x 40m in plan view, with the long axis lying in parallel to the direction of both ebb and flood tidal streams. Seawater will be abstracted through the longitudinal ports located on each flank of these structures. With the intake ports raised off the seabed by more than 1 m, and the intake head itself supported on a narrower plinth, there will be a degree of isolation between bed processes and associated potential turbulence and scour and the abstracted cooling water volume.

17.9.34 The cooling water will be discharged at a rate of approximately $125m^3sec^{-1}$, with this flow being split between two outfall headworks. Each will discharge the cooling water horizontally in an offshore (cross-tidal) direction at mid depth towards times of low tide, or in the lower part of the water column at all other tidal states. Given the relative difference in temperatures between this discharged volume and the local receiving water, the discharged effluent will tend to rise to the sea surface, whilst also being advected by tidal currents, forming a tidally oscillating buoyant thermal plume.

17.9.35 It is likely that at times of low water, particularly during Spring tides, the large volume discharges at each outfall will cause scour of local soft sediments. This effect is likely to be confined to the immediate vicinity of the outfall itself and will most likely serve to resuspend materials accumulated during the previous Neaps and also the sediment deposited at the previous slack water. As described earlier, the nature of the Inner Bristol Channel is that soft sediments are subject to continuous processes of tidal resuspension. Erosion to the bedrock is common during Spring tides. The element of scour caused by the outfall plume is likely, therefore, to enhance the natural process of periodically removing sediment to that bedrock surface, which locally is at shallow depth. Modelling results of the thermal plume (see **Chapter 18** of this volume on Marine Sediment and Water Quality), with and without a lateral discharge momentum applied offshore, suggest no effect upon bed shear forces beyond 2 grid cells (i.e. a maximum distance of 100 m).

17.9.36 Due to its reduced density relative to the cooler receiving water, the tidally oscillating thermal plume will tend to impose a degree of thermal stratification within its midfield area, potentially extending several kilometres downstream on the tide. Salinity stratification does occur locally after heavy rain, but is limited to the plume of the Parrett Estuary, which can occasionally be an extensive feature extending out towards the HPC site following periods of high river flow. The effect of stratification on the suspended solids regime will be to reduce vertical mixing to some degree and thus reduce the likely vertical exchange of these materials through the water column. As no suspended material will be removed from the water taken into the cooling water system and what is then discharged will be virtually identical to the surrounding water, the effect on the receiving water's turbidity regime will be negligible. The light climate, governed by turbidity and suspended matter, will not be altered significantly for the same reason.

17.9.37 The local wave climate will not be altered by the thermal plume itself.

17.10 Mitigation of Construction Effects

a) Introduction

17.10.1 This section describes the proposed mitigation measures to manage and reduce, wherever possible, effects on the sediment transport regime and the hydrodynamics of the local coastal environment during the construction of the site.

17.10.2 Given the very high suspended sediment concentration of the Inner Bristol Channel, the marine waters and the physical habitats associated with them have a particularly low sensitivity to potential releases of sediment-laden water during the construction and operation phases. Similarly, as stated previously, the extremely dynamic nature of the Inner Bristol Channel (i.e. an extreme hyper-tidal range, associated with high current speeds), its physical scale and the level of temporal and spatial variance that are already the norm, due primarily to tidal processes, strongly suggest that in order for any significant change to occur a human intervention in the system would, itself, have to be very significant indeed. Within this context, the main marine infrastructure components considered as a part of this development are, in comparison, either of a very small scale (e.g. the intake-outfall structures) or designed so as to offer little hindrance to coastal processes (e.g. the temporary jetty).

b) Means of Mitigation

17.10.3 The primary means of mitigating effects on the sediment transport regime and the hydrodynamics of the local coastal environment during the construction of HPC is through appropriate engineering design and good practice in construction methodology.

17.10.4 Works on the sea wall will be limited to a defined 30 m wide corridor at the head of the shore and all associated works managed so as to prevent more widespread disturbance to the physics of the shore and, in particular, the loss of control of any solid or liquid arisings from the works. A limited barge landing area has been defined (see **Volume 2**, **Chapter 19**) in the vicinity of the historical Hinkley Point A and B graving dock, should it prove necessary to land rock armour materials for this sea wall from seaward.

17.10.5 Appropriate management arrangements will be developed and agreed with the Environment Agency regarding the potential for the area protected by the rock armour awaiting placement to tend to trap storm-driven sediments moving in to it or retard the loss of any such materials already present.

17.10.6 Works to construct the temporary jetty are likely to cause disturbance to the limestone and shale fabric of the cross-shore rocky platform. The extent of this effect will be limited by restricting the works to within a predefined corridor flanking the line of the jetty, but there is likely to be a need to make good the microtopography of the shore through reinstatement of longshore drainage channels, should localised damage occur. As a consequence, piles will be introduced from seaward rather than landward as far as it is practicable to do so. In addition, damage to the superficial geology will be limited by use of an appropriate temporary roadbed established within the access corridor.

17.10.7 The use of jack-up rigs over the lower shore could cause a similar effect to the rock surface, though over a much reduced area. Where works pass across the area of the limestone platform that dominates the middle and lower intertidal areas, any alteration to the existing microtopography and the associated long-shore drainage routes will be restored by remodelling after both construction and removal of the jetty.

17.10.8 As noted when describing the dismantling of the jetty, above, piles will be cut to rock head level across the intertidal area and the exposed voids filled and plugged. Those in the sub-tidal area would likewise be cut to seabed level, and the resultant voids allowed to backfill naturally.

17.10.9 The use of a berthing pocket allied with the jetty will give rise to localised effects upon the sediment transport regime but these will be confined to the subtidal area and be of limited extent. Good practice will be employed in managing both capital and maintenance dredging requirements in order to limit resultant effects.

17.10.10 The FRR discharge line will not be driven across the shore surface but introduced by microtunneling or similar means from landward under the sea wall and intertidal shore to reach a small low-profile seabed outfall. Thus, aside from the temporary jetty, no cross-shore works will be engaged and no cross-shore structures will persist.

17.10.11 The connection between the development site itself and the offshore cooling water intake and outfall headworks will be via tunnels bored under the shore and seabed from landward and, aside from these headworks themselves and the FRR outfall structure, there will be no structures on the seabed.

17.10.12 The construction and installation of the sea wall have the potential to release sediment into near-shore waters due to runoff from the works, excavation of the cliff face and other allied activities. This release will be constrained by application of best practice in the design of any temporary construction roadbeds and the management of the works themselves.

c) Residual Effects

17.10.13 Measures set out to mitigate the effects of construction associated with the jetty upon the cross-shore rocky platform, longshore drainage and microtopography will reduce the predicted magnitude of these effects to low.

17.10.14 The application of good practice in the management of both capital and maintenance dredging allied with the jetty berthing pocket and the introduction of the offshore intake and outfall structures will reduce the predicted magnitude of the effect to low.

17.10.15 The application of good practice in the construction of the sea wall and, should it prove necessary, to land rock armour components from seaward will reduce the predicted magnitude of any effects to low.

17.11 Mitigation of Operational Effects

17.11.1 The primary means of mitigating effects on the sediments and hydrodynamics of the local coastal environment during the operational phase will be through the engineering design incorporated into the project.

17.11.2 The sea wall will fit within the current plan form of the existing cliff line. During the operational life of the development site no structures, such as groynes or discharge lines, will extend across the intertidal shore, thus avoiding constraints on longshore sediment transport.

17.11.3 The FRR outfall structure headworks will be positioned in the near subtidal within an area of exposed rock and will not have a significant effect on either sediment transport or the tidal regime.

17.11.4 The cooling water intake and outfall headworks will be positioned well offshore. Although limited areas of scour will occur around these structures, these will have no more than a negligible effect on the local tidal and sediment regimes.

17.12 Cumulative Effects

17.12.1 This section determines whether any of the identified effects associated with individual components of the HPC development itself could be additive or combine in such a manner that they could lead to a change (e.g. increase in effect or alteration in an area affected) that would be different to that determined for the individual components alone. The potential for cumulative effects with other components of the HPC Project, namely Combwich Wharf, as well as other proposed and reasonably foreseeable projects are considered in **Volume 11** of this ES. With respect to the HPC Project it should be recognised, however, that because of the spatial separation between project components, their temporal extent and the localised effects predicted on hydrodynamic and sediment transport processes, the potential for any interaction and therefore for cumulative effects to occur is very limited.

a) Hydrodynamic Flows

17.12.2 The berthing pocket for the temporary jetty will not result in any reduction of the tidal prism as the pocket lies below the low water mark and will never be exposed. The relatively small size of the berthing pocket relative to tidal height and the open water area means that only very localised changes in flow will arise, and any such alteration will not propagate beyond a few tens of metres from that feature itself. No significant hindrance or alteration to sediment transport is expected.

17.12.3 The intake and outfall structures will lead to localised changes in current flows which will cause some scouring of sediment around the structures. However, these effects will be confined to within a few metres of the structures themselves and no wider propagation of these effects is considered likely. The structures will not have any effect on sediment transport processes within the Inner Bristol Channel as there will be no loss in sediment availability; the small-scale alteration in current velocities around the structures will be negligible in the context of the wider tidal current flows generated as a result of the hyper-tidal regime. Given that regime, there is very limited potential for interaction between the effects generated by the individual structures and any cumulative effect will thus be negligible. Therefore, overall, HPC will not have a discernible effect on the hydrodynamics of the Inner Bristol Channel.

b) Sediment Transport

17.12.4 Calculation of scour around the intake and outfall structures (Ref. 17.3) indicates that they will not significantly affect either the suspended sediment or bedload transport regimes. The sea wall, as previously discussed, will have a negligible effect on this regime and even then only potentially upon storm driven sediment transport along the upper foreshore. Hence no significant cumulative effect on sediment transport is predicted as a result of the interaction of different HPC components.

17.13 Monitoring Requirements

a) Introduction

17.13.1 Monitoring will be undertaken to inform the need for adjustment to the mitigation measures proposed and to inform the requirement for maintenance dredging.

17.13.2 Monitoring of the marine environment local to HPC will also be undertaken in order to maintain an understanding of long term trends of potential significance to engineering design.

17.13.3 The proposals below are indicative; detailed monitoring and allied contingency protocols will be subject to further development.

b) Dredging

17.13.4 For operational reasons, there will be a need to establish and maintain monitoring of vertical profiles of mud density within the temporary jetty berthing pocket. Maintenance dredging is anticipated only when densities increase to a magnitude that will permit this activity to be both needful and effective.

c) Cross-shore Profiles

17.13.5 Although an estimate of downcutting local to the sea wall has been derived on the basis of experience elsewhere, there is a risk that actual lowering may be more rapid than expected leading to premature exposure of the toe of sea wall. There is also a risk of an increased rate of lowering over the historical graving dock area with sea level rise.

17.13.6 An appropriate monitoring programme will thus be applied to secure an understanding of actual rates of cross shore profile change over the life of the site. The information that arises will be relevant to the Periodic Safety Review (PSR) process (the periodic review of trends in external hazards is a routine procedure allied with civil nuclear operations in the UK; the provision of site specific observational data is a key means of supporting this adaptive process) that will be applied by the site operator, permitting a routine review of the nature of the external hazards relevant to continued safe operation and directing forward engineering plans appropriately if any trend in these hazards is found to be outwith prior expectations.

d) Sea Level, Tidal Height and Waves

17.13.7 Climate change has introduced an element of uncertainty in future predictions of extreme sea level. Although a series of plausible extreme values have been taken into account in designing the sea wall, this uncertainty underlines the need to monitor the rates of change that will be observed over the life of HPC. The periodic review of trends in external hazards is a routine procedure allied with civil nuclear operations in the UK, termed Periodic Safety Review, and the output of such a review will lead to alterations to plant design or management procedure should this be shown to be necessary. The provision of site specific observational data is a useful means of supporting this adaptive process.

17.13.8 A 'Class A' long term Mean Sea Level tide gauge is maintained at the Hinkley Point site as a component of the Permanent Service for Mean Sea Level (PSMSL) network, maintained by the UK Proudman Oceanographic Laboratory. This instrument is currently mounted on the HPB station cooing water intake headworks. It is recognised as a long term installation. Data are available on-line at: http://www.psmsl.org.

17.13.9 A 'Waverider' directional wave and temperature recording buoy has been established in 10m of water off Hinkley Point since December 2008. This buoy is maintained as a part of the BEEMS project, although it has also been adopted as a component of the national WaveNet wave monitoring network, managed by Cefas. This deployment will be maintained throughout the construction period of HPC both to continue to secure a baseline of local wave conditions and provide management information for operations associated with the temporary jetty. The need for longer term maintenance of this deployment will be dependant on operational safety case considerations at HPC. Data are available on line at: http://www.cefas.defra.gov.uk.

e) Sediment Transport

17.13.10 On the basis of both specific studies and expert advice, evidence has been gained in the course of in this assessment that the rate of longshore transport of gravel and cobble sized material along the top of the shore and towards potential sinks to the east of Hinkley Point is limited. Given the relative sparsity of data on this sediment transport regime, the cross-shore profiling activity described above will be combined with an assessment of mobile sediment load and distribution on the Hinkley Point frontage, utilising ground based remote sensing techniques.

f) Cross-shore Platform Integrity

17.13.11 The possibility of enhanced erosion of the cross-shore rocky platform has been identified, allied with the construction and dismantling of the temporary jetty. To guard against untoward effects on the longshore drainage regime and the sensitive habitats associated with these, monitoring will assess both the establishment of the remedial measures involved and the longer term consequence of these activities, prompting further efforts in mitigation if shown to be required.

g) Scour

17.13.12 A limited degree of seabed scour will be associated with the offshore components of the temporary jetty, the cooling water intake structures, the cooling water outfall structures and the discharges arising from these latter structures. Likewise, there is the possibility of linear bathymetric features developing in association with the jetty berthing pocket.

17.13.13 The areal extent of scour associated with these structures and features will be monitored by sidescan and/or swathe sonar survey following station commissioning, and the need to revisit this effort reviewed on the basis of initial findings.

h) Technical Review Procedure

17.13.14 In consultation with the relevant regulatory bodies EDF Energy will establish and maintain a technical working group to:

- maintain active stewardship of the monitoring objectives described both above and in **Volume 2**, **Chapters 18** and **19**;
- elaborate upon the long term management strategy for the Hinkley Point frontage and, with the aid of the monitoring activities listed above, establish a Hinkley Point Coastal Monitoring Plan;
- advise upon the appropriate level of detail of these efforts; and
- review outcomes, advising on any necessary consequent action.

17.13.15 The technical working group will be made up of a number of recognised technical specialists, an independent chairman and be supported by a secretariat, all operating under agreed Terms of Reference. An interface with regulatory technical nominees will be maintained throughout and their active involvement as observers of the technical review process encouraged.

17.13.16 The group will report to EDF Energy. It is envisaged that this technical review procedure will continue to operate throughout the period of HPC construction and into the early years of generation.

17.14 Conclusions

17.14.1 The estuarine and marine environment local to Hinkley Point is dominated by an extreme, hyper-tidal regime, resulting in continuous processes of suspension/deposition/resuspension of available fine sediments and, thus, equally extreme turbidity. The primary sediment transport regime within this estuarine system is consequently tidally driven, although wave driven processes become proportionately more significant in shoaling and intertidal areas.

17.14.2 The intertidal area fronting the development site is dominated by a wide rock platform which will be subject to gradual erosion. Sediment supply from the cliff margin at the head of this and other local shores is very limited and long-shore transport of sediments to adjacent shores equally so.

17.14.3 The jetty, by design, will be open pier structure and provide limited hindrance to waves and tides. It will bridge the existing cliff line and thus have no direct effect upon it. Construction and removal activities may have an effect on the rock cross-shore platform, but appropriate means of mitigation such as limiting access from landward, employing a temporary roadbed and biasing the works towards those from seaward, have been identified to deal with this.

17.14.4 A berthing pocket will be established in connection with the temporary jetty. Dredging will be required to establish this pocket and maintenance dredging, potentially at intervals, thereafter. The consequence of these operations for the local hydrodynamic and geomorphological regimes will be negligible.

17.14.5 A series of cooling water intake and outfall structures will be established on the seabed offshore. Although a very limited area of scour will develop around these structures, as well as the more offshore pile supports of the jetty, no more than a negligible effect on either the hydrodynamic or geomorphological regimes is foreseen.

17.14.6 The sea wall will be constructed within the line of the current cliff line and, aside from the temporary jetty, no structures will extend across the shore itself. Although this sea wall will deny some sediment supply to the sediment transport regime the quantity involved will be very small. With time the intertidal area will narrow due both to progressive downcutting of the shore and relative sea level rise; the only influence of the sea wall will be to retard the landward evolution of the cross-shore profile.

17.14.7 In this context, and with the application of appropriate engineering design, the development proposals described here will not have a significant effect on existing coastal, estuarine and marine hydrodynamic and geomorphological processes within the area concerned.

CHAPTER 18: MARINE WATER AND SEDIMENT QUALITY

CONTENTS

TABLES

FIGURES

APPENDICES

18. MARINE WATER AND SEDIMENT QUALITY

18.1 Introduction

18.1.1 This chapter of the Environmental Statement (ES) provides an assessment of the potential impacts to marine water quality during the construction, commissioning and operation of the proposed Hinkley Point C (HPC) power station (see **Chapters 2**, **3** and **4** of this volume of the ES for details). The assessment also considers sediment quality characteristics that could affect marine water quality. Freshwater systems are considered within **Volume 2**, **Chapter 16**. The assessment proposes suitable mitigation to manage any potential adverse impacts that are identified.

18.2 Scope and Objectives of Assessment

18.2.1 The scope of the assessment has been determined following consultations with statutory consultees and feedback from the Stage 1, 2 and 2 Update consultation processes. The assessment has been undertaken adopting the methodologies described in Section 18.4 below.

18.2.2 The objectives of the assessment are to:

- identify all water quality receptors within the study area that may be affected by the HPC development;
- characterise the baseline environmental conditions for marine water and sediment quality within the study area;
- detail the impacts associated with HPC's construction, commissioning and operation on marine water quality receptors;
- recommend mitigation measures, if determined necessary, to reduce the impacts of the HPC development on marine water quality receptors; and
- assess the residual impacts of the HPC development on marine water quality.

18.2.3 The study area and baseline conditions for the assessment are described in Section 18.5. In the absence of adequate historical data, the baseline conditions are based on the results of a series of marine water monitoring and sediment core sampling campaigns undertaken in 2009. Section 18.5 also identifies existing and possible future receptors.

18.2.4 Section 18.6 assesses changes HPC might cause to the baseline marine water quality of the site and potential impacts generated by these changes are identified. The potential exists for a period of overlapping generation involving both Hinkley Point B (HPB) and HPC, which is relevant to this assessment. The assessment methodologies applied within this chapter, therefore, reflect this.

18.2.5 The elements of the development during the construction phase that could lead to marine water quality being affected are:

- surface drainage and groundwater discharges to the foreshore;
- construction of the construction outfall;
- construction of the temporary jetty;
- treated sewage effluent from the temporary sewage works;
- drilling of the cooling water tunnel;
- installation of the cooling system head structures;
- operation and dismantling of the temporary jetty;
- construction of the sea wall; and
- hydrocarbons from plant.

18.2.6 The elements of the development during the commissioning phase that could lead to marine water quality being affected are the:

- surface drainage and groundwater discharges to the foreshore (until the cooling water system becomes available, which would then become the route of discharge);
- treated sewage effluent from the temporary sewage works (until the permanent treatment works are in place and the cooling water system is made available, which would then become the route of discharge); and
- discharge of commissioning test waters (to the foreshore for 'cold' tests, and to the subtidal via the cooling water outfall once available for 'hot' tests).

18.2.7 The elements of the development during the operational phase that could lead to marine water quality being affected are the:

- surface drainage and groundwater discharges via the cooling water tunnel;
- groundwater discharge to the foreshore via the percolated sea wall drainage system;
- discharge of the operational cooling water (including operational chemical contributions) to the Bristol Channel; and
- treated sewage effluent, from an on-site sewage treatment works, via the cooling water tunnel.

18.2.8 Consideration is also given to the potential impact of unplanned (accidental) events and incidents.

18.2.9 Appropriate mitigation measures aimed at preventing, reducing or off-setting any potential adverse impacts of the proposed development that are identified to be of significance in Section 18.6 are identified in Section 18.7 and any residual impacts following implementation of the mitigation measures are assessed.

18.3 Legislation, Policy and Guidance

18.3.1 This section identifies and describes legislation, policy and guidance of relevance to the assessment of potential marine water quality impacts associated with the construction, operation and post-operational phases of the proposed development.

18.3.2 As stated in **Volume 1, Chapter 4**, the Overarching National Policy Statement (NPS) for Energy (NPS EN-1), when combined with the NPS for Nuclear Power Generation (NPS EN-6), provides the primary basis for decisions by the IPC on applications for nuclear power generation developments that fall within the scope of the NPSs.

18.3.3 Notwithstanding this, the IPC may consider other matters that are both important and relevant to its decision-making. This could include Planning Policy Statements (PPSs), Planning Policy Guidance Notes (PPGs), regional and local policy documents, although, if there is a conflict between these and the NPS, the NPS prevails for the purposes of IPC decision making.

18.3.4 Further, the Planning Act 2008 provides that the IPC must, in making its decision on an application, have regard to any Local Impact Report (LIR) prepared by relevant local authorities. It is anticipated that the LIRs will rely in part on PPSs, PPGs, regional and local policy to provide a context for their assessment. On this basis, regard has been given to these documents (where relevant to the technical assessment) since they are likely to inform the LIRs prepared by the relevant local authorities.

a) International

18.3.5 Many standards for water quality are regulated at EU level through a range of environmental directives. The most relevant of these to the proposed development are:

- Water Framework Directive (2000/60/EC) (Ref. 18.1).
- Priority Substances Directive (2008/105/EC) (Ref. 8.2).
- Dangerous Substances Directive (76/464/EEC) (Ref. 18.3).
- Birds Directive (Directive 2009/147/EC – this is the codified version of Directive 79/409/EEC as amended) (Ref. 18.4).
- Habitats Directive (92/43/EC) (Ref. 18.5).
- Marine Strategy Framework Directive (2008/56/EC) (Ref. 18.6).
- Urban Waste Water Treatment Directive (91/271/EEC) (Ref. 18.7).
- Freshwater Fish Directive (2006/44/EC - this is the codified version of Directive 78/659/EEC as amended) (Ref. 18.8).
- Revised Bathing Waters Directive (2006/44/EC) (Ref. 18.9).
- Shellfish Waters Directive (2006/113/EC – this is the codified version of Directive 79/923/EEC) (Ref. 18.10).

i. Water Framework Directive

18.3.6 The Water Framework Directive (WFD) is a key piece of legislation relating to the protection of water quality and the ecological status of fresh and coastal waters.

18.3.7 The WFD provides a mechanism by which disparate regulatory controls on human activities that have the potential to impact on water quality may be managed effectively and consistently. In addition to a range of inland surface waters and groundwater, the WFD covers transitional waters (estuaries and lagoons) and coastal waters up to one nautical mile from mean low water (baseline from which territorial waters are measured). Existing regulations that will eventually be subsumed by the WFD include the Freshwater Fish Directive (consolidated as 2006/44/EC) (Ref. 8.8), Shellfish Waters Directive (consolidated as 2006/113/EC) and the Dangerous Substances Directive (76/464/EEC) (Ref. 8.3). The WFD is implemented in England and Wales primarily through the Water Environment (Water Framework Directive) (England and Wales) Regulations 2003 (known as the Water Framework Regulations) (Ref. 8.11).

18.3.8 UK surface waters have been divided into a number of discrete units termed ‘water bodies’, with meaningful typologies that relate to their physical and ecological characteristics. Based upon ecology and water quality, these water bodies have been classified as falling into different status classes. The WFD requires that all inland and coastal waters must reach at least ‘good’ status by 2015 and that the status of all surface water bodies should not deteriorate. Individual water bodies that have been modified by man to the extent that it will not be possible for them to meet the WFD targets are categorised as Heavily Modified Water Bodies and need to reach ‘good’ potential.

18.3.9 Member states have the option to defer meeting WFD objectives by 2015 if it is considered technically unfeasible and/or financially disproportionate to do so. In the UK, a number of water bodies have had meeting their objectives deferred until 2027, including some of those around Hinkley Point.

18.3.10 Implementation of the WFD is primarily achieved through a system of river basin management planning. The water bodies of England and Wales have been allocated to river basin areas depending on catchment areas and a management plan has been drawn up for each. The plans contain a programme of measures tailored to each catchment and designed to ensure the constituent water bodies achieve and maintain the appropriate status in accordance with the timelines set out in the WFD.

ii. Dangerous Substances Directive

18.3.11 The Dangerous Substances Directive (DSD) (76/464/EEC) (Ref. 8.3) and its ‘daughter’ directives are concerned with controlling the level of discharges that may contain dangerous substances that may reach inland, coastal and territorial waters. The Directive identified substances for which limit values and Environmental Quality Standards (EQS) were established at European Level (List I). Some of these EQS have now been superseded by no less stringent standards established by the Priority Substances Directive 2008/105/EC (Ref. 18.2) for substances identified in Annex X of the WFD. Where this is not the case, limit values and environmental quality standards set by the DSD ‘daughter’ Directives listed in Annex IX of the WFD remain in force.

18.3.12 The DSD also defined substances where standards were to be set by the Member State (List II). For marine waters these were implemented by the Surface Waters (Dangerous Substances) (Classification) Regulations 1997 (Ref. 8.12). Again, some of these standards have already been superseded by standards set by Member States for specific pollutants defined in defined in Annex VIII of the WFD.

18.3.13 The River Basin Districts Typology, Standards and Groundwater Threshold Values (Water Framework Directive) (England and Wales) Directions 2010 (Ref. 8.13) complete the transposition of the Priority Substances Directive in England and Wales.

iii. Priority Substances Directive

18.3.14 The Priority Substances Directive (PSD) (Ref. 8.2) replaces the Dangerous Substances Directive (Ref. 8.3) and establishes environmental quality standards (EQS) for an initial 33 priority and priority hazardous substances. Compliance with these standards forms the basis of Good surface water chemical status under the WFD.

18.3.15 The PSD (Ref. 8. 2) is a daughter directive of the WFD. It establishes environmental quality standards for a first list of 33 priority substances and priority hazardous substances or groups of substances which now form Annex X of the WFD. Compliance with these standards forms the basis of good surface water chemical status under the WFD.

18.3.16 Birds Directive The codified Birds Directive (2009/147/EC) (Ref. 8.4) provides a comprehensive scheme of protection for all wild bird species naturally occurring in the European Union. The Directive recognises that habitat loss and degradation are the most serious threats to the conservation of wild birds. It emphasises the protection of habitats for endangered and migratory species (listed in Annex I) via the establishment of a coherent network of Special Protection Areas (SPAs) comprising all the most suitable territories for these species.

18.3.17 Since the implementation of the Habitats Directive in 1994, all SPAs form an integral part of the Natura 2000 conservation network, and in UK law are offered protection via the regulations applied under the Habitats Directive (Conservation of Habitats and Species Regulations 2010) (Ref. 8.14).

iv. Habitats Directive

18.3.18 The Habitats Directive (92/43/EC) (Ref. 8.5) is designed to promote biodiversity by requiring Member States to take measures to maintain or restore natural habitats and wild species. The Directive is transposed into UK law under the Conservation of Habitats and Species Regulations 2010 (Ref. 8.14).

18.3.19 The Habitats Directive requires Member States to:

- maintain or restore European protected habitats and species listed in the Annexes at or to a favourable conservation status as defined in Articles 1 and 2; and
- contribute to a coherent European ecological network of protected sites by designating Special Areas of Conservation (SACs) for habitats listed on Annex I and for species listed on Annex II.

18.3.20 Together with SPAs designated under the Birds Directive (Ref. 8.4), SACs form an integral part of the Natura 2000 conservation network.

18.3.21 Under the Habitats Directive, it is necessary to consider whether an activity is likely to have a significant impact alone or in combination with other plans, projects and activities. For an activity to be approved, the assessment should conclude that there will be no adverse affect on the integrity of a European site, otherwise it is necessary to show that there are no alternatives and that the project is necessary for reasons off overriding public interest. Further information regarding the Habitats Directive is presented in **Volume 2**, **Chapter 19** (Marine Ecology) and the **Habitats Regulations Assessment Report** (Ref. 8.15).

18.3.22 For significant discharges to a water body it is necessary to assess whether any hazard identified is likely to affect the interest features of the European site. Where possible the aim should be to avoid rather than reduce any adverse impact on the integrity of the European Sites. Natural England and Environment Agency guidance lists the following types of hazards for habitats, species and birds:

- toxic contamination;
- pH;
- siltation;
- turbidity;
- nutrient enrichment;
- physical damage;
- salinity;
- thermal regime; and
- organic enrichment.

v. Marine Strategy Framework Directive

18.3.23 The objective of the Marine Strategy Framework Directive (MSFD) (Ref. 8.6) is to achieve ‘good environmental status’ in Europe’s seas by 2020, enable the sustainable use of the marine environment and to safeguard its use for future generations.

18.3.24 The MSFD establishes a comprehensive structure within which EU Member States are required to develop and implement the cost effective measures necessary to achieve or maintain “good environmental status” in the marine environment.

18.3.25 The Directive establishes European Marine Regions and requires Member States to apply an ecosystem based approach to the management of human activities. The timetable for implementation of the strategy is from July 2010 through to December 2016. In the UK, the Directive is implemented via the Marine Strategy Regulations 2010 (Ref. 8.16) and the Regulations will ensure the definition of environmental targets and indicators for marine waters by July 2012.

18.3.26 In coastal waters out to one nautical mile, both the WFD and the MSFD apply. However, in these areas the MSFD only applies for aspects of good environmental status that are not already addressed by the WFD. These include issues such as the impacts of marine noise and litter, and certain aspects of biodiversity but not water quality.

vi. Urban Waste Water Treatment Directive

18.3.27 The Urban Waste Water Treatment Directive (Ref. 8.7) seeks to protect the environment from the adverse effects of discharges of sewage and some industrial effluents of a similar nature. It sets treatment levels on the basis of size of discharge and the sensitivity of the receiving waters.

vii. Freshwater Fish Directive

18.3.28 The Freshwater Fish Directive (Ref. 8.8) is concerned with protecting and improving the quality of rivers and lakes to encourage and sustain healthy fish populations. The Directive is the source of many of the EQS (particularly those that are not specified by the WFD) that are used within this assessment as screening thresholds in the absence of appropriate saltwater limits.

viii. Bathing Waters Directive

18.3.29 The revised Bathing Waters Directive (2006/44/EC) (Ref. 8.9) is concerned with protecting and improving the quality of designated bathing waters. Bacterial and visual quality objectives are set and monitoring is required for designated bathing waters. The Directive includes public information requirements and procedures for management of bathing waters in the light of monitoring results.

ix. Shellfish Waters Directive

18.3.30 The Shellfish Waters Directive (2006/113/EC) (Ref. 8.10) is concerned with protecting and improving the quality of designated shellfish waters. Physical and chemical water quality objectives are set and monitoring is required for designated areas.

18.3.31 The Directive was originally adopted in 1978 and consolidated in 2006, but it will be repealed in 2013 by the WFD.

b) National

i. Water Quality and Resources

18.3.32 The Environment Agency is the principal regulator of water quality in England and Wales, and has regulatory authority under the following water-related legislation:

- Environmental Permitting (England and Wales) Regulations 2010 (Ref. 8.17).
- Environment Act 1995 (Ref. 8.18).
- Water Resources Act 1991 (Ref. 8.19).
- Environmental Protection Act 1990 (Ref. 8.20).
- Pollution Prevention and Control Act 1999 (Ref. 8.21).
- Surface Waters (Dangerous Substances) Regulations 1989 (Ref. 8.22).
- Water Environment (Water Framework Directive) (England and Wales) Regulations 2003 (the Water Framework Regulations) (Ref. 8.23).
- Marine Strategy Regulations 2010 (Ref. 8.16).
- The River Basin Districts Typology, Standards and Groundwater threshold values (Water Framework Directive) (England and Wales) Directions 2009 (Ref. 8.13).
- Marine and Coastal Access Act 2006 (Ref. 8.24).
- Water Act 2003 (Ref. 8.25).

ii. Environmental Permitting (England and Wales) Regulations 2010

18.3.33 The Environmental Permitting Regulations 2010 (Ref. 8.17) provide a consolidated system for environmental permits, and exemptions, for activities which include discharges to surface waters. It also sets out the powers, functions and duties of the regulators. The Environmental Permitting Regulations repeal parts of the Water Resources Act 1991 (Ref. 8.19).

iii. Environment Act 1995

18.3.34 The Environment Act 1995 (Ref. 8.18) established basic terms of reference for the Environment Agency. The Act provides the Environment Agency with a duty to take action when necessary to conserve, enhance and secure the proper use of water resources in England and Wales. In terms of land drainage and flood defence functions, the Act places a duty on the Environment Agency with respect to the conservation of natural beauty and sustainable development.

iv. Water Resources Act 1991

18.3.35 The Water Resources Act 1991 (Ref. 8.19) (as partly amended by the Water Act 2003 (Ref. 8.25)) sets out the regulatory controls and restrictions that provide protection to the water environment through controls on abstraction, impounding and discharges as well as identifying water quality and drought provisions. This Act set the framework for surface water management over the past two decades in the UK, but elements of the Act have now been superseded by the Environmental Permitting (England and Wales) Regulations 2010 (Ref. 8.17).

v. Environmental Protection Act (EPA) 1990

18.3.36 Part IIA of the Environmental Protection Act 1990 (Ref. 8.20) describes a regulatory role for Local Authorities in dealing with contaminated land, including assessment of any resulting pollution of controlled waters.

vi. Pollution Prevention and Control Act 1999

18.3.37 The Pollution Prevention and Control Act 1999 (Ref. 8.21) provides a legal framework under which pollution prevention and control for emissions to air, land and water is regulated.

vii. Surface Waters (Dangerous Substances) (Classifications) Regulations 1989

18.3.38 The Surface Waters Regulations (Ref. 8.22) prescribe a system for classifying the quality of inland freshwaters, coastal waters and relevant territorial waters with a view to reducing the pollution of those waters by dangerous substances (as defined by the Dangerous Substances Directive (Ref. 8.3)). The Regulations require the Environment Agency to monitor the effect of discharges containing dangerous substances.

viii. Water Environment (Water Framework Directive) (England and Wales) Regulations 2003 (the Water Framework Regulations)

18.3.39 The Water Environment Regulations 2003 (Ref. 8.23) make provision for the purpose of implementing the WFD (Ref. 8.1). The Environment Agency is required to carry out detailed monitoring and analysis in relation to each river basin district. The results of the Environment Agency's technical work, the environmental objectives and proposals for programmes of measures are brought together in a River Basin Management Plan (RBMP) for each river basin district. The South West RBMP covers the study area for the surface water assessment (see paragraph 18.3.62 below).

ix. Marine Strategy Regulations 2010

18.3.40 The Marine Strategy Regulations 2010 (Ref. 8.16) make provision for the purpose of implementing the MSFD (Ref. 8.6). The regulations require the competent authority (undecided at present, but likely to be one of the Environment Agency, Natural England or the Marine Management Organisation) to make an assessment of the current state of English and Welsh seas, and develop a detailed description for Good Environmental Status for those waters by July 2012. A monitoring programme will be developed and implemented by July 2014, with the aim of establishing a programme of measures for achieving Good Environmental Status by July 2016.

x. Marine and Coastal Access Act 2009

18.3.41 The Marine and Coastal Access Act 2009 (Ref. 8.24) aims to enable better protection of marine ecosystems and prevent a decline in marine biodiversity. The Act sets out provisions for more coherent planning in the marine environment in terms of issuing consents and permits for activities in the marine and coastal environment (Marine Licences; see 'Marine development' below). The Act also contains provisions to allow for the designation of Marine Conservation Zones (MCZs) and the creation of a network of Marine Protected Areas (MPAs).

xi. Water Act 2003

18.3.42 The Water Act 2003 (Ref. 8.25) is the regulatory framework for the management and regulation of surface and groundwater resources in England and Wales. The Act provides a legislative framework to facilitate both sustainable water resources management and economic growth through its provisions.

18.3.43 For the purpose of the HPC development the key piece of water quality legislation is the Environmental Permitting Regulations 2010 (Ref. 8.17). The Environmental Permitting Regulations supersede the Water Resources Act, 1991 (Ref. 8.19) in this regard. Discharges of cooling water to the Bristol Channel and surface drainage waters to the foreshore area would both be subject to environmental permit control.

18.3.44 Statutory port and harbour authorities also have important roles in managing some aspects of water quality. For example, the Port of Bridgwater has in place an oil spill contingency plan.

Marine Development

18.3.45 The Marine Management Organisation (MMO) is the principal regulator for development below the level of mean high water spring tides (MHWS) in English waters and exercises control on such development (including marine works, dredging and dredgings disposal) through the issue of marine licences under the Marine and Coastal Access Act 2009 (Ref. 8.24).

18.3.46 The proposed construction and operation of the HPC Power Station is a nationally significant infrastructure project under the Planning Act 2008 and is required to be authorised by a Development Consent Order (DCO). However, the marine works aspects of the development (including construction below MHWS and dredging at sea) also require separate Marine Licences from the MMO. Marine licences replace, *inter alia*, those formerly issued under the Food and Environment Protection Act (FEPA) 1985 (Ref. 8.26).

Wildlife Conservation

18.3.47 The Wildlife and Countryside Act 1981 (Ref. 8.27) (as amended) provides for notification of areas down to low water mark as sites of special scientific interest and for their protection, as well as affording protection to particular species listed in the 1981 Act wherever they are.

18.3.48 Similar protection will be applied to MCZs that can be designated at sea under the Marine and Coastal Access Act 2009 (Ref. 8.24).

18.3.49 Proposals that affect the intertidal zone are regulated by the Environment Agency in accordance with Shoreline Management Plans. Further regulatory powers are also extended to Natural England and the Countryside Council for Wales as statutory consultees, particularly where development proposals fall within designated (Natura 2000) European Marine Sites.

c) National Planning Policy

i. Planning Policy Statement 1 (PPS1): Delivering Sustainable Development (2005)

18.3.50 PPS1 (Ref. 8.28) was published in 2005 and sets out the Government's overarching planning policies on the delivery of sustainable development through the planning system.

18.3.51 Paragraph 22 of PPS1 advises that regional planning authorities and local authorities should promote, amongst other things, the sustainable use of water resources and the use of sustainable drainage systems in the management of run-off.

ii. Planning Policy Statement 23 (PPS23): Planning and Pollution Control (2004)

18.3.52 PPS23 (Ref. 8.29) is intended to complement the pollution control framework under the Pollution Prevention and Control Act 1999 (Ref. 8.30) and the Pollution Prevention and Control Regulations 2000 (Ref. 8.31). The statement advises of the importance of the planning system in determining the location of developments that may give rise to pollution, either directly or indirectly. The statement also ensures that other uses and developments are not, as far as possible, affected by major existing or potential sources of pollution.

18.3.53 PPS23 (Ref. 8.29) advises that, amongst other things, the following matters may be material in the consideration of individual planning applications where pollution considerations arise:

- *"…the possible adverse impacts on water quality and the impact of any possible discharge of effluent or leachates which may pose a threat to surface or underground water resources directly or indirectly through surrounding soils; and*

- *the need to make suitable provision for the drainage of surface water…"* (Page 12)

iii. Technical Advice Note 5: Nature and Conservation Planning (2009)

18.3.54 As material dredged from the offshore developments may be disposed to the Cardiff Grounds, Welsh Planning Policies also need to be taken into consideration. Planning Policy Wales (2011) (Ref. 8.32) provides the policy framework for land-use planning and development in Wales, and is supplemented by 21 topic-based Technical Advice Notes (TANs).

18.3.55 Technical Advice Note 5: Nature and Conservation Planning (2009) (TAN5) (Ref. 8.32) provides advice on how the land-use planning system should contribute to protecting and enhancing biodiversity and geological conservation. The TAN provides advice for local planning authorities on:

- the key principles of positive planning for nature conservation (water quality is an important contributor to the diversity and ecological status of aquatic ecosystems);
- nature conservation and local development plans;
- nature conservation in development management procedures;
- developments affecting protected internationally and nationally designated sites and habitats; and
- developments affecting protected and priority habitats and species.

iv. Environment Agency Guidance to New Nuclear Build

18.3.56 In response to recent government commitments to nuclear power generation, and the expectation of a number of planning and permitting applications for new nuclear power stations, the Environment Agency has produced specific guidance to developers relating to their discharges. Guidance papers are available on:

- Numerical modelling (for cooling water discharges) (Ref. 8.33);
- Temperature thresholds for TRaC waters receiving thermal discharges (Ref. 8.34); and
- Discharges during the construction phase (Ref. 8.35).
- Guidance on permitting non-nuclear discharges (Ref. 18.36).

d) Regional Planning Policy

18.3.57 The Government's revocation of regional strategies was quashed in the High Court on 10 November 2010. However, on that same date the Government reiterated in a letter to Chief Planners its intention to revoke regional strategies through the Localism Bill. This letter was also challenged but, on 7 February 2011, the High Court held that the Government's advice to local authorities that the proposed revocation of regional strategies was to be regarded as a material consideration in their planning development control decisions should stand. The decision of the High Court was upheld by the Court of Appeal on 27 May 2011. Therefore, the regional strategies remain in place but in the case of development control decisions it is for planning decision makers to decide on the weight to attach to the strategies (see

Volume 1, Chapter 4 for a full summary of the position regarding the status of regional planning policy).

ii. Regional Planning Guidance 10 for the South West 2001 – 2016 (RPG10) (2001)

18.3.58 RPG 10 (Ref. 8.37) sets out the broad development strategy for the period to 2016 and beyond. Policy RE1 (Water Resources and Water Quality) states that to achieve the long term sustainable use of water, water resources need to be used more efficiently. The policy also states that the quality of inland and coastal water environments must be conserved and enhanced.

iii. The Draft Revised Regional Spatial Strategy (RSS) for the South West Incorporating the Secretary of States Proposed Changes 2008 – 2026 (July 2008)

18.3.59 Chapter 7 of this strategy (Ref. 8.38) deals with Enhancing Distinctive Environments and Cultural Life. Policy RE6 (Water Resources) states that the region's network of ground, surface and coastal waters and associated ecosystems will be protected and enhanced; surface and groundwater pollution risks must be minimised so that EQS are met (and, where possible, bettered); local planning authorities must ensure that rates of planned development do not exceed the capacity of existing water supply and wastewater treatment systems; and local planning authorities allow developments to proceed ahead of essential planned improvements to these systems wastewater treatment systems.

iv. Somerset & Exmoor National Park Joint Structure Plan Review 1991-2011 (2000)

18.3.60 The Somerset & Exmoor National Park Joint Structure Plan (Ref. 8.39) was adopted in 2000 with relevant policies saved from 27 September 2007. All policies have been saved with the exception of Policy 53 which is unrelated to marine water quality impacts. The Plan provides a strategic base for all land use planning within the plan area for the period up to 2011.

18.3.61 Policy 59 (Safeguarding Water Resources) states that protection will be afforded to all surface, underground and marine water resources from development which could harm their quality or quantity.

v. River Basin Management Plan, South West River Basin District (2009)

18.3.62 The South West River Basin Management Plan (SWRBMP) (Ref. 8.40) has been prepared for the South West River Basin District's rivers and coastal areas under the requirements of the WFD. The plan describes the river basin district and the pressures that the water environment faces. It shows what this means for the current state of the water environment, and what actions will be taken to address the identified pressures. It sets out what improvements are possible by 2015 and how the actions will make a difference to the local environment – the catchments, the estuaries and coasts, and the groundwater.

18.3.63 The plan sets out that development planning plays a key role in sustainable development and that the Environment Agency will continue to work closely with planning authorities to ensure that planners understand the objectives of the Water Framework Directive and area able to translate them into planning policy (page 29).

18.3.64 The plan presents current and future water body status objectives (Annex B) and thus site specific Environmental Quality Standards (EQS) can to be derived.

18.3.65 For the Bridgwater Bay and the River Parrett WFD water bodies, achievement of objectives has been deferred until 2027.

e) Local Policy

i. West Somerset District Local Plan (2006) (Policies 'saved' from17 April 2009).

18.3.66 The West Somerset Local Plan forms part of the development plan for West Somerset. The Local Plan (Ref. 18.41) was adopted in April 2006 (with relevant policies 'saved' from 17th April 2009). The Proposals Map indicates that the site is not subject to any specific marine water quality designations. The site lies outside of the defined Development Boundary.

18.3.67 The following saved policies are considered to be potentially relevant:

18.3.68 Policy W/2 (Surface Water Protection) states:

> *"Development which would adversely affect the quantitative and quality aspects of surface, underground or coastal waters will only be permitted where acceptable mitigating works are undertaken as an integral part of that development."*

18.3.69 Policy CO/1 (The Coastal Zone):

> *Development proposals in any part of the Coastal Zone, including those areas of existing developed coast, will only be permitted where:*
>
> *i) the development and its associated activities are unlikely to have an adverse affect, either directly or indirectly on:*
>
> *a) heritage features;*
>
> *b) landscape character areas;*
>
> *c) nature conservation interests, including sub-tidal and marine habitats; and*
>
> *d) residential amenities.*
>
> *ii) the development is unlikely to have an adverse affect on the character of the coast and maintains and where possible, enhances, improves or upgrades the environment particularly in derelict and/or despoiled coastal areas; and*
>
> *iii) the development requires a coastal location.*

ii. West Somerset District Local Development Framework (LDF) Core Strategy (Options Paper) (January 2010)

18.3.70 The West Core Strategy (Ref. 8.42) is at a preliminary stage of preparation and the Options Paper does not include any specific policies relating to surface water impacts. The paper does however identify the types of policy that WSC considers could be included in the Core Strategy, including a requirement that new developments incorporate measures to mitigate flood risk and manage surface water runoff through appropriate use of SUDS (sustainable drainage systems) (page 15).

iii. Supplementary Planning Guidance

18.3.71 Sedgemoor District Council and West Somerset Council have jointly prepared draft supplementary planning guidance in relation to the HPC Project. Public consultation on the Consultation Draft version of the Hinkley Point C Project Supplementary Planning Document (the draft HPC SPD) commenced on 1 March 2011 and concluded on 12 April 2011. EDF Energy has submitted representations which object to the draft HPC SPD. See Volume 1, Chapter 4 for a full summary of the position regarding the status of the draft HPC SPD.

18.3.72 Box 10 in the draft HPC SPD sets out the approach to Masterplanning and Design of the Main Site. In relation to marine water quality, Box 10 states that the HPC project promoter will be expected to, amongst other things:

> *"…identify appropriate mitigation measures for impacts on protected species or Biodiversity Action Plan Priority Species and nature conservation interests, including:*
>
> *…Effects on water quality and migratory fish populations."*

18.3.73 Further planning policy context is provided in the Legislative and Planning Policy Context chapter (**Volume 1**, **Chapter 4**) and the Introduction chapter for this volume (**Volume 2**, **Chapter 1**).

f) Best Practice Guidance

18.3.74 A range of best practice guidance is of relevance to this assessment including the following (only those specifically referred to in the assessment of impacts are included in the reference list):

- Environment Agency Pollution Prevention Guidance notes (PPG) (Ref. 8.43), including:
  - PPG 1 General guide to the prevention of water pollution;
  - PPG 2 Above ground oil storage tanks;
  - PPG 3 Use and design of oil separators in surface water drainage systems;
  - PPG 4 Disposal of sewage where no mains drainage is available;
  - PPG 5 Works in, near or liable to affect watercourses;
  - PPG 6 Working at construction and demolition sites;
  - PPG 8 Safe storage and disposal of used oils; and
  - PPG 21 Pollution incident response planning.
- Construction Industry Research and Information Association (CIRIA) Report C532: Control of Water Pollution from Construction Sites (Ref. 8.44);
- CIRIA Report C650502: Environmental Good Practice on Site (Ref. 8.45).

- CIRIA Culvert Design and Operation Guide (C689) (Ref. 8.46).
- CIRIA: The SUDS Manual (C697) (Ref. 8.47).
- Designing for Exceedence in Urban Drainage – Good Practice, C635 (2006) (Ref 8.48). This has been used in the determination of an appropriate drainage strategy for the HPC development site HPC.

18.4 Methodology

18.4.1 The assessment and supporting surveys have been conducted in accordance with relevant best practices and standard methodologies. The survey programme was undertaken in accordance with standard protocols for sampling set out in the British Standard for Water Quality Sampling BS EN ISO 5667: 2006 (Ref. 8.49). Samples from the baseline surveys were analysed at MCerts and UKAS accredited testing laboratories. **Volume 1**, **Chapter 7** presents the EIA methodology framework within which this assessment has been carried out. A summary of the work undertaken, and the methodologies adopted to assess the significance of potential impacts, is provided in the following sections.

a) Study Area

18.4.2 The geographical extent of the area under consideration is shown in **Figure 18.1**, and comprises:

- the foreshore and intertidal area receiving existing and proposed surface drainage freshwater discharges; and
- the marine waters offshore from Hinkley Point to a radial distance of 5km, as this encompasses the furthest modelled physical extent of the cooling water discharge plume.

b) Baseline Assessment

18.4.3 Baseline characterisation of the marine water quality and sediments was identified through:

- collection and analysis of marine water samples from within the study area offshore of Hinkley Point (see paragraphs 18.4.5 – 18.4.13);
- chemical analysis of sediment collected from within the study area offshore of Hinkley Point (see paragraphs 18.4.5 – 18.4.13);
- numerical modelling of the cooling water plume from Hinkley Point B (HPB);
- review of the scientific literature relating to the water and sediment quality of the Bristol Channel;
- review of marine water quality assessments, modelling and reporting undertaken by British Energy Estuarine and Marine Studies (BEEMS); and
- consultation with appropriate statutory bodies (e.g. Environment Agency, Natural England, Countryside Council for Wales, MMO); see paragraph 18.4.16.

18.4.4 The Environment Agency has only limited historical data available for the waters off Hinkley Point. Data held by the Centre for Environment, Fisheries and Aquaculture Science (Cefas; a Defra body) are reviewed in BEEMS (2011) (Ref. 8.50). Given the limited data available, a marine water quality programme was developed and undertaken during 2009 (Ref. 8.51). A brief summary of this programme is provided here.

Marine Water Quality Survey

18.4.5 The sampling approach adopted for the study was to obtain seasonal 'snap shots' of water quality conditions from four sampling visits. The sampling visits were carried out in January, May, June and September 2009. The dates for each campaign were selected so that the complete data set contains data collected across a range of tidal conditions (e.g. neap and spring tides) and during different seasons.

18.4.6 The sampling approach, and proposed suite of parameters, was discussed and agreed with the Environment Agency (confirmed by email) in December 2008 on the understanding that historical data would also be reviewed. The field sampling was conducted on the following dates:

- 27-28 January 2009: spring tide;
- 1-2 May 2009: neap tide;
- 27-28 June 2009: spring tide; and
- 12-13 September 2009: neap tide.

18.4.7 The location of sampling points was originally defined in late 2008 to reflect initial engineering design assumptions on proposed locations for the HPC cooling water intake and outfall structures. One sampling zone was established within a polygon around a point approximately 2.5km offshore, and another around a point approximately 5km offshore. The locations of the sampling areas are shown in Figure 18.2.

18.4.8 Within each of the two sampling zones, ten water quality sampling point locations and eight water profiling point locations were identified. Following the final decision on the locations of intake and outfall, additional sampling points were added to show spatial differences and gradients across the offshore sampling area.

18.4.9 At each monitoring location, three water samples were collected; one from approximately 0.5m below the surface, one at mid-depth and one just above the sea bed.

18.4.10 The full suite of chemical parameters and minimum reporting values (MRV) are presented in **Table 18.1**.

18.4.11 *In situ* water quality parameter profiling through the water column was undertaken at five stations in the offshore sampling area, at five stations in the near shore area, and an additional four intermediate locations added after the first sampling campaign. Water temperature, dissolved oxygen and salinity were measured using a pre-calibrated multi-probe sonde.

18.4.12 During all campaigns a replicate set of samples was collected from one location selected at random. A blank sample was also submitted for analysis to act as further quality assurance of sample handling and analysis. There was good agreement between the main and replicate samples.

Table 18.1: Suite of Chemical Determinands Tested During Marine Water Quality Sampling

Determinand	MRV	Units	Accreditation?
Aluminium	5	µg/l	Y
Ammonium as NH4 (mg/l)	0.03	mg/l	N
Arsenic (total and dissolved)	1	µg/l	Y
Biochemical Oxygen Demand	2	mg/l	N
Boron (total and dissolved)	5	µg/l	Y
Cadmium (dissolved)	1	µg/l	Y
Cadmium (total)	1	µg/l	Y
Chemical Oxygen Demand	2	mg/l	N
Chloride	1	mg/l	Y
Chloroform	1	µg/l	N
Chromium (total and dissolved)	1	µg/l	Y
Copper (total and dissolved)	1	µg/l	Y
Detergents	100	µg/l	N
Dibromo acetic acid	1	µg/l	N
Dibromoacentonitile	1	µg/l	N
Dibromochloromethane	1	µg/l	N
Dichlorobromomethane	1	µg/l	N
Dichloromethane	1	µg/l	N
Ethanolamine	0.01	mg/l	N
Free Chlorine	100	µg/l	Y
Hydrazine	0.1	mg/l	N
Iron (total and dissolved)	5	µg/l	Y
Lead (total and dissolved)	1	µg/l	Y
Lithium	10	µg/l	N
Manganese	5	µg/l	Y
Mercury (dissolved)	0.1	µg/l	Y
Mercury (total)	0.1	µg/l	Y
Morpholine	0.01	mg/l	N
Nickel (total and dissolved)	1	µg/l	Y
Nitrate	1	mg/l	Y
Nitrite	0.05	mg/l	N
Ortho Phosphate as PO_4	0.02	µg/l	N
pH	0.1	units	Y
Phosphates	5	mg/l	N
Salinity	1	ppt	N
Silicates	5	µg/l	N
Sodium	1	mg/l	Y

Determinand	MRV	Units	Accreditation?
Sulphate	1	mg/l	Y
Total Petroleum Hydrocarbons (C8 – C35)	10	µg/l	Y
Total Suspended Solids	5	mg/l	N
Trihalomethanes	1	µg/l	N
Turbidity	2	mg/l	N
Zinc (total)	1	µg/l	Y

18.4.13 Additional water samples were taken during Cefas BEEMS surveys in December 2010 to investigate hydrazine concentrations further using techniques with lower limits of detection than used previously. Samples were taken at the HPB outfall and at a reference location to the northwest. Hydrazine was not detected at all, using a limit of detection of approximately 0.1µg/l.

Marine Sediment Quality Survey

18.4.14 During November and December 2009, sampling of the sea bed sediments in the vicinity of the proposed temporary jetty and cooling water intake and outfall locations was undertaken by Fugro Seacore Ltd. This sampling was primarily intended for sub-seabed geophysical appraisal, but advantage was taken of this in order to obtain sediment samples for chemical analysis both at surface and depth (**Figure 18.3**).

18.4.15 It is proposed that material dredged for the offshore infrastructure, including the jetty berthing pocket and arisings from drilling the vertical shafts, would be disposed of at sea within the study area if doing so would not significantly affect the sub-tidal ecology. If disposal within the study area is not acceptable, dredged material and/or drilling arisings would be removed to an existing licensed marine disposal site (e.g. Cardiff Grounds). A licence for the disposal of dredged material at sea would be sought from the appropriate authorising body (either the MMO if material is dispersed locally, or the Welsh Assembly if the material is removed to the Cardiff Grounds).

c) Consultation

18.4.16 Extensive consultation has been undertaken throughout the EIA process to discuss all stages of the assessment, including specific aspects of the development. Details of these consultations are given below and further information may be found in the **Consultation Report**.

18.4.17 A range of informal consultations was undertaken with stakeholders prior to publication of the Stage 1 consultation document; these are summarised in **Table 18.2.**

18.4.18 In particular, prior to the commencement of sampling campaigns, consultations were undertaken with local Environment Agency personnel in December 2008 to agree the sampling locations, approach and analytical test parameters for the marine sampling programme.

18.4.19 A number of other consultation meetings (in addition to the formal consultation reports produced) have taken place as part of the EIA process and these are also included in **Table 18.2**.

18.4.20 Meetings were held with the Marine Authorities Liaison Group (MALG) to discuss all elements of the HPC development that might influence the marine environment, including specific elements of engineering and construction design.

18.4.21 MALG members include Cefas, the Countryside Council for Wales (CCW), Natural England, the Environment Agency, the MMO, Somerset County Council, West Somerset Council and Sedgemoor District Council. Minutes were produced for each of the MALG meetings but formal written consultation responses were not provided by the attendees.

Table 18.2: Summary of Marine Water and Sediment Consultations

Date of Consultation	Consultees Attending	Issues Discussed Relating to Marine Water Quality
15/12/2008	Environment Agency	Discussion and agreement of water quality monitoring strategy
28/4/2009	Environment Agency, Natural England, Sedgemoor District Council	Discussion of need for collection and analysis of offshore sediment samples
11/5/2009	Environment Agency	Discussion of discharges and consenting
19/5/2009	MALG	Discussion of offshore sediment investigation studies
24/6/2009	MALG	Discussion of offshore sediment survey and analysis Discussion of the jetty development Discussion of application for discharge consents Presentation of terrestrial and marine water quality monitoring results Discussion of proposed discharge strategy
28/7/2009	MALG	Further discussion of offshore borehole investigations Discussion of proposed dredging and piling works for the temporary jetty
2/9/2009	MALG	Design discussion of the temporary jetty Discussion of dredging and FEPA licensing Discussion of information required on discharge consents during construction
30/9/2009	MALG	Discussion of temporary jetty design
14/10/2009	Environment Agency	Discussion of drainage strategy and culverting of Holford Stream
1/12/2009	MALG	Discussion of temporary jetty development
6/1/2010	MALG	Discussion of licensing required for jetty development and disposal of dredging waste
2/3/2010	MALG	Discussion of jetty berthing pocket and design to reduce maintenance dredging needs
21/1/2010	Environment Agency	Discussion of preliminary works discharge consenting Discussion of Holford Stream culvert Discussion of drainage discharge strategy
14/4/2010	MALG	Discussion on foreshore discharges Discussion of two stage approach for the jetty development

Date of Consultation	Consultees Attending	Issues Discussed Relating to Marine Water Quality
		Discussion of jetty scour studies
24/05/2010	Environment Agency, Internal Drainage Board, Natural England	Discussions of drainage strategy during site preparation including foreshore discharges
18/11/2010	MALG	Discussion of possible chlorination strategy as part of Fish Recovery and Return discussions
3/03/2011	Environment Agency, Natural England, Countryside Council for Wales, Marine Management Organisation	Discussion of numerical modelling of thermal and chemical plumes
18/03/2011	Environment Agency, Natural England, Countryside Council for Wales, Marine Management Organisation	Discussion of sensitivity analysis of near-field numerical modelling of thermal and chemical plumes
7/06/2011	Environment Agency, Natural England, Countryside Council for Wales, Marine Management Organisation, West Somerset Council	HRA workshop. Thermal and chemical modelling session.
20/0602011	Environment Agency	Discussion of construction discharges
13/07/2011	Environment Agency	Discussion of operational discharges

18.4.22 Three public consultations have been undertaken: Stage 1, Stage 2 and a Stage 2 Update in November 2009, July 2010 and February 2011, respectively, and a range of comments were received from the consultees. Responses to these comments, including an indication of how they were accounted for within the studies, are provided in the **Consultation Report**. The subsequent marine water quality assessment and reporting have taken the comments received into account.

d) Assessment Methodology

18.4.23 **Volume 1**, **Chapter 7** of this ES describes the assessment methodology adopted for this EIA. In addition, the following specific methodology was applied for the determination of receptor value and sensitivity (see **Table 18.3)** and impact magnitude (see **Table 18.4**) with respect to marine water quality.

Value and Sensitivity

18.4.24 The marine water quality off Hinkley Point contributes towards the status of nationally and internationally important features (e.g. in the Bridgwater Bay SSSI and the Severn Estuary SAC). To this end it has an explicit importance. However, for the purposes of this chapter and determining the significance of impacts on water quality, the sensitivity of the receptor to change is considered to be more relevant because of the dynamic nature and buffering capacity of the system (see below)..

18.4.25 As described in **Volume 2**, **Chapter 17**, the Inner Bristol Channel is extremely dynamic in nature (i.e. it has an extreme hyper-tidal range, associated with high current speeds), has a large physical scale and a high degree of temporal and spatial variance. In addition, as a result of the very high suspended sediment concentration of the Inner Bristol Channel, the marine waters and the physical habitats and assemblages associated with them have a particularly low sensitivity to localised disturbances to the sediment regime. Essentially, the area off Hinkley Point, and the inner Bristol Channel, is a very large and highly dynamic environment, that naturally experiences a very high level of variation in physico-chemical parameters.

18.4.26 **Table 18.3** sets out the generic criteria used in defining the sensitivity of the marine water quality receptor. Where a receptor could reasonably be assigned more than one level of sensitivity, professional judgement has been used to determine which level is applicable.

Table 18.3: Criteria Used to Determine the Sensitivity of Marine Water Quality Receptors

Sensitivity	Guidelines
High	The water quality of the receptor supports or contributes towards the designation of an internationally or nationally important feature and has a very low capacity to accommodate any change to current water quality status, compared to baseline conditions.
Medium	The water quality of the receptor supports high biodiversity and has low capacity to accommodate change to water quality status.
Low	The water quality of the receptor has a high capacity to accommodate change to water quality status due, for example, to large relative size of the receiving water and capacity for dilution and flushing. Background concentrations of certain parameters already exist.
Very low	Specific water quality conditions of the receptor are likely to be able to tolerate proposed change with very little or no impact upon the baseline conditions detectable.

18.4.27 No specific sediment receptors have been identified as part of this assessment, because changes or disturbances to marine sediments affect water quality status. For example, disturbance of bed sediments as a result of construction activities may cause the mobilisation of potential pollutants into the water column and increase in suspended solid concentrations, with associated effects upon water quality status. Investigation and assessment of marine sediment quality thus forms an important part of this EIA and this chapter.

Magnitude

18.4.28 Prediction of the magnitude of potential impacts has been based on the consequences that the proposed HPC development might have upon the marine water quality status (see **Table 18.4**).

18.4.29 These descriptions of magnitude are specific to the assessment of marine water quality impacts and are considered in addition to the generic descriptors of impact magnitude presented in **Volume 1**, **Chapter 7**. Potential impacts have been considered in terms of permanent or temporary, adverse (negative) or beneficial (positive) and cumulative effects.

18.4.30 Where an impact could reasonably be assigned more than one magnitude, professional judgement has been used to determine which rating is applicable.

Table 18.4: Criteria Used to Determine the Magnitude of Marine Water Quality Impacts

Magnitude	Guidelines
High	Very significant change to key characteristics of the water quality status of the receiving water feature, e.g. modelled as significant under the Environment Agency H1[1] assessment. Water quality status degraded to the extent that permanent change and inability to meet (for example) EQS is likely.
Medium	Significant changes to key characteristics of the water quality status taking account of the receptor volume, mixing capacity, flow rate, etc. Water quality status likely to take considerable time to recover to baseline conditions.
Low	Noticeable but not considered to be significant changes to the water quality status of the receiving water feature. Activity not likely to alter local status to the extent that water quality characteristics change considerably or EQS are compromised.
Very low	Although there may be some impact upon water quality status, activities predicted to occur over a short period. Any change to water quality status will be quickly reversed once activity ceases.

[1] The H1 Assessment is a risk assessment methodology developed by the Environment Agency to be used by developers to ensure that they do not harm the environment (Ref. 8.52)

18.4.31 Many aspects of the HPC project have been designed to mitigate environmental impacts. These are included in the assessments of magnitude; that is mitigation by design is considered when determining magnitude. Legislative compliance (which includes discharges to marine waters under an environmental permit) is assumed in the determination of impact magnitude.

Significance of Impacts

18.4.32 The significance of impacts is assessed by relating the magnitude of an effect to the sensitivity (or value) of the resource. This relationship is presented as an Impact Assessment Matrix in **Volume 1**, **Chapter 7**.

18.4.33 In addition to the predominantly qualitative assessment criteria defined in **Table 18.3** and **Table 18.4**, the description of baseline conditions and the assessment of potential impacts has also included comparison with water quality assessment criteria. The most recent, and relevant, statutory environmental standards for transitional and coastal waters are those of the WFD. These are given in the River Basin Districts Typology, Standards and Groundwater threshold values (Water Framework Directive) (England and Wales) Directions 2010 (Ref. 8.19). Where no statutory environmental standard is available, comparison has been made with the existing baseline concentrations, or ecotoxicological effect levels as appropriate.

18.4.34 Where relevant, the description of the baseline conditions provided and the assessment of potential impacts includes comparison to relevant water quality assessment criteria. A hierarchical approach was adopted to the criteria used, as follows:

- Where a substance has an EQS defined under WFD, that EQS was the standard against which the assessment was made.
- Where there is no WFD EQS available, the pre-WFD EQS was the standard against which the assessment was made.
- Where there is no EQS available, then a Probable No Effect Concentration (PNEC) was used as the assessment criterion.

- Where there is neither a WFD EQS nor a PNEC available, comparison was made to the existing baseline concentrations determined from the sampling programme undertaken in 2009 (Ref. 8.42).

Assessment Criteria for Marine Water Quality

18.4.35 The majority of environmental standards used to assess the marine water quality offshore of Hinkley Point are those provided within the Directions for Transitional and Coastal ('TRaC') Waters (see **Table 18.5** for those relevant to the development) as determined for the WFD (Ref. 8.19).

Table 18.5: Water Quality Standards Used to Assess Marine Surface Waters and Proposed UK EPR Reactor Discharges at Hinkley Point

Determinands	Units	MRV	Pre-WFD Saltwater EQS Values	WFD TRaC Waters EQS Values[4]	Ecological Risk Standard[6]

Assessment Criteria for Marine Sediment Quality

18.4.36 There are no quantitative EU or UK EQS values for sediments. The only pertinent guidance for sediment quality is given for most of the EC Dangerous Substances Directive List 1 substances and is defined as 'standstill (no deterioration)' though this is not carried through into the Water Environment Regulations (Ref. 8.23). In the absence of any quantified UK standards, common practice for characterising baseline sediment quality conditions is to compare against two separate criteria sets:

- Cefas Guideline Action Levels for the disposal of dredged material (Ref. 8.54);
- Canadian Sediment Quality Guidelines for the Protection of Aquatic Life (Ref. 8.55).

18.4.37 Cefas Guideline Action Levels are used as part of a 'weight of evidence' approach to assessing suitability of material for disposal at sea, but are not themselves statutory standards. The majority of the materials assessed against these standards arise from dredging activities. These Action Levels are used in conjunction with a range of other assessment methods (e.g. bioassays) and other data to assess risk to the environment. Current Action Levels are set out in **Table 18.6.**

Table 18.6: Cefas Guideline Action Levels for the Disposal of Dredged Material

Cefas Action Levels		
Contaminant/Compound	**Action Level 1**	**Action Level 2**
	mg/kg Dry Weight (ppm)	
Arsenic	20	100
Cadmium	0.4	5
Chromium	40	400
Copper	40	400
DBT (dibutyltin)	0.1	1
DDT (dichlorodiphenyltrichloroethane)	0.001	None
Dieldrin	0.005	None
Lead	50	500
MBT (mono-butyltin)	0.1	1
Mercury	0.3	3
Nickel	20	200
PCB's, sum of 25 congeners	0.02	0.2
PCB's, sum of ICES 7	0.01	None
TBT (tributyltin)	0.1	1
Zinc	130	800

Table notes:
Action levels taken from Cowes Outer Harbour Project (Ref. 8.56). Consistent with those action levels presented within a report on Flamborough Head cSAC (Ref. 8.54

18.4.38 Cefas guidance indicates that, in general, contaminant levels below Action Level 1 are of no concern and are unlikely to influence the licensing decision. Material with contaminant levels above Action Level 2 is generally considered unsuitable for disposal at sea. Dredged material with contaminant levels between Action Levels 1 and 2 requires further consideration and testing before a decision can be made. The action levels should not be viewed as pass/fail thresholds.

18.4.39 The Canadian Interim Sediment Quality Guidelines (ISQGs) were developed by the Canadian Council of Ministers of the Environment for evaluating the potential for adverse biological effects in aquatic systems. They have been derived from available toxicological information, reflecting the relationships between sediment concentrations of chemicals and any adverse biological effects resulting from exposure to these chemicals. ISQGs exist for only a few metals.

18.4.40 Again, the ISQGs are not statutory standards and should be used with caution, with the findings being treated only as indicative. They were designed specifically for Canada and are based on the protection of pristine environments. But, in the absence of suitable alternatives it has become commonplace for these guidelines to be used by regulatory and statutory bodies in the UK, and elsewhere, as part of a 'weight of evidence' approach.

18.4.41 The Canadian guidelines are presented in **Table 18.7**, and comprise two assessment levels. The lower level is referred to as the threshold effects level (TEL) and represents a concentration below which adverse biological effects are expected to occur only rarely (in some sensitive species for example). The higher level, the probable effect level (or PEL), defines a concentration above which adverse effects may be expected in a wider range of organisms. The three ranges of chemical concentrations (<TEL, between TEL and PEL, and >PEL) indicate those concentrations that are rarely, occasionally and frequently associated with adverse biological effects, respectively.

Table 18.7: Selected Interim Marine Sediment Quality Guidelines (ISQG)

Contaminant	ISQG/TEL	PEL	Incidence of Adverse Biological Effects		
	mg/kg Dry Weight		% ≤ ISQG	% Between ISQG and PEL	% ≥ PEL
Arsenic	7.24	41.6	3	13	47
Cadmium	0.7	4.2	6	20	71
Chromium	52.3	160	4	15	53
Copper	18.7	108	9	22	56
Lead	30.2	112	6	26	58
Mercury	0.13	0.7	8	24	37
Zinc	124	271	4	27	65

Table notes:All values taken from the Canadian Council of Ministers of the Environment (2002) (Ref. 8.55).

18.4.42 A discussion of the marine sediment radiochemical results is presented in **Volume 2**, **Chapter 21**.

Assessment of Cooling Water Discharge Plume

18.4.43 The most significant impacts on the marine environment associated with a direct-cooled power station tend to be associated with cooling water abstraction and subsequent discharge. The primary characteristic of the discharge from such a station is its elevated temperature and, when introduced to coastal waters such as those at Hinkley Point, this discharge will tend to form a buoyant tidally oscillating, progressively diluting plume. A secondary characteristic is that this plume will also transport any chemical residuals or wastes discharged within that same cooling water flow.

18.4.44 To assess the impact of the cooling water discharge plume, a mixing-zone approach was used. In a regulatory context, as defined by in the 2010 European Commission Technical Guidelines (Ref. 8.57), a mixing zone is described as *"... the part of a body of surface water which is adjacent to the point of discharge and within which the concentrations of one or more contaminants of concern may exceed the relevant Environmental Quality Standard (EQS), provided that compliance of the rest of the water body with the EQS is not affected"*. The mixing zone is set by the competent permitting authority (the Environment Agency in England and Wales).

18.4.45 The most appropriate method for estimating the extent of an existing cooling water plume is direct field observation, either by remote sensing or extensive field survey. Where such a plume already exists at a site where further development is being considered, observations of the behaviour of that existing plume provide very considerable advantage in terms of supporting the development, validation and calibration of the numerical hydrodynamic models used to predict behaviour of the new plume.

18.4.46 Adequately calibrated numerical models can be used to predict the behaviour of plumes from new cooling water discharges for a range of possible intake and outfall configurations. Used at the design stage, such modelling allows the design to be configured such that recirculation to both existing and new plant (and the associated thermal efficiency losses) is minimised, as well as limiting the influence of that plume on potentially sensitive receptors.

18.4.47 Once established, the same models that simulate heat transport can be modified or supplemented to examine the dispersion of chemical contaminants, as well as other evolutions in the water quality regime, including potential impacts on DO.

18.4.48 In accordance with Environment Agency guidance (Ref. 8.33), two different hydrodynamic models (Delft3D and the General Estuarine Transport Model (GETM)) were used to model temperature changes off Hinkley Point when HPC is running with an average cooling water flow of $125m^3/s$. **Appendix 18A** presents a summary of model development in line with the requirements of the Environment Agency (Ref. 8.33). For a more detailed assessment of the two models, and description of how they differ, refer to BEEMS Technical Reports 186 (Ref. 8.50), 182 (Ref. 8.58) and 177 (Ref. 8.59).

18.4.49 Discussions with the Environment Agency highlighted differences between the two models, particularly with regard to the behaviour of the plume at the initial discharge point. It was agreed that outputs from GETM underestimate the initial thermally-related buoyancy of the plume near the outfall, and that this increases the predicted area of the total plume. In comparison, the Delft model underestimates the extent of the plume (BEEMS 2011; Ref. 8.50).

18.4.50 GETM outputs are, therefore, considered precautionary and used in the plume assessments. GETM is likely to overestimate water temperature outputs (by approximately 0.5-0.75°C).

18.4.51 An upper range temperature of 20.4°C (98 percentile Hinkley Point based on 32 years of Cefas data) was also used as the basis for a precautionary assessment.

18.4.52 Hourly model outputs, plotted against a selected set of variables, were used to produce time series means and averages. Five runs, A to E (described in **Table 18.8**), were used to produce detailed thermal predictions from both models in order to establish baseline conditions (i.e. HPB operating alone) and to represent a range of potential operational conditions in the future (i.e. HPC operating alone and HPC operating simultaneously with HPB).

18.4.53 For temperature assessments, any areas of water predicted to exceed an increase of 2.6°C above the 98 percentile background value of 20.4^{o}C at the surface and seabed (i.e. which would cause temperatures to rise above 23°C; UKTAG standard) are considered to constitute the mixing zone.

18.4.54 GETM was also used to model chemical dispersion within the cooling water discharge plume for dissolved oxygen (DO), un-ionised ammonia, total residual oxidants (TRO; the active agents following chlorination of seawater for anti-fouling purposes), chlorination by-products (CBPs) and hydrazine.

Table 18.8: Description of Numerical Modelled Operational Scenarios ('Model Runs')

Run ID	Description
Run A	HPB operating at 70% output
Run B	HPB operating at 100% output
Run C	HPC operating at 100% output
Run D	HPB operating at 70% output + HPC operating at 100% output
Run E	HPB operating at 100% output + HPC operating at 100% output

Water Framework Directive and Habitats Regulations Assessment

18.4.55 This chapter of the ES considers the implications of the proposals for the water quality status of the study area within the context of the relevant EQS, PNECs or baseline concentrations (as indicators of general water quality health). This is in line with the approach adopted across the EIA in considering predicted effects of the HPC Project on the study area as a whole (within the zone of potential influence) as well as on individual receptors within it. Compliance with the WFD and the Habitats Directive has not been assessed herein, because the assessment approaches recommended with respect to these Directives differ from the standard method applied for EIA. In addition, they are only concerned with a subset of the wider resource that has the potential to be affected (e.g. WFD water bodies or relevant designated interest features). The requirement to undertake WFD and Habitats Regulations Assessments has not been ignored, however, and separate assessments, or information required to make the assessments, have been prepared. See Ref. 18.15 for information to support the Habitats Directive assessment, and **Appendix 18B** (associated with this chapter) for the assessment against WFD.

Cumulative Effects

18.4.56 Cumulative effects potentially arising from the interaction of the different elements of the HPC development, for example the land clearance works, the sea wall construction and the dredging associated with the jetty, are considered within this chapter (i.e. additive and interactive effects between impacts generated within the site boundary and HPC study area). Cross reference is made, where necessary, to other assessments that are closely linked to the assessment of marine water quality, such as marine ecology, **Volume 2**, **Chapter 19**.

18.4.57 **Volume 1**, **Chapter 7** details the methodology adopted for the assessment of cumulative effects. HPC Project-wide cumulative impacts (i.e. activities and impacts generated at distance from the site and study area), and in-combination impacts with other proposed or reasonably foreseeable projects are presented in **Volume 11**.

e) Limitations, Constraints and Assumptions

18.4.58 Given the limited specific historical information on marine water quality, baseline conditions have been primarily derived from monitoring campaigns established for this project. The characterisation of local marine systems provided by these campaigns is adequate for undertaking this impact assessment.

18.4.59 Samples were taken to reflect a range of typical tidal conditions, but other conditions may be exhibited following extreme events (e.g. storms).

18.4.60 Where HPC-specific data are not available, for example certain discharges during the operational phase, surrogate data have been sourced from the Flamanville 3 site, in Manche, north-western France as they are representative of twin EPR operation.

18.4.61 Where uncertainties have been identified with respect to chemical discharge concentrations, a precautionary approach has been adopted.

18.4.62 All relevant assumptions and uncertainties are described alongside calculations and impact assessments.

18.5 Baseline Environmental Characteristics

a) Introduction

18.5.1 This section describes the marine water and sediment quality baseline for the proposed HPC development. The development site is bordered immediately along its northern edge by Bridgwater Bay, which forms part of the Inner Bristol Channel.

18.5.2 Current understanding of the key physical features of the Inner Bristol Channel and Severn Estuary is detailed in **Volume 2**, **Chapter 17**. The bathymetry and dynamics of the Inner Bristol Channel, and the immediately associated Severn Estuary, make it unique in the UK. It is a highly turbid system, although much of the seabed itself is bare of soft sediment. There appears to be no modern source of sand and gravel within the system and small grain fractions of sediment are constantly reworked in suspension. What sediment there is on the seabed is strongly affected by the

Spring/Neap tidal cycle and is highly mobile. Where subtidal sediment is found, its depth and composition change significantly over time. The main elements that are relevant to water quality are summarised in **Table 18.9**.

Table 18.9: Key Physical Features of the Bristol Channel and Severn Estuary that are Relevant to Marine Water and Sediment Quality (see **Volume 2, Chapter 17**)

Key Physical Features	Comment
Large branching estuary with freshwater inputs	The sub-estuaries within the Bristol Channel and Severn Estuary absorb energy at tidal frequencies, but input energy at longer frequencies because of river flow variation. The Parrett, Usk and other sub-estuaries contribute a relatively significant freshwater influx.
High salinity variation	There is a high salinity variation as a result of the seasonal and tidal variation. The discharge from the Parrett significantly adds to this variation in the Hinkley Point area.
Estuary controlled by geological constriction with influences mixing	The geological constriction in the area of the Holm Islands, between Cardiff and Brean Down (constraining the Estuary in terms of both width and depth) is the key large scale physical feature. To landwards, the waters of the Severn Estuary are generally vertically mixed (in terms of salinity). To seawards, the waters of the Inner Bristol Channel are less uniform and may at times be density (by salinity) stratified. The constriction also acts to divide different suites of physical sedimentary processes, regarding waves, currents and sediment transport.
Hypertidal	This area experiences one of the highest tidal ranges in the world and is classified as hypertidal, being > 6 m. The range at Hinkley Point, between mean high and low water Spring tides, is 10.7m. This regime has direct consequences for physical mixing and flushing of water and sedimentary processes and sediment transport.
Periodic energy inputs	Spring to Neap changes are very large, with Spring tides having a mean value of 10.7m and Neaps 4.8m, resulting in a system with a major component of fortnightly change (as well as other tidal periods). Long periods of low winds reduce the suspended solids concentrations, at least in surface waters. The sedimentary system is thus periodic, directly impacting upon the light regime (hence production), the benthic habitats and the benthos.
Waves dominant in shallow water	In shallow areas, waves are dominant over the effects of tidal currents. Most important in the Hinkley Point area are the intertidal and shallow 'flats' where it is waves that are mostly responsible in terms of mobilising and/or changing the physical environment and thus affecting the biota.
Sediment starved and mud in suspension	The vast majority of the seabed in the Bristol Channel and Severn Estuary system is rock or coarse gravel; there is relatively little sand, and most (though not all) of the mud is in suspension or is intermittently mobilised.
Physics makes change in subtidal habitats the norm, not the exception	Changes to the sediment transport system have the potential to induce major changes in habitat. Changes in sediment distribution (natural and man made) are likely and these will affect habitats.
Highly turbid environment (unique in UK)	High concentrations of sediment are present within the water column (in both permanent and temporary suspension and is intermittently deposited) but there is relatively little contribution from the rivers or from the outer Bristol Channel.
Existing Parrett plume affects the intertidal area	Existing freshwater runoff peaks are significant in that they affect the extent of the plume across Bridgwater Bay.
Periodic major changes in bed elevation	Erosion/deposition cycles occur naturally and periodically, especially in outer Bridgwater Bay.

Key Physical Features	Comment
Residual circulation	Tidal averaging of flows shows strong outward residual flow from Flat Holm to the south side of the Channel off Kilve. Recirculation cells occur to north and south. This could trap both persistent contaminants and effluent, however, given the small magnitude of any residual circulation compared to the regular tidal flows the significance of this feature is uncertain.

18.5.3 Information from the scientific literature has been used to characterise the wider marine environment of the Bristol Channel and upstream Severn Estuary.

18.5.4 Results from the offshore water quality sampling campaigns undertaken in 2009 offer a complementary source of localised water quality data offshore of Hinkley Point.

b) Study Area Description

i. Suspended Sediment

18.5.5 A detailed description of sediment distribution and dynamics is provided in Section 17.6, **Volume 2**, **Chapter 17**. However, a summary of the key issues relevant to suspended sediment is provided here.

18.5.6 Due to the large tidal range and strong currents operating in the Bristol Channel and Severn Estuary the sedimentary regime is very dynamic. Deposits of fine sediments in the Bristol Channel are highly mobile and a large amount of mobile fine sediment is present in the system at any one time. Suspended sediment concentrations are relatively high and the process of bedload sediment erosion, transport and deposition is complex, with many areas subject to continual or periodic reworking. The majority of fine sediment in the Severn Estuary and Bristol Channel is material eroded originally from the surrounding catchments and supplied via rivers. The hard bedrock and coastal cliffs are not a major source of fine sediment.

18.5.7 The dynamic processes operating in the Bristol Channel and Severn Estuary, in particular the strong tidal currents, lead to erosion of intertidal and shallow subtidal deposits and active re-suspension of muddy seabed sediments. The suspended sediment levels in the Inner Bristol Channel can be exceptionally high. A field campaign, recorded suspended sediment concentrations in the Inner Bristol Channel within the range of less than 100mg/l to approaching 200,000mg/l (fluid mud) (Ref. 8.60).

18.5.8 Surveys have found strong variation in surface to bed values for suspended sediment between Spring and Neap tides in the study area; with the greatest concentrations recorded close to the seabed. Concentrations are strongly linked to tidal current velocity, with levels being greater on the flood than the ebb, greater during Spring tides than Neaps and generally proportional to tidal range. Overall, and for the purposes of this assessment, background suspended sediment concentrations within the Inner Bristol Channel are considered to be in the order of 1g/l within 5m water depth.

18.5.9 Given the very high suspended sediment concentration of the Inner Bristol Channel, and its variability, the marine waters and the physical habitats associated with them have a particularly low sensitivity to changes in suspended sediment levels or additional inputs from terrestrial sources.

ii. Marine Water Quality Contaminant Inputs

18.5.10 The River Severn is the major freshwater input to this estuarine and coastal system, providing approximately a quarter of the total flow to the Severn Estuary and Bristol Channel (Ref. 8.61). A number of other major rivers (e.g. Avon, Usk, Parrett, Taff and Wye) flow into the Severn and Bristol Channel, and it is estimated that sewage and industrial inputs contribute approximately 3% and 1% of the freshwater flow, respectively (Ref. 8.62).

18.5.11 The bulk of the contaminant input to the Bristol Channel is reported from the early scientific literature (Ref. 8.63) to be from discharges upstream of the River Parrett, i.e. upstream of the proposed HPC development. In addition to point source contaminant inputs, diffuse chemical inputs to the Severn and Bristol Channel arise from runoff from agricultural land to tributaries such as the Avon, Usk and Parrett (Ref. 8.64), runoff from urban centres, and deposition from aerial emissions.

18.5.12 The Severn Estuary has historically received large loadings of contaminants from sewage and industrial inputs. Historical contaminants are highly varied in type and include metals, organo-metals, hydrocarbons, nutrients, mineral acids, solvents, biocides, fungicides, PCBs, pesticides and radionuclides.

iii. Dissolved Contaminants

18.5.13 Combined industrial and sewage inputs have historically contributed the larger proportion of the mercury, cadmium, unionised ammonia and orthophosphate, and riverine inputs accounted for most of the total inorganic nitrogen (Ref. 8.48).

18.5.14 BEEMS (2010) (Ref. 8.61) reports a decreasing concentration trend for the majority of dissolved metals measured (arsenic, cadmium, chromium, copper, iron, nickel, lead, zinc, mercury) for various sites from the Severn through to the Bristol Channel. Most metal concentrations were below EQS as defined by the Dangerous Substances Directive (Ref. 8.3). Some individual samples from inner Severn Estuary sites were reported in Langston et al (2003) (Ref. 8.63) to have occasionally exceeded the EQS levels for arsenic, cadmium, copper, nickel, lead, zinc and mercury, but in all cases average values were below the respective EQS. Data for 2005 to 2008 for an outer Severn site (Langston et al., 2007) (Ref. 8.65) indicate that dissolved cadmium and mercury concentrations are one to two orders of magnitude below their respective EQS values. Although the datasets indicate that the concentrations of some metals show a marked decrease from values reported in the 1970s, Langston et al. (2007) (Ref. 8.65) suggest that the high variability in measured dissolved concentrations of metals may be attributable to sediment remobilisation and the degree of re-suspension at the time of sampling.

iv. Summary of 2009 Marine Water Quality Monitoring Surveys

18.5.15 In the absence of adequate historic water quality information for the area adjacent to Hinkley Point, a marine water quality sampling programme was undertaken during 2009.

18.5.16 The dates of the monitoring campaigns and the tidal state are shown in **Table 18.10** below. The results of this monitoring work have been summarised and reported in Ref. 8.51. A brief summary of the monitoring programme is provided in here.

18.5.17 The programme was designed to assess the water quality characteristics of the local marine environment and specifically to define the baseline concentrations for those chemicals that may be expected within planned discharges from the EPR units. Chemical analysis of the marine water samples were compared with the marine water quality standards presented in **Table 18.5**.

Table 18.10: Sampling Dates, Tidal State and the Number of Individual Samples that were Found to Exceed the Dissolved Copper and Dissolved Mercury EQS Thresholds

Marine Water Sampling Campaign	Tidal State	Dissolved Copper *Individual* Exceedances of the Annual Average EQS	Dissolved Mercury EQS Exceedances
Campaign 1 (27 and 28 January 2009)	Spring	13	3
Campaign 2 (1 and 2 May 2009)	Neap	17	1
Campaign 3 (27 and 28 June 2009)	Spring	8	0
Campaign 4 (12 and 13 September 2009)	Neap	1	0

18.5.18 *In situ* water quality parameter profiling was also undertaken at 14 locations across the offshore sampling area, as shown on **Figure 18.2**. At each location water temperature, dissolved oxygen and salinity were measured throughout the water column.

18.5.19 Several chemicals expected to be present in the discharges during the commissioning and operational phases have no saltwater EQS or Environmentally Acceptable Level (EAL) value, so a hierarchical approach is adopted (Ref. 8.52). The EQS is used if available, followed by a background mean ambient concentration for naturally non-toxic substances, and finally a Predicted No-Effect Concentration (PNEC) for potentially toxic substances.

18.5.20 **Table 18.11** lists the parameters that have been included in the analysis of samples from the 2009 monitoring campaign for which PNEC values have been developed (see Ref. 8.52).

Table 18.11: Proposed PNEC Values for Chemical Parameters Based on Review of Ecotoxicity Studies (Ref. 8.52)

Chemical Parameter	Acute Marine PNEC	Chronic Marine PNEC
Hydrazine	0.004µg/l	0.0004µg/l
Ethanolamine	160µg/l	160µg/l
Morpholine	28µg/l	17µg/l

v. Marine Water Quality Monitoring Results

18.5.21 The key findings from the marine water quality monitoring results are:

- All chemicals, for which there are WFD EQS, had mean values below the EQS.
- Concentrations of the organic chemicals expected to be discharged from HPC were all below the laboratory's 'Minimum Reporting Values' (MRV)', but it should be noted that some of those MRVs are greater than the relevant environmental threshold values.
- The waters off Hinkley Point are characterised by high concentrations of suspended solids increasing with depth. The mean value was 264mg/l with a maximum of 1,795mg/l. These high suspended solids concentrations arise from sediment mobilisation under bed-scouring flows associated with the high tidal range (and associated tidal currents). There is a corresponding low water transparency which restricts light penetration and limits primary productivity by marine algae.
- There was a general trend of increasing total metals concentrations with depth. This is likely to result from metal adsorption on sediment particles which display a corresponding increase in concentration with water depth.
- Although the mean value of dissolved copper (3.95µg/l) was below the EQS (5µg/l annual average), it was not uncommon to find an individual sample above 5µg/l (**Table 18.10**).
- The EQS for dissolved mercury is expressed as both a Maximum Acceptable Concentration (MAC) and an Annual Average (AA). The MAC of 0.07µg/l was exceeded on a limited number of samples but the mean value for all samples (0.02µg/l) was below the Annual Average EQS threshold value of 0.05µg/l.
- Free chlorine was recorded in collected samples up to values of 0.3 mg/l. However, there are no known sources of chlorinated discharges in the vicinity of Hinkley Point (therefore these results are considered to reflect analytical interference by manganese than actual values).
- pH values were typical of seawater, with a range of 7.04 to 8.05.
- Salinity varied among the sampling campaigns reflecting the position in the spring/neap cycle and seasonally-based variations in freshwater flow. The range of salinity values recorded during the sampling campaigns was 23.5 to 33.5 with a mean of 30.4. The first *in situ* sampling campaign (January 2009) had somewhat lower salinity conditions (range of 23 to 25) compared with the later campaigns, presumably due to increased winter river flows.
- Under WFD, the assessment of dissolved inorganic nitrogen status is based on the mean winter concentration calculated from samples collected between the 1st November and the 28th February. Although only one of the four sampling visits (January 2009) fell within this period, 60 samples were taken which is sufficient for a valid assessment
- The WFD EQS for dissolved inorganic nitrogen in TRaC waters varies with salinity and turbidity. The EQS for 'Good' dissolved inorganic nitrogen status in very turbid waters is 270µM/l, expressed as the 99th percentile. The 99th percentile value for dissolved inorganic nitrogen in the January 2009 campaign was 130.1µM/l, representative of 'Good' status.

18.5.22 Analyses were undertaken to determine if there were significant spatial or tidal differences in the mean concentrations of tested parameters. Comparison of the overall mean concentrations at each site was made using an 'F-test' to determine if there was a significant difference in the variances of the two data sets. Following this initial testing, an appropriate two-tailed 't-test' (i.e. for equal or unequal variances depending upon the results of the F-test) was used to determine if there was a significant difference between the mean values for inshore and offshore sampling areas, or for neap or spring tide conditions.

18.5.23 Full details of the campaigns are reported in Ref. 8.51, but the paragraphs below report the key findings.

18.5.24 The key findings from the comparison of inshore and offshore water chemistry are:

- **General water quality parameters**: These results showed a degree of variability across the sampling area and with depth. Statistical comparison of the overall mean values across the range of parameters indicated that the only significant difference occurred for chemical oxygen demand (COD) which was higher in the inshore sampling area.
- **Metals**: There was spatial (inshore and offshore) and depth variability for the range of total and dissolved metals that were analysed. However, the only significant difference was for total lead for which higher concentrations were recorded within the inshore sampling area.
- **Organic chemicals**: No results above laboratory minimum reporting values were recorded at any of the sampling sites across all four sampling campaigns.

18.5.25 The comparison of the data for inshore and offshore water quality indicates a high degree of homogeneity when considered as a whole across all sampling sites and campaigns. Some local spatial and depth variations are evident within data collected for each campaign. The high degree of homogeneity is likely to be associated with the high tidal flow velocities creating well mixed water quality conditions in the marine waters off Hinkley Point.

18.5.26 The key findings from the comparison of water chemistry over neap and spring tide are:

- **General water quality parameters:** Seven general water quality parameters differed significantly between neap and spring tide periods. During neap tide periods higher overall mean levels of pH and concentrations of orthophosphate were recorded. On spring tides, higher mean values of nitrate, phosphate, suspended solids, BOD and COD were found. There was a significant difference in suspended solid concentrations during neap and spring tide periods with respective mean concentrations of 185 and 351mg/l.
- **Metals:** Statistical analysis of the data sets comparing overall mean concentrations from neap and spring tide periods found four total metal and two dissolved metal parameters that showed significant differences. Higher mean concentrations of total copper, iron and boron were found during neap tides (boron was only analysed in samples during sampling campaigns 3 and 4). Higher mean concentrations of total chromium, dissolved nickel and dissolved boron were recorded during spring tide periods.

- **Organic chemicals**: No results above laboratory minimum reporting values were recorded.

18.5.27 Water quality parameters exhibited greater significant variability between neap and spring tide periods than between inshore and offshore sampling areas.

vi. *In situ* Monitoring Results

18.5.28 *In situ* data from the 2009 water quality monitoring campaign indicate that dissolved oxygen levels, temperature and salinity were within the expected range for coastal waters. There was no evidence of thermal, saline or dissolved oxygen stratification, indicating a well-mixed system.

18.5.29 The WFD defines threshold values for dissolved oxygen in transitional and coastal water bodies. For marine waters the 'Good' category threshold is defined by:

Dissolved Oxygen (mg/l) = 5 – (0.028 x salinity)

18.5.30 The most precautionary EQS threshold indicative of Good status, therefore, is calculated using the lowest monitored salinity (23.5), which produces a value of 6.13mg/l. The 5^{th} percentile calculated for the entire monitoring data set was 6.40mg/l, which is in fact representative of High status.

vii.Marine Sediment Chemistry

18.5.31 The chemistry of marine sediments in the vicinity of Hinkley Point is relevant because activities associated with the HPC development, such as dredging and construction of marine infrastructure, may lead to mobilisation of sediments and any associated contaminants. The disturbance of sediments may, therefore, lead to localised affects on water quality conditions.

18.5.32 The sediments of the Severn Estuary and Bristol Channel have been the subject of past research (Refs. 8.65, 8.66 and 8.67) and these studies have been reviewed. To supplement previously published information, sediment samples were collected for chemical analysis during offshore geotechnical surveys in the vicinity of Hinkley Point undertaken in November and December 2009 (described above).

viii. Association between Metals and Suspended Particulate Matter

18.5.33 Contaminants from anthropogenic sources may become associated with particulates (in particular the fine fractions) through adsorption and complexation; dissolved metals tend to be sequestered from the water by fine grained particulate material in suspension or bed sediments. Sediment type and distribution thereby influence the distribution of particulate bound contaminants and associated water quality.

18.5.34 A variety of sea bed sediments is found in the Bristol Channel ranging from fine clays (<20 µm diameter) to pebbles (>100 mm diameter). Exposed bedrock covers extensive sections of the channel bottom, particularly across the central channel. Tidal velocity is an important factor influencing the distribution of sea bed sediment and respective grain size within the Bristol Channel and large areas of the channel are characterised by thin veneers of sand and gravel that are mobile on the bed. Reference should be made to **Volume 2**, **Chapter 17** for specific discussions regarding sediment distribution.

18.5.35 The high tidal range and strong tidal currents ensure that the bed sediment is subject to much reworking. For this reason, the spatial distribution of contaminants is often associated with the sediment distribution patterns within the Severn Estuary and Bristol Channel. A consequence is that, rather than forming distinct hotspots, contamination tends to be widely dispersed at relatively low concentrations.

18.5.36 Total metal concentrations in the water column vary with tidal conditions, higher concentrations being expected during spring tide periods through mobilisation of bed sediments and reduced settlement under higher flow velocities.

ix. Sediment Chemistry Data

18.5.37 Langston et al. (Refs. 8.64, 8.65 and 8.68) provide a thorough overview of sediment contaminant trends in the Severn Estuary and Bristol Channel. Most of the studies that these reports are based upon were undertaken during the 1970s and 1980s. More recent data to characterise contaminant status, incorporated in the Langston et al. reports (Refs. 8.64, 8.65 and 8.68) are from Environment Agency surveys undertaken in the autumn and winter of 2004 that included a sampling location in Bridgwater Bay to the east of Hinkley Point.

18.5.38 Langston et al. (Refs. 8.64, 8.65 and 8.68) reviewed historic contamination of the Severn Estuary for cadmium and zinc from industrial discharges in the Avonmouth area, to the north-east of the Hinkley Point site. This is well documented in a number of studies (e.g. Little and Smith; Ref. 8.66). Langston et al. (Refs. 8.64, 8.65 and 8.68) also quote studies reporting contamination of finer sediment fractions with lead, copper, silver and mercury. Although the majority of metal contamination is associated with clay particle fractions, aluminium (not necessarily of anthropogenic origin) is associated with coarser sand fractions (Ref. 8.66).

18.5.39 Results from Environment Agency surveys undertaken in 2004 indicated correlations between total metal concentrations and total suspended solids concentrations for copper, iron, mercury, lead, zinc, chromium and nickel. For dissolved metals the relationship with suspended sediments is less clear although elevated concentrations of dissolved cadmium and iron in the lower water column of Bridgwater Bay have been reported and associated with re-suspension of particulates (Ref. 8.67). Similar effects were implied by the results of the Environment Agency assessment in 2004 for dissolved iron, zinc and chromium.

x. Sediment Chemical Analytical Results and Interpretation – Metals

18.5.40 As set out above, to supplement existing knowledge, sampling of the marine sediments at 22 locations in the vicinity of the proposed temporary jetty was undertaken during November and December 2009 (Ref. 8.69). Recovered core samples were subject to chemical analysis for a wide range of determinands, to provide the necessary information available for the grant of the necessary licences for dredging activities under the marine licensing regime. Due to the highly dynamic conditions, and extensive tidal movement of sediments, in the Bristol Channel, results from these samples are considered representative of sediments in the wider Hinkley Point area.

18.5.41 A summary of the sediment contamination data compared to the relevant threshold values (see **Table 18.6** and **Table 18.7**) is provided below. Further analysis of these data, with regard to metals entering the dissolved phase and comparison with marine water EQS values, is provided in Section 18.6.

Results of Sediment Chemistry Analysis

18.5.42 A number of samples were extracted from each individual core to get a representative measurement and identify contaminant 'hot-spots' within each core. However, it is most appropriate to review the average concentration for each core against relevant benchmarks, because any sediment plume caused as a result of offshore works (piling, dredging, etc.) would consist of disturbed sediment from all depths.

18.5.43 Comparison of data with Cefas action levels and Canadian ISQGs found elevated metal concentrations to be widespread, but very few of the metal concentrations recorded could be considered highly contaminated. None of the average concentrations for any of the sediment cores was found to exceed either the CEFAS Action Level 2 or the Canadian PEL. When analysis of individual spot samples (rather than core averages) is considered, four individual samples were found to be above the Canadian PEL. **Table 18.12** summarises data from each core.

Table 18.12: Number of Sediment Guideline Value Exceedences Found (x/y = x out of y Average Core Concentrations > the Relevant Standard)

Metal	Cr	Ni	Cu	Zn	As	Cd	Pb	Hg
CEFAS Action Level 1	6/15	13/15	0/15	6/15	1/15	2/15	5/15	1/15
CEFAS Action Level 2	0	0	0	0	0	0	0	0
Canadian TEL	1/15	n/a	8/15	8/15	15/15	0/15	13/15	8/15
Canadian PEL	0	n/a	0	0	0	0	0	0

18.5.44 Concentrations of nickel were found to be above the CEFAS Action Level 1 in 13 of the 15 cores (average concentration data). The concentrations of nickel are relatively consistent across all samples and are likely to be the result of historical contamination. The mean nickel concentration was 32mg/kg, with a standard deviation of 10.9mg/kg.

18.5.45 For arsenic, all average core concentrations exceeded the Canadian TEL threshold, but use of the Cefas Action Level 1 threshold shows only one core (VCJ18) with an exceedence (and 10 individual exceedences out of a total of 57 samples). This result demonstrates the more precautionary nature of the Canadian threshold.

18.5.46 Some individual core samples had chromium concentrations above CEFAS Action Level 1 and the Canadian TEL, but the mean values were below both levels.

18.5.47 All other samples were below CEFAS and Canadian thresholds.

18.5.48 Seven of the locations (VCJ10, VCJ17, VCJ18, VJC21, VC33, VCJ6 and VCJ7) had generally decreasing contamination with depth. At these locations, highest contaminant concentrations were found within the top metre of sediment.

18.5.49 As the upper portion of the sediment is known to be highly mobile and constantly reworked, surficial sediments disturbed by dredging (for example) would have metal concentrations that are no different to those mobilised on an almost continual basis within the Bristol Channel due to tidal currents. Deeper material, disturbed during construction, is likely to have lower metal concentrations (Ref. 8.69).

xi. Sediment Chemical Analytical Results and Interpretation – Organic Contaminants

Polycyclic Aromatic Hydrocarbons (PAHs)

18.5.50 PAHs occur throughout the environment and may be derived from natural sources (e.g. coal) but are usually associated with anthropogenic activity. PAHs are usually associated with sediments because of their affinity for particulates (particularly higher molecular weight PAHs). Lower molecular weight PAHs are toxic to marine organisms and the metabolites of higher weight PAHs sometimes exhibit carcinogenic properties. Langston et al. (Ref. 8.64) found PAH concentrations in the Severn Estuary often exceeded ISQG TEL and occasionally PEL. The primary source for PAHs in the Severn Estuary is considered to be anthropogenic (Refs. 8.64, 8.65 and 8.68), and their source offshore of Hinkley Point is thought to be coal dust (Ref. 8.70).

18.5.51 Elevated concentrations relative to the CEFAS Action Level 1 of all selected PAHs were found in the surface sediments but no elevated concentrations were found below approximately one metre.

18.5.52 PAH concentrations in some surface sediments exceeded the more precautionary Canadian threshold for both the TEL and the PEL. PAH concentrations did not exceed either of the Canadian thresholds in samples taken from below approximately one metre.

Organotins

18.5.53 Organotin substances, such as tributyltin (TBT) and dibutyltin (DBT) are endocrine disruptors, and at higher concentrations act as immunosuppressants. They are highly toxic and, even at low concentrations, may cause mortality of marine planktonic larvae. Until recent years, organotins were extensively used as antifouling coatings on ships and are still found in a variety of other industrial applications. From the literature (Refs. 8.64, 8.65 and 8.68), analyses of sediments in dredge disposal sites around the Severn Estuary suggest that there may be localised reservoirs of elevated TBT concentrations near major ports such as Newport and Cardiff.

18.5.54 All results from offshore Hinkley Point showed organotin concentrations below CEFAS Action Level 1 and were, therefore, not investigated further.

Polychlorinated Biphenyls (PCBs)

18.5.55 PCBs have low water solubility and a high affinity for suspended solids, particularly those with high organic carbon content. PCBs are one of the most persistent environmental contaminants and, due to their high solubility in fats, can bioaccumulate. In marine organisms, PCBs generally lead to chronic (rather than acute) effects on the endocrine system and suppression of the immune system. Royal Haskoning (2008) (Ref. 8.71) report that PCB concentrations in the Severn Estuary are amongst the highest in the UK, and that PCBs are homogenously distributed throughout the estuary with levels only slightly above the TEL.

18.5.56 For some years, most routine PCB analysis has concentrated on a representative subset of 7 PCB congeners (PCB congeners 28, 52, 101, 118, 138, 153 and 180) as recommended by the International Council for the Exploration of the Sea (ICES) (Ref. Ref. 8.72). A CEFAS action level exists for the sum of 'ICES 7' and also the sum of a larger subset of 25 congeners (including the ICES 7).

18.5.57 At no location did the average PCB level in cores exceed the CEFAS 25 threshold; but 6 cores did exceed the CEFAS Action Level 1 threshold for the ICES 7 congeners. Analysis of individual spot sediment samples found several in excess of the CEFAS Action Level 1, all of which were from the top metre of each core.

18.5.58 A single spot sample (1 of 57) was found to have a PCB concentration in excess of the CEFAS Action Level 2, this being sampling location VCJ9. However, as this same sample (VCJ9-1.0m) also showed relatively high metals, total hydrocarbons and PAH concentrations, it appears to be an isolated pocket of relatively high contamination and atypical of sediment in the area.

Organochlorine Pesticides (OCP)

18.5.59 OCPs have similar properties to PCBs in that they are very persistent in the environment and can bioaccumulate. Many are toxic and some are endocrine disrupters. Dichlorodiphenyltrichloroethane (DDT), and its degradation products / metabolites, has been analysed in this study as representative of OCPs.

18.5.60 Generally, concentrations were found to be low in all samples. Three individual spot sediment samples were found to be above the Cefas Action Level 1 and the Canadian ISQG TEL for DDT. Average concentrations across the same cores are below the guideline value. No individual spot samples exceeded the Canadian PEL threshold.

xii.Thermal Plume from HPB

18.5.61 As set out in Section 18.4 above, in order to establish baseline conditions for the existing plume from HPB (and validate the numerical models), GETM runs A and B represent HPB operating at 70% and 100% (**Table 18.8**). The reasons for running variations on the HPB operating scenario relate to a reduction in HPB operating output during the modelling verification and calibration stage. It should be noted that it is not envisaged that operation of HPB at 70% reflects long term operating conditions at HPB. Modelling the operation of HPB at 70% and 100%, however, does provide the ability to assess a range of conditions under which the station could operate both now and in the future (i.e. it reflects the range of current baseline conditions). The calculated areas of the thermal plumes for HPB running at 70% and 100% are presented in (**Table 18.13**).

Table 18.13: Area of Plume (hectares) Exceeding 23°C (98%-ile) and 3°C (uplift) WFD Good Status Thresholds (Ref. 8.73)

Model Run	23°C (98%-ile)		3°C (Uplift)	
	At Bed	At Surface	At Bed	At Surface
Run A (GETM) HPB at 70%	0.4	4.1	0.03	0.8
Run B (GETM) HPB at 100%	106	197	41	86

xiii. Thermally-related Reductions in Dissolved Oxygen in HPB plume

18.5.62 DO concentrations in the baseline HPB plume were also modelled using GETM. The outputs are presented in (**Table 18.14**). These modelled data supplement the *in situ* monitoring data described earlier in this section. As can be seen, for HPB operating at 100% DO is representative of Good Status (the difference between these modelled data and the *in situ* data being that modelled data are only for the thermal plume, whereas the *in situ* data were collected from the wider study area; see Section 18.4 and **Figure 18.2**).

Table 18.14: Mixing Zones (hectares) for Thermally Induced Reductions in Dissolved Oxygen for 'High' Status (Threshold = 6.2mg/l) and 'Good' Status (threshold = 4.4mg/l).

Model run	Bed		Surface	
	High	Good	High	Good
Run B (GETM) HPB at 100%	546	0.0	631	0.0

xiv. Baseline Water Quality Sensitivity

18.5.63 With respect to marine water and sediment quality, the relevant receptor is water quality status. Three high level pressures that could affect water quality have been identified: alterations to suspended sediment concentrations, chemical discharges and the thermal discharge at Hinkley Point.

18.5.64 As described above, the marine waters off Hinkley Point are characterised by powerful and wide-ranging tidal flows that cause mixing and dissipation of inputs and mobilise sediments, resulting in high suspended solid concentrations. These physical characteristics mean that the receptor (marine water quality) has different sensitivities to different pressures.

18.5.65 In terms of the main pressures identified, the sensitivities of the water body are as follows:

- Due to the very high concentrations of suspended sediment already in the system, the receptor has a low sensitivity to changes in its suspended sediment load. Therefore, the receptor is assigned low sensitivity to changes in suspended sediment concentration.
- Due to the very high tidal movements that characterise the study area, the chemical substances entering the system are, generally, rapidly mixed and disperse quickly. This would suggest that sensitivity to chemical change would be low. However, chemical discharges may occur over a sustained time period, and

some chemicals are more persistent than others so, on a precautionary basis, the receptor has been assigned a medium sensitivity to changes in chemical quality.

- Although the system is well mixed (see above), the natural temperature is already naturally high (98%-ile is only 2.6°C below the thermal threshold for 'Good' status), and so the receptor is assigned a medium sensitivity rating for thermal change.

18.5.66 The receptor and sensitivities assessed within this chapter are summarised in **Table 18.15**.

Table 18.15: Marine Water Quality Status and its Sensitivities

Receptor	Pressure	Sensitivity
Marine water quality status	Change in suspended sediment load	Low
	Change in chemical status	Medium
	Change in temperature	Medium

18.6 Assessment of Impacts

a) Introduction

18.6.1 In this section, potential impacts on the marine water quality receptor associated with all phases of the proposed HPC development are assessed against the baseline described above (including the effect of mobilisation of sediment-bound contaminants). The assessment of impact magnitude, where relevant, takes into account design measures developed to reduce the potential for impacts to occur.

18.6.2 The key elements of HPC's construction phase for which environmental effects are assessed include:

- construction of the construction outfall;
- surface water, sewage effluent and groundwater discharges from the foreshore outfall structure;
- construction of the temporary jetty and temporary aggregates storage area;
- construction of the sea wall and drainage system;
- discharges from the sea wall drainage system;
- discharge of effluent during construction of the cooling water tunnel infrastructure and Fish Recovery and Return (FRR) system;
- disturbance to sediments during dredging for offshore infrastructure;
- disturbance to sediments during vertical drilling of offshore infrastructure;
- discharge of drilling waste;
- disturbance of sediments during the capital dredge of the berthing pocket at the temporary jetty;
- disturbance of sediments due to operation of the temporary jetty (including vessel movements and maintenance dredging); and
- dismantling of the temporary jetty.

18.6.3 Dredging is a common feature of many of the marine work aspects of the HPC Project mentioned above, and a common approach would be applied to the disposal of all dredged material. If the relevant Marine Licence criteria are met, it is proposed that any dredged material from the construction process (including from creation of the berthing pocket for the temporary jetty and installation of the cooling water infrastructure) would be disposed of locally within the sediment transport system that exists at Hinkley Point. If the criteria are not met, the dredged material would be removed for disposal at a licensed site (e.g. Cardiff Grounds). A licence for disposal of dredged material will be sought from the appropriate authorising body.

18.6.4 The key elements of HPC's commissioning and operational phase for which environmental effects are assessed include:

- discharges associated with cold and hot flush commissioning tests;
- discharges to the foreshore from the seawall drainage system;
- discharges associated with the operation of the cooling water system (including operational and domestic, e.g. sewage, discharges);
- disturbance of sediments due to scouring around the cooling water infrastructure; and
- disturbance of seabed sediments from maintenance dredging around the intake structures.

18.6.5 For all phases, the potential exists for the risk of accidents and incidents to occur which, if unmanaged, could have an adverse impact on water quality. The probability of occurrence can be reduced through the use of good engineering design and site specific monitoring and management. Furthermore, the magnitude of any impact would be managed through the implementation of the **Pollution Incident, Control Plan (PICP)** (**Annex3; Appendix 8**). In general, potential environmental impacts arising from the HPC development would be managed through a range of control measures and monitoring procedures (to be outlined in the main **Environmental Management and Monitoring Plan** (**EMMP; Annex 3**)).

b) Mitigation by Design

18.6.6 As mentioned in Section 18.4, a number of aspects of the HPC Project have been designed in such a manner that environmental impacts are reduced without the need for additional mitigation. Mitigation that is an integral part of the design, and its resulting reduction in environmental impacts is included in this section, as opposed to being considered separately.

18.6.7 The main aspects of the design that are relevant to reducing impacts on marine water quality are described in **Table 18.16** below.

Table 18.16: Features Built into the Design of the HPC Project to Mitigate Potential Environmental Impacts

Design Feature	Mitigating Benefit
Single construction outfall	Use of a single outfall for construction and commissioning discharges made to the foreshore means that only one area of the foreshore would be impacted by those discharges. Multiple outfalls, although preferable to enable discharges to be made closer to works activities, would lead to several locations along the foreshore being potentially affected. Potential environmental impacts, in terms of ecological receptors, were reduced further by using hydraulic modelling to identify the location that would least affect the intertidal ecology (see **Volume 2**, **Appendix 19A**).
Percolating design of sea wall for groundwater	The sea wall is designed to allow groundwater to percolate through and drain more naturally to the foreshore. The design essentially mimics the normal drainage pattern that presently occurs from the existing cliff face. The percolating drainage is achieved by having drainage holes placed routinely along the entire length of the sea wall.
Temporary sewage treatment plant with tertiary treatment	During the construction phase, a temporary sewage treatment plant would be used for construction staff. It is proposed that the treatment plant would have a tertiary level treatment (ultra-violet treatment) to ensure that the resulting effluent is suitable for discharge across the foreshore. Target criteria for discharge parameters (agreed with the Environment Agency) are: • Biological Oxygen Demand (BOD) ≤ 20mg/l; • Suspended solids ≤ 30mg/l • Ammonia (total) ≤ 5mg/l (to meet unionised EQS of ≤ 21µg/l).
Facility for treatment of tunnelling discharges	In the unlikely event that mud-assisted drilling is required when boring the horizontal cooling water tunnels, a treatment facility would be used to recover the bentonite, reduce (if necessary) suspended sediment concentrations and balance the pH. The treatment would ensure that the resulting liquid is suitable for discharge across the foreshore.
Facility for treatment of commissioning discharges	During the commissioning phase, a number of substances would need to be discharged during the flushing periods of the cold and hot functional tests. Before the main cooling water system is operational, discharges from cold functional tests would need to be discharged across the foreshore. To ensure that water quality is not affected by these discharges, a treatment facility would be built to treat the discharges such that when they are discharged they are compliant with their respective EQS.
Offshore locations for cooling water outfall structures	Numerical modelling was used to assess the effect of location of the cooling water intakes and outfalls on the behaviour and scale of the cooling water discharge. The reason for doing this modelling was two-fold: (1) from an operational perspective it was critical to identify the best locations to reduce re-circulation of the warm discharged cooling water back into the intakes, and (2) to ensure that, as much as possible, the cooling water plume does not impact on intertidal or nearshore subtidal ecological receptors. By placing the intakes and outfalls approximately 3km and 2km offshore, respectively, the cooling water plume is modelled to fulfil these objectives.
Risk-based chlorination strategy with intermittent dosing	It is considered extremely unlikely that chlorination would ever be required at HPC because operational experience indicates there is only a very low risk of biofouling. However, should biofouling occur a site-specific, risk-based and intermittent chlorine dosing strategy would be used. This would ensure that only the minimum levels of chlorination required to ensure safe operation of HPC would be used, thus minimising the impacts of chlorination on water quality.

Design Feature	Mitigating Benefit
Facility for treatment of hydrazine	Hydrazine is an oxygen-scavenging chemical that is used as a condition agent within the cooling water circuit. It is very toxic, however, it is also very unstable and rapidly breaks down into ammonia. The HPC EPR design has a treatment facility built in to the nuclear island such that hydrazine discharges are as low as practicable. EDF Energy is also examining ways to improve treatment further by treating hydrazine within the conventional island.
Attenuation pond (HXO facility)	All collected surface water will be discharged via an attenuation pond (or HXO building). This facility provides settlement facilities for suspended sediment and oil separators. The attenuation pond also provides a storage facility for retention of more contaminated discharges resulting from spillages or major leaks. Material held in the retention tank can either be treated (if feasible) or removed to a container for removal off-site.
Water Management Zones (WMZs)	WMZs are designated areas for managing the quality of discharges to the receiving water and minimising potential impacts on water quality. WMZs would ensure that sufficient surface water storage capacity is provided to control discharge rates and provide the opportunity for treatment prior to discharge, for example oil separation and pH adjustment. Attenuation also encourages the settlement of suspended sediment and would provide the opportunity for isolation of accidental spills or pollution during the construction phase; offering a further level of protection to the intertidal area. It has been agreed with the Environment Agency that discharges from WMZ would meet the following criteria: • suspended solids: 250mg/l; • pH: 6 to 8.5; and • no visible oils.
Sustainable Drainage Systems (SuDS)	SuDS, such as soakaway systems, are a common mitigating feature designed in to site drainage to reduce potential impacts of run-off on water quality in the receiving water.

18.6.8 In addition to the designed-in mitigation features, a number of management techniques to reduce environmental impacts are also an integral part of the construction process, including subject specific annexes of the EMMP including: the **Water Management Plan (WMP)** (**Annex 3**; **Appendix 3**) and the **PICP** (**Annex3**; **Appendix 8**) .

c) Potential Impacts during Construction

18.6.9 Initial works to the site would involve large scale changes to topography and surface drainage patterns through the removal of vegetation, excavation and reworking of soils and stockpiles, construction of haul routes and the development of construction platforms. The two key activities that may impact on marine water quality are: the large-scale earthworks to create development and construction platforms and the development of a surface water drainage system. Potential risks to water quality therefore include an increase in suspended sediment and any soil contamination present within the earthwork area. Residues of hydrocarbons are often present in surface water drainage on construction sites and result from wash-off from plant during movements and operations. Elevated pH may also be a feature as a result of leachate from concrete and washwater used for concrete manufacturing equipment. Discharge of concrete washwater is only anticipated during the construction phase until the concrete batching plant becomes operational. However, elevated suspended solids, hydrocarbons and elevated pH associated with concrete use may have an adverse impact on water quality.

18.6.10 Any surface water created by alteration to the existing landscape could potentially impact on existing surface watercourses. In terms of impacts on marine water quality, the HPC drainage ditch which drains the northern end of the development site (Built Development Area West (BDAW) and Built Development Area East (BDAE)) is the most relevant, as it discharges directly to the foreshore. Impacts on surface water discharges to freshwater receptors are considered in **Volume 2**, **Chapter 16.**

18.6.11 It is proposed that, initially, the surface water in the northern area of the site (BDAW and BDAE), including the aggregates storage area associated with the jetty development, would be collected and directed to a water management zone (WMZ) and then discharged to the existing HPC drainage ditch and across the foreshore. Subsequently, the existing drainage ditches would be backfilled and three spine drains would be installed. These spine drains would eventually combine to a single discharge point to the foreshore close to the graving dock and the existing outfall of the HPC drainage ditch (see **Figure 18.4**).

18.6.12 The location of a single discharge point has been chosen, following numerical hydraulic modelling, to cause the least impact on the existing ecology of the foreshore (see **Appendix 19A**, **Volume 2**). Additional WMZs would be developed to manage discharges into the spine drains. In addition to surface water, it is proposed that this discharge would comprise pumped ground water from the excavation works for the nuclear islands, and waste water from the tunnel boring operations.

18.6.13 The WMP (**Annex 3**; **Appendix 3**) would implement techniques to reduce sediment run-off, such as containment and location of stockpiles away from the foreshore area. Barriers to reduce sediment run off from newly excavated areas would also be considered, in addition to sediment removal techniques, should concentrations be significantly elevated. The movement of heavy vehicles around the site would be closely managed and plant access would be restricted to pre-defined corridors where access across soft sediments is required. For further details of the proposed control measures, see **Chapter 16**, **Volume 2**.

18.6.14 **Chapter 14**, **Volume 2** presents information regarding the potential for contamination within the soils of the development area. Information collated to date indicates no soil contamination, with the exception of a small isolated area in the east of the site.

IMPACT: Generation of Sediment and Discharged Waters Associated with Construction of the Construction Outfall

18.6.15 Activities associated with the construction of the construction outfall, specifically the use of concrete (and dewatering), have the potential to impact on water quality status because concrete discharges can cause sharp increases in pH. In addition, residues of hydrocarbons may be expected in surface drainage water from the working area due to wash-off of lubricants from construction plant. These pollutants may potentially impact upon the water quality status of the standing-water pools across the intertidal area under low tide conditions, although given the likely small scale of these discharges, they are not expected to have any discernible impact upon the water quality status of the wider marine environment. The location of the single discharge point has been chosen, following numerical hydraulic modelling, to cause the least impact on the existing ecology of the foreshore (**Appendix 19A**, **Volume 2**). Potential impacts would be temporary and direct.

18.6.16 Good working practices and pollution prevention techniques would be implemented during the construction of the foreshore outfall infrastructure (enforced as part of a site specific WMP (**Annex 3**; **Appendix 3**). Based on the small footprint of the proposed works, the proposed drainage management and the characteristics of the intertidal area, the potential magnitude of this effect is predicted to be very low (see **Table 18.4**). Marine water quality status has been assessed to have a low sensitivity to changes in suspended sediment concentration and medium sensitivity to changes in chemical quality (see **Table 18.15**). The impact significance for generation of sediment is thus assessed to be **negligible**, and for contaminated discharge waters is assessed to be **minor adverse**.

IMPACT: Surface Drainage Discharges to the Foreshore

18.6.17 All surface waters would be directed to the surface water drainage system. Where necessary, suspended sediment concentration would be reduced, hydrocarbons would be removed and pH would be adjusted, prior to controlled discharge to the foreshore. Design measures that are incorporated into the surface water drainage system that would minimise sediment generation, as described above, include:

18.6.18 As a result of these measures, impacts from the foreshore discharge are predicted to be of a low magnitude (see **Table 18.4**). In terms of contamination of surface drainage arising from soil excavation, the impact magnitude is predicted to be very low, based on results of the contaminated land surveys. Potential adverse impacts upon water quality status would be local and temporary in nature. The sensitivity of the marine water quality status is considered to be low for changes in suspended sediment concentration and medium for changes in chemical quality (as presented in **Table 18.15**).

18.6.19 Taking the above into account, all potential impacts associated with surface drainage discharges to the foreshore are assessed to be of **minor adverse** significance for the marine water quality receptor.

IMPACT: Discharge of Sewage Effluent to the Foreshore

18.6.20 Until the temporary discharge outfall to the old graving dock area is operational, treated sewage effluent would be collected in a sealed storage tank for off-site disposal.

18.6.21 Currently, it is proposed that there would be three package sewage treatment plants located close to the main spine drain C to the west of the site. The package treatment plants would be installed during the site preparation phase and would become operational during the main site construction phase. If the level of treatment is sufficient to meet any discharge consent, the treated effluent from these plants would discharge directly into the western spine drain and ultimately would discharge via the foreshore discharge location, otherwise it would discharge into a WMZ first. These plants would only collect and treat sewage and, therefore, their discharges would not vary according to weather conditions. Storm overflows at these plants would not be required.

18.6.22 The discharges of sanitary waste effluent may potentially have an adverse impact on intertidal marine water quality status. It is proposed that the effluent would be treated to tertiary level before discharge to reduce both microbiological and chemical parameters associated with sanitary waste (i.e. suspended solids, ammonia and BOD). Parameters agreed with the Environment Agency are: Biological Oxygen Demand (BOD) ≤ 20mg/l; suspended solids ≤ 30mg/l and ammonia (total) ≤ 5mg/l (to meet unionised EQS of ≤ 21µg/l).

18.6.23 The receptor for the discharges of treated sanitary effluent would be the marine water quality which is assigned a medium sensitivity for chemical quality (see **Table 18.15**). Design measures, including tertiary treatment, are incorporated into sanitary waste treatment to minimise the impact on marine water quality status. These measures would ensure that the impacts from the discharge of sewage effluent across the foreshore would have a very low magnitude (see **Table 18.4**). Potential adverse impacts upon water quality status would be local, temporary and direct in nature.

18.6.24 Taking into account the design measures of the treatment system, all potential impacts associated with treated effluent discharges to the foreshore are assessed to be of **minor adverse** significance for the water quality receptor through all stages of the tidal cycle.

IMPACT: Pumped Discharge from Dewatering of Groundwater

18.6.25 It is anticipated that groundwater de-watering would be required throughout the construction process. Modelling indicates a steady state discharge rate to the foreshore of 12 l/s, to be made via the surface drainage system (see **Volume 2**, **Chapter 15** and **Chapter 16**). During the initial stages of dewatering, discharge rates are expected to be higher (up to 140 l/s).

18.6.26 Discharges of contaminated groundwater from the foreshore outfall may have an adverse impact on intertidal water quality status. The worst case scenario would arise when this discharge occurs at low tide, when the intertidal area is exposed and there is no immediate dilution available to offset potential impacts on marine ecology. At low tide, this effect would be local to the intertidal area down-shore of the discharge location and short-term, because the discharge would be diluted and flushed during the next flood tide. The sensitivity of marine water quality status to changes in chemical quality is medium (see **Table 18.15**).

18.6.27 Groundwater chemical quality is discussed in **Volume 2**, **Chapters 15** and **16**. Pumped groundwater would be subject to monitoring prior to discharge and to stringent controls. Where necessary, contaminated groundwater would either undergo pre-treatment prior to discharge or be disposed of off-site. Given these design measures, the impact magnitude associated with groundwater dewatering discharges is predicted to be very low.

18.6.28 Thus the impact of groundwater discharges on marine water quality status is assessed to be **minor adverse**.

IMPACT: Surface Water Discharges Direct to Marine Waters resulting from Construction of the Jetty

18.6.29 The proposed access road to the foreshore would not have a surface water collection system and, therefore, any run-off would be directly to the Hinkley intertidal area without the benefit of pre-discharge treatment within a WMZ. Surface drainage from this access road may have elevated levels of suspended solids and residual hydrocarbons from construction plant movements. Suspended solids and hydrocarbons may potentially impact upon the water quality status of the receiving intertidal area. The potential impact associated with this would be local and temporary.

18.6.30 The marine water quality status in the area around Hinkley Point has been assigned a low sensitivity to changes in suspended sediment concentration and a medium sensitivity to changes in chemical quality (see **Table 18.15**). The magnitude of this impact is expected to be very low (see **Table 18.4**) given that the road would be constructed from roadstone, incorporating lateral soak away drainage that would reduce the volume of surface run-off reaching the intertidal area. Vehicle movements would also be limited and, therefore, it is not anticipated that significant levels of suspended solids and hydrocarbon contaminants would be present within the surface drainage.

18.6.31 Given the very low magnitude of the potential impact and the low sensitivity of the water quality status of the intertidal area to changes in suspended sediment, the significance of this potential impact is assessed as **negligible**. With respect to the potential change in chemical status a **minor adverse** impact is predicted.

IMPACT: Generation of Sediment and Discharged Waters during Construction of the Sea Wall

18.6.32 Excavation of the existing cliff face and foreshore during construction of the sea wall could lead to the generation of relatively large quantities of sediment, and consequently drainage from the working area could have high concentrations of suspended solids. The sensitivity of the marine water quality receptor to potential impacts has been assessed as low for changes in suspended sediment and as medium for changes in chemical quality (see **Table 18.15**)

18.6.33 However, given the location of the sea wall on the uppermost part of the shoreline (i.e. above MHWS level), the potential for any significant effect on water quality in the nearshore intertidal zone is low. Under high tide conditions, it is anticipated that any discharges from the construction area, even if containing relatively high suspended sediment concentrations, would be rapidly dispersed and it is likely that background conditions would be restored close to the points of discharge. Under low tide conditions, discharges across the intertidal area would infiltrate the existing permeable substrates and any fine sediment would settle into the upper beach fabric or be deposited in existing intertidal mudflat habitats.

18.6.34 If monitoring demonstrates that the water being discharged meets relevant quality criteria it would be discharged directly to the foreshore during high tide periods, when it would be subject to immediate dilution. Otherwise, it would be pumped to a shore based WMZ for treatment prior to discharge (under an environmental permit) via the construction outfall. Based on these design approaches for management of the drainage, and the baseline characteristics of the intertidal area, the impact magnitude has been assessed as very low (see **Table 18.4**).

18.6.35 Taking into account the described design measures, potential impacts associated with surface drainage discharges to the foreshore from construction of the sea wall are assessed to be of **negligible** significance in terms of suspended sediment and **minor adverse** in terms of chemical quality for the marine water quality receptor.

IMPACT: Sediment Disturbance and Mobilisation of Contaminants Resulting from Offshore Construction Works, Including Dredging

18.6.36 The design and construction details for the offshore infrastructure (cooling water intake and outfall structures and temporary jetty) are presented in **Volume 1**, **Chapters 2** and **3**.

18.6.37 Many of the predicted impacts relating to construction of the offshore infrastructure relate to increased suspended sediment or the potential for the release of sediment-bound contaminants. This could potentially result from:

- capital dredging of the jetty berthing pocket;
- disturbance as a result of piling (in the case of the jetty construction); and
- dredging of offshore areas in advance of intake and outfall head installations.

18.6.38 Dredging activities have the potential to increase sediment concentrations through sea bed disturbance, and have been subject to site-specific assessment in order to determine whether sediment-bound contaminants could be mobilised and impact marine water quality status.

18.6.39 Due to the relatively small areas to be dredged (in relation to the scale of the Bristol Channel), and the high concentrations of naturally occurring suspended solids in the area, modelling of potential impacts from suspended sediment plumes was not considered to be necessary. Additionally, any sediment suspended within the water column would be quickly dispersed into existing sediment transport processes.

18.6.40 In order to assess the potential for contamination of the water column from sediment disturbance, a detailed desk based assessment was undertaken using the information provided by the 2009 sediment quality survey. In summary the method:

- estimated the maximum increase in suspended solids concentration as a result of dredging activities;
- multiplied the maximum contaminant concentration recorded in sediment cores with the estimated concentration increase to give a concentration of pollutant released into the water column;
- used partition coefficients to estimate the concentration of pollutant that is likely to enter the dissolved phase; and
- compared estimated maximum values of dissolved contaminant with marine water EQSs.

18.6.41 Multiple depth chemical data collected during the 2009 offshore borehole sampling campaign were analysed for 14 sets of data from vibrocores taken at locations around the temporary jetty and the offshore and intake locations. **Table 18.17** presents the calculated maximum concentrations of metals entering the water column from disturbed sediment, and compares the resulting dissolved contaminant concentrations with marine water EQS. The calculations presented are based upon a worst-case scenario (i.e. although the calculation has been made, it is not realistic that all the sediment disturbed in one episode would be contaminated to the maximum concentration value).

18.6.42 The baseline mean water quality contaminant concentration values are taken from the 2009 marine monitoring campaign data (Ref. 8.51).

Table 18.17: Estimated Maximum Concentrations of Metals Entering the Water Column and the Dissolved Phase from Disturbance as a Result of Marine Sediment Dredging

Determinand	Max overall conc. (mg.kg^{-1})[1]	Total conc. in suspen. (mg.l^{-1})[2]	Total conc. in susp. (µg.l^{-1})	Partition Coeff. [3]	Conc. entering diss. phase (µg.l^{-1})	Backgnd mean conc (µg.l^{-1})[4]	Total diss conc (µg.l^{-1})[5]	WFD Marine EQS
Arsenic	30	0.015	15	10000	1.50E-03	2.3	2.3015	25 AD
Cadmium	1.5	0.00075	0.75	130000	5.77E-06	<0.01	<0.01	0.2AD
Chromium	67	0.0335	33.5	191000	1.75E-04	0.02	0.0202	0.6 AD*
Copper	51	0.0255	25.5	61000	4.18E-04	3.95	3.9504	5 AD

Zinc	307	0.1535	153.5	4860	3.16E-02	39.27	39.302	40 AD

Notes:

*A = Average; D = Dissolved; * = chromium VI;*

1 *Maximum individual metal concentration taken from Cefas testing results of sea bed sediment cores undertaken by Fugro Seacore Ltd in Nov and Dec 2009 – see Fugro (2010) (Ref. 8.69);*

2 *Assumes maximum increase in suspended solids concentration resulting from dredging to be 500mg/l (Ref. 8.74);*

3 *Partition coefficients taken from ABPmer (2010) (Ref. 8.75);*

4 *Mean values taken from 2009 sampling (Ref. 8.51);*

5 *Additional dissolved concentration + Background concentration.*

18.6.43 After the application of partition coefficients, the predicted concentrations of metal contaminants entering the dissolved phase are several orders of magnitude below the EQS set by the WFD and Dangerous Substances Directive.

18.6.44 The sensitivity of marine water quality to increases in suspended solids is considered to be low given the already high background concentrations (**Table 18.15**). The sensitivity of the local marine water quality conditions to increases in contaminant mobilisation associated with sediment disturbance is also considered to be low, given that contaminants tend to be present in the upper sediment layers which are subject to regular mobilisation under tidal flows. Potential impacts arising from disturbance of the marine sediments by these construction activities would be temporary in nature and localised.

18.6.45 Where practical, the construction techniques used for pile installation and offshore dredging would adopt techniques that cause minimal disturbance of marine sediment deposits. Given these construction approaches, the magnitude of any impacts is assessed as very low (see **Table 18.4**) for piling works and low for capital dredging activities.

18.6.46 The adoption of best practice construction techniques, the ability of the environment to accommodate such changes (maximum contaminant mobilisation scenario does not affect marine water EQS) and the temporary nature of the dredging, means that the associated significance of sediment disturbance would be **minor adverse** for capital dredging and **negligible** for piling on the marine water quality receptor.

IMPACT: Drilling of the Offshore Vertical Shafts for the Cooling Water System and Installation of Headworks

18.6.47 Six vertical shafts would be drilled using wet drill techniques in the offshore zone. Four of these would be excavated with an aperture diameter of 5m to a depth of 30m below seabed, approximately 3.3km offshore, and would be associated with the two horizontal intake tunnels. The two other vertical shafts, associated with the outfall tunnel, would be excavated to 20m below seabed, with an aperture diameter of 8.3m.

18.6.48 Wet drilling would be undertaken from a rig platform fixed to the seabed with piles and anchors. Arisings from the operation would either be discharged at sea within the study area (if doing so would not impact on the local ecology) or collected and separated for disposal at licensed marine disposal grounds (Cardiff Grounds). Whether deposited locally or at licensed grounds, a licence for disposal of material at sea would be sought from the appropriate authorising body (either the MMO if material is dispersed locally, or the Welsh Assembly if the material is removed to the Cardiff Grounds).

18.6.49 For disposal at licensed grounds, the arisings would be contained and transported from the working face below to the platform itself, where the solids and water would be separated. The processed water would then be discharged back into the Bristol Channel, and solids would be transported away by barge for disposal. At the water discharge point, some suspended sediment would be released into the water column. However, the concentration of sediment in the discharge water would be constrained to a level comparable to that found in suspension locally.

18.6.50 The presence of the rig platforms would locally alter the hydrodynamics due to change in flows around the piles and anchors. However, given the negligible size of the structures relative to the extent of the surrounding seabed and the Inner Bristol Channel, the changes to the hydrodynamic processes, and hence changes in sediment distribution and contaminant mobilisation, would be limited and within the range of natural variability. In addition, the works would be of a temporary nature and, after the removal of the rig, the seabed would be expected to revert to its pre-construction condition.

18.6.51 The sensitivity of the marine water quality receptor to changes in suspended sediment has been assessed as low (see **Table 18.15**).

18.6.52 Given that disturbance of sediments and the associated potential for contaminant mobilisation into the water column has been assessed as insignificant, when combined with consideration of the baseline conditions and design features of the drilling approach, the magnitude of this impact is assessed as very low (see **Table 18.4**). Therefore the significance of the drilling operations to the marine water quality status in the area around Hinkley Point would be **negligible**.

IMPACT: Concrete Leachate Associated with Construction

18.6.53 Concrete has the potential to impact on marine waters because it can cause a sharp increase in pH. During both the jetty and sea wall construction there are a number of activities that would require pouring of wet concrete *in-situ* or close to the marine environment, including the:

- installation of piles;
- construction of the jetty head;
- construction of the sea wall; and
- construction of drainage system foreshore outfall.

18.6.54 There would be limited opportunity for collection of concrete leachate or contaminated drainage during the direct use of concrete in the marine environment. However, there may be potential for any concrete contaminated water that accumulates in the footings excavated for the sea wall to be pumped to shore for treatment within the WMZs, rather than direct discharge to the intertidal area. This high pH water would be subject to adjustment within the WMZs prior to discharge through the foreshore outfall. Regardless, water with a high pH may impact locally upon marine water quality status. Such a potential impact would be temporary and direct.

18.6.55 In order to reduce the risk of this impact as far as possible, due regard would be paid to the Environment Agency's PPG note 5 (Ref. 8.43), and measures to control leachate spillages put in place. For example, quick set concrete would be used and concreting for intertidal structures would be undertaken during periods of low tide wherever possible, where clean up can easily occur.

18.6.56 The sensitivity of marine water quality to changes in chemical quality is defined as medium (see **Table 18.15**). Given the control measures that would be adopted, and the high dilution available in relation to low volumes of water with elevated pH, the magnitude of this impact is assessed to be very low (see **Table 18.4**). Consequently, the significance of this potential impact is assessed as **minor adverse**.

IMPACT: Hydrocarbon Residues Associated with Construction

18.6.57 Activities and movement of construction plant across the intertidal area during construction of the temporary jetty, foreshore outfall structure and sea wall would give rise to some wash-off of hydrocarbons and lubricants. Residues may also be expected from construction platforms operating in the subtidal areas during construction of the subtidal elements of the jetty, and the offshore infrastructure.

18.6.58 Hydrocarbons entering the marine environment may have an adverse impact on water quality status, although the main impacts relate to subsequent effects on marine biota.

18.6.59 The sensitivity of marine water quality in this context is assessed as medium (**Table 18.15**) The intertidal would be at its most sensitive during low tide periods, although any potential impact would be short-lived due to tidal inundation and subsequent flushing and dilution of any residual hydrocarbons.

18.6.60 Design measures would be implemented to reduce the magnitude of this potential impact, including restriction on refuelling and storage of fuels and lubricants on the intertidal area, adoption of best practice measures on handling of fuels and, where possible, the use of biodegradable lubricants. Given the very small volumes of hydrocarbons that would be lost in relation to the receiving environment, and the implementation of appropriate control measures, the magnitude of this potential impact is predicted to be very low.

18.6.61 Based on the receptor sensitivity and predicted magnitude, the significance of hydrocarbon loss during these construction activities is assessed as **minor adverse** in relation to marine water quality status.

IMPACT: Sediment Disturbance and Mobilisation of Contaminants Resulting from Operation of the Temporary Jetty

18.6.62 A potential impact upon water quality within the Bristol Channel during the operation of the jetty could result from the following activities:

- maintenance dredging;
- vessel movements; and
- scouring of sediment from the seabed around the jetty's infrastructure (e.g. piles and berthing pocket).

18.6.63 The majority of sediment disturbance would result from maintenance dredging of the berthing pocket, because this activity has the greatest potential to increase suspended solids concentrations and lead to localised mobilisation of sediment contaminants.

18.6.64 The area of the berthing pocket is within a zone of mud deposition which on average appears to be accumulating at about 2cm a year, and is thought to have a mud source to the east. There may be large variations in the magnitude and continuity of this rate, and there is little information about the resulting mud density.

18.6.65 Because of the depth increase locally due to the dredged berth and alteration of tidal velocities in relation to the tidal cycle, the berthing pocket would tend to trap some material and delay the remobilisation of mud on Spring tides. It is not possible to provide a firm estimate of the resulting balance of the differing settlement and remobilisation rates, as the operation of the berth itself would add a further factor. The berth would be used frequently whilst sea conditions permit and the movement of the vessels would influence the rates of both settlement and re-suspension. There would thus be a chronic level of disturbance throughout the period of jetty operation which is likely to affect sedimentary processes in the area of the berthing pocket.

18.6.66 The implication is that, with frequent vessel usage alternating with periods of bad weather, the need for any maintenance dredging would be reduced. Ignoring the complexities associated with the operational regime described above, it is estimated that settlement in berthing pocket settlement in the range 60,000$m^3.yr^{-1}$ to 200,000 $m^3.yr^{-1}$ could arise (see **Volume 2**, **Chapter 17**). However, in practice, the operator would monitor sediment accumulations in the berthing pocket in order to trigger a maintenance dredge should this prove necessary.

18.6.67 Of the dredging techniques available, a hydrodynamic method is likely to be better suited for maintenance dredging (ploughing / bed levelling, agitation or water injection,. Any disturbance associated with this activity would be almost identical to the effects of the tidally driven semi-diurnal and Spring / Neap cycles of widespread mobilisation/deposition/remobilisation of superficial finer sediments in the locality and would thus be of very little consequence.

18.6.68 The potential impact on water quality of any maintenance dredging or tidal scour can be determined with reference to the assessment of sediment disturbance and contaminant mobilisation during the construction of the jetty (i.e. the capital dredging and piling works). This assessment concluded that the levels of contamination recorded within the sediments are unlikely to vary from those found already within the estuary (essentially as a result of re-working of the mobile surface sediment layer).

18.6.69 The marine water quality receptor has been assessed to have a low sensitivity to changes in suspended sediment (see **Table 18.15**).

18.6.70 In assessing the magnitude of the potential impacts arising from sediment disturbance, the relatively small area of the dredging pocket, the localised nature of scour around the piled jetty, the high background concentrations of suspended solids, the dynamic nature of seabed sediment deposits under tidal flows and the low potential for partitioning of sediment pollutant into the water column has been taken into account. Accordingly, the magnitude of the potential impact associated with sediment disturbance resulting from scour and dredging is assessed to be very low (see **Table 18.4**). The impact significance is, therefore, assessed as being **negligible** for the marine water quality status around Hinkley Point.

IMPACT: Surface Water Discharge from the Jetty During Operation

18.6.71 All discharges from the temporary aggregates storage area would be collected via the proposed drainage system for the main site. Surface drainage from this area would be routed to a WMZ and treated prior to discharge via the foreshore outfall. The impacts from these discharges have been addressed above.

18.6.72 However, surface water would be discharged directly from the jetty deck to both the intertidal and subtidal areas. This drainage water may contain both suspended solids and hydrocarbon residues. Contamination of the surface drainage with cement is not expected, given the sealed delivery system proposed for unloading of cement from vessels to the silos in the temporary aggregates storage area. Potential impacts arising from the untreated drainage water would persist over the operating lifespan of the jetty. The marine water quality receptor has been assessed to have a low sensitivity to changes in suspended sediment and a medium sensitivity to changes in chemical quality (see **Table 18.15**).

18.6.73 Given that the engineering design includes for covering all conveyors, the proposed import of prefabricated materials, the small surface area of the jetty, and that the volume of surface drainage in relation to the volume of the receiving marine water quality receptor would be very low, the magnitude of this drainage impact on marine water quality status is predicted to be very low.

18.6.74 The significance of this potential impact is, therefore, assessed as **negligible** with respect to suspended sediment and **minor adverse** with respect to chemical status.

IMPACT: Re-suspension and Deposition of Sediment during Dismantling of the Temporary Jetty

18.6.75 Following an operational period of eight years, it is proposed that the jetty would be dismantled and the site restored. Compared to the dredging required during construction and operation, sediment disturbance during dismantling would be small in scale and mainly related to movement of offshore plant and removal of piles. In the case of activities in the intertidal areas, the potential for disturbance would be very limited because the large majority of the intertidal area is comprised of exposed wave-cut platforms (i.e. rock rather than sediment) and working would preferentially occur at low tide. Any potential impacts associated with sediment disturbance would be local to the jetty area, direct and temporary in duration.

18.6.76 The sensitivity of the marine water quality status to changes in suspended sediment has been assessed as low (see **Table 18.15**).

18.6.77 The magnitude of any impact associated with jetty dismantling would be dependent on the techniques adopted by the appointed contractor but, given the limited amount of plant likely to be working in the subtidal area, the limited potential for sediment disturbance in the intertidal area and the baseline conditions, impacts on marine water quality are likely to be of a very low magnitude (**Table 18.4**). A **negligible** impact is therefore predicted on marine water quality status.

IMPACT: Drilling of the Horizontal Tunnels for the Cooling Water and Fish Return Systems

18.6.78 The construction process for the drilling of these tunnels is described in **Volume 1**, **Chapters 2** and **3**. The water from these processes would be discharged across the foreshore. Given the underlying geology and tunnel boring machine working specifications, mud-assisted boring (slurry-mode) is not expected to be required; however, it potentially may be needed for the last few hundred metres of the tunnels. If mud-assisted drilling is used, the discharge would, following initial treatment, contain suspended solid concentrations of approximately $1g.l^{-1}$ (including 5% bentonite), would be of high pH (about 9.0) and contain an organic polymer. The discharge would be at a rate of about $60m^3$ per hour. This turbidity level is within the existing range in estuarine waters local to the site itself. If mud-assisted drilling is not used, the discharge would only contain water with suspended sediments and potentially elevated pH (as a result of some concrete use in tunnel construction). Mud-assisted drilling is, therefore, the worst-case scenario. Waste water from mud-assisted drilling would be subject to treatment either through a dedicated treatment plant or through routing to a WMZ prior to discharge to the intertidal area. Discharges from these operations would be subject to an environmental permit in terms of discharge flow rate and chemical quality.

18.6.79 Given that the sediment concentrations estimated to be discharged through a mud-assisted drilling (and non-mud assisted drilling) process are similar to the background suspended sediment concentrations recorded in the area, the effect on sedimentary processes is predicted to be insignificant. The additional loading to the Bristol Channel's sediment budget locally would simply contribute to existing trends in deposition, adding to these to a very minor degree, across a very wide area. Other aspects of the discharges from mud-assisted drilling, however, would impact marine water quality.

18.6.80 The sensitivity of marine water quality status is assessed as low for changes in suspended sediment concentration and as medium for changes in chemical quality (see **Table 18.15**). Given the proposed treatment of the drilling effluent the magnitude of this impact is assessed as low (see **Table 18.4**). Taking into account the sensitivity of the marine water quality receptor the significance of any impact is assessed to be **minor adverse**.

RISK: Construction Accidents and Incidents

18.6.81 There is a risk of potential impacts occurring as a result of accidents or incidents. It is not likely that accidents and incidents would arise under normal circumstances, hence these scenarios are presented as risks rather than as impacts.

18.6.82 In terms of marine water quality, the following risks have been identified during the construction phase as being of potential concern:

- failure of water management infrastructure such as pipe collapse, balancing pond breach, pump failure etc. due to an extreme rainfall event requiring emergency discharge to the intertidal area;
- accidental release of suspended sediments to intertidal area;
- failure of the sewage treatment system resulting in untreated discharges of sanitary waste to the foreshore;
- emergency discharge from horizontal tunnel operations to the foreshore;
- accidental spillage of chemicals or materials used in construction;
- accidental spills of fuels or oils;
- emergency discharges associated with firewater; and
- accidental spillage of wet concrete and/or cement.

18.6.83 These risks, and their likelihood of occurrence, would be managed and minimised through the use of good practice measures to be included in the EMMP and other associated subject-specific management plans, particularly the WMP (**Annex 3; Appendix 3**). These management plans may not influence the significance of an incident should it occur, but are a design measure to reduce the risk of occurrence to a very low level of probability.

18.6.84 In combination with the site specific management plans, a PICP (**Annex 3; Appendix 8**) is being developed by EDF Energy as a design measure to establish the response and management techniques that would be applied for a range of different incident types, should they occur. The implementation of this plan effectively acts as the mitigation to any incident through provision of measures to reduce impact magnitude, primarily through containment.

18.6.85 Routine monitoring and inspection, together with a system of efficient incident reporting, would trigger the EICP when incidents were identified. For the EICP to be effective, rapid implementation of the containment or other mitigation measures is required to reduce the potential impact to a non-significant level. The EICP, therefore, would act as the overarching mitigation measure for managing incidents and accidents and reducing their impact significance.

d) Cumulative Construction Impacts

18.6.86 Cumulative impacts on marine water quality in terms of the potential combined works at HPC are considered here. Cumulative impacts of the proposals with the wider HPC Project and other potential projects are assessed in **Volume 11**. There are two elements of the proposed development that could give rise to cumulative effects during the construction period and these are discussed below.

IMPACT: Increases in Suspended Solids

18.6.87 Each of the elements of the project that could give rise to increases in suspended solids are located some distance away from one another. For example, the jetty is located approximately 800m away from the foreshore discharge. Many of the sediment generating activities would also be separated temporally, e.g. the seawall and construction outfall would be carried out at different times to other sediment generating activities. Control measures through the WMZs would be in place to reduce the suspended solid concentrations within discharges from the land. Predicted impacts associated with the jetty dredging and cooling system drilling and dredging operations, although difficult to control, are expected to be insignificant, predominantly due to the already naturally high concentrations of suspended solids and strong tidal currents. Any temporary increases in suspended solid concentrations within the vicinity of Hinkley Point are, therefore, likely to be dispersed to background concentrations rapidly.

18.6.88 Given the temporary nature of each of the predicted impacts that may give rise to an increase in suspended solids, and the spatial extent of the impacts (i.e. localised to the source and rapidly diluted), cumulative impacts are not predicted (i.e. **no cumulative impact**).

IMPACT: Increases in Contaminants

18.6.89 All of the assessments that have considered the potential for contamination within the existing site soils have concluded that contamination is either comparable to baseline conditions or the risk of finding significant contamination is low. The risk of releasing contaminated sediment into surface water during the site works is therefore low. Additionally, control measures through the use of WMZs within the drainage system would be put in place in order to reduce the potential risk of discharging contamination to the surface water drainage system.

18.6.90 Any water quality contamination associated with sediment mobilisation resulting from dredging, offshore drilling and scour associated with offshore infrastructure is predicted to be comparable to baseline conditions. Cumulative impacts in terms of contamination and potential exceedences of EQS are, therefore, deemed to be unlikely (i.e. **no cumulative impact**).

e) Potential Impacts during Commissioning

18.6.91 In advance of operation of the EPR units there would be a period of commissioning tests and flushing. The primary purpose of this flushing is to clean and condition the pipework used within the cooling water circuits, using demineralised water with a range of chemical additives. The demineralised water used during this phase would be produced by a dedicated on-site plant that would be provided with a mains water supply. The commissioning tests have two distinct phases known as cold flush testing (CFT) and hot flush testing (HFT).

18.6.92 Due to the construction phasing of the two proposed EPR units, one would be completed and commence commissioning tests whilst construction on the second is completed. The cooling water system is not expected to be completed and operational until the commencement of the HFT phase for the first EPR unit. CFT discharges from this unit would, therefore, be directed to the construction phase spine drain system and discharged via the temporary foreshore outfall. All subsequent commissioning phase discharges would then be made through the cooling water system with offshore discharge and dispersion.

IMPACT: Cold Flush Testing

18.6.93 The main substances likely to be used/created during CFT are as follows (see also **Table 18.18**):

- Ammonia - added to the circuits to adjust the pH in the systems treated with hydrazine. Ammonia would also be present as a result of hydrazine breakdown.
- Reverse Osmosis / Demineralised Water.
- Ethanolamine - added to demineralised water to alkalinise water in steam cycles, for example.
- Hydrazine - used as an oxygen scavenger in the primary circuit. Note: the majority of hydrazine (>99.9%) would be expected to breakdown during this process.
- Iron and iron oxide – corrosion products.
- Phosphate – added to demineralised water as a corrosion inhibitor.
- Suspended solids - produced during corrosion of circuits and crud formation during construction.

Table 18.18: Estimated maximum concentrations ($\mu g.l^{-1}$) of cold-flush commissioning substances discharged across the foreshore per quarter over 2 years of commissioning

Commissioning substance	2016				2017			
	Q1	Q2	Q3	Q4	Q1	Q2	Q3	Q4
Mean daily volume of reverse osmosis and demineralised water (m^3)	250	197.8	195.7	2,60.9	266.7	263.8	195.7	130.4
Ammonia (total)	3,333	1,111	1,389	1,042	1,666	1,666	2,222	2,501
Ammonia (unionised; pH7)	13	4	5	4	7	7	9	10
Ammonia (unionised; pH9)	948	316	395	296	474	474	632	711
Ethanolamine	16,667	556	1,111	833	833	833	555	834
Hydrazine	2,000	1,111	1,944	1,458	1,458	1,458	833	1,250
Iron oxide	16,667	8,333	8,331	20,831	20,831	16,663	16,663	8,336
Iron	125,000	4,167	4,166	4,166	4,166	4,166	5,554	8,336
Iron + Iron oxide	29,167	12,50	12,497	24,997	24,997	20,828	22,217	16,671

Commissioning substance	2016				2017			
		0						
Phosphate	16,667	11,111	16,663	20,831	20,831	41,657	55,542	83,356
Suspended solids	3,333	1,111	1,666	2,083	2,083	2,083	1,111	1,667
Suspended solids + Iron oxide	20,000	9,445	9,998	22,914	22,914	18,745	17,773	10,003

***Note**: Data assumes continuous discharge (over each quarterly period) based on mean daily flow rate, rather than batch discharges.*

18.6.94 Comparison of the expected discharge concentrations of chemicals in the CFT phase with EQS values for transitional and coastal waters indicates that the discharges of all substances listed in **Table 18.18** would exceed their respective EQS, with the exception of suspended solids and ammonia in pH7 flush water. Therefore, untreated discharges could impact upon the local marine water quality status. It is proposed, therefore, that wastewater from the CFT would be subject to on-site treatment in order to meet or better respective EQS concentrations prior to discharge into the spine drain system and ultimately to the foreshore. This waste stream would also be subject to an environmental permit.

18.6.95 The sensitivity of the marine water quality receptor to changes in chemical quality is assessed as being medium (see **Table 18.15**) and any potential impacts would be direct, temporary and local. Given the incorporation of a comprehensive treatment system into the design, the magnitude of this potential discharge is predicted as low. It could be argued that because immediate dilution is available at high tide the magnitude would in fact be very low, but because the discharge would also go across the foreshore at low tide, a precautionary magnitude of low is assumed (see **Table 18.4**). The significance of this impact for the marine water quality receptor is, therefore, assessed as **minor adverse**.

18.6.96 Discharges from the CFT of EPR Unit 2 would be made offshore, via the cooling water system and impacts are assessed below.

IMPACT: Hot Flush Testing

18.6.97 HFT for the first EPR unit and both the CFT and HFT for the second EPR would commence when the direct sea water cooling system is made operational. Therefore wastewater from these phases would be discharged directly into the cooling water flow, which would provide a high degree of dilution.

18.6.98 During the HFT two additional chemicals, boric acid and lithium hydroxide, would be added to the chemically dosed demineralised water used in the CFT (see **Table 18.18**). Boric acid dosed water used in the HFT for commissioning of the first EPR unit would be recycled for use with the second EPR.

18.6.99 Screening of the discharges from HFT was undertaken using a H1 type assessment based on data derived from Flamanville 3 commissioning discharges. The assessment assumed a worse-case scenario of 24 hour loading values, with both plants being subject to HFT simultaneously, together with a reduced discharge cooling flow due to only two of the four cooling water system pumps being operational. Furthermore, the assessment assumed continuous discharge and combined discharge (in reality, tests and their respective discharges would be batched for a phased discharge to the environment). Therefore, these discharges may impact upon the water quality status of the subtidal area. However, treatment facilities from the CFT would remain in place for use during HFT if required, and immediate dilution would occur at the point of discharge. Where it is determined that HFT discharge concentrations may not meet EQS, the treatment facilities (including simple dilution with seawater) or batched release would be used. Ultimately, HFT discharges would be subject to the limits defined within the operational discharge licence.

18.6.100 The receptor for these commissioning discharges into the cooling water system has been assigned a medium sensitivity to changes in chemical quality (see **Table 18.15**). Given the measures proposed above, the magnitude of this impact is assessed as being low. Subsequently the significance of this potential impact on marine water quality status has been assessed as **minor adverse**.

f) Potential Impacts during Operation

IMPACT: Discharges of Surface Water Drainage, Groundwater and Sanitary Effluent to the Marine Environment

18.6.101 The proposed surface drainage system would collect all surface water run-off and effluent from the permanent sewage treatment works. This water, along with pumped groundwater, would feed into a discharge holding pond and then would be discharged to sea via the cooling water outflow. The design of the drainage network allows for any necessary treatment (i.e. oil interceptors) to be undertaken prior to discharge. Discharges of treated sanitary effluent from the permanent treatment works would be subject to conditions, in terms of volume and chemical and microbiological quality, under an environmental permit. Since this water would be significantly diluted by the large volumes associated with the cooling water flows, impacts on the water quality status of the subtidal area are considered unlikely. Some groundwater from behind the sea wall would continue to discharge to the foreshore directly through a series of drains installed at 10m intervals at the foot of the wall. This diffuse drainage approach for the sea wall has been designed to approximate to the existing baseline condition where there is seepage of groundwater through the cliff face. No additional effects on water quality from these sources of wastewater to those identified for the construction phase above are identified.

18.6.102 The construction phase drainage system, and construction outfall, would no longer be used and would be dismantled towards the end of the construction phase (some elements may be left in position but would be redundant). In relation to the service road, surface drainage would be dispersed through lateral soakaways. Volumes from this source are expected to be very low and, therefore, large volumes of water are not predicted to be discharged across the foreshore.

18.6.103 Marine water quality status has been assessed to have medium sensitivity to changes in chemical quality and low sensitivity to changes in suspended sediment (see **Table 18.15**). However, given the design measures discussed above, and the very low volume compared with the main cooling water discharge volume, the magnitude of these discharges is considered to be less than very low magnitude and, therefore, there is predicted to be **no impact.**

IMPACT: Sediment Disturbance Associated with Cooling Water Infrastructure Operation

18.6.104 Large quantities of water would be required for cooling, with the return water being discharged at a rate of approximately 125m^3/sec. A discharge of this magnitude has the potential to mobilise and redistribute local sediment deposits through the force of the discharge flow. The mobilisation of sediment may impact upon the local marine water quality status of the subtidal area, which is assessed to have a low sensitivity to changes in suspended sediment concentrations (see **Table 18.15**). The outfall heads at the end of the discharge tunnel have been designed so that they are raised above the sea bed. This would assist in reducing the effect of scour associated with the cooling water discharge.

18.6.105 As described previously, high concentrations of suspended solids and the constant reworking of bed sediments reflect the natural conditions of the area. The majority of the sediments that would be mobilised through scour are of relatively recent origin and, while they are known to contain a range of contaminants (Ref. 8.50), these sediments are reworked on a regular basis. This leads to a constant redistribution and deposition of contaminants within the system and suggests that the release of sediment from scour associated with the discharge would be unlikely to raise contaminant levels in the water column or suspended sediment loads significantly with regard to existing EQS values. The potential impact is, therefore, considered to be of very low magnitude (see **Table 18.4**).

18.6.106 There may also be a need to periodically dredge sediments from around the cooling water intake and outfall structures during the operational period. These intermittent dredging works would lead to the temporary mobilisation of suspended sediments and associated contaminants. Again, impacts are considered to be of low magnitude as re-suspension of this sediment is considered to be within the range of natural processes.

18.6.107 Given the above, the significance of the impact on marine water quality status is predicted to be **negligible**.

IMPACT: Discharge of Cooling Water - Thermal Properties

18.6.108 The primary characteristic of the cooling water discharge would be the increased temperature relative to the surrounding water. Under normal operating conditions, the HPC EPRs' water would be discharged up to 12.5°C above ambient temperature. In line with the WFD, to ensure that all transitional and coastal waters are at least at good status by 2015, UKTAG 2008 (Ref. 8.73) has produced draft thermal standards for rivers which, in the absence of any other standards, are being used for TraC waters until such time as standards specific to TraC waters are determined. These temperature standards are recommended by the Environment Agency specifically for nuclear new build developments (Ref. 8.34) and by the BEEMS Expert Panel (Ref. 8.76); hence they were used for this assessment. UKTAG 2008 (Ref. 8.73) states that in order to achieve WFD good status, maximum temperatures at the edge of the mixing zone (as thermal impacts are largely related to point discharges) must not exceed 23°C, based on an annual 98 percentile, and that outside the mixing zone temperatures should not rise by more that 3°C.

18.6.109 Further, more stringent, temperature standards are applicable to an assessment of potential impacts on Natura 2000 designated areas and these are presented within the **Habitats Regulations Assessment Report** (Ref. 8.58).

18.6.110 Using the model runs described in Section 18.4, the three relevant scenarios for the consideration of potential impacts are runs C, D and E. These correspond to HPC operating in isolation at 100% output, HPC operating at 100% output simultaneously with HPB operating at 70% and HPC operating at 100% simultaneously with HPB at 100%, respectively:

- Run C calculates the thermal plume conditions in relation to the operation of HPC only (i.e. the effects of HPB are removed). This reflects conditions that would occur in the future when HPB ceases generation.
- Run D reflects a time whereby HPC is operating at full capacity and HPB is operating, but potentially below consented maxima (as described above). Run D thus provides the opportunity to assess impacts on the potential lower range of HPB operation.
- Run E is considered to represent the upper limit of potential combined operation, i.e. both HPC and HPB are operating at maximum consented levels.

18.6.111 For the purposes of this assessment, run E represents the worst-case scenario, i.e. HPB and HPC power stations operating in combination at maximum consented levels.

18.6.112 **Figure 18.5** presents the thermal plume model output for HPC operating at 100% in isolation and the temperature contours of the plume.

18.6.113 **Table 18.19** and **Table 18.20** present the calculated mixing zones on the basis of the output from the GETM model. Figures 18.6 to 18.8 show the modelled mixing zones for Runs C, D and E, respectively. Similar to standards for chemical substances, all thermal standards apply to the environment beyond an acceptable mixing zone. As defined in Section 18.4, in a regulatory context a mixing zone is "...the part of a body of surface water which is adjacent to the point of discharge and within which the *concentrations of one or more contaminants of concern may exceed the relevant EQS".*

Table 18.19: Area of Plume (hectares) Exceeding 23°C WFD Good Status Thresholds (Ref. 8.64)

Model run	At bed	At surface
Run C GETM	2	38
Run D GETM	936	1058
Run E GETM	1225	1424

Table 18.20: Area of Plume (hectares) Exceeding 3.0°C WFD Mean Temperature Uplift Criterion for WFD Good Status (Ref. 8.64)

Model run	At bed	At surface
Run C GETM	0.4	9
Run D GETM	390	426
Run E GETM	806	839

18.6.114 Thermal discharges clearly may impact upon marine water quality status, which is assessed to have a medium sensitivity to changes in the thermal regime (see **Table 18.15**).

18.6.115 Comparison of the plume areas that have been predicted to be greater than the WFD thresholds (i.e. the proposed mixing zones) with the definitions of magnitude provided in **Table 18.4** allows a potential worst case impact magnitude for each of the model runs to be determined. Assessment of magnitude has been based on comparison of the area of the mixing zone with the area of the receiving water. For the purposes of this assessment the 3 main bodies of water offshore of Hinkley Point have been deemed to be the receiving water: the mouth of the Parret Estuary, Bridgwater Bay, and the southern part of the inner Bristol Channel. These provide a combined area of 50,061ha.

18.6.116 **Table 18.21** presents the predicted magnitude of the potential impact associated with thermal discharges. The magnitude predicted for impacts at the surface were found to be the same as the equivalent magnitude at the bed, in all instances. It should be noted, however, that in terms of any associated impacts upon marine ecology (i.e. the ultimate environmental receptor), it is the potential impact at the bed which is of primary interest, because it is benthic organisms which are most susceptible to chronic temperature regime changes (due to relative immobility).

Table 18.21: Magnitude of Potential Thermal Discharge Impacts upon Water Quality Status

	Bed	Surface
Run C GETM	Very low	Very low
Run D GETM	Low	Low
Run E GETM	Low	Low

18.6.117 Given the very large area of the receiving water (>50,000ha), and the comparatively small area of the plume, at the bed and at the surface (2 and 38ha respectively), the magnitude of potential impacts upon marine water quality off Hinkley Point is determined to be very low for HPC operating on its own (model run C). The plumes at the bed and the surface for HPC and HPB operating simultaneously (model runs D and E) are considerably larger (1,058 and 1,424 at the surface, respectively) than for HPC operating on its own, but are still small compared to the total area of the receiving water (>50,000ha). The magnitude of thermal impacts for both stations operating simultaneously is determined to be low. Potential impacts resulting from the thermal discharge may be expected to be regional and permanent (for operational life of HPC). Given that the sensitivity of marine water quality status has been determined to be medium for changes in thermal regime, the impact significance for all operational three scenarios is predicted to be **minor adverse**.

IMPACT: Thermal effects on Dissolved Oxygen Levels under Normal Operating Conditions

18.6.118 Other issues associated with the cooling water discharge include the impacts of increased temperature on dissolved oxygen (DO). An increase in temperature directly affects the amount of oxygen dissolved in water as the solubility of gases reduces.

18.6.119 In terms of DO standards, the WFD now includes threshold values for TraC waters. For waters of varying salinity, such as those off Hinkley Point, the standards are calculated according to salinity:

- for 'High' status, the standard is: 7 – (0.037 × (salinity)); and
- for 'Good' status, the standard is: 5 – (0.028 × (salinity)).

18.6.120 Based on the baseline DO data for Hinkley Point and taking account of differing salinities (which affects oxygen solubility) in the inner and outer estuary, Hinkley Point DO concentrations are consistent with High status. However, there are occasions when DO concentrations in the Parrett Estuary are low. The Environment Agency reported DO values of around 2mg.l^{-1} in 2001, although data were based on three sites from the inner Parrett Estuary and may not reflect conditions in the outer estuary (Langston *et al*; Ref. 8.68).

18.6.121 The approach used by BEEMS in order to investigate the extent of oxygen consumption (or demand) from saturation, most appropriately in August when DO levels are likely to be close to their lowest levels and salinities would be high, is detailed in BEEMS TR186 (Ref. 8.50) and BEEMS Short Position Paper 064 (Ref. 18.77). The concentrations of DO resulting from the discharge of the cooling water plume at 12.5°C were then modelled and a figure showing DO concentration contours is presented as **Figure 18.9a**. However, in order to provide a more accurate picture of likely DO concentrations, the application of a biological oxygen demand was also applied, based on information gathered during the 2009 survey work. **Figure 18.9b** presents the revised DO concentrations.

18.6.122 For HPC operating at 100% (run C), the DO concentration in the area immediately influenced by the thermal plume is reduced to around 6.5 mg.l^{-1}. When taking in to account the biological demand, DO concentration is depressed further (to around 5.30 mg.l^{-1}). Compared with the threshold for 'High' status (6.2 mg.l^{-1} for a salinity of 22), HPC operating in isolation (run C) would have a mixing zone of 1280ha, and the mixing zone would increase if HPB was still operating at the same time (run E) (**Table 18.22** and **Figure 18.10**). Compared with the threshold for 'Good' status (4.4 mg.l^{-1} for a salinity of 22), there is no mixing zone (i.e. DO always remains above 4.4 mg.l^{-1} for all operational scenarios (**Table 18.22**).

Table 18.22: Mixing Zones (hectares) for Thermally Induced Reductions in Dissolved Oxygen for 'High' Status (Threshold = 6.2mg.l^{-1}) and 'Good' Status (Threshold = 4.4 mg.l^{-1})

	Bed		Surface	
	High	Good	High	Good
Run C GETM	1106	0.0	1280	0.0
Run E GETM	2380	0.0	2578	0.0

18.6.123 The receiving water has a very large area (>50,000ha) in comparison with the modelled mixing zones presented in **Table 18.22**. Furthermore, the assessment for DO is extremely precautionary, because in reality the low salinities against which the assessment has been made (22) only occur during the winter months when freshwater run-off is increased. The dominant forcing factor for DO, however, is temperature. Consequently, reduced DO is typically only a problem during the summer months when sea temperatures are warmer; high sea temperatures in-combination with low salinity, as used in this worst-case model scenario, do not occur in the natural environment. The real areal impact of temperature on DO is, in reality, likely to be significantly less to that presented here as a very worst case.

18.6.124 Given the large area of the receiving water, and the very precautionary nature of the assessment, the impact magnitude for DO with respect to the standard for 'High' status under WFD is deemed to be low. With a receptor sensitivity of medium for changes in chemical quality (**Table 18.15**), the impact significance is predicted to be **minor adverse** in relation to 'High' water quality status. There is **no impact** for DO on 'Good' status which is the target objective for WFD.

IMPACT: Thermal effects on Un-ionised Ammonia Levels under Normal Operating Conditions

18.6.125 In terms of ammonia, the un-ionised form of ammonia is more toxic to aquatic biota than the ionised form and the proportion of un-ionised ammonia increases with increasing temperature and pH, but decreases with increasing salinity. The equilibrium is particularly sensitive to pH values around neutral; whereas a temperature increase of 10°C (from 10°C to 20°C) doubles the proportion of un-ionised ammonia, a pH increase from 7 to 8 produces an approximately tenfold increase (Ref. 8.50).

18.6.126 There is, therefore, the potential for the increased temperature of the cooling water discharge to alter the natural equilibrium of ammonia:un-ionised ammonia, whereby concentrations of the more toxic un-ionised form would increase..

18.6.127 The GETM was based on the ammonia concentrations already present in the discharge (informed by baseline data collection and the 2009 monitoring) and also took into consideration loadings of nitrogen that would be required as part of operation of the two EPRs. Un-ionised ammonia values were then calculated using the Environment Agency calculator for seawater (Ref. 8.78) to determine the un-ionised ammonia concentrations. **Figure 18.11** presents the predicted un-ionised ammonia contours.

18.6.128 The maximum resulting un-ionised ammonia concentration contour was 11.2µg.l^{-1} for HPC operating at 100% alone (Run C). For HPB operating at 100% in addition to HPC at 100%, the maximum resulting un-ionised ammonia concentration contour was 16µg.l^{-1}. For all model runs, the maximum value is less than the EQS of 21µg.l^{-1} annual average for un-ionised ammonia.

18.6.129 Considering the un-ionised ammonia modelling results, the potential impact upon marine water quality status is predicted to have a low magnitude. The receptor sensitivity to changes in chemical quality is medium (**Table 18.15**) and so the impact significance is assessed to be **minor adverse** for marine water quality status.

IMPACT: Discharge of Cooling Water - Thermal Interaction with Background Concentrations of Contaminants

18.6.130 In the area around Bridgwater Bay and the River Parrett, the finer sediments tend to accumulate higher loads of associated contaminants. Temperature may affect availability and, therefore, the toxicity of sediment bound contaminants. In estuaries, pH and salinity are other important factors that can influence contaminant availability and toxicity. Bryan and Langston (Ref. 8.79) identified four factors that affect metals in sediments, e.g. mobilisation of metals to the interstitial water and their chemical speciation, as follows: transformation (e.g. methylation) of metals including arsenic, mercury, lead and tin; the control exerted by major sediment components (e.g. oxides of iron and organics) to which metals are preferentially bound; competition between sediment metals (e.g. copper and silver, zinc and cadmium) for uptake sites in organisms; and the influence of bioturbation, salinity, redox or pH on these processes. Potentially, therefore, interaction between elevated plume temperatures could facilitate enhanced release rates for some sediment-associated contaminants.

18.6.131 As a matter of expert judgement, it is considered that the rate of remobilisation of sediments and contaminants in this area is sufficiently high already as to make temperature-enhanced release over a localised area insignificant in degree or extent.

18.6.132 Given the above, the impact magnitude of the thermal plume on sediment contaminant remobilisation is predicted to be very low. The receptor sensitivity to change in chemical quality is medium (**Table 18.15**) and, therefore, a **minor adverse** impact is predicted upon the local water quality status.

IMPACT: Discharge of Cooling Water - Discharge of Contaminants

18.6.133 As summarised in **Table 18.23**, during the operational phase the cooling water is predicted to contain the following main contaminants:

- metals (aluminium, copper, chromium, iron, manganese, nickel, lead and zinc);
- boric acid;
- boron;
- lithium hydroxide;
- hydrazine;
- morpholine and associated breakdown products: ethanolamine, acetates, formiates, glycolates, oxalates;
- total nitrogen as N, un-ionised ammonia;

- phosphates;
- detergents;
- chemicals used for maintenance of demineralised plant reverse osmosis membranes, e.g. ATMP, HEDP, Phosphoric acid and Sodium Polyacrylate; and
- suspended solids.

Table 18.23: Operational Phase Chemical Discharges for Two EPR Units (Ref. 8.52)

Substance	Circuit conditioning ($kg.yr^{-1}$)	Sanitary waste discharge ($kg.yr^{-1}$)	Producing demineralised water ($kg.yr^{-1}$)[5]	Maximum 24-hour loading ($kg.d^{-1}$)	Maximum annual loading ($kg.d^{-1}$)
Boric Acid	14,000	--	--	5,630	14,000
Acetic Acid	--	--	14	0	14
Acrylic acid	--	--	165	1	165
Aluminium	5	--	--	1	5

Suspended solids	2,800	1,916	88,000	875	92,716
Total residual	--	--	--	--	--

Substance	Circuit conditioning (kg.yr^{-1})	Sanitary waste discharge (kg.yr^{-1})	Producing demineralised water (kg.yr^{-1})[5]	Maximum 24-hour loading (kg.d^{-1})	Maximum annual loading (kg.d^{-1})
oxidants[4]					
Unionised Ammonium (NH_3)[3]	1,184	150	--	74	1,334
Zinc	5.6	--	--	1.2	5.6

Notes:

[1] *Boron is calculated by dividing the loading for boric acid (H_3BO_3) by 5.72 to obtain loading of B alone.*

[2] *24 hour flow of hydrazine is based on input data from Flamanville EPR.*

[3] *Un-ionised ammonia was calculated as 11.7% (annual loading) or 22.9% (24 hour loading) of the total nitrogen flow (assuming all nitrogen was in the form of ammonia, NH_4^+), based on pH =8.11, salinity = 23.3psu and temperatures of 35.5^{o}C (annual loading) and 48^{o}C (24 hour loadings). For the purpose of worst-case assessment of 24 hour loadings it is assumed that only two of the four cooling water pumps are in operation. (see Ref. 18.52 for further detail).*

[4] *Total residual oxidants are assumed to have a concentration of 200µg.l^{-1} at the discharge point.*

[5] *Loadings include discharges associated with desalination and demineralisation units. Desalination plant loading values have been retained to provide bounding conditions in terms of a worst-case discharge scenario.*

18.6.134 Modelling of all process chemicals to be discharged to the marine environment via the cooling water discharge has been undertaken according to an Environment Agency H1-type assessment methodology (Ref. 8.52). The first tier of assessment screens out discharges considered to be of no environmental significance. Chemical parameters found to be at significant concentrations are then subject to more detailed analysis for a range of scenarios.

18.6.135 Waste water from the power station circuits, would be discharged initially to the attenuation pond (HXO facility). The HXO facility would hold water for testing prior to controlled release into the cooling water discharge stream for final discharge offshore. The concentration of process chemicals in the HXO facility could be very high, and in excess of EQS. Under normal circumstances, controlled pumping into the cooling water discharge water provides a very large degree of dilution, resulting in the normal operation discharge concentrations.

18.6.136 A detailed breakdown of the modelling work undertaken in this regard is presented in Ref. 8.52 and it was concluded that the resultant depth average environmental concentrations at 100m and 500m from the discharge point are below concentrations of environmental significance for all chemicals considered, with the exception of hydrazine.

18.6.137 Given the above, the magnitude of impacts from operational chemicals (other than hydrazine) is assessed to be very low (**Table 18.4**). The marine water quality receptor has medium sensitivity to changes in chemical quality (**Table 18.15**). The impact significance of operational chemical discharges, other than hydrazine and unioinsed ammonia, is, therefore, assessed to be **minor adverse**.

IMPACT: Discharge of Cooling Water – Discharge of Hydrazine

18.6.138 In order to further assess the potential impact of hydrazine on marine water quality, an extension of the modelling described for the thermal plume was undertaken (Ref. 18.50). At the mean CW flow rate of 125m^3.s^{-1} the average concentration at the discharge point is 7.1ng.l^{-1}, producing a mixing zone of 77 hectares at the seabed and 191 hectares at the surface in relation to the chronic PNEC of 0.0004µg.l^{-1}. The mixing zone for the acute PNEC is only exceeded at the surface in the model grid cells neighbouring the outfall (**Figure 18.12**).

18.6.139 Hydrazine breaks down rapidly into nitrogen and water, and so by storing it prior to discharge concentrations can be significantly reduced. Breakdown may also be enhanced by thermal degradation, which produces ammonia as a breakdown product. Storage and treatment is already part of the existing EPR design for HPC (the discharge loading stated in **Table 18.23**, and assessed in Ref. 8.50, includes that storage and treatment). EDF Energy is continuing to evaluate potential improvements to hydrazine storage and treatment. HPB does not discharge hydrazine, so the impact of hydrazine from HPB plus HPC is not assessed.

18.6.140 The hydrazine discharge plume was modelled using GETM, which allowed the area affected by a hydrazine concentration above the acute and chronic PNEC to be defined. **Table 18.24** presents the area of the cooling water plume with a hydrazine concentration greater than the chronic PNEC concentration (0.0004 µg.l^{-1}).

Table 18.24: Area of Plume (hectares) >0.0004 µg.l^{-1} Hydrazine Concentration as an Annual Average at the Bed and Surface

Area of plume >0.0004 µg.l^{-1}	Bed	Surface
HPC hydrazine discharge (0.007 µg.l^{-1})	73	191

18.6.141 The receptor has been assessed to be of medium sensitivity to changes in chemical quality (see **Table 18.15**). Given that the discharge outfall is located at a distance of 2km offshore, and the modelled discharge plume runs parallel to the shore, there is not expected to be any influence on the intertidal areas. Taking into account the proposed engineering design to reduce the concentrations of hydrazine in the cooling water discharge and the environmental degradation of hydrazine (see **Table 18.17** and **Table 18.4**), the impact magnitude is predicted to be very low. The GETM outputs for the hydrazine plume may also be viewed as conservative given that the actual hydrazine would not be continuous and thus the actual hydrazine plume may have opportunity to degrade and disperse in the environment. Based upon these impact descriptors, the impact significance is predicted to be **minor adverse** on the marine water quality receptor.

IMPACT: Discharge of Cooling Water – Discharge of Total Residual Oxidants

18.6.142 Within the General Design Assessment (GDA), under normal conditions for EPR units, worst case chlorination would involve dosing to 0.5mg.l^{-1} of active chlorine applied sequentially once every 30 minutes per cooling channel.

18.6.143 However, the review of operational information and the risk assessments undertaken for biofouling at HPB identify that, unlike other sites operated in the UK by EDF Energy, chlorination of the intake heads, shafts, tunnels and forebays is not required to control biological fouling. But this local understanding is exceptional and the standard operating procedure that applies to EDF Energy's coastal power stations

(BEOM006; Ref. 8.80) requires that a means of dosing nonetheless is maintained in case of need.

18.6.144 BEOM006 requires that the effective level for long term treatment of mussels in cooling water circuits is 0.15 $mg.l^{-1}$ TRO. Operational control is generally found to be insensitive at the ± 0.05 $mg.l^{-1}$ level, hence the normal practice is to dose at a target residual of 0.2 $mg.l^{-1}$ TRO to account for error.

18.6.145 The chlorination strategy for HPC is currently being developed. This will be a risk based, intermittent dosing regime that respects the operational needs of the plant, the WFD EQS and the Habitats Regulations thresholds.

18.6.146 Detailed analysis regarding the modelling approach used to determine the potential impacts associated with discharges of chlorine to the subtidal area is provided in BEEMS (Ref. 8.50). The GETM model outputs for the chlorination assessment were used to calculate areas of the plume at the surface and bed that exceed the chlorine EQS of 0.01 $mg.l^{-1}$ expressed as total residual oxidants (presented in **Table 18.25**).

Table 18.25: Mixing Zones (hectares) for TRO for WFD EQS (0.1 $mg.l^{-1}$)

Chlorine plume configuration at surface as a 95% >0.01 $mg.l^{-1}$	At Bed	At Surface
HPC 0.2 $mg.l^{-1}$ (Run TRO3tC)	63	159
HPC 0.2 $mg.l^{-1}$ + HPB 0.3 $mg.l^{-1}$ (Run TRO3tE)	132	251

Notes: Run TRO3tC = HPC alone at a discharge concentration of 0.2 $mg.l^{-1}$; Run TRO3tE = HPC at 0.2 $mg.l^{-1}$ TRO in combination with HPB at a discharge concentration of 0.3 mg/l TRO.

18.6.147 Results for a modelled discharge from continuous dosing to achieve 0.2 $mg.l^{-1}$ at the condensers for HPC operating alone at 100%, indicate that 63 hectares of the seabed and 159 hectares of the surface would exceed the TRO EQS of 0.01 $mg.l^{-1}$. **Figure 18.13** shows the predicted plume extent. The corresponding mixing zones at the bed and surface for HPC dosing at 0.2 $mg.l^{-1}$ plus HPB dosing at its consented 0.3 $mg.l^{-1}$ TRO, are 132 hectares and 251 hectares respectively (Ref. 8.50; **Figure 18.14**).

18.6.148 If chlorination is not used there will be **no impact**.

18.6.149 If the risk of biofouling is deemed to increase, such that chlorination is necessary, consideration of the TRO mixing zone plumes (**Table 18.26**) in relation to the very large area of the receiving water justifies an allocation of a very low magnitude in relation to potential TRO discharges. The marine water quality receptor has a medium sensitivity to changes in chemical quality (see **Table 18.15**) and, hence, a **minor adverse** impact is predicted.

IMPACT: Discharge of Cooling Water – Discharge of Chlorinated By-Products

18.6.150 In terms of formation of chlorinated by-products (CBPs), bromoform is invariably the most common in seawater cooled power station effluents, but other trihalomethanes, haloacetic acids, haloacetonitriles and halophenols are also found (Ref. 8.50). Given that chlorination has never occurred at the Hinkley Point site, the likely level of CBP production, particularly bromoform production, is unknown.

18.6.151 However, extensive monitoring around existing nuclear power plants, whilst confirming the presence of many CBPs, showed that concentrations measured in the cooling water outfalls are approximately 1,000 times lower than acute toxicity thresholds. Additionally, these CBPs are not bio-magnified in the food chain (Ref. 8.50). BEEMS (Ref. 8.50) presents all information available and concludes that the evidence for CBPs indicates that discharge concentrations are likely to be below calculated thresholds of effect and that concentrations would further decrease within 1km of the discharge. Impacts associated with CBPs are not, therefore, predicted to occur.

18.6.152 Given the above, the magnitude of the impact of chlorinated by-products on the marine water quality receptor (of medium sensitivity) is predicted to be very low, giving an impact significance is therefore predicted to be minor adverse.

IMPACT: Discharge of Cooling Water under Maintenance Conditions - Thermal Properties and Effects on DO and Un-ionised Ammonia

18.6.153 In order to consider the potential impact under the different conditions indicative of operating conditions, model simulations were undertaken on the basis of both HPC reactors operating at normal capacity but with only two out of the four cooling water pumps working. This effectively would lead to a reduced cooling water flow ($63m^3.s^{-1}$ as opposed to $125\ m^3.s^{-1}$) but at an increased temperature (25°C as opposed to 12.5°C) compared to normal operating conditions. Again full details of the modelling undertaken are provided in BEEMS (Ref. 8.50).

18.6.154 In summary, the change in operating conditions leads to a stronger thermal stratification which leads to a more rapid rate of heat loss as the hotter waters rise to the surface in the immediate vicinity of the outfall. As a consequence, temperatures in the immediate vicinity are higher than those predicted under the normal operating scenario, however, reduced temperatures occur further afield due to the quicker heat loss. Cooler seabed temperatures would also result from the increased stratification, thus the extent of the plume at the seabed would be less than that under normal operating conditions. **Table 18.26** summarises the differences in predicted mixing zones at the surface and seabed for both normal operating conditions and maintenance conditions.

Table 18.26: Thermal Mixing Zones (hectares) at Surface Calculated for Normal Operating Conditions and Maintenance Conditions

Temperature	Run C (operational) GETM	Run C (maintenance) GETM
3°C	9	18

18.6.155 **Table 18.21** presents the predicted magnitude of potential impacts associated with thermal discharges from HPC operating under normal conditions. The magnitude ratings have been assigned using the definitions presented in **Table 18.4**.

18.6.156 Under maintenance conditions the magnitude of potential impacts upon water quality status off Hinkley Point is determined to be very low. Potential impacts resulting from the thermal discharge can be expected to be regional and permanent (for the operational life of HPC). The sensitivity of marine water quality status to thermal effects is assessed to be medium (see **Table 18.15**) and, consequently, the impact is predicted to be of **minor adverse** significance.

18.6.157 Because of the increase in temperature, the potential for this operating scenario to impact on DO and un-ionised ammonia levels has been considered. Modelling indicates that the proposed DO concentrations are slightly lower than the standard operational conditions but all values are predicted to be greater than $4.4mg.l^{-1}$ (the lower boundary for 'Good' Status at a salinity of 22; see also Sections 18.6.118 – 18.6.124).

18.6.158 In terms of un-ionised ammonia, the maximum predicted concentrations were $12.4\mu g.l^{-1}$, a slight increase on the predictions for the normal operating scenario. However, again, this value is significantly below the EQS.

18.6.159 Given that the magnitude of the impact in terms of DO and un-ionised ammonia is predicted to be similar to (DO) and lower (un-ionised ammonia) than that predicted for normal operating conditions, the impact significance is predicted to be lower. Normal operating conditions are therefore considered to be the worst case scenario.

IMPACT: Discharges from the Desalination and Demineralisation Plant

18.6.160 The HPC development would not include a desalination plant, but would include a demineralisation plant for the treatment of mains water.

18.6.161 The precise composition of discharges from the demineralisation plant is unknown and, therefore, in order to carry out an assessment of the potential impacts upon water quality status, a scenario has been assessed that accommodates all likely outcomes. Data used in this scenario are taken from discharges associated with a combined desalination and demineralisation plant (based upon Flamanville 3 EPR, France) and adjusted to account of Bristol Channel sea water characteristics. The data includes maintenance chemicals known to be required for the reverse osmosis membranes in the plant.

18.6.162 Data have been assessed using the Environment Agency's H1 Environmental Risk Assessment framework, in conjunction with all other chemicals discharged within the cooling water discharge flow. The assessment found that even under the worst-case scenario (lowest discharge flow conditions and maximum loading values), there would be no significant impact on water quality status. This assessment may also be viewed as precautionary in nature, given that the actual discharge chemicals from the HPC demineralisation plant would have lower loading values, when compared to this bounding case.

18.6.163 Taking into account the H1 assessment results discussed above, the potential impact upon marine water quality status from demineralisation plant discharges is judged to have a very low magnitude. The marine water quality receptor is judged to have medium sensitivity in terms of changes to chemical quality (see **Table 18.15**) and, therefore, the potential impact significance is determined to be **minor adverse**.

RISK: Operational Accidents and Incidents

18.6.164 In terms of marine water and sediment quality, the following risks have been identified during the operational phase:

- failure of water management infrastructure, such as pipe collapse, pump failure etc., due to an extreme rainfall event;
- blockages of drainage infrastructure;
- accidental spills of fuels or oils;
- accidental spills of other chemicals;
- emergency discharges associated with firewater;
- emergency overflow from the HXO building; and
- emergency overflow from the forebay.

18.6.165 Although the risk of these accidents or incidents cannot be fully avoided, likelihood of occurrence and impacts can be managed and minimised through the use of good practice measures.

18.6.166 A **Pollution Incident Control Plan (PICP)** (**Annex 3; Appendix 8**) is to be developed that would set out the response and management techniques that would be applied for a range of different incident types, should they occur. The implementation of this plan would mitigate the extent any incident through providing measures to reduce the impact magnitude, primarily through containment.

18.6.167 The EICP would be instigated in response to routine monitoring and inspection and through a system of efficient incident reporting. To be effective, rapid implementation of the containment or other mitigation measures is required to reduce the potential impact to a insignificant level.

g) Cumulative Operational Impacts

18.6.168 Potential cumulative impacts associated with the operation of HPC on marine water quality are considered in this section. Cumulative impacts of the proposals with the wider HPC Project and other projects are assessed in **Volume 11**. There are two elements of the proposed development that could give rise to cumulative effects during the operational period and these are discussed below.

IMPACT: Increase in Suspended Solids

18.6.169 Potential inputs of suspended solids to the marine water environment during the operational phase which could produce a cumulative impact include:

- discharges of surface water drainage from the HPC operational site via the cooling water outflow;
- scour of local sediment deposits around the intake and outfall structures as a result of the cooling water flow; and
- maintenance dredging during the operational phase around the marine infrastructure.

18.6.170 There is not likely to be any cumulative impacts associated with these activities occurring in combination.

18.6.171 Discharges of surface water drainage from the HPC site during the operational phase are unlikely to contain high elevated concentrations of suspended solids because these discharges would be primarily made up of rainfall runoff from the developed site and would have been subject to management controls.

18.6.172 Scour effects around the offshore infrastructure are likely to only impact upon the immediate vicinity surrounding the structures and any measurable effect upon the local suspended solids concentrations within the Bristol Channel is expected to be highly localised. Suspended solids concentrations within the baseline environment are very high.

18.6.173 Maintenance dredging during the operational phase around the offshore infrastructure may not be required. If maintenance dredging is found to be required, it is likely that this activity would not result in elevated suspended sediment concentrations beyond those which are routinely experienced over a normal tidal cycle in the Bristol Channel. Scour effects from the discharge flow (see above) may assist in minimising the requirements for dredging and any increase in suspended sediment concentration as a result of in-combination impacts are expected to be negligible, relative to background concentrations.

18.6.174 The potential for a cumulative increase in suspended solids to occur is deemed to be minimal and would not represent an increased magnitude of potential impact beyond the magnitude of the independent impacts themselves. Hence **no cumulative impact** is predicted.

IMPACT: Increase in Contaminants

18.6.175 All surface water discharges during the operational phase would be discharged via the cooling water outflow and the screening assessments against EQS values have taken this into account. Cumulative impacts have, therefore, already been assessed as part of the discussion regarding impacts of the cooling water discharge.

18.6.176 In theory, in-combination contributions to marine contaminant concentrations from cooling water inputs and contaminants mobilised from sediment disturbance may occur. In reality, because of the high tidal energy, vigorous currents and extensive scouring of bed sediments which occurs under baseline conditions, contaminants that may be associated with local sediments would already have been captured within the assessment as part of the baseline water quality characterisation. In other words, any re-mobilisation of contaminants associated with scour activities is predicted to be similar to that already experienced under baseline conditions. The potential for a cumulative increase in water quality contaminant concentrations to occur is deemed to be minimal and would not represent an increased magnitude of impact beyond the magnitude of other independent operational impacts. Hence **no cumulative impact** is predicted.

18.7 Mitigation of Impacts

18.7.1 **Table 18.27** summarises the impacts predicted and demonstrates that they are all assessed to be of minor adverse or negligible significance. This reflects both the dynamic nature of the baseline environment, with dominant tidal flows and high levels of suspended sediment, and the mitigation measures that are built into the design (see Section 18.6 above).

18.7.2 However, additional mitigation measures are proposed on the basis of a good practice approach to protect the local environment. Mitigation techniques would be applied in a flexible manner to meet the conditions that are encountered on site. **Table 18.27** sets outs the significance of the impact predicted both prior to and with mitigation in place (i.e. the Residual Impact); however, the significance of all residual impacts are predicted to remain as predicted above.

a) Construction Phase

i. Site Drainage

18.7.3 Mitigation measures for the management of terrestrial surface water, e.g. construction site drainage, and the minimisation of suspended solids are presented in **Volume 2**, **Chapter 16**. These measures are very relevant in the context of marine water quality, given that discharges are to be made to the foreshore.

18.7.4 An **Environmental Monitoring and Management Plan (EMMP)** has been produced (**Annex 3** of this **ES**). This plan contains specific details regarding pollution prevention management and would implement many of the mitigation measures recommended for protecting surface water, including those set out in the Environment Agency PPGs. The plan covers measures such as fuel oil delivery, storage and use, procedures to deal with spillages, containment of contaminated run-off and disposal of contaminated drainage. Of specific relevance to the protection of marine water quality, there would be no stockpiling of materials or fuels on the intertidal areas.

18.7.5 A **Water Management Plan (WMP)** (**Annex 3; Appendix 3**) would also be implemented for the construction of HPC (with the objective of minimising suspended sediment, amongst others) and a **Pollution Incident Control Plan (PICP)** (**Annex 3; Appendix 8**) would be developed for the site. A full suite of equipment would be made available by the contractors for managing the range and magnitude of potential spillages. This would include emergency spill kits and equipment for containment and clean-up

ii. Discharges to Hinkley Foreshore

18.7.6 Until the foreshore discharge structure is complete, surface drainage discharges to the Hinkley foreshore would be made via the HPC drainage ditch. As part of the drainage design, the WMZs would provide an element of settlement and treatment.

iii. Discharges of Contaminated Water to Marine Environment

18.7.7 Where on-site water-treatment facilities are deemed unsuitable or inadequate to treat specific contaminants, off-site disposal to a suitable facility would be implemented.

iv. Construction of the Sea Wall

18.7.8 The construction of the new sea wall would follow PPG guidance to prevent accidental spillage of concrete in particular. Bunded casing/shuttering and the use of quick setting concrete formulas would mitigate potential marine water quality impacts. Any spillages would be contained immediately. Drainage from excavated areas would be managed to prevent water containing high suspended sediment and other contaminants entering the marine environment. No storage of waste or construction materials would be permitted on the foreshore.

v. Accidents and Incidents

18.7.9 As set out above, spillage of hydrocarbons into terrestrial watercourses and the marine environment would be minimised through the adoption of best practice working procedures. For example, fuels would be stored within bunded areas, refuelling would be undertaken in designated areas, and plant would be well maintained and regularly serviced. In addition, a **PICP** (**Annex 3; Appendix 8**) would be put in place to respond to spillage incidents (and fire water discharges, see below) swiftly and effectively. Pollution prevention/management equipment would be made available in order to minimise the severity of a potential spillage.

18.7.10 The site surface water drainage system would incorporate oil interceptors to collect hydrocarbon inputs to drainage water prior to discharge both routinely and during emergency.

18.7.11 These measures would also be applied in the operational phase.

b) Operational Phase

i. Background

18.7.12 The impact assessment determined that the operational phase of the proposed development is not likely to result in significant marine water quality related impacts (as identified in Section 18.6 and **Table 18.27**).

ii. Total Residual Oxidants (TRO)

18.7.13 Although the unmitigated impact assessment of TRO for HPC suggests the risk is minor, a more precautionary site-specific dosing strategy has been proposed to reduce impact further The following proven approach would be adopted to minimise the amount of chlorination required:

- A strategy would be implemented based on BEOM006 (Ref Ref. 8.80), which involves developing a site-specific risk-based protocol to prevent biofouling. This is an important difference from the approach described in the GDA.
- The BEOM006-based strategy involves screening, cleaning and dosing in that order of preference and is compliant with best practice (Ref. 8.81). Effective screening and cleaning are the first lines of defence, so appropriate plant and practices would be put in place at HPC to achieve these. Screening and filtration help prevent systems from becoming fouled, but eventually the systems would need to be cleaned. Chemical dosing is a means of limiting fouling but is only carried out in conjunction with screening and cleaning and would not be relied on as the sole means of preventing fouling.
- Identifying the need for chlorination would also be closely linked to monitoring protocols for fouling, including monitoring of the condenser efficiency, examination of growth in circuits and monitoring populations of organisms in the surrounding sea.

18.7.14 If this site-specific, intermittent dosing strategy is used the magnitude is predicted to be reduced to very low. However, the sensitivity of the receptor to changes in water quality is medium (**Table 18.15**) and so the significance of TRO impacts remain **minor adverse.** Although the impact assessment remains unchanged in terms of its rating according to the methodology, the impact is nonetheless reduced due to reduced magnitude.

iii. Hydrazine

18.7.15 Mitigation of hydrazine is already designed-in to the existing EPR design. However, EDF Energy is presently assessing whether further treatment is possible within the overall EPR design.

18.8 Post-construction and Operational Monitoring

18.8.1 A number of monitoring measures linked to both the performance of the infrastructure and potential environmental effects are proposed, as set out below. These measures are designed to provide useful data that could be used to modify potential management requirements and also to ensure that mitigation measures (see above) are effective and appropriate to deal with the predicted and identified environmental impacts.

a) Construction Phase

- For operational reasons, there would be a need to establish and maintain monitoring of vertical profiles of mud accumulations within the temporary jetty berthing pocket. Maintenance dredging is anticipated when densities increase to a magnitude that would permit this activity to be both needful and effective.
- Areas subject to natural freshwater discharges and areas subject to discharge from the HPC drainage system would be monitored for: pH, temperature, turbidity, dissolved oxygen, ammonia and hydrocarbons. Monitoring would be undertaken on each individual waste stream prior to discharge into the spine drain system. The scope of monitoring of waste streams would be set by the WMP (**Annex 3; Appendix 3**) and the conditions of each environmental permit. Supplementary monitoring may also be undertaken at the foreshore outfall location.

b) Commissioning

- During commissioning, monitoring of the cold and hot flush water would be undertaken in order to ensure compliance with environmental permits.

c) Operational Phase

- Continuous long-term monitoring of intake water temperature would be necessary to characterise long-term changes within larger seasonal and inter-annual variations. Measurements should include: temperature, salinity and pH.
- Monitoring of the thermal plume through the water column would be undertaken in the vicinity of the discharge point and at more remote monitoring locations. This monitoring would be combined with measurements of *in-situ* water quality measurements and the collection of samples for chemical analysis. Chemical parameters that would be proposed for the water quality testing programme include DO, un-ionised ammonia, hydrazine, dissolved nutrients, dissolved metals and selected organics used within the operational station (for example ethanolamine). The scope of these assessments in terms of sampling locations, frequency and duration of the monitoring programme and range of test parameters would be agreed with the Regulators in advance.
- Monitoring would be used to detect and assess the onset of biofouling in front of the main condenser and on the emergency cooling water system. If these

monitors remain clean, then the use of chlorine would not be justified. Evidence of biofouling may prompt the use of chlorine treatment.

- If chlorine treatment is used at any stage during the operation of HPC, the following additional monitoring would be necessary: TRO and chlorine by-products; bromoform, bromodichloromethane, chlorodibromomethane, monobromoacetic acid, dibromoacetic acid and 2, 4, 6, tribromophenol. If concentrations of these compounds are found to be low, monitoring for bromoform only may be acceptable once the effluent has been characterised.
- Fixed monitors would be installed at the outlet from the condenser and (if possible) close to the discharge for temperature, pH, DO and TRO (if chlorination is required).

Table 18.27: Summary Table of Marine Water Quality Impacts and Associated Mitigation Measures

Potential Impact	Water Quality Receptor	Magnitude	Description	Sensitivity	Impact Significance Rating (without Mitigation)	Proposed Mitigation or Good Practice	Residual Impact Assessment (after Mitigation)
Construction Phase							
Generation of Sediment and Discharges Associated with Construction of the Construction Outfall							
Discharges with elevated concentrations of suspended sediment	Marine water quality status	Very low	• Local • Temporary • Possible • Adverse • Direct	Low	Negligible	None required	Negligible
Discharges with residues of hydrocarbons	Marine water quality status	Very low	• Local • Temporary • Possible • Adverse • Direct	Medium	Minor	None required	Minor
Discharges containing concrete leachate	Marine water quality status	Very low	• Local • Temporary • Possible • Adverse • Direct	Medium	Minor	None required	Minor
Surface Water Discharges to the Foreshore							
Discharges with elevated concentrations of suspended sediment	Marine water quality status	Low	• Local • Temporary • Possible • Adverse • Direct	Medium	Minor	None required	Minor

Potential Impact	Water Quality Receptor	Magnitude	Description	Sensitivity	Impact Significance Rating (without Mitigation)	Proposed Mitigation or Good Practice	Residual Impact Assessment (after Mitigation)
Discharges with residues of hydrocarbons	Marine water quality status	Low	• Local • Temporary • Possible • Adverse • Direct	Medium	Minor	None required	Minor
Discharges containing concrete leachate	Marine water quality status	Low	• Local • Temporary • Possible • Adverse • Direct	Medium	Minor	None required	Minor
Discharges containing contamination arising from soil excavation	Marine water quality status	Very low	• Local • Temporary • Unlikely • Adverse • Direct	Medium	Minor	None required	Minor
Sewage Effluent							
Discharges of sewage effluent to the foreshore (during main site construction phase only)	Marine water quality status	Very low	• Local • Temporary • Certain • Adverse • Direct	Medium	Minor	None required	Minor
Groundwater Dewatering							
Pumped discharges from dewatering of groundwater	Marine water quality status	Very low	• Local • Temporary • Possible	Medium	Minor	None required	Minor

Potential Impact	Water Quality Receptor	Magnitude	Description	Sensitivity	Impact Significance Rating (without Mitigation)	Proposed Mitigation or Good Practice	Residual Impact Assessment (after Mitigation)
			• Adverse • Direct				
Surface water discharges associated with construction of the temporary jetty							
Discharges (e.g. from the proposed access road) with elevated concentrations of suspended sediment	Marine water quality status	Very low	• Local • Temporary • Possible • Adverse • Direct	Low	Negligible	None required	Negligible
Discharges with residues of hydrocarbons	Marine water quality status	Very low	• Local • Temporary • Possible • Adverse • Direct	Medium	Minor	None required	Minor
Construction of the sea wall							
Discharges with elevated concentrations of suspended sediment	Marine water quality status	Very low	• Local • Temporary • Possible • Adverse • Direct	Low	Negligible	None required	Negligible
Discharges with residues of hydrocarbons	Marine water quality status	Very low	• Local • Temporary • Possible • Adverse • Direct	Medium	Minor	None required	Minor

Potential Impact	Water Quality Receptor	Magnitude	Description	Sensitivity	Impact Significance Rating (without Mitigation)	Proposed Mitigation or Good Practice	Residual Impact Assessment (after Mitigation)
Discharges containing concrete leachate	Marine water quality status	Very low	• Local • Temporary • Possible • Adverse • Direct	Medium	Minor	None required	Minor
Offshore construction works							
Sediment disturbance and mobilisation of contaminants resulting from offshore construction works, specifically offshore piling	Marine water quality status	Very low	• Local • Temporary • Certain • Adverse • Direct	Low	Negligible	None required	Negligible
Sediment disturbance and mobilisation of contaminants resulting from offshore construction works, specifically capital dredging activities	Marine water quality status	Low	• Local • Temporary • Certain • Adverse • Direct	Low	Minor	None required	Minor
Wet drilling of vertical shafts and installation of headworks – generation of suspended sediment	Marine water quality status	Very low	• Local • Temporary • Certain • Adverse • Direct	Low	Negligible	None required	Minor
Other construction phase discharges							
Drainage contaminated with concrete leachate from activities such as	Marine water quality status	Very low	• Local • Temporary	Medium	Minor	None required	Minor

Potential Impact	Water Quality Receptor	Magnitude	Description	Sensitivity	Impact Significance Rating (without Mitigation)	Proposed Mitigation or Good Practice	Residual Impact Assessment (after Mitigation)
installation of piles; construction of the jetty head; construction of the seawall; and construction of drainage system foreshore outfall			• Possible • Adverse • Direct

CHAPTER 19: MARINE ECOLOGY

CONTENTS

TABLES

FIGURES

APPENDICES

19. MARINE ECOLOGY

19.1 Introduction

a) Introduction

19.1.1 This chapter of the Environmental Assessment (ES) assesses the potential impacts of the construction and operational phases of Hinkley Point C (HPC) on marine ecosystems at Hinkley Point and, where appropriate, the wider Bridgwater Bay and Inner Bristol Channel environment. Details of these phases are provided in **Volume 2**, **Chapters 2, 3** and **4**.

19.1.2 The assessment of potential impacts has been undertaken in accordance with the methodology outlined in **Volume 1**, **Chapter 7**. Available published data and grey literature have been examined, which includes data derived from ongoing impingement and entrainment sampling at Hinkley Point B (HPB) intake screens. To secure the marine science base to support consideration of this development, both in terms of environmental assessment and appropriate engineering design, a range of investigations were instigated by British Energy under the umbrella of the British Energy Estuarine and Marine Studies (BEEMS) process, subsequently adopted by EDF Energy. These investigations were designed to gather baseline data across appropriate temporal and spatial scales for the key ecological components of the surrounding ecosystems.

19.1.3 Following initial assessment, if an impact has the potential to be of moderate adverse significance or greater, where possible, mitigation measures have been identified to reduce predicted impacts. In some instances, mitigation measures are an integral aspect of the initial project design (e.g. the temporary aggregate jetty design or the cooling water outfall location).

b) Study Area

19.1.4 The geographical extent of the area of interest for the marine ecological assessment is principally determined by the potential zone of effect, and especially the mixing zone (i.e. the area in which the initial dilution of a discharge occurs). Particularly sensitive habitats or species that have conservation or commercial status in adjacent areas have also been considered.

19.1.5 The extent of dedicated survey and assessment effort has also been dependent upon an understanding of the highly dynamic physical processes that govern the ecology of the Inner Bristol Channel (see **Volume 2**, **Chapter 17**).

19.1.6 For the purpose of descriptions in this chapter, the HPC Development Site is located on a rocky section of the southern shore of the Inner Bristol Channel, and marks the western limit of Bridgwater Bay, itself bound to the north and east by the promontory of Brean Down. Within Bridgwater Bay, a substantial intertidal area is split into two parts by the estuarine channel of the River Parrett, with Stert Flats and the outer Gore Sands to the south and Berrow Flats to the north. The Inner Bristol Channel extends from a line between Hurlestone Point (west of Minehead, Somerset) and

Nash Point (Glamorgan) to the west, and Brean Down (Somerset) and Lavernock Point (Glamorgan) to the east, upstream of which lies the Severn Estuary. The Bristol Channel as a whole is taken to extend as far seaward as a line running approximately between Hartland Point on the Cornish coast and Old Castle Head on the Pembrokeshire coast.

19.1.7 The HPC Development Site is located within and adjacent to a number of national and international conservation designations that cover a range of marine ecological interests (see **Figure 19.1**). These designations and the species and habitats for which they are designated have been of prime consideration for the assessment process. Ecological receptors with protected status have been identified. Where a species or habitat is of conservation or general ecological importance, but does not have protected status, it has also been discussed in more detail. Where a species is fished commercially or has been subject to similar scrutiny, potential impacts have been assessed in relation to understandings of the size of the population involved.

c) Scope of Assessment

19.1.8 To identify the scope of the issues to be covered in the assessment, an initial evaluation of the potential for interactions between defined project activities and the receiving environment was undertaken. This resulted in a number of activities being identified which have the potential, on the basis of likelihood and the known response of the ecological parameters, to cause interactions/effects. These interactions are identified and listed in **Table 19.1**. The table does not provide an exhaustive list of potential interactions, but solely those for which further assessment work was considered necessary.

Table 19.1: Marine Ecology - Sources of Potential Interactions with Defined Project Activities for a Range of Key Receptors

Receptor	Phytoplankton	Zooplankton	Epifauna	Benthic flora	Subtidal invertebrates	Intertidal habitats (including *Sabellaria*)	Fish	Marine mammals
Construction								
Physical damage to habitats (e.g. construction on the seabed, dredging etc.)			✓	✓	✓	✓	✓	
Disturbance to habitats and species			✓	✓	✓	✓	✓	✓
Changes in water quality	✓	✓	✓	✓	✓	✓	✓	✓
Noise impacts (piling and vessels)			✓				✓	✓

Receptor	Phytoplankton	Zooplankton	Epifauna	Benthic flora	Subtidal invertebrates	Intertidal habitats (including *Sabellaria*)	Fish	Marine mammals
Operation								
Loss or change in habitat caused by presence of structures			✓	✓	✓	✓	✓	✓
Entrainment and impingement impacts on intake screens	✓	✓	✓	✓	✓		✓	
Water quality - temperature, flow and chemical impacts from thermal plume	✓	✓	✓	✓	✓	✓	✓	✓
Water quality - chemical discharges	✓	✓	✓	✓	✓	✓	✓	✓
Maintenance dredging			✓	✓	✓	✓	✓	✓
Noise impacts from maintenance vessels			✓				✓	✓

19.1.9 There is a potential for a period of overlapping generation involving both HPB and HPC, relevant to this assessment. The assessment methodologies applied within this chapter reflect this understanding.

19.1.10 The potential effects of climate change on certain species and populations are touched upon but no attempt is made by this ES to predict the level of change that might occur to the mix of species that are found in the marine and estuarine waters around Hinkley over the life of HPC.

d) Consultation with Regulatory Bodies

19.1.11 Consultation in relation to marine ecological interests has been undertaken with various stakeholders throughout the development of the project. Further information may be found in the **Consultation Report**. A summary of the key meetings at which the scope of the assessment work has been discussed is provided in **Table 19.2**.

19.1.12 This summary does not represent a full account of all meetings held, only those where marine ecology and other marine issues relevant to the assessment process were discussed.

Table 19.2: Summary of Consultation Meetings Undertaken to Determine Scope and Nature of Marine Ecological Assessment and Survey Work

Date	Attendees	Consultee Discussion/Comments
20/08/08	Natural England (NE), Environment Agency and Countryside Council for Wales (CCW)	Marine ecology issues discussed – some gaps identified in initial data review. Coastal processes and coastal protection also discussed. Possible need for offshore surveys identified. Fisheries data to be requested from CCW, identification of coastal workshop attendees required, methods for offshore surveys to be discussed with NE. Such gaps in provision of data were subsequently corrected by assimilation of BEEMS programme. Environment Agency identified a lack of sufficiently detailed water quality data: see **Volume 2, Chapter 18**. Also discussed coastal monitoring and defence issues and management of discharges.
22/09/08	CCW Correspondence	Water dependent features within the assessment area should be detailed as previously suggested in consultation.
03/11/08	NE	Terrestrial ecology and marine ecology scoping meeting with the purpose to discuss and agree scope of proposed surveys. The proposed sampling design for the local scale surveys was presented at this meeting. NE confirmed it was content with range and scope of proposed surveys, but requested that a full 12 month survey period was applied for certain key species, specifically fish. It was discussed that shad (protected Annex II species under the EC Habitats Directive (92/43/EEC), see Section 19.3) abundance tends to peak in July/August and therefore likelihood of catching this species increases during these months so sampling was extended to cover this period.
16/01/09	NE and CCW	CCW comments on marine ecology methodology were received on 09/02/09. NE comments on marine ecology were received on 12/02/09. Other than extension of surveys as decided at the 03/11/08 meeting no other changes to survey design were requested.
11/03/09	CCW, NE, Environment Agency and Sedgemoor District Council (DC)	Marine Authorities Liaison Group Meeting was held to discuss consents and estuary issues.
24/06/09	Environment Agency, Royal Haskoning, NE, Somerset County Council, Marine and Fisheries Agency and West Somerset Council	Meeting held to discuss Marine Authorities. Discussed offshore investigations, shore access arrangements and Sea Protection Group. Also discussed, water abstraction and discharge, soil, groundwater and ground gas, surface and marine water.
28/07/09	Environment Agency, Marine Fisheries Agency, English Heritage, West Somerset Council, Somerset County Council, ARUP	Status presentation on studies regarding shore access, sea protection wall, abstraction and discharge, water quality, contaminated land, groundwater, ground gas.

19.2 Legislation and Policy

19.2.1 In the context of marine ecology, this section describes the main legislative and planning policy considerations in relation to the proposed development. Such legislation and policy provides controls on the types of development which can be conducted within the marine environment and sets out the measures and processes that should be implemented to protect designated sites and biodiversity interests.

a) Legislation and Policies Relevant to the Marine Biodiversity and Conservation Interests of the Study Area

i. International Conventions

The Ramsar Convention of Wetlands of International Importance 1971

19.2.2 The Ramsar Convention provides the framework for national action and international co-operation for the conservation and considerate use of wetlands and their resources. Suitable wetlands are designated for inclusion in the List of Wetlands of International Importance. In order to promote the conservation of Ramsar sites, the UK implements the Convention through the Sites of Special Scientific Interest (SSSI) system, with some overlap with Special Area of Conservation (SAC) and Special Protection Area (SPA) sites (see paragraphs 19.5.8 to 19.5.10 on EC Birds Directive and Habitats Directive). The Ramsar Policy Statement 2000 offers Ramsar Sites equivalent protection to Natura 2000 sites. Of relevance to the proposed development is the Severn Estuary Ramsar designation.

19.2.3 The Severn Estuary Ramsar site is designated due to a combination of a number of attributes including; the large tidal range, presence of Annex I habitats protected under the Habitats Directive (see paragraphs 19.5.11 to 19.5.13 for Habitats Directive), the presence of unusual estuarine communities (reduced diversity and high productivity), the run of migratory fish between the sea and river via the Severn Estuary, the fish of the whole estuarine and river system (which is one of the most diverse in Britain) and wildfowl and wader assemblages and species/populations of international importance. The Bridgwater Bay National Nature Reserve (NNR) is also designated a wetland of international importance under the Ramsar Convention.

The Convention on Biological Diversity 1992

19.2.4 This Convention focuses on the conservation of all species and ecosystems and therefore provides protection to all biodiversity. The Convention requires the development of national strategies, plans or programmes for the conservation and sustainable use of biodiversity. In accordance with this, the UK has developed Biodiversity Action Plans (BAPs). For intertidal and subtidal zones, Species, Habitat, and BAPS have been developed. These action plans provide guidance for the conservation and management of biodiversity within the natural environment. This Convention is transposed into UK law by the Countryside and Rights of Way Act (2000).

The Convention for the Protection of the Marine Environment of the North-East Atlantic (OSPAR)

19.2.5 Annex V of the Convention provides a framework for contracting parties to develop their own conservation measures. Article 2 requires parties to 'take necessary measures to protect and conserve the ecosystems and the biological diversity of the maritime area, and to restore, where practicable, marine areas which have already been adversely affected'.

b) European Directives

i. EC Directive on the Conservation of Wild Birds (209/147/CE) (Birds Directive)

19.2.6 The 'Birds Directive' aims to protect all wild birds, their eggs, nests and habitats within the EC. It also provides for the protection, management and control of all species of naturally occurring wild birds that are considered rare or vulnerable within the EC as listed in Annex I of the Directive. Under the Directive the most suitable areas for the conservation of these species (land and sea) are classified as SPAs. In England and Wales the Directive is implemented under the Wildlife and Countryside Act 1981 (as amended) and the Conservation (Natural Habitats, &c) Regulations 1994 (as amended). Of relevance to the proposed development is the Severn Estuary SPA.

19.2.7 The Severn Estuary qualifies as an SPA under Article 4.1 of the Birds Directive because it is classified as a wetland of international importance regularly supporting at least 20,000 waterfowl. In addition, it supports internationally important Annex I populations of over-wintering Bewick's swan *(Cygnus columbianus bewickii)*, curlew *(Numenius arquata),* dunlin *(Calidris alpina alpina),* pintail *(Anas acuta)*, redshank *(Tringa totanus)* and shelduck *(Tadorna tadorna)*, and on passage ringed plover *(Charadrius hiaticula)*.

19.2.8 The implications of HPC with respect to the designated interests of the SPA are covered in the chapter on Terrestrial Ecology and Ornithology (**Volume 2**, **Chapter 20**) and in the Habitats Regulations Assessment (HRA) Report.

ii. EC Directive on the Conservation of Natural Habitats and of Wild Fauna and Flora (92/43/EEC) (Habitats Directive)

19.2.9 Under the Habitats Directive, SACs can be designated to maintain or restore the habitats listed in Annex I and the species listed in Annex II of the Directive to 'Favourable Conservation Status'. This is defined in the context of habitats, as the establishment of conditions which will ensure that the extent and range of the habitat, and the populations of the species within that habitat, will be maintained or increased over time. In relation to species, the viability, population size and range of the species should be maintained in the long-term. In England and Wales the Directive is implemented under the Conservation (Natural Habitats) Regulations 1994 (as amended). Of relevance to the proposed development is the Severn Estuary Special Area of Conservation (SAC).

19.2.10 In 2009, the Severn Estuary was nominated as a SAC under the Directive. The designation is primarily due to the presence of the Annex I habitats: 'Atlantic salt meadows', 'estuaries' and 'mudflats and sandflats not covered by seawater at low tide'. The Annex I habitats: 'sandbanks which are slightly covered by seawater all the time' and 'reefs' are also present as qualifying features, but are not the primary reasons for the designation. The site is also designated due to the presence of the Annex II species: twaite shad, sea lamprey and river lamprey.

19.2.11 Ref. 19.158 gives the most recent guidance on the implementation of the Habitats Directive and the recent judgements regarding compensatory mechanisms where plans or projects affect the conservation objectives of a designated site. The implementation of the Habitats Regulations relies on determining the impact of the plan or project on the Conservation Objectives of the European Site. The Conservation Objectives for the European Sites and the qualifying features for the Ramsar sites are given in Ref. 19.159.

19.2.12 A report to inform the relevant Habitats Regulations Assessment (HRA) is being submitted in parallel to this ES as part of the DCO application.

iii. The Water Framework Directive (2000/60EC)

19.2.13 The Water Framework Directive (WFD) requires that all inland and coastal waters within defined river basin districts must reach at least 'good status' (or 'good potential', if considering a heavily modified water body) by 2015 and defines how this should be achieved through the establishment of environmental objectives and ecological targets for surface waters. Under the requirements of the Directive, the present water quality status must be assessed and any significant water quality issues identified. The overall aim is to enhance water resource quality, reduce pollution and promote sustainable use of water resources.

19.2.14 The WFD is implemented in the UK under The Water Environment (England and Wales) Regulations 2003. Coastal and estuarine waters have been split up into water bodies by the "competent authority" (Environment Agency for England and Wales) and these bodies are assessed individually. Bodies are grouped according to a type defined by hydromorphological assessment, physico-chemical criteria and are designated as coastal or transitional. The area of the Inner Bristol Channel under consideration is regarded as a coastal water from the English shore across to the Welsh shore and the Parrett is a transitional (estuarine) water.

19.2.15 WFD prioritises ecological assessment as a way of classifying water bodies but also includes physico-chemical assessment and the use of environmental chemical standards for priority substances and specific pollutants, as well as an assessment of defined hydromorphological criteria.

19.2.16 Five biological groups of metrics (quality elements) are used to assess ecological status in transitional waters: phytoplankton, macroalgae, angiosperms, benthic invertebrate fauna and fish, and three quality elements for coastal waters: phytoplankton, macroalgae plus angiosperms and benthic invertebrate fauna. Macroalgae and angiosperms are combined for coastal waters but not for transitional waters. Angiosperms cover both sea grasses and salt marshes.

19.2.17 A WFD assessment is provided in Appendix 18B.

iv. EU Marine Strategy Framework Directive

19.2.18 The objective of the EU's Marine Strategy Framework Directive is for EU marine waters to achieve good environmental status by 2021 and to protect the resource base upon which marine-related economic and social activities depend. This Directive constitutes the environmental component of the EU's future maritime policy which has been designed to achieve the full economic potential of the oceans and seas while conserving the marine environment.

19.2.19 Under the Directive, each Member State within a marine region is required to develop strategies for their marine waters. These strategies must contain a detailed assessment of the state of the environment, a definition of "good environmental status" at a regional level and the environmental targets and the establishment of monitoring programmes. Cost-effective measures must be drawn up which include an impact assessment which details a cost-benefit analysis of the proposed measures.

19.2.20 The overall goal of the Directive is in line with the objectives of the Water Framework Directive which requires surface freshwater and ground water to be ecologically sound by 2015 for which the first review of the River Basin Management Plans should take place in 2020. It has been agreed that where the Marine Strategy Framework Directive (MSFD) overlaps with the WFD in coastal waters those assessments undertaken for WFD do not need to be repeated under MSFD. However there are a number of biological components where the MSFD requires assessment and WFD does not, such as cetaceans, fish and birds as well specifically mentioning inputs of energy. Specific standards or methods are not yet determined but are likely to be less detailed than those created for the WFD.

c) National Legislation

i. The Conservation of Habitats and Species Regulations 2010

19.2.21 These Regulations succeed the original Conservation (Natural Habitats, &c) Regulations 1994 and consolidate all the various amendments made to the 1994 Regulations in respect of England and Wales (herein referred to as the Habitats Regulations).

19.2.22 The Regulations implement the Habitats and Birds Directives (described earlier). The Regulations make provision for the protection and management of sites, including the control of potentially damaging operations that may affect designated sites.

ii. The Wildlife and Countryside Act 1981

19.2.23 The Wildlife and Countryside Act (WCA) (as amended by the Countryside and Rights of Way Act 2000 (CRoW)) consolidates and amends existing legislation to implement the Bern Convention and the Birds Directive. The WCA strengthens provisions under the National Parks and Access to the Countryside Act 1949 to establish NNRs in England and Wales. The legislation provides for the designation, protection and management of NNRs which can be established on land and land covered by water, so it can therefore extend into the intertidal zone, but not below low water (e.g. the Bridgwater Bay NNR). These areas can be designated for their flora, fauna or geological interests. The WCA provides for the designation of SSSIs, and Marine Nature Reserves.

19.2.24 Bridgwater Bay is a designated SSSI and comprises a wide range of habitats ranging from extensive intertidal mudflats and saltmarsh to shingle beach and grazing marsh intersected by freshwater and brackish ditches. It is important both nationally and internationally for the overwintering and passage of large numbers of migrant waders and waterfowl. Bridgwater Bay was designated a wetland of international importance under the Ramsar Convention and a NNR under Section 23 of the National Parks and Access to the Countryside Act 1949.

iii. Countryside and Rights of Way Act 2000

19.2.25 The Countryside Rights of Way (CRoW) Act provides for public access on foot to certain types of land, amends the law for public rights of way, increases protection for SSSIs and strengthens wildlife enforcement legislation and provides for better management of Areas of Outstanding Natural Beauty (AONB).

iv. The Water Environment (Water Framework Directive) (England and Wales) Regulations 2010 SI 3242

19.2.26 The Regulations provide the mechanism to implement river basin districts within England and Wales in accordance with the WFD. The Regulations require a new strategic planning process to be established for the purpose of managing, protecting and improving the quality of water resources.

v. Water Resources Act 1991

19.2.27 The Water Resources Act (WRA) came into effect in 1991 and replaced corresponding sections of the Water Act 1989. The WRA sets out the responsibilities of the Environment Agency in relation to water pollution, resource management, flood defence, fisheries, and in some areas, navigation. The WRA regulates discharges to controlled waters, namely rivers, estuaries, coastal waters, lakes and groundwaters. This is distinct from the drainage of water or trade effluent from trade premises into a sewer. Discharge to controlled waters is only permitted with the consent of the Environment Agency. An aim of the Act is to ensure that the polluter pays the cost of the consequences of their discharges.

vi. Planning Policy Statement 9 (PPS9) Biodiversity and Geological Conservation

19.2.28 Planning Policy Statement 9 (PPS9) sets out the Government's national planning policies on the protection of biodiversity and geological conservation through the planning system. Government objectives in relation to biodiversity and geological conservation aim to conserve, enhance and restore biodiversity, and promote sustainability. The aims and objectives of PPS9 are delivered via Regional Spatial Strategies and Local Development Frameworks implemented by the regional and local planning bodies.

19.2.29 PPS9 establishes a series of key principles that regional planning bodies and local planning authorities should adhere to in order to ensure that the potential impacts of planning decisions on biodiversity and geological conservation are fully considered. This is accompanied by Office of the Deputy Prime Minister (ODPM) Circular 06/2005 which provides administrative guidance on the application of the law relating to planning and nature conservation. There is the need to determine environmental effects under other EC Directives, such as the Habitats Directive (92/43/EEC), the Wild Birds Directive (79/409/EEC), the Integrated Pollution Prevention and Control Directive (96/61/EC) or the Control of Major Accident Hazards Directive (96/82/EC). There are links between all of these even though their requirements and those of the EIA Directive are independent of each other. Advice on the links between these, as enabled by the Habitats Regulations, is in PPG 9 on Nature Conservation (or, in Wales, Planning Guidance (Wales) Planning Policy First Revision), and on the links between the Town and Country Planning system and the IPPC authorisation system in PPG 23 on Planning and Pollution Control (or, in Wales, Planning Guidance (Wales) Planning Policy First Revision and Planning Guidance (Wales) Technical Advice Note (Wales) 5 'Nature Conservation and Planning') (Ref. 19.160).

19.2.30 This guidance advises that planning policies and decisions should aim to maintain and enhance, restore or add to biodiversity and geological conservation interests. A strategic approach to the conservation, enhancement and restoration of biodiversity and geology should be taken, recognising the contribution that sites, areas and features (both individually and in combination) make to conserving these resources. Development should contribute to rural renewal and urban renaissance by enhancing biodiversity in green spaces and among developments so that they are used by wildlife and valued by people.

19.2.31 Networks of natural habitats are considered within PPS9 to represent a valuable resource. To reflect their importance, emphasis is placed upon Local Planning Authorities to maintain networks by: “avoiding or repairing the fragmentation and isolation of natural habitats through policies in plans”.

vii. The Marine and Coastal Access Act 2009

19.2.32 The Marine and Coastal Access Act 2009 aims to enable better protection of marine ecosystems and prevent a decline in marine biodiversity. The Act sets out provisions for more coherent planning in the marine environment in terms of issuing consents and permits for activities in the marine and coastal environment. The Act also contains provisions to allow for the designation of Marine Conservation Zones (MCZs) and the creation of a network or Marine Protected Areas (MPAs).

viii. UK Biodiversity Action Plan

19.2.33 The UK BAP is the UK response to the Convention on Biological Diversity 1992. The Plan describes the UK’s biological resources and commits a detailed plan for the protection of these resources. Within the plan, a list of priority species and habitats is developed, for which specific action should be taken to conserve these species and habitats. The implementation of the BAP is the responsibility of various statutory and non-statutory organisations. This is a requirement of the CRoW (2000).

ix. Salmon and Freshwater Fisheries Act 1975

19.2.34 The Salmon and Freshwater Fisheries Act 1975 (SAFFA), as modified by the Marine and Coastal Access Act 2009, applies to salmon, trout (including sea trout) and freshwater fish. The 1975 Act contains rules governing the: Prohibition of Certain Modes of Taking or Destroying Fish, Obstructions to Passage of Fish, Times of Fishing and Selling and Exporting Fish, Fishing Licences, Authorisations, Administration and Enforcement.

x. Eel Management Plans

19.2.35 In accordance with Article 4 of Council Regulation (EC) No 1100/2007 of 18 September 2007, which established measures for the recovery of the stock of European eel, the UK submitted 15 Eel Management Plans for approval by the Commission in December 2008. These plans are set at the River Basin District level, as defined under the Water Framework Directive 2000/60/EC, covering England and Wales, Scotland and Northern Ireland.

19.2.36 Eel Management Plans have been implemented for the Severn Catchment which aim to provide an escapement of silver eel biomass that is at least equal to 40% of the potential escapement to be expected in the absence of anthropogenic influence. In addition, the European Eel Regulation requires that a system is in place to ensure that by 2013, 60% of eel less than 12 cm long which are caught commercially each year are used for restocking in suitable habitat.

19.2.37 To meet the European Eel Regulation cited above, the Eels (England and Wales) Regulations 2009 (Statutory Instrument No. 3344) came into force on 15 January 2010. These Regulations establish measures for the recovery of the stock of European eel for England and Wales. These domestic regulations will enable the protection and sustainable management of the populations of European eel by addressing the passage of eels. Part 4 of the Regulations provides the Environment Agency with powers to serve notice on an owner, occupier or responsible person to: 'make provisions for the passage of eels through dams and other obstructions, and require the placement of screens that will protect eels over some intakes and outlets (i.e. in a diversion structure)'.

d) Regional Planning Policy

i. Somerset and Exmoor Joint Structure Plan 1996-2016

19.2.38 The Joint Structure Plan (JSP) provides the strategic base for all land use planning in the combined area covered by Somerset and the Exmoor National Park for the period up to 2016. The Plan has been prepared as a JSP between Somerset County Council and the Exmoor National Park Authority. The JSP policies relevant to marine ecology in the vicinity of the proposed development include Policy 1: Nature Conservation and Policy 15: Coastal Development. These are described as:

- Policy 1 - Nature Conservation, states that the biodiversity of Somerset (and the Exmoor National Park) will be protected, conserved, restored, enhanced, and managed in accordance with the UK and relevant regional and local BAPs. Spatial target habitats are provided for coastal sand dune, coastal vegetated shingle, and *Sabellaria alveolata* reef. Maintenance target areas are set for coastal sand dune and coastal vegetated sand dune, however, the full extent of *S. alveolata* reef is not known. A target has been set to mitigate the natural loss of coastal sand dune, although establishment and restoration targets are ongoing for coastal vegetated shingle and *S. alveolata* reef.
- Policy 15 - Coastal Development, predominantly considers development on the coast and emphasises the importance of protecting and enhancing natural marine resources including those afforded international protection.

19.2.39 Of the habitats listed above, all have a maintenance target area and all, but *Sabellaria* reefs and seagrass beds, have targets for the years 2010 and 2020. The aforementioned habitats are described as having non-quantifiable future target areas. In addition, quantifiable maintenance and target areas are not provided for littoral sand and gravel habitats. It is stated, however, that for these habitats, the retention of the existing extent and realisation of opportunities for their expansion, is very important.

e) Local Planning Policy

i. West Somerset Council Local Development Framework

19.2.40 West Somerset Council is currently undertaking public consultation on the Local Development Framework Core Strategy.

ii. West Somerset Council Local Plan (2006)

19.2.41 The West Somerset Local Plan covers the administrative area of West Somerset, excluding Exmoor National Park which has a separate Local Plan.

iii. Local Biodiversity Action Plan LBAP (Sedgemoor and West Somerset)

19.2.42 The Local Biodiversity Action Plan for the Sedgemoor District is currently being prepared. Under the West Somerset BAP, coastal vegetated shingle and *Sabellaria alveolata* reefs are identified as priority habitats.

19.3 Methodology

a) Introduction

19.3.1 The methodology adopted for assessing the potential environmental impacts on the marine environment from the HPC development is set out in **Volume 1, Chapter 7** and this is outlined, together with areas where the marine environment impact assessment is unique, in the following sections.

19.3.2 There is currently no statutory defined methodology for carrying out Environmental Impact Assessment (EIA) in the UK, although there is Government guidance. Accordingly, the approach adopted herein is based on best practice methodology from a number of key UK guidance documents on EIA including, but not limited to, the Department for Communities and Local Government (2000) (Ref. 19.256), Institute of Environmental Management and Assessment, IEMA (2004) (Ref.19.257), Environment Agency (2002) (Ref.19.258) and Institute of Ecology and Environmental Management, IEEM (2006) (Ref. 19.259).

19.3.3 Numerous studies have been conducted examining the biological assemblages of the Severn Estuary and Bristol Channel (e.g. Refs. 19.1, 19.2 and 19.3). In addition, some studies have specifically focussed on the ecology of the area surrounding Hinkley Point (e.g. Refs. 19.4 to 9.14). An important long-term data set, the ‘Severn Estuary Data Set’ (SEDS) is also available from the monthly sampling of the intake screens at HPB, instigated in January 1981 and continuing to this day. The collection of this data set was begun by the Central Electricity Generating Board

(CEGB) and provides relative abundance data for fish (>80 species), macroinvertebrates (>20 species) and planktonic organisms (>40 species).

b) Marine Studies Specific to Hinkley Point C

i. Introduction

19.3.4 A series of field investigations has been undertaken to provide additional baseline data and appropriate numerical modelling tools have been developed in order to inform both environmental assessment procedures and support considerations of appropriate engineering design. Experience of construction and operational impacts of other UK power stations indicate that the likely impacts of HPC will be evident at different spatial scales. For example, construction of the cooling water intake and outfall structures will be likely to result in localised impacts, whereas the effects of a thermal plume created by cooling water discharged from the outfall could potentially extend over many kilometres. The overall aim of the field survey effort was to establish a contemporary baseline for the intertidal and subtidal species and habitats found on and around Hinkley Point, with respect to both potential localised impacts and potential wider scale impacts such as the cooling water discharges.

19.3.5 A key component of the marine studies has been the British EDF (previously British Energy) Estuarine and Marine Studies (BEEMS) programme. As this programme was acquired by EDF together with British Energy early in 2009, by which time both parties had established marine surveys in the vicinity of Hinkley Point, the programme of survey efforts utilised in this Environmental Statement (ES) reflects the process of rationalisation and integration that subsequently followed.

19.3.6 Where available, methods used for the surveys were based on best practice recommendations including those outlined in the Marine Monitoring Handbook (Ref. 19.15). Aspects of the UK National Marine Monitoring Programme Green Book (Ref. 19.16) were also considered. These documents provide detailed standard methodologies for intertidal and subtidal sampling.

19.3.7 Additional methodologies have been developed or adapted as appropriate from past examples of best practice by BEEMS utilising, when appropriate, expert advice from an Expert Panel established within that framework. These needs have occurred where standard methodologies have been lacking in definition (e.g. for cooling water entrainment, impingement and thermal plume assessment, including numerical modelling approach), in order to inform WFD metrics, or where there has been advantage in asking such a group to consider the site specific context (i.e. key features). The relevant Scientific Advisory Reports issued by the BEEMS Expert Panel are listed in **Table 19.3**.

Table 19.3: BEEMS Scientific Advisory Reports bearing on Methodology and Approach

BEEMS SAR Number	Title	Date	Source
SAR 001 (Ref. 19.17)	Key features of the marine ecosystem off Hinkley Point in relation to new nuclear build	September 2010	Expert Panel
SAR 005 (Ref. 19.18)	Methodology for the measurement of entrainment	March 2011	Expert Panel
SAR 006 (Ref. 19.19)	Methodology for the measurement of impingement	March 2011	Expert Panel
SAR 007 (Ref. 19.20)	Methodology for the measurement of plumes	May 2011	Expert Panel
SAR 008 (Ref. 19.21)	Thermal standards for cooling water from new build nuclear power stations	March 2011	Expert Panel
SAR 009 (Ref. 19.199)	Chlorination by-products in power station cooling waters.	2011	Expert Panel

19.3.8 As described above, the approach and the initial extent of the survey programme was discussed in detail and agreed with stakeholders, including Natural England (NE), the Environment Agency and the Countryside Council for Wales (CCW). Subsequent developments in that programme, further to EDF Energy's acquisition of British Energy, have been discussed both with these bodies separately and in a common forum within the HPC Marine Authorities Liaison Group (MALG), as appropriate.

19.3.9 Relevant reports arising from the BEEMS effort are listed in **Table 19.4** below.

Table 19.4: Feeder Reports Utilised in Preparing the Hinkley Point Marine Ecology Synthesis

(NB this does not include all BEEMS reports relevant to Hinkley Point: others are referenced separately in **Volume 2**, **Chapters 17 and 18**)

ii. Description of Surveys

19.3.10 Following the initial review of the tidal regime of the area and likely extent of any cooling water plume related issue, a series of high resolution bathymetric surveys using sidescan and swathe sonar of a wide area of the subtidal off Hinkley Point were completed (Ref. 19.25). In combination with high resolution LIDAR (Light Detection and Ranging) survey data obtained from the Environment Agency, the results were analysed to produce detailed maps of bed morphology (**Figure 19.2**) and surface sediment habitat type (**Figure 19.4**), leading in turn to habitat and biotope mapping (**Figure 19.18**).

19.3.11 An initial set of offshore biological surveys was instigated in February 2008 and covered a broad area of the Severn Estuary up to 15km from the proposed position of HPC (the estimated extent of any thermal influence of cooling water discharges) (**Figure 19.5**). The programme then extended to include further off-shore surveys in June, August and November of 2008 and May 2009 for:

- subtidal benthic infauna, sampled with a 0.1m^2 Day grab;
- subtidal benthic epifauna, sampled with a 2m beam trawl;
- benthic fish, sampled with a beam trawl;
- fish egg and larval abundance, as sampled by Gulf VII high speed plankton net; and
- zooplankton and phytoplankton using standard plankton nets.

19.3.12 Intertidal habitats were surveyed in July 2008. In order to ensure comprehensive spatial coverage of the various biotopes involved, this intertidal sampling was directed by the use of existing biotope maps, where available, arising from earlier studies carried out for Natural England. The area surveyed covered both soft and hard sediments ranging from the intertidal mud and sandflats up to approximately 8km north of the River Parrett Estuary, to the shoreline approximately 15km west of Hinkley Point (**Figure 19.3**). In total 55 sample sites were selected, which consisted of 40 soft sediment locations, 12 rocky shore sites and three sites located on saltmarsh. Sample sites were chosen to cover as wide a range of biotopes as possible within the intertidal zone in the main study area.

19.3.13 A more detailed description of the survey programme is available in Ref. 19.23, 19.27, 19.28 and 19.33.

19.3.14 Findings from the benthic and intertidal studies were subsequently utilised to validate a series of biotope maps that were initially developed on the basis of habitat mapping derived from remote sensing.

iii. Surveys for Intertidal Fish and Mobile Epifauna

19.3.15 Following a review of the existing biological datasets it was recognised that there was a lack of data relating to the utilisation of the intertidal zone by fish and mobile invertebrates. The location of HPC borders a large expanse of intertidal sediments: initial work had identified that this area could fall within the footprint of the thermal plume from the cooling water discharge. A study was initiated in August 2009 with an aim of increasing the knowledge base regarding the numbers and types of species utilising these habitats on both a temporal and spatial basis. To date, six surveys have been conducted over August, October and December 2009 and February, April and June 2010.

19.3.16 To gain a comprehensive understanding of the species utilising these habitats, the survey was designed to incorporate a range of techniques. Although primarily designed to target fish, mobile epifauna caught as bycatch were also recorded. The sampling strategy for fish was designed to follow the best practice WFD ‘multi-method’ approach, utilising a combination of static fyke nets and marginally deployed seine nets. Three sites were selected which were considered to provide a range of habitats and flows typical of the wider area of Bridgwater Bay, which are shown in **Figure 19.5**.

iv. Fish on Screen Surveys

19.3.17 As a check on the long-term fish on screens monitoring at HPB, an additional programme of such monitoring was established utilising a more comprehensive methodology designed to obtain a quantitative, rather than semi-quantitative assessment of the station catch over the course of a year. The methodology used was directly comparable (e.g. Ref. 19.207) to that used for scaling mitigation benefits associated with cooling water intake design improvements at previous nuclear power station developments in the UK.

c) Ecological Impact Assessment Methodology

19.3.18 Specific elements relating to marine ecology have been incorporated into the methodology where appropriate, as set out in the following tables.

i. Value and Sensitivity of the Receptor

19.3.19 The value of a receptor is determined based on geographical context (e.g. international, national, regional, see below) and conservation designations. Where appropriate, the criteria assigned for determining the sensitivity of receptors has been based on information derived from the Marine Life Network (MarLIN). The criteria utilised are summarised in **Table 19.5**.

Table 19.5: Criteria used to Determine Sensitivity and Value for Marine Ecology

Definition	Value and Sensitivity Guidelines
High	**Value** Feature/receptor possesses key characteristics which contribute considerably to the distinctiveness, rarity and character of the site/receptor e.g. Designated features of International/National designation/importance e.g. SAC, SSSI, Ramsar, SPA, BAP. Feature/receptor possess important biodiversity, social/community value and/or economic value. Feature/receptor is rarely sighted. **Sensitivity** Receptor populations are identified as having very low capacity to adapt to, or recover from, proposed form of change i.e. population is highly sensitive to change.
Medium	**Value** Feature/receptor possesses key characteristics which contribute considerably to the distinctiveness, rarity and character of the site/receptor e.g. designated features of Regional/County designation/importance e.g. BAP, Nature Reserves. Feature/receptor possess moderate biodiversity, social/community value and/or economic value. Feature/receptor is occasionally sighted. **Sensitivity** Receptor is identified as having low capacity to accommodate proposed form of change i.e. is moderately sensitive.

Definition	Value and Sensitivity Guidelines
Low	**Value** Feature/receptor only possesses characteristics which are of District or Local importance. Feature/receptor not designated or only designated at the district or local level e.g. LNR. Feature/receptor possesses some biodiversity, social/community value and/or economic value. Feature/receptor is relatively common. **Sensitivity** Feature/receptor is identified as having tolerance to changes within the range of natural variation i.e. is only slightly sensitive.
Very Low	**Value** Feature/receptor characteristics do not make a contribution to the character or distinctiveness locally. Feature/receptor not designated. Feature/receptor possesses low biodiversity, social/community value and/or economic value. Feature/receptor is abundant. **Sensitivity** Feature/receptor identified as being generally tolerant of the proposed change i.e. of low sensitivity.

ii. Magnitude of Impact

19.3.20 The criteria used to assign magnitude to an effect, with specific regard to marine ecological interests, are set out in **Table 19.6**.

Table 19.6: Criteria for Determining Magnitude for Effects on Marine Ecology

Magnitude of impact	Criteria
High	The quality and availability of habitats and species are degraded to the extent that locally rare populations and habitats are destroyed and protected species and habitats experience widespread change, such that the integrity of the ecosystem and the conservation status of a designation may be compromised. Activities predicted to occur and affect receptors continuously over the long-term, and during sensitive life stages. Recovery, if it occurs, would be expected to be long-term i.e. ten years following the cessation of activity. Impacts not limited to areas within and adjacent to the development.
Medium	The quality and availability of habitats and species are degraded to the extent that the population or habitat experiences reduction in number or range. Activities predicted to occur and affect receptors regularly and intermittently, over the medium to short-term and during sensitive life stages. Recovery expected to be medium term timescales i.e. five years following cessation of activity. Impacts largely limited to the areas within and adjacent to the development.
Low	The quality and availability of habitats and species experience some limited degradation. Disturbance to population size and occupied area within the range of natural variability. Activities predicted to occur intermittently and irregularly over the medium to short-term. Recovery expected to be short-term i.e. one year following cessation of activity. Impacts limited to the area within the development.

Magnitude of impact	Criteria
Very Low	Although there may be some impacts on individuals it is considered that the quality and availability of habitats and species would experience little or no degradation. Any disturbance would be in the range of natural variability. Activities predicted to occur occasionally and for a short period. Recovery expected to be relatively rapid i.e. less than approximately six months following cessation of activity. Impacts limited to the area within the development.

iii. Significance

19.3.21 The significance of the impact is judged on the relationship between the magnitude of effect and the assessed value and sensitivity of the receptor. The methodology used to assess the predicted significance of impacts, without mitigation, is outlined in **Volume 1, Chapter 7**.

19.3.22 For the purpose of this impact assessment, statutory designations and any potential breaches of environmental legislation take precedence in determining significance, because the protection afforded to a particular receptor or resource has already been established as a matter of law. Thus, using the defined criteria and IAM, features to which designations apply have automatically been determined to be of high value (or of a higher value than non-designated features), and as a result any impact tends to be of a greater significance than an impact on features to which no designation applies. Hence, for designated features, the use of the value criteria leads to an initial presumption that impacts will be of a high significance. Information on sensitivity can then be used to modify or maintain this initial assessment as appropriate.

d) Definition of Area of Effect

i. Introduction

19.3.23 The layout of the existing HPA and HPB cooling water (CW) intake and outfalls, together with the analogous HPC intakes and outfalls, is shown in **Figure 19.6**.

19.3.24 Thermal plume modelling was undertaken using both the General Estuarine Transport Model (GETM) and Delft 3D models (see Refs. 19.59, 19.65, 19.38, 19.67) to determine the area of effect of HPC on the marine environment. These models have been employed as a complementary 'ensemble' following Environment Agency guidance (see Ref. 19.68 and **Appendix 18A** to **Volume 2 Chapter 18**), and utilise the same physical data inputs but different algorithms for the solution of a range of variables in order to gain greater confidence over the degree of predictive uncertainty involved.

19.3.25 Both models were subject to the same degree of independent peer review, and identical requirements for calibration and validation against independent data sets. This ensemble was used to support both engineering design considerations and environmental considerations.

19.3.26 Model outputs used to inform this particular appraisal have been obtained primarily from the GETM model which, from experience in its use together with other models in similar circumstances, is known to predict slightly higher seawater temperatures in the mid to far field area of the thermal plume. The GETM outputs thus provide an indication of the upper bound of the temperature range likely to be experienced, whilst the Delft 3D outputs can be considered to reflect a lower boundary. Differences between such models, even when utilising the same input values and subject to audit against a standard set of criteria, are to be expected.

19.3.27 The outputs described here are provided in order to illustrate the extent of the thermal plume across the whole tidal cycle for neap and spring tides and thereby the area of effect of HPC.

19.3.28 The sea temperature of Bridgwater Bay and the River Parrett Estuary has been known to range naturally from 2 - 23ºC (Ref. 19.3). Key modelling outputs required to inform the assessment, indicating modelled increases above ambient temperature due to the thermal plumes of both HPC and HPB, are provided in **Volume 2**, **Chapter 18** of this ES, 'Marine Water and Sediment Quality' and are briefly summarised below.

19.3.29 As the key environmental sensitivity associated with the behaviour of the thermal plume is the impact on habitats, primarily the marine ecology in intertidal areas of Bridgwater Bay, the extent of plume intrusion into these areas has been taken to be the key indicator of environmental impact when evaluating possible intake and outfall locations. The modelling outputs have been employed in support of an assessment of the functional ecological implications of plume behaviour, described later within this chapter and within the HRA.

ii. Baseline and other Scenarios Tested

19.3.30 Three scenarios for HPC intake and outfall configurations were tested to simulate the range of potential locations and their effects on the environment. The range of intake and outfall positions tested is illustrated by **Figure 19.7**.

Table 19.7: Total Estimated Areas (in km^2) of Mean Annual Temperature Uplift due to Thermal Plumes from Different Power Station Intake/Outfall Configurations and Operational Regimes (from Ref. 19.59)

Configuration under Test		Thermal Uplift					
Hinkley Point C Load	Hinkley Point B Load	>1 °C Area (km^2)	>2 °C Area (km^2)	>3 °C Area (km^2)	>4 °C Area (km^2)	>5 °C Area (km^2)	>6 °C Area (km^2)
Tests for initial selection of Hinkley Point C discharge location – with simulated cooling water volumes of $120m^3/sec^{-1}$ at an average temp. of 12.2°C							
Cross shore discharge; 100% - Configuration 2	0%	22.6	6.22	1.502	0.377	0.166	0.053
Intermediate discharge; 100% - Configuration 3	0%	27.2	4.10	0	0	0	0
Offshore discharge; 100% - Configuration 1	0%	25.2	0.43	0	0	0	0

Configuration under Test		Thermal Uplift					
Hinkley Point C Load	Hinkley Point B Load	>1 °C Area (km^2)	>2 °C Area (km^2)	>3 °C Area (km^2)	>4 °C Area (km^2)	>5 °C Area (km^2)	>6 °C Area (km^2)
Tests using refined engineering information on selected offshore discharge location (configuration 5a) – with simulated cooling water volumes of 125m³/sec at an average temp. of 11.6°C and, for Hinkley Point B station (100% load) 53m³./sec⁻¹ at an average temp. of 10°C							
0%	100%	6.9	1.35	0.036	0	0	0
0%	70%	4.0	0.05	0	0	0	0
100%	70%	40.3	11.42	0.471	0.007	0	0
100%	0%	29.6	2.86	0.003	0	0	0

19.3.31 Allowing the cooling water of HPC to discharge directly onto the intertidal area west of Hinkley Point (termed 'Configuration 2') was found to result in a transport of heated water to the east, close to shore, resulting in an area of 1.4km^2 of intertidal habitat being exposed to an annual increase in water temperature of >2°C. Moving the outfall a moderate distance offshore ('Configuration 3') reduced this impact to 0.4km^2 and moving it a long distance offshore reduced the area of intertidal habitat subject to >2°C increase to zero ('Configuration 1').

19.3.32 'Configuration 1' thus produced the least thermal effect on the intertidal habitat and so became subject to engineering refinement in order to capture a realistic flow regime, a refined inlet design and modified intake/outfall locations informed by subsea geology, resulting in test 'Configuration 5a'. On testing, this configuration maintained the area of habitat subject to >2°C annual temperature uplift at essentially zero.

19.3.33 Further modelling was then undertaken to predict the combined effect of the proposed HPC station using 'Configuration 5a', with HPB at its current loading of approximately 70%. This in-combination configuration (termed 'Configuration 6a') showed a large intersection between thermal plume and intertidal habitat (see **Table 19.8**). This simulation estimated that an area of 2.55km^2 (2550ha) of Stolford Bay and Stert Flats would be exposed to temperature increases of >2°C. This comprises 2.31km^2 of low Total Prey Availability (TPA) and 0.24km^2 of medium TPA habitat (see Ref. 19.14), based on a formal classification of the invertebrate populations involved, and their availability as prey to higher trophic levels (this measure describes the availability of the overall macro-infauna food resource, using the summed biomass of all species present at a particular location; in this respect, it takes no account of individual preferences for particular prey species, summarising the total potential food available to birds across the site). Such an in-combination impact would only occur over a period in which both HPB and HPC were operational.

19.3.34 HPB is currently scheduled to cease operation in 2016. If it does so then there will be no overlap between the operation of HPB and HPC and, therefore, no in-combination impact involving the thermal plumes would arise. However, EDF Energy has stated that it will seek life extensions across its Advanced Gas-cooled Reactor (AGR) fleet (which includes HPB) of an average of 5 years, and longer if safe and economic to do so. There is thus a possibility that the operation of HPB may be extended beyond 2016. As a result there is a need to assess the impact of the continued generation of the two power stations both alone (HPB for baseline purposes) and in combination with respect to the influence of the thermal plume on marine ecology. For further discussion of the baseline assumptions incorporated in this assessment, see **Section 19.5** on **Scope of Assessment** below.

19.3.35 Should HPB operate at 100% load, the estimates provided in **Table 19.7** and **Table 19.8** suggest that the operation of HPC alone, using the distribution of the >2°C uplift, would effectively have no impact over potentially sensitive areas.

Table 19.8: Estimated Areas (in km^2) of Intertidal Habitat Impacted by Mean Annual Temperature Uplift Due to Thermal Plumes from Different Power Station Operational Regimes, Utilising Offshore Hinkley Point C Discharge Location (from Ref. 19.59)

Operational Regime		TPA Class	Thermal Uplift

iii. General Understanding of the Ecological Effects of a Thermal Plume

19.3.36 A review of available literature and research findings has been undertaken to ascertain the potential effects that the change in the thermal regime associated with the HPC cooling water discharge may have on the marine environment. The material reviewed relates to a range of situations in which thermal impacts have been investigated in a range of geographical locations. Sources include the body of information generated during the BEEMS programme of studies.

19.3.37 A number of studies have been undertaken over the past 30-40 years to investigate the impacts of thermal effluent discharges on aquatic ecosystems around the world. These studies have indicated that the long-term discharge of thermal effluents into the coastal environment can result in significant community changes (Ref. 19.69) and have the potential to affect all components of estuarine ecosystems. These studies also indicate that these effects are commonly limited to a restricted area within a few hundred metres of the vicinity of the discharge point, depending on local tidal conditions (Ref. 19.70).

19.3.38 Ref. 19.21 lists some other studies on the response of marine communities to power station discharges outside the UK.

19.3.39 The water column of an estuary is generally well-mixed in terms of temperature and the temperature-stratification of a plume is predicted to vary depending on environmental factors such as temperature of the surrounding water and meteorological conditions. Turbulent conditions (e.g. from storms) will increase heat-loss by mixing with the receiving waters, while high winds will increase heat-loss by radiation to the air. Generally, the heated plume will be less dense and thus more buoyant than the receiving water, and so will rise to the surface and restrict direct impingement of the discharge water on the seabed. However, the plume may be the only layer of water in direct contact with shallow littoral habitats (see **Volume 2**, **Chapters 17** and **18**, and Ref. 19.20).

19.3.40 The potential impacts of a thermal discharge can be classed as direct or indirect impacts. The direct potential temperature impacts of thermal plume discharge fall into four categories (Ref. 19.71):

- the mean temperature in relation to normal temperature (the water is warmer);
- the absolute temperature (as it may approach lethal levels);
- short-term fluctuations in temperature (particularly tidally-driven); and
- barriers to fish migration.

19.3.41 Responses of marine organisms to the conditions allied with a thermal discharge can range from physiological effects, extended growing and reproductive seasons, increased metabolism, and behavioural changes associated with perceived stress (e.g. emigration) or use of defence mechanisms such as shell closure in bivalves, to debilitation (possibly increasing susceptibility to predation) or mortality. Other than the last two, such responses may be positive or negative. Generally, warmer-water species (those distributed further south in the northern hemisphere) are more tolerant of higher temperatures than are colder-water species. Species whose distribution includes the littoral zone are more tolerant than those from the sublittoral, and, within species, different populations are adapted to different thermal tolerances as a result of selection to their ambient habitat (Ref. 19.21).

19.4 Baseline Environment

a) Influence of the Physical Environment

19.4.1 The Severn Estuary has one of the largest tidal ranges in the world, reaching in excess of 13m at Avonmouth, a regime classified as 'hypertidal'. The extreme tidal and turbidity regimes of the Severn Estuary make it unique amongst British estuaries, with the physical environment strongly influencing the distribution and productivity of the biological assemblages present.

19.4.2 A consideration of these physical key features (see Ref. 19.17) is provided in **Volume 2**, **Chapter 17**, Coastal Hydrodynamics and Geomorphology, of this ES. Where particularly relevant to discussion within this chapter, certain key physical features are repeated here. **Table 19.9** below summarises the key ecological features that, in large part, arise from these dynamic conditions.

Table 19.9: Key Features of the Severn Estuary and Bristol Channel Relevant to the Marine Ecology of Hinkley Point (after Ref. 19.17)

Key Features: Physical	Comment
Large funnel shaped estuary facing the Atlantic	Influences fish species (particularly migratory) and other physical features, particularly tidal regime.
Large branching estuary	Sub-estuaries absorb energy at tidal frequencies, but input energy at longer frequencies because of river flow variation. The Parrett, Usk and others are not insignificant regarding freshwater influx into the system.
High salinity variation	Seasonal and tidal variation – River Parrett significantly adds to this in the Hinkley Point area.
Hypertidal	Rare at global scale – includes Bay of Fundy (Canada), the Seine and the Somme (France).
Periodic energy inputs	Spring to neap changes are major in magnitude, resulting in a system with a major component of fortnightly change (as well as other tidal periods). Long periods of low winds reduce the suspended solids concentrations, at least in surface waters. The sedimentary system is therefore periodic, which directly affects the light regime (hence production), the benthic habitats and thus the benthos.
Waves dominant in shallow water	In shallow areas, waves are dominant over the effects of tidal currents. Most important in the Hinkley Point area are the intertidal and shallow 'flats' where it is waves that are mostly responsible in terms of mobilising and/or changing the physical environment and thus affecting the biota.
Surprisingly sediment starved	The vast majority of the seabed in the Bristol Channel and Severn Estuary system is rock or coarse gravel; there is relatively little sand, and most (though not all) of the mud is in suspension or is intermittently mobilised.
Physics makes change in subtidal habitats the norm not the exception	Changes to the sediment transport system have the potential to induce major changes in habitat. Changes in sediment distribution (natural and man made) are likely and these will affect habitats – by definition.
Highly turbid – unique in UK	High concentrations of sediment are present within the water column (in both permanent and temporary suspension and is intermittently deposited) but there is relatively little contribution from the rivers or from the Outer Bristol Channel.
Entrance to Parrett – mobile banks	The mouth of the Parrett has a variety of intertidal and subtidal banks, which consist of layered sediments and are extremely mobile. They thus tend to have low density biota.
Existing Parrett plume impact on intertidal area	Freshwater runoff peaks are significant in that they affect the extent of the existing HPB thermal plume across Bridgwater Bay.
Periodic major changes in bed elevation	Erosion/deposition cycles occur naturally and periodically, especially in outer Bridgwater Bay.

Key Features: Physical	Comment
Coastline and seabed near Parrett susceptible to change	The Stert Flats peninsula is susceptible to breaching in the longer term (century scale), and breaching would significantly affect cooling water flows across the (greatly changed) intertidal habitats.
Residual circulation	Tidal averaging of flows shows strong outward residual flow from Flat Holm to the south side of channel off Kilve. Recirculation cells occur to north and south. This could both trap persistent contaminants or effluent, and provide routes for fish migration. Crudely summarised as: 'fish in north, out south'. This feature persists to the Holm Islands. Given the small magnitude of any residual circulation compared to the regular tidal flows, the significance of this feature is uncertain.
Benthic production dominated by intertidal compared to subtidal	Due to a combination of the distribution of tidally driven bed shear forces and the extreme levels of turbidity present in the water column, there is an apparent discontinuity in ecological production with little subtidally and that, over the soft intertidal areas, driven largely by microphytobenthos. The balance of primary production is thus skewed towards the intertidal zone.
Contains sub-systems which are relatively simple	The Bridgwater Bay ecosystem is relatively simple with few species dominant. Mysids, crabs and brown shrimp (*Crangon*) are important links in the food chain.
Migratory fish corridor	Important for a number of species of conservation interest (shad, salmonids, eel, lampreys).
Impoverished subtidal benthos	Extremely poor compared to other estuaries, because of periodic highly mobile seabed.
Highly productive intertidal soft shore benthos	Stable highly productive mud flats. The mudflats are of two general types: (1) eroding Holocene muds and clays, which are relatively resistant to erosion and able to form a habitat for infauna, and (2) periodically layered mobile sands and muds.

19.4.3 Recent hydrographic studies show that at offshore sites (1km to approximately 5km from the coast) tidal currents may reach a maximum velocity of $1.7 m.s^{-1}$ on spring tides and $1.4 m.s^{-1}$ on neap tides. Velocities were slightly lower at the nearshore site approximately 500m from the coast (peak of $1.5 m.s^{-1}$ on springs and $1.0 m.s^{-1}$ on neaps). Ebb currents were found to be stronger than on the flood tide at all locations.

19.4.4 An estimated 10 million tons of sediment is carried in suspension within the estuary on spring tides (Refs. 19.74 and 19.75). The consequent extreme turbidity levels within the estuary reduce the depth of the photic zone and limits growth of phytoplankton. Turbidity data for sites located off Hinkley Point (>1.5km from the coast) indicate that suspended solids can reach concentrations of $1 g.l^{-1}$ on both the ebb and flood of spring tides. At some locations, advective processes may be more important than local re-suspension processes in terms of determining suspended solid loads.

19.4.5 Literature relating to the invertebrate fauna of the Severn Estuary and the Bristol Channel describe the benthic macrofauna of the region as impoverished when compared with other estuaries, both in terms of the number of species and their abundance (Refs. 19.92, 19.93, 19.94 and 19.242). This finding is supported by the recent BEEMS studies (e.g. Refs. 19.28 and 19.40) around Hinkley Point. The large tidal movements and associated turbidity regime result in an extremely stressful physical environment in which benthic assemblages are primarily influenced by powerful tidal shear forces and the regular deposition, re-suspension and mobilisation of bottom sediments. These stressors restrict the number of species able to tolerate conditions within the estuary. In addition, no macroalgae occur subtidally as a result of a predominance of muddy sediments and the high turbidity of the water. Extreme storm events can also raise turbidity levels within the estuary and result in further temporary changes to estuarine assemblages in the vicinity of Hinkley Point.

19.4.6 The major drivers influencing the macrofaunal populations and species diversity and abundance are thus the high tidal shear forces and chronic sediment surface instability combined with the high turbidity, limiting subtidal primary production. In contrast, the shallower intertidal areas where tidal shear becomes progressively less significant are relatively stable, providing opportunity for the algal growth that is effectively restricted within the water column itself.

b) Phytoplankton and Other Sources of Primary Production

19.4.7 Due to the high suspended sediment concentrations, the photic depth in the estuary is confined to the immediate surface waters, which greatly limits the primary production of phytoplankton (Refs. 19.76-79). Although some phytoplankton are present in the highly turbid sections of the Bristol Channel, primary production rates are far greater in the less turbid areas. Intertidal sediments in the Severn Estuary are known to support microphytobenthic populations, which are frequently dominated by diatoms (Ref. 19.80). The re-suspension of these algae (and the substrates they inhabit) has been demonstrated in the Ems Estuary in The Netherlands, a large, physically dynamic estuary similar to the Severn (e.g. see Ref. 19.81). This strongly suggests that it is largely re-suspended microphytobenthos that contributes to the phytoplankton recorded in local open waters.

19.4.8 There is limited published information available regarding phytoplankton populations in the Bristol Channel and Severn Estuary. Refs 19.82 and 19.83 provide some data on phytoplankton species recorded in the Inner Bristol Channel. Of the diatom species indicated in these records some species are primarily benthic (e.g. *Actinoptychus* spp., *Bacillaria paxillifer, Gyrosigma* spp., *Melosira arctica* and all the *Nitzschia* species), while planktonic species include *Asterionella* spp., *Chaetoceros* spp, *Ditylum brightwellii*, *Odontella* spp. and *Helicotheca tamesis*. This suggests that at least some of phytoplankton component has a microphytobenthic origin.

19.4.9 In total 21 species were recorded off Hinkley Point from the phytoplankton surveys carried out between November 2008 and October 2009. The most frequently recorded species between November 2008 and July 2009 was the diatom *Odontella regia* which was present at all, or nearly all, of the sites on each occasion. This species also had the greatest density with the highest values recorded in July 2009 (reaching up to 1006 individuals per m^{-3}). However, this species was not recorded in the August and October 2009 samples, with *Paralina sulcata* being present at all sites in August and *Odontella sinensis* present at nearly all sites during October. The densities of phytoplankton varied among sampling periods with the highest phytoplankton densities recorded in July 2009, at a mean density of 278 individuals per m^{-3} (which was mainly due to high numbers of *O. regia*). However, when compared with other British coastal waters, phytoplankton densities were relatively low (Ref. 19.84).

19.4.10 The most frequently recorded species, *Odontella regia*, is regarded as a planktonic form. This species was found to occur in a 'low light' group of algae at Helgoland, in the North Sea around Germany (Ref. 19.85) suggesting it may be capable of growth within the extreme conditions of the Severn Estuary. In contrast, *G. delicatula* and *S. unipunctata* are more typical of coastal waters, suggesting they may have been transported into the estuary.

19.4.11 Ref. 19.253 summarises the carbon production budgets for the Bristol Channel. This analysis found annual primary production to be 165g $C.m^{-2}.y^{-1}$ in the Outer Bristol Channel but only 6.8g $C.m^{-2}.y^{-1}$ in the Inner Bristol Channel (excluding a contribution from the *Phaeocystis pouchetti* bloom which occurred in most years in the Central Channel in June). Peak production in the Outer Channel occurred in May/June and June/July in the Inner Channel. Both sub regions had a similar standing crop of phytoplankton, but the annual primary production in the Inner Channel was only 4% of that in the Outer Channel due to rapid light attenuation and the rate of vertical mixing in the turbid waters of the Inner Channel. A further study concluded that advection and dispersion by currents determined the phytoplankton concentration in the Inner Channel rather than local production. Ref. 19.254 suggests that production of microphytobenthos (MPB) on the exposed inter-tidal flats is a major source of primary production in the Inner Channel that may exceed phytoplankton production and that resuspended MPB could be a significant contributor to measured chlorophyll a values. This same study calculated that MPB primary production on the intertidal flats was approximately 33g $C.m^{-2}.y^{-1}$.

19.4.12 The relative importance of different production sources can best be appreciated by considering measurements of Total Particulate Carbon (TPC) in the Inner Channel in July of 2,800mg $C.m^{-3}$, of which 107mg $C.m^{-3}$ was 'phytoplankton' (calculated from chlorophyll a measurements) and 2.8mg $C.m^{-3}$ was zooplankton (Ref. 19.253). At its July peak the zooplankton stock was 50mg $C.m^{-2}$ (2.8 $C.m^{-3}$ x mean depth of 18m) compared with typical values from a thermally stratified Celtic sea site of 1000 to 3000mg $C.m^{-2}$ and 700mg $C.m^{-2}$ in the Outer Channel. Ref. 19.253 concluded that the majority of the TPC and chlorophyll a was allochthonous in origin, i.e. detritus mostly of a terrestrial origin, and that the low values of phytoplankton and zooplankton demonstrated the minor role that the plankton plays in this sub region.

c) Zooplankton

19.4.13 The limitation of primary production due to elevated turbidity levels within the Bridgwater Bay area has the potential to reduce production of any zooplankton which feed on these microscopic plants (Refs. 19.86-88). Estuarine zooplankton, however, are primarily detritivores and it is considered that the main factor limiting zooplankton growth within this system is the need to process high levels of solids for relatively little gain.

19.4.14 Surveys of zooplankton were carried out by the Institute for Marine Environmental Research (IMER) between 1971 and 1981 (Refs. 19.89, 19.90 and 19.253). Ref. 19.89 describes the species assemblages, biomass and seasonal cycles of zooplankton in the Bristol Channel and Severn Estuary. These assemblages were typical of estuaries in northern latitudes, both in terms of their abundance and species composition. Species diversity of the zooplankton in the Bristol Channel, and in the Severn Estuary in particular, has been reported as being relatively low when compared to other coastal shelf areas around the UK (Ref. 19.90) but such limited diversity is typical of the estuaries themselves, where only relatively few species occur although sometimes in very high numbers.

19.4.15 The holoplankton of the Inner Bristol Channel and Bridgwater Bay is dominated by calanoid copepods, primarily those of the genera *Acartia* and *Eurytemora* (Ref. 19.89). The dominant species are the estuarine resident species *Eurytemora affinis* together with the seasonal estuarine resident *Acartia bifilosa*, although *Centropages hamatus* may also occur in moderate densities as well as, less frequently, *Pseudocalanus*. These copepods have been recorded in maximum densities in July following increases in abundance in March, April and May (Refs. 19.89 and 19.90). These same references record the fact that mysids (particularly *Schistomysis spiritus*) also constitute a large part of the total zooplankton biomass in summer (approximately 80%). Meroplankton are generally only present in low numbers in the Bridgwater Bay area (Ref. 19.89).

19.4.16 Salinity and temperature are understood to be important environmental variables affecting zooplankton distribution; the powerful tidal movements also have a considerable influence (Ref. 19.90). When considering the biomass of zooplankton in the Bristol Channel and Severn Estuary, Williams, 1984 (Ref. 19.89) identified a gradient from higher biomass at the seaward extent to lower values further upstream. This gradient was more pronounced in spring for the omnivores and in summer for the carnivores (reflecting the pattern of food availability). Peaks in biomass in the omnivorous zooplankton occurred throughout the year. Carnivorous species such as *Sagitta* and *Pleurobrachia* tended to be more abundant in the latter half of the year.

19.4.17 Qualitative entrainment sampling for zooplankton from HPB has been undertaken monthly for the last 35 years (Ref. 19.91). Ref. 19.259 provides details of the community structure from samples collected between August 1994 and July 1995. Numerically the most abundant zooplankton in the HPB samples were copepods dominated by *Acartia* spp (>50% by number), followed by mysids dominated by *Schistomysis spiritus.*

19.4.18 A total of 43 taxa were recorded during the period between April 2007 and June 2009. The most abundant group of macrozooplankton collected over this sampling period was mysid shrimps, which form a significant component of the diet of pelagic and demersal fish in this area. The mysids showed a strong seasonal pattern in abundance and species-complement in relation to the salinity-cycle, with lowest numbers occurring in January and February. A notable feature of this long-term dataset has been the significant increase in mysid abundance over the last 30 years: peak mysid abundance is now almost six times the level observed in the 1980s and 1990s (peak of approximately 3000 individuals in 2008 HPB samples in comparison with maximum of 500 individuals per sample in the 1980s and 1990s). Since the commencement of sampling, the mysid assemblage has been dominated by three species, *Schistomysis spiritus, Mesopodopsis slabberi* and to a lesser extent *Gastrosaccus spinifer*.

d) Ichythyoplankton

19.4.19 Zooplankton surveys conducted as part of the BEEMS programme were dedicated towards gaining an understanding of ichthyoplankton (fish larvae and egg) abundance and distribution. Overall, fish eggs from nine taxa were recorded (anchovy *(Engraulis encrasicolus)*, rocklings (Lotidae), gurnard (Triglidae), European sea bass *(Dicentrarchus labrax)*, Dover sole *(Solea solea)*, solonette *(Buglossidium luteum)*, mackerel *(Scomber scombrus)*, pilchard *(Sardina pilchardus)*, scaldfish *(Arnoglossus laterna)*) and some unidentified eggs were also collected in June 2008 and May 2009. Larvae of herring (Clupeidae), sprat *(Sprattus sprattus)*, sandeel (Ammodytidae), dragonet (Callionymidae), gobies (Gobiidae), Dover sole, European sea bass and solenette were also recorded (Ref. 19.33). The majority of ichthyoplankton were caught during the May 2009 surveys.

19.4.20 The most frequently recorded component of the ichthyoplankton was anchovy eggs which were collected at over 30% of the stations, with a maximum abundance of 6.51 eggs per m^2 (where abundance is standardised to the number of units under $1m^2$ of sea surface). Historically, anchovy have been rarely reported in the area and its presence here (in particular, the presence of eggs, indicating local spawning) might indicate an increased northward distribution of the species from southern waters. The second most abundant ichthyoplankton group was goby larvae; goby eggs were also collected at 35% of the stations, with a maximum abundance of 2.46 eggs per m^2 (Ref. 19.33). High densities of sea bass larvae were recorded during the May 2009 surveys whereas previously these had not been recorded. With the possible exception of anchovy, the ichthyoplankton species identified during these surveys are not uncommon in coastal or inshore waters and did not have distributions which could be construed as unusual.

e) Subtidal Benthic Infauna

19.4.21 The benthic fauna of the Inner Bristol Channel and Severn Estuary is generally regarded as being an impoverished assemblage dominated by opportunistic species, as a result of the high instability of the sediments (Refs 19.92 and 19.93). The authors of Ref. 19.94 surveyed the bottom fauna at 155 stations in the Bristol Channel from Lundy Island to just above the Holm Islands, and found the area around Hinkley Point to have a reduced hard-bottom community owing to the effects of strong tidal scour. A more recent survey of the fauna of the deep-water channel and marginal areas of the Severn Estuary between Flatholm Island and King Pool, upstream of Hinkley Point, found the benthic fauna of *Sabellaria*-dominated seabed was impoverished when compared to similar habitats in the Bristol Channel and elsewhere in the British Isles (Ref. 19.95).

19.4.22 The recent BEEMS surveys, which sampled the benthos during five quarterly surveys in 2008 and 2009 (Refs. 19.28, 19.39, 19.40; sampling site locations are shown in **Figure 19.5**), found a total of 47 macroinfaunal taxa including *Sabellaria* spp., together with three hyperbenthic taxa (*Crangon crangon* and mysids) and sessile epifauna (bryozoans, hydroids, barnacles). Overall species richness and individual abundance were both very low, and in each of the quarterly surveys, several stations had no macrofauna in any of the samples taken (27% of some 300 grab samples taken across the study period contained no fauna at all). Where fauna were present, on average only 3 individuals were found per $0.1m^2$ sample – and the average number of taxa per $0.1m^2$ sample was <2.

19.4.23 The total numbers of taxa recorded across a single survey were higher in February, June and August of 2008 (23 to 26 taxa) than in the 2008-2009 winter (11 to 15 taxa), while densities of individuals were typically lowest in both winter periods.

19.4.24 Only nine species contributed significantly to this sparse assemblage across the whole study period. The bivalve molluscs *Macoma balthica* (mean abundance 22 individuals per m^2) and *Nucula nucleus* (32 individuals per m^2) dominated in terms of abundance and biomass and, together with the cumacean *Diastylis rathkei* (5.8 individuals per m^2), in terms of occurrence. *Macoma* was found primarily at only two sampling locations directly in front of HPA and HPB, with one observed density of 420 individuals per m^2, but elsewhere was rare. Three species of polychaete characteristic of muddy sands, *Nephtys hombergii* (mean 5.9 individuals per m^2), *Scoloplos armiger* (4.4 individuals per m^2) and *Aphelochaeta marioni* (1.6 individuals per m^2), were the only other taxa recorded in all quarters. The oligochaete *Tubificoides amplivasatus* was recorded in most quarters, while the gastropod *Hydrobia ulvae*, the amphipod *Harpinia pectinata* and the polychaete *Sabellaria alveolata* were the only other taxa to occur at an average density of one individual per m^2 or more, and in the case of the last three in only one quarter (survey).

19.4.25 In general, both macrofaunal species number and densities were found to be highest in nearshore locations and were lower at the sampling sites further offshore, but the data were too sparse to demonstrate any relationship between the “community” and the substratum type.

19.4.26 These low densities represent a high degree of impoverishment and reflect the dynamic conditions of the estuary. Surveys undertaken in autumn 2008 and spring 2009, using 0.5mm mesh sieving rather than the more usual 1.0mm mesh, identified a further component of the fauna. These surveys found that the oligochaete *Tubificoides amplivasatus* (potentially a significant food resource for fish and invertebrates) was the numerically dominant species, with average densities ranging between 200 individuals per m^2 (offshore, April 2009) to 2000 individuals per m^2 (nearshore, May 2009). Otherwise, the results confirmed that the benthic assemblages across the survey area were characterised by the same few dominant species, all at relatively low densities compared with populations elsewhere in the UK, but without any particular distinction in densities between nearshore and offshore stations.

19.4.27 Owing to the impoverished assemblages that make up the Hinkley subtidal benthos, attempts at multivariate analyses in order to explore pattern and its potential drivers tend to provide unsatisfactory results. Equally, it is difficult to attempt to correlate the assemblages that have been observed with the UK biotope classification (Ref. 19.96), although the assemblage present is closest to SS.SMu.SMuVS.NhomTubi *Nephtys hombergii* and *Tubificoides* spp. in variable salinity infralittoral soft mud.

f) Sabellaria

19.4.28 There are two species of the polychaete genus *Sabellaria* ('honeycomb-reef worms') found in the UK. *Sabellaria alveolata* is a Lusitanian species, commonly occurring in the low littoral but also extending into the sublittoral to depths of 20m or more; *Sabellaria spinulosa* is a colder water species, predominantly infralittoral/sublittoral, and mainly distributed off northern and eastern shores of the UK. Both species build sandy tubes; in the case of *S. alveolata* these tubes are normally colonial, and aggregate to form what can be substantial reef structures; *S. spinulosa* tubes are normally built horizontally on hard substrata, but may also aggregate to form reef-like structures (e.g. off the Wash, Eastern England).

19.4.29 Although these species have no statutory protection, their larger aggregations of tubes are considered to be biogenic reefs, consistent with the priority habitat 'reefs' in the sense of Annex 1 of the Habitats and Species Directive and as such *Sabellaria* is a qualifying feature of the Severn Estuary SAC. Biogenic reefs have a number of ecosystem functions: they may stabilise a sedimentary environment, provide hard substratum to which other sessile organisms may attach, can provide additional crevicial habitat, and can alter local hydrodynamics, leading to deposition or erosion of fine sediment particles and their associated organic matter (Ref. 19.97). These structures are therefore considered of some conservation importance under the UK Biodiversity Action Plan (Ref. 19.244).

19.4.30 A *Sabellaria* reef has been defined arbitrarily as a dense aggregation of worms (over 1000 per m^2), generally forming a thick (2cm or more) crust of tubes, covering an area generally exceeding $25m^2$, although patchily (Ref. 19.98). In practice, even the largest *S. alveolata* reefs are more patchy than extensive.

19.4.31 *S. alveolata* predominates on hard substrata both littorally and sublittorally in the Severn Estuary and Bristol Channel. The recent offshore surveys recorded *S. alveolata* (and possibly, but rarely, *S. spinulosa*) but only sparsely and on few occasions. Despite the recorded occurrence of sublittoral *S. alveolata* reefs in this vicinity (e.g. Refs. 19.2, 19.94 and 19.99), no aggregations of reef size were found in the recent Hinkley Point offshore surveys, although remote sensing surveys gave some signals which might suggest some *Sabellaria* reefs in the area.

19.4.32 *S. alveolata* reefs are common on the lower shore along the rock platform fronting HPA, up to 2m above Mean Low Water Spring (MLWS), and within the midfield dispersion pattern of HPB thermal plume. Surveys carried out locally on the intertidal area at Hinkley (Refs. 19.8, 19.11, and 19.12) found that the reefs growing within the flow of the cooling water discharge from the power station were substantially larger, commonly greater than 15cm in height and over 1m across, than those recorded elsewhere along this shore. These larger reef-units also supported a denser and more diverse associated fauna. Tube-building in *S. alveolata* has been shown to be greatest above 15ºC, lower at 10ºC and absent at 5ºC (Yves Gruet, pers. comm.). The greater size of the outfall reefs at Hinkley is attributed to continued growth of the worm (and thus its tubes) during winter periods, while reefs elsewhere were suppressed or even killed by winter frosts.

19.4.33 Recent surveys (Ref. 19.55) have confirmed the persistence of the *Sabellaria* reefs within the lower intertidal areas off Hinkley Point. Based on the classifications summarized in Ref. 19.96 these reef areas are considered to be generally of 'reduced quality', with some areas of 'moderate quality'.

g) Subtidal Epibenthos and Hyperbenthos

19.4.34 The epifauna is made up of species living on (above) the surface of the substratum, or living on other species which are themselves living on or protruding through that surface. The hyperbenthos includes those species living just above the sediment surface. This group includes the mobile epifauna, such as bottom-living shrimps, and prawns. *S. alveolata* is a member of the epifauna, and offers substratum to other sessile epifaunal species including bryozoans and hydroids; this species has largely been dealt with above.

19.4.35 Results from epifaunal surveys (Ref. 19.33) show the area in the vicinity of Hinkley Point to be supporting only a limited diversity of larger, mobile benthic invertebrates, with just 77 benthic invertebrate taxa identified over the three years of survey work. The Crustacea were the most diverse phyla found during the survey programme, accounting for 32-42% of all species recorded. Mollusca and Cnidaria (primarily colonial hydroids) were also key components of the community. The bivalve *Nucula nucleus* was the most abundant species observed, accounting for >38% of all individuals observed. Other key species observed were the cumacean *Diastylis rathkei* and the bivalve *Macoma balthica*.

19.4.36 The epibenthic invertebrate community varied spatially across the sampling area with significant differences in assemblage patterns apparent between nearshore and offshore communities. Assemblage patterns were also closely correlated to substratum, with diversity and abundance of species higher in the soft sedimentary environments in the centre of the survey area and the east of Hinkley Point, compared with communities on the coarse and mixed substrata to the west, which were typically less diverse and abundant. No clear temporal trends could be identified from the survey data.

19.4.37 The dominant species was the common shrimp, *Crangon crangon*, the most important prey species in this region for demersal and benthic fish (and various bird species); *C. crangon* was taken in every survey, and at more stations than any other species. *Crangon* is of some local commercial importance owing to the artisanal fishery on Stert Flats: studies in the 1980s (Ref. 19.100) showed that the Bristol Channel and Severn Estuary population size was of the order of 10^7 to 10^9 individuals, depending upon season.

19.4.38 The other dominant species were also decapod crustaceans, the swimming crab *(Liocarcinus holsatus)* and the pink shrimp *(Pandalus montagui)* being most common. Hermit crabs *(Pagurus bernhardus)* and edible whelks *(Buccinum undatum)* were occasionally present, and most other species incidental.

19.4.39 Impingement and entrainment studies carried out at HPB over the last 35 years have provided extensive information on the local mobile epifauna. The common shrimp *C. crangon* has been the most commonly caught species and has had the greatest abundances (Ref. 19.101). The *Crangon* population is known to remain relatively stable (although there was a year of exceptional recruitment in 2002), although it also exhibits trends both in relation to average water temperature from January to August, and with the Winter North Atlantic Oscillation Index (Ref. 19.102). The abundance of this species has shown seasonality in relation both to recruitment and to the seasonal salinity regime at Hinkley (Ref. 19.103).

19.4.40 Other common species caught at HPB intake screens included the common prawn *(Palaemon serratus)*, and the pink shrimp, which have both shown a clear gradual trend of increasing abundance locally (Ref. 19.102) as well as similar patterns of seasonality in relation to salinity (Ref. 19.103).

h) Intertidal Flora and Fauna

19.4.41 Hinkley Point is fronted by an area of cross-shore rock platforms. That area is flanked by further expanses of intertidal rock, with occasional pockets of sediment, extend to the west. To the east lie the intertidal mudflats of Bridgwater Bay and the saltmarsh areas lining the estuary of the River Parrett.

19.4.42 Given the extreme turbidity regime, the soft-shore microphytobenthos, the macroflora of the intertidal rocky areas and the saltmarshes provide the dominant contribution to primary production within the system (Ref. 19.104). In addition, subtidal benthic assemblages in the Severn Estuary and Inner Bristol Channel generally show low density and diversity (Refs. 19.1 and 19.28). Ecological activity in the Severn Estuary is thus disproportionately concentrated in the intertidal zone.

19.4.43 A number of surveys of the intertidal area at Hinkley Point were undertaken between 1982 and 2001, including environmental impact assessment (EIA) surveys for the proposed CEGB nuclear power station project (Ref. 19.10 and 19.105), and surveys investigating the presence of the mussel *(Mytilus edulis)* (Refs. 19.4, 19.11, 19.13 and 19.106). The results of these surveys indicated a stable community with low faunal and floral diversity.

19.4.44 Habitat and biotope mapping has been completed for this intertidal area (Ref. 19.55) and the mapping of the area fronting the HPC site is shown in **Figures 19.8** to **10**.

19.4.45 The rock platform at Hinkley Point is made up of relatively thin strata of mudstone and limestone which dip some 5° seaward. Erosion of the softer mudstone and progressive fragmentation of the harder limestone has resulted in a series of seaward-inclined limestone pavement platform ledges, running approximately parallel to the shoreline. The upper boundaries of these ledges form small “cliffs” or steps, up to 1m high, behind which water-filled gullies are retained over most or all of the tidal cycle. The angle of strike of the beds fronting the HPC Development Site is such that there is a clear trend in longshore drainage across these platforms whilst the tide is out, from east to west.

19.4.46 The limestone platforms support dense beds of fucoid algae, with a typical zonation from *Pelvetia canaliculata* at the upper-shore, through *Fucus spiralis* and *F. vesiculosus* to *F. serratus* and *Ascophylum niodosum* in the mid- to lower-shore. Hybrids of the *Fucus* species are present, and *Vertebrata lanosa* is common on the *Ascophyllum*. Macroalgae are absent below MLWS, owing to the lack of light in the highly-turbid waters, a condition which extends along this coastline from Kilve to

Sharpness (Refs. 19.3 and 19.107). The top of the shore supports green algae, notably *Ulva intestinalis*, *Ulva prolifera*, *Blidingia minima*, and *Blidingia marginata*.

19.4.47 The area supports a particularly impoverished red-algal flora (Ref. 19.3). There are, however, locally important red-algal communities and one such provides a distinctive feature on the Hinkley frontage: a series of *Corallina* 'run-offs' or 'swards' (Ref. 19.7 and 19.9). These coralline turf habitats have developed on the cross-shore rock platforms, where breaches in the upslope limestone scarps allow water to flow from these longshore drainage lines down across the relatively flat limestone pavement itself, locally maintaining a constant shallowly wetted area whilst the tide is out. A turf of *Corallina* forms dense carpets constrained entirely within the boundaries of these flows (see **Figure 19.11**). The position of these turf run-offs in the intertidal areas local to Hinkley Point has remained stable with time, as they are defined by the shore topography. The annual green algae *Ulva lactuca* can also be found around the margins of these coralline turf areas, as is *Fucus serratus* (Ref. 19.3 and 19.13).

19.4.48 Particularly extensive swards of *Corallina* are to be found adjacent to Hinkley Point and at a locale 3km east of Watchet; the *Corallina* swards found along this rocky intertidal area are thus locally unusual features. These swards provide a refuge habitat that harbours greater diversity than the surrounding rock, in much the same way as *Sabellaria* reefs. As such, these habitats are functionally important and considered worthy of special consideration in the assessment process. The *Corallina* run-offs at Hinkley were found to provide habitat for 38 species, including several which have not been recorded elsewhere in the locality, such as the isopod *Jaera praehirsuta*, the pycnogonid *Anoplodactylus pygmaeus*, and the polychaete *Platynereis dumerilii* (Refs. 19.7 and 19.9). In conservation terms, these mats and their associated communities can be considered as one of the more important intertidal habitats within the region (Ref. 19.3). It has been suggested that these features form part of the 'red algal turf' biotope and are recognized as nationally scarce, and have been designated as a notable community of the hard substrate habitat sub-feature of the SAC (Ref. 19.30).

19.4.49 The other distinctive and important habitat within the intertidal zone at Hinkley Point is that provided by the consolidated agglomerations of *Sabellaria alveolata* tubes, in some areas forming low or moderate grade reefs (as described earlier within this Chapter) – see **Figure 19.11**. Other species that have been found to be significant locally include barnacles, limpets, periwinkles, top shells, dog whelks and anemones, whilst the authors of Ref. 19.13 also noted the presence of rock-boring piddocks *(Pholas dactylus)*.

19.4.50 The area has a very low mussel population (maximum of ten individuals recorded in any one survey) with no naturally occurring, breeding populations of *Mytilus edulis* in the area (Ref. 19.6). When mussels have been found, they have always been in poor condition with low growth rates, and this has been attributed to the high turbidity providing a very low scope for growth for such filter feeding species.

19.4.51 Wide rock pool areas are present on the shore and between the limestone scarp ledges, but, owing to the high turbidity of the water, and the tidally driven cycles of deposition and re-suspension of muds within them, are either poorly colonized or un-colonized. Under-boulder communities are similarly sparse or absent, although shore crabs *(Carcinus maenas)* are present, particularly amongst the low-shore

Sabellaria reefs, where they are a major predator of *S. alveolata* (fragmenting and destroying the reef-units).

19.4.52 Areas of intertidal soft sediment are found predominantly to the east of the Point. The author of Ref. 19.5 surveyed the littoral fine-mud substratum immediately to the east of Hinkley Point (the "Submarine Forest"). The dominant macrofaunal species in that area were the bivalve *Macoma balthica* and the polychaete worm *Nepthys hombergii*. Juvenile gastropods and small spionid polychaetes were also frequent. Perhaps owing to the intense predation pressure on these species, from birds during low tide and from aquatic predators such as fish and decapod crustaceans (particularly *C. crangon*) when covered by the tide, individuals of these species are commonly small and fast maturing, as their survival to reproduction is highly constrained.

19.4.53 Recent surveys (Ref. 19.23) examined 40 soft-sediment sampling stations across the intertidal zone between Brean Down and Hinkley Point (see **Figure 19.5**). A total of 40 macrofaunal taxa were recorded, with a mean of only 6.6 taxa per station. The areas with the highest macrofaunal densities were generally found along the higher-shore regions of Berrow Flats and near the mouth of the River Parrett. Similarly, areas with the greatest macrofaunal biomass were along the upper shore region of Brean Down and Berrow Flats and towards the west of Stert Flats. Neither elevation nor median sediment grain size correlated with macrofaunal biomass or numbers of individuals. Biomass was dominated by three taxa: the Baltic tellin (*Macoma balthica* – 63%), ragworm (*Hediste diversicolor* – 15%) and the laver spire-shell (*Hydrobia ulvae* – 8%). The most widely distributed taxa were *H. ulvae* and *M. balthica* (each observed at 36 stations), with *M. balthica* more dominant on the mid to lower-shore, and ragworm more dominant on the upper shore. Average numbers of *Macoma balthica* over the surveys were 492 individuals per m^2. These species, particularly the tellin, represent the main food-resource for shore-birds and demersal fish and decapods.

19.4.54 The only other macrofaunal species of notable occurrence were the spionid polychaete *Pygospio elegans*, the amphipod *Corophium volutator*, and, at two sites on the south side of the River Parrett, the cleaner-sand-associated amphipod *Bathyporeia pelagica*.

19.4.55 The presence of mobile invertebrate species and the level of fish usage over the soft intertidal areas to the east of Hinkley Point intertidal surveys of the Hinkley Point frontage have been assessed using seine and fyke nets (Ref. 19.61). The commonest invertebrate species recorded were the shrimp *C. crangon*, the prawns *Palaemon elegans*, *Palaemon longirostris* and *Palaemonetes varians* and the mysids *Mesopodopsis slabberi*, *Neomysis integer* and *Schistomysis spiritus*. All of these are important prey species for the fish populations within the estuary.

19.4.56 Unicellular algae are the dominant source of primary production locally. Ref. 19.80 describes the 'intertidal epipelic (sediment surface) floral assemblages' (otherwise known as 'microphytobenthos') from samples collected between 1990 and 1991. Diatoms comprised over 95% of the living cells in most of these samples and occasionally the non-flagellated euglenoid *Euglena deses* was also abundant. Over 60 diatom taxa were identified with 15 to 20 of these recorded regularly throughout the survey period.

19.4.57 There are large fringes of saltmarsh in the estuary. *Spartina* spp. are particularly common and are abundant in Bridgwater Bay NNR (especially around the mouth of the River Parrett); *Spartina anglica* was planted in that area in 1929 as a flood defence measure. In Bridgwater Bay, this particular species now covers an area 3km long and 0.3 to 0.45km wide with an area of approximately 120ha (Ref. 19.108). The total area of saltmarsh habitat in the Severn Estuary as a whole is reported as 1521ha, the majority of which (75%) occurs on the English side (Ref. 19.3). The saltmarshes are regarded as significant nature conservation features and contribute to the SPA, Ramsar and SAC designations.

i) Coastal Squeeze

19.4.58 Loss and gain of intertidal area due to relative sea level rise, coastal squeeze and the possible responses within this particular area are discussed in several documents (see **Volume 2**, **Chapter 17**), although the quantitative estimates of the amounts involved are either missing, poorly explained or poorly defined. Several sources suggest that this will happen locally, without providing estimates. The description of Cell 11 within the current Shoreline Management Plan 2, which includes the Hinkley Point site, suggests that in the short-term (up to 2028) it will experience marginal erosion of 10-30% saltmarsh, although this depends on the evolution of the River Parrett (Ref. 19.109); the uncertainties in this estimate increase from 2058-2108.

19.4.59 Ref. 19.110 indicates an overall habitat loss of 1200ha from Land's End to St David's Head and a gain of >200ha but these values have not been broken down further for Severn Estuary. Lyn Jenkins (Environment Agency, unpubl.) gives a prediction for the Severn estuary of 700ha lost by 2026, 1300ha by 2056 and 2600ha by 2106 for sea level rise.

19.4.60 Ref. 19.111 emphasises that significant effects of sea level rise are likely on the European sites Severn Estuary SAC, SPA and Ramsar sites and that, as recognised by the Shoreline Management Plan 2, there will be the need for new seawalls thus exacerbating coastal squeeze, habitat loss and habitat fragmentation. That report suggests the general changes that are expected: saltmarshes and mud/sandflats will be reduced in the next two decades with a 7% decrease predicted for the whole Severn Estuary. With Bridgwater Bay potentially accreting, thus leading to a local extension of intertidal habitats, the wider intertidal loss may be minimal over the next two decades, but will then be followed by a 5-10% decrease over the next 50 years and 10-20% over the next century (Refs. 19.109, 19.110 and 19.111).

19.4.61 **Volume 2**, **Chapter 17** considers the likely change in the cross-shore profile fronting HPC, driven by relative sea level rise and down-cutting associated with both continuing erosion and dissolution of the limestone platforms. As distribution of both *Corallina* swards and *Sabellaria* reef are interlinked to the geomorphology of the area, then any long-term evolution in cross-shore profiles relative to tidal range will also lead to an alteration in the distribution of these species.

j) Predation by Waterfowl

19.4.62 A local 'assemblage of waterfowl species' is protected under the Severn Estuary SAC designation (Ref. 19.114), as a notable species sub-feature of the estuary feature. This assemblage is also included in the Severn Estuary SPA and Ramsar site designations (again see Ref. 19.114). The following key species are identified in the SPA and Ramsar designations:

- Bewick's swan *(Cygnus columbianus bewickii).*
- European white-fronted goose *(Anser albifrons albifrons).*
- Dunlin *(Calidris alpina alpina).*
- Redshank *(Tringa totanus).*
- Shelduck *(Tadorna tadorna).*
- Gadwall *(Anas strepera)*.

19.4.63 Curlew *(Numenius arquata)*, pintail *(Anas acuta)*, ringed plover *(Charadrius hiaticula)*, grey plover *(Pluvialis squatarola)*, Eurasian teal *(Anas crecca)*, lesser black-backed gull *(Larus fuscus)*, wigeon *(Anas penelope)*, pochard *(Aythya ferrina)*, spotted redshank *(Trynga erythropus)* and tufted duck *(Aythya fuligula)* are also included as components of the overall assemblage (Ref. 19.114).

19.4.64 It is beyond the remit of this chapter to provide an in-depth analysis of spatial and temporal patterns in the bird populations utilising the site; these issues are dealt with in **Volume 2**, **Chapter 20** Terrestrial Ecology and Ornithology. What is of interest here is the degree of dependency these species have on intertidal prey. Tidal flats are known elsewhere to be an important food resource for aquatic birds, which in temperate regions may remove 10-30% of macrofaunal biomass per year (Refs. 19.112 and 19.113).

19.4.65 Understanding the trophic relationships between components of an ecological system is important when attempting to predict the effects of marine operations, as changes in food sources may impact on consumers such as birds if they have particular food requirements. Thus, with an understanding that the thermal plume associated with HPC will extend across a part of the intertidal area of Bridgwater Bay, a functional investigation of the links between the Bridgwater Bay waterfowl assemblage and their potential intertidal food resource became necessary. A full description of the various allied studies that make up this functional assessment may be found in Ref. 19.14.

19.4.66 Information on the bird species frequenting Bridgwater Bay was extracted from local ornithology surveys and identification of the main intertidal-feeding species achieved by examination of their feeding preferences.

19.4.67 Bird count summaries were based on the 2002 to 2007 Wetland Bird Survey (WeBS) high tide Bridgwater Bay and October 2008 to March 2009 low tide western Bridgwater Bay core count data. The low water surveys recorded all wetland birds feeding or resting within the area of coastline or mudflats being surveyed, within two hours either side of the low tide. The mudflats to the east of Hinkley Point were surveyed from two fixed points, at Stert Flats and from Stolford. To the west of Hinkley Point, the coastline was walked from the bay near Lilstock to the west, to the boundary of Hinkley Point power station.

19.4.68 The existing dataset did not however provide all of the necessary information, as it lacked observations for September 2008; these were necessary to fully characterise the over wintering bird populations that feed on the mudflats outside of the breeding period. Thus, an additional September bird count dataset from surveys during 2010 was utilised to understand site usage in the month of September. Surveys were carried out from four observation points on Stert Flats, recording bird counts and behaviour. Surveys were conducted over six hours, allowing a description of changes or pattern in bird distribution across the tidal cycle.

19.4.69 Forty species were recorded as present in Bridgwater Bay during surveys undertaken in 2008, 2009 and September 2010; where 18 species accounted for 99% of all records. Four of the six SPA species were regularly recorded in the bay during 2008 and September 2010. European white-fronted geese and gadwall were not present over that period (although three or four gadwall have since been seen in the area; see **Volume 2**, **Chapter 20**). Three of the SPA species were commonly recorded (dunlin, redshank and shelduck), while a small number (no more than ten) of Bewick's swans were recorded in Stert Flats on two occasions in 2008. The swans were not observed feeding on the intertidal flats (**Table 19.10**).

Table 19.10: Commonly Encountered Bird Species Recorded as Feeding in Bridgwater Bay, ordered by dominance (from Ref. 19.51)

Common Name	Count	% of Total Count	Cumulative %
Dunlin	3602	45.8	45.8
Herring gull	677	8.6	54.3
Knot	602	7.6	62.0
Eurasian curlew	520	6.6	68.6
Common shelduck	509	6.5	75.1
Black-headed gull	435	5.5	80.6
Black-tailed godwit	375	4.8	85.3
Eurasian wigeon	316	4.0	89.3
Eurasian oystercatcher	188	2.4	91.7
Grey plover	116	1.5	93.2
Mallard	108	1.4	94.6
Northern lapwing	90	1.1	95.7
Northern pintail	77	1.0	96.7
Common redshank	65	0.8	97.5
Ruddy turnstone	38	0.5	98.0
Dark-bellied Brent goose	25	0.3	98.3
Ringed plover	18	0.2	98.6
Little egret	13	0.2	98.7
Meadow pipit	12	0.1	98.9

Note: Count represents the sum of bird counts per month, based on data from October 2008 to April 2009. SPA designation species are highlighted.

19.4.70 Information on the Stert Flats birds' feeding preferences comes mainly from the literature (see **Table 19.11**). Observations on feeding behaviour in other locations are not necessarily applicable to Bridgwater Bay, as species may have site-specific preferences. However, they can give a good general overview of the prey species likely to be consumed by the birds, especially if supported by site-specific information.

Table 19.11: Potential Prey of Regularly Occurring Bird Species in the Bridgwater Bay Intertidal Area (table adapted from Ref. 19.114)

Species	Common Name	Potential Prey	Notes	Important Intertidal Feeder?
SPA Species				
Calidris alpina	Dunlin	Small *Scrobicularia plana*, small *Macoma balthica*, *Hydrobia ulvae*, *Corophium volutator*, *Hediste diversicolor*, *Talitrus* spp, *Carcinus* spp		Yes
Tadorna tadorna	Shelduck	***Hydrobia ulvae***, ***Corophium volutator***, young ***Macoma balthica***, young *Mytilus edulis,* young *Cerastoderma edule, Hediste diversicolor,* Nematoda, Polychaeta, Nereididae, Copepoda, Ostracoda, Amphipoda, Mollusca, Tellinacea, Platyhelminthes, Coleoptera, Tipulidae	Feeds on small poly- and oligochaetes when *H.ulvae* in short supply	Yes
Tringa totanus	Redshank	*Mya* spp, *Scrobicularia plana*, *Macoma balthica*, *Hydrobia ulvae*, *Corophium volutator*, *Hediste diversicolor*, *Nephtys* spp,small *Carcinus maenas*, *Crangon crangon, Talitrus* spp		Yes
Cygnus columbianus bewickii	Bewick's swan (Tundra swan)	Seeds, fruits, leaves, roots, rhizomes and stems of aquatic plants grasses sedges, reeds	Intertidal resources are not the main food	
Anas strepera	Gadwall	Seeds, leaves, roots and stems of aquatic plants grasses and stoneworts	Intertidal resources are not the main food	

Species	Common Name	Potential Prey	Notes	Important Intertidal Feeder?
Common Species				
Larus argentatus	Herring gull	Fish, earthworms, crabs, molluscs, echinoderms or marine worms, adult birds, bird eggs and young, rodents, insects berries and tubers	Highly opportunistic diet, exploit almost any superabundant source of food, scavenger	?
Calidris canuta	Knot	*Mytilus edulis*, *Mya* spp, *Scrobicularia plana*, *Macoma balthica*, *Hydrobia ulvae*, *Hediste diversicolor*	Low knot populations have been attributed to low *Macoma* populations	Yes
Numenius arquata	Curlew	*Mya* spp, *Cerastoderma edule, Scrobicularia plana, Macoma balthica, Hediste diversicolor, Arenicola marina, Carcinus maenas,* *Skenea* spp, *Corophium volutator*, Nematoda, *Hydrobia ulvae*		Yes
Larus ridibundus	Black-headed gull	Aquatic and terrestrial insects, earthworms, molluscs, crustaceans, marine worms, fish, rodents agricultural grain	Highly omnivorous, shows scavenging behaviour	?
Limosa limosa	Black-tailed godwit	*Scrobicularia plana*, *Macoma balthica*, *Hediste diversicolor* Possibly also *Skenea* spp, *Corophium* spp, Nematoda, *Hydrobia ulvae*	Bridgwater Bay represents one of the most important sites in the country for this species	Yes
Anas penelope	Eurasian wigeon	Leaves, seeds, stems and root bulbs of pond weeds, fine grasses, horsetails and eelgrass, as well as algae	Herbivorous bird; animal material can however be taken incidentally	
Haematopus ostralegus	Oystercatcher	*Mytilus edulis*, *Mya* spp, *Cerastoderma edule, Scrobicularia plana, Macoma balthica, Hediste diversicolor, Arenicola marina, Carcinus maenas*		Yes
Pluviatilis squatarola	Grey plover	*Scrobicularia* spp, *Macoma balthica*, *Hydrobia ulvae*, *Hediste diversicolor, Arenicola marina*		Yes

Species	Common Name	Potential Prey	Notes	Important Intertidal Feeder?
Anas platyrhynchos	Mallard	Seeds and the vegetative parts of aquatic and terrestrial plants, terrestrial and aquatic invertebrates (insects, molluscs, crustaceans, worms) and occasionally amphibians and fish	Omnivorous and opportunistic species, it shows preference for freshwater and brackish habitat	Unknown
Vatellus vatellus	Northern lapwing	Adult and larval insects, spiders, snails, earthworms	Intertidal resources are not the main food	
Anas acuta	Northern pintail	Algae, seeds, tubers, vegetative parts of aquatic plants, sedges, grasses, aquatic invertebrates (insects, molluscs and crustaceans), amphibians, small fish	Omnivorous and opportunistic	Unknown
Arenaria interpres	Turnstone	*Mytilus edulis*, *Mya* spp, *Scrobicularia* spp, *Macoma balthica*, *Hydrobia ulvae*, *Corophium volutator, Hediste diversicolor*		Yes
Branta bernicla	Dark-bellied Brent goose	Algae, seaweeds, other aquatic plants (e.g. *Zostera* spp, *Ruppia maritima*, *Spartina alterniflora*, *Salicornia* spp)	Mainly herbivorous but it may occasionally take animal matter	Unknown
Charadrius hiaticula	Ringed plover	*Hydrobia ulvae, Corophium volutator, Hediste diversicolor*		Yes
Egretta garzetta	Little egret	Mainly small fish, aquatic and terrestrial insects (e.g. beetles, dragonfly larvae, mole crickets and crickets), crustaceans (e.g. *Palaemonetes* spp., amphipods), amphibians, molluscs (e.g. snails and bivalves), spiders, worms, reptiles and small birds	Highly opportunistic feeder	Unknown
Anthus pratensis	Meadow Pipit	Insects (e.g. flies, beetles and moths) and spiders	Lives on open grassland, tundra, dunes	

Note: *Prey sources identified as being consumed by birds utilising Stert Flats, confirmed by microscopic or molecular faecal analysis (Ref. 19.54), are <u>underlined</u> and those confirmed by both the literature and faecal analyses are shown* ***in bold****. Information on non-mudflat feeding SPA species occurring in Bridgwater Bay is included for reference. Birds are listed in order of dominance at the site.*

19.4.71 Faecal analyses of birds utilising Stert Flats were conducted under the BEEMS programme during 2010 and early 2011 (see **Table 19.12**). Droppings were collected from the vicinity of bird flocks observed on Stert Flats in April, July, September and November 2010 and January 2011. Shelduck was mainly targeted (as it was both common and important in a conservation context) although other droppings were collected, where possible. The faeces were subject to microscopic and molecular analysis, to provide a qualitative estimate of the birds' diets. Microscopic analysis aimed to qualify all identifiable food sources, while molecular analyses aimed at *Hydrobia ulvae*, *Macoma balthica*, *Hediste diversicolor* and nematodes. Full details of the analyses are given in Ref. 19.45-48 and 19.54.

Table 19.12: Dietary Constituents of Birds Utilising Stert Flats during 2010 and early 2011, as Identified from Microscopic and Molecular Analyses of Bird Faeces (Ref. 19.54)

	April 2010		**July 2010**		**November 2010**[a]		**January 2011**	
	N = 4 Shelduck n = 2 Unknown species n = 2		N = 5 Shelduck n = 3 Godwit/curlew n = 2		N = 34 Shelduck n = 27 Knot/dunlin n = 3 (no microscopy) Unknown species n = 4 (no microscopy)		N = 20 Shelduck n = 20	
	Mic	Mol	Mic	Mol	Mic	Mol	Mic	Mol
Nematoda	[b]	(1)	[e]	(1)		(15)		(19)
Polychaeta								
Nereididae								
Hediste diversicolor		(2)		(1)		(5)		
Copepoda	[c]							
Ostracoda								
Amphipoda								
Corophium sp.			[e]					
Mollusca								
Tellinacea[f]								
Macoma balthica		(3)		(1)		(6)		(8)
Hydrobia ulvae	[b]	(2)	[e]	(2)		(10)		
Skenea sp			[d]					
Platyhelminthes	[b]							
Coleoptera	[c]							
Tipulidae								

Note: Surveys focussed on shelduck, although droppings from other species were collected, where possible. Table entries refer to shelduck droppings, unless otherwise stated.

Mic = microscopic analysis; Mol = molecular analysis; (#) Numbers in parentheses indicate the number of droppings in which the prey taxon was identified. Molecular analyses aimed only at *Macoma balthica, Hediste diversicolor, Hydrobia ulvae* and nematode.s and data are presented for the species overall.

[a] All samples subject to molecular analysis; only the first 20 were microscopically analysed.

[b] Only recorded in droppings from unknown species.

[c] Recorded in shelduck and unknown species droppings.

[d] Only recorded in godwit/curlew droppings.

[e] Recorded in shelduck and godwit/curlew droppings.

[f] Likely to be *Macoma balthica*, as no other Tellinacean recorded at Stert Flats during the BEEMS surveys.

19.4.72 Taken together, the analyses suggest that shelduck foraging on the flats have relatively diverse diets (Ref. 19.14). Molecular analysis (Ref. 19.54) confirms that local shelduck consume *Hydrobia ulvae*, *Macoma balthica*, *Hediste diversicolor* and nematodes. The molecular tools suggest uptake of additional prey species (the large number of bands detected on the analysis gels indicates the presence of other species) and microscopic examination of the droppings confirms polychaetes, platyhelminths, insects and a range of crustacea are consumed, as well as, potentially, microphytobenthos or macroalgae (some droppings were tinted green, though the source of this colouration is yet to be identified). Godwits/curlew (the droppings were recovered from a mixed godwit/curlew flock and could not be differentiated) on Stert Flats consume nematodes, *Corophium* species, *Hydrobia ulvae* and *Skenea*, another gastropod genus.

19.4.73 The qualitative nature of the analytical methods employed negates the possibility of ascertaining the precise extent to which the birds consume the various prey sources, and these analyses relate mainly to shelduck. However, the fact that the results support the food sources identified in the scientific literature increases confidence that the food preference is generally-sourced.

k) Distribution of Bird Prey Resources

19.4.74 Initial investigations of bird-invertebrate food web links focussed on the overall prey resource. This is a useful initial approach, when a variety of bird species are of interest and/or where specific feeding preferences are not known. In order to do this, a measure of food availability, 'Total Prey Availability' (TPA) (Ref. 19.29), was used. This measure describes the availability of the overall macro-infauna food resource, using the summed biomass of all species present at a particular location. In this respect, it takes no account of individual preferences for particular prey species, summarising the total potential food available to birds across the site.

19.4.75 TPA is calculated as: $TPA_z = E \int B_i$ where E = emersion time at station Z, and Bi = total biomass of all individual prey species > 1mm at station Z. Biomass was utilised, rather than the number of individual prey items, as this is more closely related to the energetic requirements of foraging birds (Re.19.116). Details of the calculations are given in Ref. 19.14 and the process is shown in **Figure 19.12**.

19.4.76 The total biomass of all potential prey items varied across the site. A trend of increasing biomass with increasing station elevation was visible for transects to the north of the Parrett estuary mouth, but this pattern was less clear to the south (**Figure 19.12 A**). After weighting biomass by emersion time, the importance of high shore sites was further increased (**Figure 19.12 B**) so that the final map of Stert Flats featured two potential feeding hotspots (**Figure 19.12 C, D**). One was located along the northern edge of the Flats close to the Parrett; the other along the southern shoreline of Stert Flats. Stolford Bay, to the east of Hinkley Point, may be a low-quality habitat for foraging birds, due to its combination of low macrofaunal biomass and shorter emersion time. Seasonal or inter-annual patterns of TPA have yet to be assessed for Bridgwater Bay. However, there was some degree of seasonal variability in the infaunal assemblages overall (although little evidence of significant short-term inter-annual variability).

19.4.77 While this approach gives a good overview of the potential food available to birds feeding on the mudflats, it does not differentiate between species likely to be consumed and those not favourable to the birds. Once further information on bird species utilising the site and understanding of their feeding preferences had been gathered, further investigations focussed on specific bird and prey species.

19.4.78 Inspection of the overall feeding preferences and infauna survey information suggests the main infauna species on Stert Flats known or likely to be consumed by the local birds are the Baltic tellin *(Macoma balthica)*, ragworm *(Hediste diversicolor)* and laver spire shell *(Hydrobia ulvae)* (see Refs. 19.23 and 19.62). They are all patchily distributed across the Bridgwater Bay intertidal flats, with *H. diversicolor* seeming to be more common in the upper shore and *M. balthica* in the lower – see **Figure 19.13**. Information on seasonal variability in these food sources was not available at the time of writing, although the mudflat fauna are known to be relatively stable between years. The predator and prey links are described in Section 19.6 ii).

l) Fish Assemblages

i. Introduction

19.4.79 This section provides information on the fish assemblages and associated resource (from a commercial perspective) of the Severn Estuary. The information covers all fish species which may potentially be impacted at some stage of their lifecycle by the marine works associated with HPC and thus includes the populations of fish which utilise the Severn Estuary as a migratory conduit between the sea and rivers flowing into the Severn Estuary, together with purely marine species which may utilise the estuary for the whole, or only part of their lifecycle.

19.4.80 When considering estuarine fish species, especially in connection with WFD requirements, it is important to understand the Ecological Use Functional Guild (EUFG) and to which guild each species belongs. The main ecological guilds for estuarine fish have recently been refined (Refs. 19.117, 19.118 and 19.119). The categories with their abbreviations are summarised below based on Ref. 19.120:

- *Estuarine Species* (ES): Can be resident (i.e. entire life cycle estuarine) or migrant (i.e. adults spawn in estuaries, marine larval phase, with juveniles returning to an estuary). Species with discrete populations in both estuarine and fully marine environments are included.
- *Marine Migrants* (MM): Adults live and spawn in marine environments, with juveniles frequently found in estuaries in large numbers. Juveniles can be opportunistic (i.e. can find suitable conditions within or outside estuaries), or dependant (i.e. require estuarine types of habitat).
- *Marine Stragglers* (MS): Live and breed in the marine environment. No estuarine habitat requirements but can enter lower reaches of estuaries. These stenohaline species generally avoid areas with salinities of less than 35‰, which can restrict up-estuary movement.
- *Anadromous* (A): Most growth occurs at sea, adults migrate from coastal marine areas to freshwaters to spawn (e.g. Atlantic salmon).

- *Catadromous* (C): Adults migrate from freshwaters to marine areas to spawn, but most growth occurs within freshwaters (e.g. European eel). Anadromous and catadromous species can be grouped together as diadromous species, i.e. migrating between marine and freshwater environments.
- *Freshwater Species* (FS): Those freshwater species found frequently, but in moderate numbers in estuaries and whose distribution only occasionally extends beyond areas of low salinity.

ii. Published Information

19.4.81 Numerous studies have been conducted examining fish assemblages within the Severn Estuary and the Bristol Channel (e.g. Ref. 19.121). As a result, information is available regarding species richness, assemblage composition and population dynamics of the Estuary and Channel (e.g. Refs. 19.122, 19.123 and 19.124), and a number of studies have been conducted to investigate the life history and migratory movement of specific species (e.g. Refs. 19.125-129).

19.4.82 No systematic targeted surveying or sampling of diadromous species is undertaken in the Estuary. Indeed, the paucity of diadromous species in long-term HPB intake records indicates that these species are highly dispersed across the Inner Bristol Channel in the Estuary, and can only be sampled in meaningful numbers when aggregated for reproduction in rivers.

19.4.83 Various data sources exist for diadromous species. Due to the high recreational, commercial and conservation value of salmon, a systematic monitoring framework exists for determining the status of various salmon fisheries. Data from rod catches and in some instances fish counters are used to estimate total run size, annually, on a river-by-river basis. The population size is then expressed in terms of the percentage of a conservation limit. The conservation limit is the number of salmon required to fully populate the river with juvenile salmon and is established for each river based largely on the area of suitable juvenile habitat present.

19.4.84 The recent SAC designation of the Wye, Usk and Tywi for shad and the Wye and Usk for sea and river lamprey under Annex I and Annex II of the Habitats Directive has created an impetus for monitoring these populations. Recent reports on lamprey (Ref. 19.130) and shad (Ref. 19.131) provide a basis for the assessment of these species. Both reports also discuss the results of surveys for these river populations in terms of the Severn Estuary. River specific datasets have been used to assess the status of riverine populations of species directly; the status of these species in the Estuary has been inferred largely from this data.

iii. The Hinkley Point B Severn Estuary Dataset (SEDS)

19.4.85 A comprehensive source of information regarding the abundance and species richness of fish in the Inner Bristol Channel is provided by the entrainment and impingement data collected at HPB since 1981. These long-term studies were instigated by the CEGB and since then monthly samples have systematically been taken and recorded. A long-term dataset of this nature is both uncommon and helpful. This dataset, currently maintained by Pisces Conservation with the sampling supported by the HPB operator and known of as the 'Severn Estuary Dataset'

(SEDS), is primarily of use in assessing the status of purely marine species, but is also relevant to some diadaromous species, most notably the eel *(Anguilla anguilla)*.

19.4.86 A total of 83 estuarine and marine fish species have been recorded since these surveys began. Between April 2006 and March 2007, 29 fish species were recorded and 42 species were recorded between January and December 2008 (P. Henderson *pers. comm.*). Prior to the relatively low species richness of the 2007 catch, the number of species caught each year ranged from a low of 33 in 1982 to a high of 46 species in 1998 (Ref. 19.124).

19.4.87 The ten most abundant species recorded within SEDS are sprat *(Sprattus sprattus)*, whiting *(Merlangius merlangus)*, sand goby *(Pomatoschistus minutus)*, poor cod *(Trisopterus minutus)*, Dover sole *(Solea solea)*, pout *(Trisopterus luscus)*, common sea snail *(Liparis liparis)*, sea, bass *(Dicentrarchus labrax)*, flounder *(Platichthys flesus)* and dab *(Limanda limanda)*. Eight of these species are marine migrants with one marine straggler (dab), and one estuarine species (sand goby). In terms of abundance and diversity, marine migrants provided the greatest contribution to the fish assemblage in the Bristol Channel around Hinkley Point, and while marine straggler species richness is relatively high, they are frequently represented by a small number of individuals.

19.4.88 The routine monitoring undertaken at HPB indicates a gradual increase in the number of fish caught, related to increasing sea temperature and decreased salinity. Increasing abundance has been observed for species which are relatively close to their northern limits in the Bristol Channel such as sole and sea bass. Conversely, species relatively close to their southern limit in the Bristol Channel (i.e. relatively cold-water preferring species) e.g. dab and sea snail, have experienced a decline in abundance. An observed step change in the set of occasional visitor species (i.e. those species with a northern distribution limit at the Bristol Channel, or just south) has also been related to increased sea temperatures.

m) Fish and Fauna

19.4.89 The high tidal flows and turbidity observed locally create harsh environmental conditions for fauna, with the subtidal seabed areas being largely depauperate in terms of invertebrates. It is often claimed that this results in a unique fish community. However, SEDS shows that the fish community is broadly similar in structure to that of other estuaries in the south of England (Ref. 19.132).

19.4.90 The impoverished benthic fauna means that the fish productivity of the Bridgwater Bay area is primarily dependant upon mysids, amphipods, and euphausids, in addition to the brown shrimp, *C. crangon* (Ref. 19.133). Few fish complete their entire life cycle in the area. Rather, most marine species exploit the productivity of the intertidal areas as juveniles, moving in and out of the Severn Estuary and Inner Bristol Channel seasonally in response to limitations of low temperature and salinity in the latter part of winter. *C. crangon* is thought to be limited by low temperature and salinity. This winter period also coincides with periods of lower prey availability, as observed in mysids and carideans (Ref. 19.134) and *C. crangon,* which are also thought to be limited by low temperature and salinity. The variable chemical and physical conditions prevalent locally, combined with low levels of small zooplankton required by larval fish, render the area unsuitable for reproduction. Adult fish thus migrate offshore to waters with more stable physio-chemical conditions and abundance of planktonic prey. On maturation, many fish move offshore. Eggs and larvae then colonise local estuarine areas via tidal movements in the summer and autumn, although some post-larval fish such as sprat and transparent goby may enter in early spring.

19.4.91 Although not unique in terms of community structure, the authors of Ref. 19.128 conclude that the extent of sheltered estuarine habitats present in the Bristol Channel means that it should be considered amongst the most important nursery areas in Britain.

i. Marine Species

19.4.92 The broader fish population of the Severn Estuary and Bristol Channel is of a similar species composition to that of other estuaries and coastal regions in south-west England (Ref. 19.132), comprising approximately 80 species. The most common species are sprat and whiting, which are present at an order of magnitude higher by number than the next most abundant species, namely poor cod, sand goby, sea snail, pout and sole. For marine species, the estuary is primarily used as a nursery ground – the extensive areas of shallow marginal mudflat provide extensive juvenile feeding opportunities, but none of the species present completes its entire life cycle within the estuary. Studies indicate that the estuary holds a single, mobile fish community and relative abundances observed at HPB are representative of the estuary between Berkeley and Minehead.

19.4.93 Recent years have seen a marked increase in the abundance and species richness of fish in the Estuary (Refs. 19.123, 19.128), which may be as much as threefold the abundance observed in the early 1980s. Although this is partially attributable to improved water quality, as proposed by Ref. 19.123, increased temperature and decreased salinity appear to be the predominant environmental factors causing this increase. To some extent this may also reflect the large natural interannual variations commonly observed in some species, notably the pelagics.

ii. Seasonality of Fish Presence, Abundance and Migration

19.4.94 Numbers of individual fish present in the Estuary, indicated by captures at HPB, show a clear seasonal pattern with lowest numbers present in April and May rising steadily through the summer and autumn to a peak in December, where numbers decline in January, February and March. Species abundance follows a similar, albeit less pronounced, seasonality. Lowest annual monthly average species counts occur in May, June and July, peaks in abundance occur in October and November and then abundance declines throughout the remaining winter months and spring.

19.4.95 The HPB SEDS data reveals patterns in abundance. Peak abundances for the 13 most common species (which comprise 95.6% of the total number of individuals) are illustrated in **Figure 19.14**. This shows that most species exhibit a peak from September to January with all species being present for all or almost all of the year. However, it is also apparent that the area is used to an appreciable extent at all times of the year, with no clear period when all fish species are in low abundance.

19.4.96 The majority of fish species which occur in the area around Hinkley Point can be regarded as opportunists, which spawn elsewhere. The tolerance of lower salinities of many of these opportunists enables them to exploit the higher productivity and/or lower predation risk present locally.

19.4.97 Larvae of these species are tidally transported from offshore areas into the Inner Bristol Channel in the late summer and autumn. Upon metamorphosis these then colonise progressively upstream areas for a number of months utilising selective tidal stream transport. Broadly speaking, young of the year migrate seaward again in winter months, in response to reducing salinity (Ref. 19.122) and/or temperature. In the case of a number of fish species, in particular gadoids, the seaward migration is closely correlated with and in response to abundance of *C. crangon* (Ref. 19.122). This pattern of progressive colonisation in late summer and autumn, peak abundance in September and October, followed by reduced abundance due to seaward migration, can be seen for sand goby, sole, dab, pout and sea bass **Figure 19.14** with similar but delayed patterns occurring for poor cod whiting and grey mullet. Such species will undertake several years migrating between estuarine regions and the sea before maturing, when they adopt a purely offshore existence.

19.4.98 As discussed above, the benthic fauna of the local sea area is generally impoverished, with the shallower margins having a relatively high benthic productivity compared to the relatively barren, deeper areas (Ref. 19.36). The shallow margins are also the preferred habitat of crustacean prey, most notably the brown shrimp *(C. crangon)*.

19.4.99 Given the benthic conditions and the associated impoverishment, the very much more productive intertidal mudflats are of primary importance to fish. Of the four most abundant flatfish in the Severn, plaice and flounder utilise tidal transport to migrate shorewards with rising tides, feeding only on intertidal areas at high tide. Dab and sole, however, also utilise subtidal habitats for feeding (Ref. 19.135) although in the case of sole, 'this year' juvenile fish (0+) were found to prefer shallower regions (Ref. 19.136). This dependence on, and preference for, intertidal areas is related to prey abundance, notably *C. crangon* which is a key prey source (Ref. 19.133). The preference for sheltered shallow areas is also noted for gadoids (Ref. 19.122) and sea bass (Ref. 19.137). Ref. 19.243 confirms that the high intertidal offers optimal habitat for the early life stages of species such as sea bass.

19.4.100 Ten marine species found within the area are UK BAP species: cod *(Gadus morhua)*, herring *(Clupea harengus)*, plaice *(Pleuronectes platessa)*, sole *(S. solea)*, whiting *(Merlangius merlangus)*, blue whiting *(Micromesistius poutassou)*, hake *(Merluccius merluccius)*, horse mackerel *(Trachurus trachurus)*, ling *(Molva molva)* and saithe (*Pollachius virens*, coalfish). The entire estuarine fish community fulfils the Ramsar Criterion 8, which considers a wetland to be internationally important if it is an important source of prey for fishes, or is a spawning ground, nursery and/or migration path on which fish stocks, either within the wetland or elsewhere, depend. These are inherent characteristics of estuaries and their associated fish communities (Ref. 19.135 and 19.138). Similarly, the area fulfils Criterion 7 in which a wetland is internationally important when supporting '"*a significant proportion of indigenous fish subspecies, species or families, life-history stages, species interactions and/or populations that are representative of wetland benefits and/or values and thereby contributes to global biological diversity*". In having a total of just over 80 species, the estuary has a species complement comparable to other similar estuaries in Europe (Ref. 19.120 and 19.138).

19.4.101 Cod and the thornback ray are listed on the OSPAR List of Threatened and/or Declining Species and Habitats, however, thornback ray is only listed as under threat and/or in decline in the Greater North Sea and not in the Bristol Channel area. Cod is rated as vulnerable on the IUCN Red List of Threatened Species (Ref. 19.140).

iii. Diadromous Fish Species

19.4.102 Diadromous fish primarily utilise the Estuary for migration between their natal rivers - most notably the rivers Wye, Usk and Severn, and marine feeding grounds. Seasonal migratory utilisation of the Severn Estuary is described in **Table 19.13.** They may also use the estuary for feeding, e.g. in the case of juvenile shad, and river lamprey. The following paragraphs describe the migratory species associated with the Severn Estuary and associated rivers.

19.4.103 Seven diadromous fish species are known to migrate through the Severn Estuary; Atlantic salmon *(Salmo salar)*, twaite shad *(A. fallax)*, allis shad *(Alosa alosa)*, river lamprey *(L. fluviatilis)*, sea lamprey *(P. marinus)*, sea trout *(Salmo trutta)* and European eel *(Anguilla anguilla)*. Each of the species is anadromous with the exception of the catadromous eel. All of these species, apart from sea trout and eel, are listed as Annex II species under the EC Habitats Directive (92/43/EEC). In addition, Atlantic salmon and river lamprey are listed under Annex V of the Directive. All of these diadromous species are afforded protection as UK BAP priority species. Sea lamprey and salmon are also on the OSPAR List of Threatened and/or Declining Species and Habitats and both sea and river lamprey are on the International Union for the Conservation of Nature (IUCN) Red List of Threatened Species (Ref. 19.140). Twaite shad is also on the IUCN Red List of Threatened Species and is listed under the Wildlife and Countryside Act 1983. All of the above mentioned species, except shad and Sea trout are protected under the Salmon and Freshwater Fisheries Act 1975 as amended by the Marine and Coastal Access Act, 2009.

19.4.104 All seven migratory species found within the estuary together form a qualifying feature of the Severn Estuary Ramsar site. Although each of these species is present, only twaite shad, river and sea lamprey are qualifying features of the SAC designation of the Severn Estuary.

19.4.105 At least two individuals of five of the seven migratory species have been recorded at the intake screens of HPB (the exceptions being allis shad and sea trout). In particular, relatively high numbers of juvenile twaite shad have been entrained at Hinkley Point with annual catches ranging from fewer than ten individuals in 1981, 1982, 1987, 1988, 1991 and 1993 to over 100 in 1989 (Ref. 19.141). Numbers of twaite shad impinged at Hinkley Point tend to peak in July and August.

iv. Estuarine Populations of Diadromous Species

19.4.106 In the context of estuarine fish species as a whole, other than eels, anadromous species of populations belonging to the adjacent rivers are rare, and infrequently recorded. For these migratory fish, the long-term data from HPB is of more limited value. Other data are required to assess these populations which, although rare, form the basis of the statutory nature conservation designations of the Estuary and the adjacent rivers. Given that anadromous fish populations are more amenable to survey when aggregated in rivers of origin, river specific data is more meaningful due to each river representing a discrete management, (and for some species, biological) unit. Riverine survey data have been relied upon and the available data, as presented for individual species below, have been interpreted in the context of the Estuary.

19.4.107 Lamprey and shad surveys carried out on the rivers Wye and Usk provide an indication of the conservation conditions for these rivers (Ref. 19.130 and 19.131). In the absence of direct data, the Severn Estuary populations for these species can be inferred. Ref. 19.130 discusses the validity of inferring the health of estuary populations from the adjacent rivers, specifically in the context of the Severn Estuary. The main uncertainty lies in the extent to which other rivers (most notably the Severn) contribute to the estuarine population, and the health of these populations. If, as has been suggested, lamprey populations are less faithful to their river of birth and the Severn population is therefore a more homogenous population, then the status of the species in any one river (e.g. the Wye or the Usk) can be considered to be representative of the estuarine population as a whole. If this is not the case, the Usk and Wye together are likely to comprise a sufficiently large proportion of the Severn Estuary population to make the assumption nonetheless correct, as only a very small percentage of lamprey in the estuary will be derived from other rivers and retain some heterogeneity.

Table 19.13: Migratory Movements of Diadromous Species found within the Severn Estuary, showing Important Months and Directions of Movement

Elvers	↑				■	■	■	■	■	■			

v. Salmon

19.4.108 Adult salmon migrate upstream primarily from July to September, with fish migrating during this time being primarily one-sea-winter salmon. Adult salmon also migrate in earlier months of the year, and although inferior in number, these comprise higher numbers of multi-sea-winter salmon. Multi-sea-winter salmon, and those which migrate upstream in earlier months (traits partially genetically determined and co-related) are of higher conservation importance than salmon generally and have undergone disproportionately large declines. This is more pronounced in the River Wye stock than perhaps any other UK river. This is reflected in their being afforded a range of specific conservation measures of both a non-statutory and statutory nature (e.g. national spring-run salmon conservation byelaws).

19.4.109 Salmon smolts migrate downstream through the estuary towards marine feeding grounds between April and June. Available evidence suggests that salmon smolt migration is characterised by selective tidal stream transport on the ebb tide, near the water surface in the areas of strongest flow, and takes place during the night (Ref. 19.142). Ref. 19.142 suggests that smolts pass rapidly through the estuary and do not require a significant period of acclimation to saline conditions.

19.4.110 Adult salmon migration within estuaries is characterised by utilisation of tidal flows, and, prior to entry to freshwater, salmon may reside in estuaries for varying periods. Ref. 19.143 found this to vary between nine hours and 190 days in the Fowey Estuary. During this time, salmon move up and down estuaries, and progress upstream by making effective use of the flood tide and seeking refuge from outflowing tidal currents (ebb tides) by utilising more marginal, lower velocity parts of the Estuary (Ref. 19.141).

19.4.111 Residence time in estuaries is largely dependant on riverine flow and temperature, with high riverine flows and low temperatures resulting in relatively quick river entry, and low flows with delayed entry whereby salmon reside in the estuary, or return to sea. An important feature of delayed entry is that this results in lower likelihood of salmon entering the river (Ref. 19.144).

19.4.112 Atlantic salmon are considered to be in unfavourable condition within both the River Wye and Usk SACs. They are currently failing to meet their Conservation Limits (CLs) set by Salmon Action Plans on the Rivers Wye and Taff/Ely. Although there is some uncertainty, the Rivers Usk and Severn appear to be complying with their CL targets. Overall, it is likely that the estuary population is below the population sought by managers to maintain its conservation and fisheries objectives.

vi. Lampreys

19.4.113 Adult river lamprey are known to enter UK rivers generally in the late autumn, although, unlike sea lampreys which undertake more extensive marine migrations, river lamprey make more use of estuarine habitats throughout their marine phase (Ref. 19.145). Sea lamprey migrate through the estuary and enter rivers to spawn in the early spring.

19.4.114 Ref. 19.122 recorded peaks in abundance of downstream migrating juvenile river lamprey in the Severn Estuary between October and January.

19.4.115 The most recent condition assessment round in 2007 classified all UK SACs with the exception of the River Usk as unfavourable for river lamprey and all but the River Wye as unfavourable for sea lamprey. In the absence of a comprehensive understanding of the amount of available lamprey habitat within each of the rivers, the current conservation status assessment procedure does not enable an assessment of standing stock to be made, therefore precluding the derivation of a species population estimate. No estimates have been made of the number of returning adults or outmigrating transformers of river or sea lamprey within the tributary rivers of the Severn Estuary.

vii.Shads – Allis Shad and Twaite Shad

19.4.116 Adult shads enter the Severn Estuary between April and June on their way to spawn in the rivers Severn, Wye and Usk, with peak immigration occurring in May.

19.4.117 Young of the year shad colonise the estuary from rivers from July, until migrating seaward in autumn. Ref. 19.122 recorded maximum numbers of juvenile twaite shad in the Severn in August and September. Juveniles may also return to the estuary the following April to May before returning seaward again in the late summer. This indicates that the estuary is more than merely a migration route for shad, and that it is of importance as a feeding ground for juveniles.

19.4.118 Inferring status of twaite shad populations in the Estuary from the adjacent riverine populations leads to an uncertain conclusion. Although data comparable to that of Ref. 19.131 does not exist for the Severn, its status is thought to be improving. However, both twaite and allis shad are currently classified as being in unfavourable status for all of their designated rivers (Usk, Wye and Tywi). Few estimates of the stock sizes of twaite or allis shad within the Bristol Channel or the Severn Estuary's tributary rivers have been made and the current conservation status sampling protocol does not enable quantitative assessments of standing stock to be made. During the derivation of the UK BAP priority species list Miran Aprahamian (pers. comm.) estimated that the twaite shad populations in the UK totalled approximately 100,000 returning adults split between the Rivers Severn, Wye, Usk and Tywi as 20,000, 50,000, 20,000 and 10,000 individuals respectively.

viii. Eel

19.4.119 Eels are catadromous, reproducing in the sea, and migrating to freshwaters to undertake most of their feeding and growth. The Severn Estuary and its rivers constitute the largest eel fishery in the UK; constituting 95% of all glass eels (juveniles migrating towards freshwater) caught in England and Wales. The majority of upstream migration of elvers (juveniles) takes place between April and September inclusive although closer to tidal limits this may be concentrated within the months of April to July (Ref. 19.146). The same authors suggest that peak downstream runs of adult eels take place between September and November.

19.4.120 European eel is categorised as Critically Endangered on the IUCN Red List of Threatened Species. Eel are considered to be under threat and have seen a significant decline in stocks. The International Council for the Exploration of the Sea (ICES) state that the European eel stock is outside safe biological limits. In 2007, the European Community entered into force a Europe-wide recovery plan (Ref. 19.147) with implementation measures which began in 2009. In March 2009, eel was also added to the Convention on International Trade in Endangered Species (CITES) Appendix II list, which details species in which trade must be controlled. In January 2010, the Eels (England and Wales) Regulations 2009 (Statutory Instrument No. 3344) came into force to meet the European measure. The new Regulations provide for consideration of passage and screening for eels.

19.4.121 Eel Management Plans have been implemented for the Severn Catchment which aim to provide an escapement of silver eel biomass that is at least equal to 40% of the potential escapement to be expected in the absence of anthropogenic influence. It is currently estimated that an escapement rate of approximately 34% is being achieved (Ref. 19.148).

19.4.122 In addition, Council Regulation (EC) No 1100/2007 of 18 September 2007 establishing measures for the recovery of the stock of European Eel (the European Eel Regulation) requires that a system is in place to ensure that, by 2013, 60% of eels less than 12cm long, which are caught commercially each year, are used for restocking in suitable habitat. On the basis of an estimate that the glass eel/elver fishery on the River Severn takes 10% of the stock it has been estimated that the glass eel population was within the region of 3 million individuals in 2008.

19.4.123 Data from long-term monitoring at HPB indicates a long- term exponential decline in catches from the commencement of records in 1980. This trend is also evident in the recruitment of glass eels to Europe which has declined since the late 1970s by as much as 99%.

ix. Sea Trout

19.4.124 Sea trout share much of the of the Atlantic salmon's biology as well as having a similar life history. Key differences include a higher degree of repeat iteroparity in sea trout (i.e. individuals have a greater propensity to survive to undertake repeated spawnings), and sea trout undertake their marine phase in coastal waters rather than undertaking the more extensive marine migrations of salmon.

19.4.125 Adult sea trout generally enter rivers in South Wales and the south-west of England from June to September, with smaller numbers entering at other times of the year.

19.4.126 Studies have indicated that sea trout smolt migratory behaviour is similar to that of salmon, taking place between April and June, utilising selective transport by ebb tides primarily at night, near the water surface in the fastest moving part of the water column (Ref. 19.142).

19.4.127 Data from rod, putcher and net fisheries indicate that sea trout occur at much inferior numbers than salmon. This is in contrast with nearby rivers in South Wales, which have strong sea trout populations (*e.g.* Tywi and Teifi). This suggests that riverine and estuarine conditions within the Severn are inherently unfavourable to sea trout. Given that the marine phase of sea trout is more coastal and estuarine than salmon, it may be that the highly dynamic nature of the Severn does not offer suitable inshore habitat.

n) Offshore Fish Surveys

19.4.128 Recent offshore surveys in support of the environmental assessment process in Bridgwater Bay in the vicinity of Hinkley Point (Ref. 19.33 and **Figure 19.5**) have recorded a total of 15 species of fish (**Table 19.14**). All fish caught were less than 30cm in length. Overall, the species with the highest catch rate were greater sandeel *(Hyperoplus lanceolatus)*, solenette *(Buglossidium luteum)* and whiting. During the four surveys (one scoping and three quarterly surveys) no significant concentrations of finfish species, commercial or otherwise, were identified.

19.4.129 These 2m beam trawl did not catch a single individual of any species of prime conservation or ecological concern, such as eel, salmonids (salmon and sea trout), smelt, and shad. However, Ref. 19.33 notes that the River Parrett, which discharges into Bridgwater Bay east of the HPC Development Site, historically had an eel population that was once heavily fished, with an estimated 10,000 eels per night in the river at peak migration times. Data collected by the Environment Agency for the period 1990 to 2006 indicate a general decline in eel density on the Parrett since the 1990s with little recruitment of small eel into the river. In 1992 maximum densities of up to 100 individuals per $100m^{-2}$ were recorded with this decreasing to below approximately 20 individuals per $100m^{-2}$ in 2006. Current European eel populations are depleted, and the evidence available suggests it is likely that only a small fraction of the historical eel run now takes place.

Table 19.14: Catch of Fish by 2m Beam Trawl (tows standardised to $1000m^2$) (Ref. 19.33)

Species	Q2/08 (Jun)	Q3/08 (Aug)	Q4/08 (Nov)	Q2/09 (May)
Dab	0	2.3	12.7	0
Five bearded rockling	1.8	0	0	0
Four bearded rockling	0.8	0	0	0
Greater sandeel	51.7	23.9	35.4	0
Grey gurnard	1.4	0	0	0
Herring	0	0	6	1.2
Lesser sandeel	0	0	29.4	0
Montague's sea snail	0.9	0	0	0
Poor cod	3.1	0	0	0
Sand goby	0	4.5	6.7	0
Solenette	58.9	8.5	22.3	60.2
Sprat	3.4	0	41.1	2.1
Thornback ray	0	1	0	0
Two spot goby	1.6	0	0	0
Whiting	0	26.6	27.6	1.1

o) Intertidal Fish Surveys

19.4.130 Intertidal fish surveys (Refs. 19.45-48) to a design compatible with Environment Agency WFD transitional waters fish sampling protocols, were instigated over Bridgwater Bay in mid 2009 and continued until early 2011. Over the latter half of 2009, a total of 2,500 fish represented by 20 species were caught. Variations in species richness, relative species composition and total abundance has been observed on both a temporal and spatial basis, with the two sampling methods (fyke and seine nets) also demonstrating selectivity in the species and life stages captured.

19.4.131 Results from these surveys (**Table 19.15**) have indicated that the intertidal zone near Hinkley Point is a foraging and nursery area for a broad range of species, including several species and life stages (such as juvenile sea bass and mullet). In accord with the findings of Ref.19.243, these species and life stages would appear to selectively use the upper intertidal zone in favour of subtidal habitats.

Table 19.15: Species Caught during the Intertidal Fish Survey

Species	Fyke Nets	Seine Nets
Atlantic cod, *Gadus morhua*	✓	
Atlantic herring, *Clupea harengus*		✓
Common goby, *Pomatoschistus microps*	✓	✓
Common sole, *Solea solea*	✓	✓
Conger eel, *Conger conger*	✓	
Couche's goby, *Gobius couchi*		✓
European eel, *Anguilla anguilla*	✓	✓
Flounder, *Platichthys flesus*	✓	✓

Sea bass, *Dicentrarchus labrax*	✓	✓
Smooth hound, *Mustelus mustelus*	✓	
Sprat, *Spratus sprattus*	✓	✓
Pollack, *Pollachius virens*		✓
Poor cod, *Trisopterus minutus*	✓	
Thinlip mullet, *Liza ramada*	✓	✓
Transparent goby, *Aphia minuta*		✓
Whiting, *Merlangius merlangus*	✓	✓
5-Bearded rockling, *Ciliata mustela*	✓	✓
3-Spined stickleback, *Gasterosteus aculeatus*		✓
15-Spined stickleback, *Spinachia spinachia*		✓

p) Fish Impingement at Hinkley Point B in 2008 and 2009

19.4.132 Forty-two species of fish were recorded from the monthly impingement samples between January 2008 and June 2009. As is normal for the Bristol Channel, whiting and sprat were the most abundant fish species. A notable feature was the large number of snake pipefish impinged on the screens (this was the first time large numbers of this species have been recorded at HPB over a sampling period extending over the last 30 years). It is likely that many snake pipefish were able to penetrate the 1cm mesh and therefore passed through the cooling water circuit. This suggests that this pelagic pipefish has recently become extremely abundant in the estuary.

19.4.133 A comparison of the relative abundances of fish impinged upon the power station screens and those sampled offshore showed that sprat and whiting dominate the fish fauna at all sampled localities. Furthermore, of the 18 recorded species impinged on the screens in 2008, 13 were also caught in one or more of the offshore samples. A comparison of the fish species and relative abundances recorded offshore and from the power station screens, showed that herring, sprat and whiting dominated the fish fauna at all localities.

19.4.134 Sixteen species of fish were recorded from the monthly impingement samples in May and June 2009. As is normal for this locality at this time of year, the catch was dominated by whiting, with Dover sole and flounder also common (737, 217 and 90 individuals caught respectively). Late spring to early summer is the time of year when fish abundance and species richness is at the minimum for the year. A notable feature of the June 2009 sample was the unusually large number of juvenile 0+ cod impinged, an indication of what has probably been the second highest level of recruitment in that stock of cod in the historical time series. This was the largest number recorded in a six hour sample since sampling at HPB began in 1981. The long term time-series of sampling maintained at HPB has tended, over the years, to mirror the spikes in cod recruitment known from fisheries studies fairly well. Data fhe Comprehensive Impingement (CIMP) survey (Ref. 19.36), operated by BEEMS in parallel to that longer term effort over 2009/10, clearly show those juvenile cod being impinged in large numbers at that time.

19.4.135 Of the 32 species impinged during the survey period (November 2008 to October 2009), 21 were sampled offshore. In addition, four species were sampled offshore which were not recorded at the intake during this period (anchovy, pearlside, sand eel, and solenette).

q) Commercial Fishing

19.4.136 This section provides baseline information on commercial fisheries within the Severn Estuary and Inner Bristol Channel area (i.e. the area around Hinkley). Ref. 19.32 considers the fisheries resources present in the area and those that depend on it in the commercial fishing sector. The catching sector supports a range of associated upstream activities, such as vessel and gear suppliers, and downstream activities such as marketing, processing and distribution. Due to the estuarine nature of the area and importance of commercial fisheries for migratory species such as eels and salmonids, these are also discussed in this section.

19.4.137 Ref. 19.32 reviews a number of data sources including:

- Radiological habits survey (Ref. 19.149).
- Coastal Fisheries of England and Wales (Ref. 19.150).
- Landing statistics from the Marine and Fisheries Agency.
- Communications with Industry Liaison Officers, North Devon Fisherman's Association and South Wales Sea Fisheries Committee.
- Data from the Environment Agency.

i. Overview of Fishing Activity in the Bristol Channel and Severn Estuary

19.4.138 Commercial fishing effort in the Outer Bristol Channel is extensive with vessels from the North Devon, Cornish and South Wales coastlines targeting a variety of species throughout the year. Fisheries include potting for lobsters, crabs and whelks, with netting and trawling targeting the ray and mixed fisheries. Targeted fisheries for squid and sea bass also occur during the summer months with some North Devon boats fishing off the sand banks in the Bristol Channel.

19.4.139 There are also commercial fisheries for migratory species, including salmon, sea trout and eels in the Severn Estuary and surrounding rivers. However, the value of rod fisheries dwarfs those of netting, and is mainly concentrated in the River Wye, targeting salmon. An Environment Agency study (Ref. 19.151) estimated the market value of fishing rights for salmon rod fisheries in England and Wales to be £128 million. This was based on an average rod catch of 15,200 fish and an average value of £8,400 per salmon caught. In contrast, the same study concluded that in 2001 the net economic capital value of salmon net fisheries in England and Wales was around £3 million.

ii. Marine Fisheries

19.4.140 The level of commercial fishing activity in the Severn Estuary and Inner Bristol Channel (Ref. 19.32) is generally much lower than on grounds to the west, principally as a result of the strong tides, together with the low density of fish above the statutory Minimum Landing Size (MLS). The Estuary acts as important nursery grounds for many commercially valuable species, including sole and sea bass and, as a result, the majority of the fish found within the Estuary are juveniles.

19.4.141 During the surveys reported in Ref. 19.149, it was noted that the level of commercial fishing was relatively low, with five full-time commercial fishers active in the area, three at Stert Flats at Stolford using stake-nets and set-nets, two at Blue Anchor also using stakenets and a further two fishers that had commercial licences but were not using them, but based out of Watchet. Commercial fishing for crustaceans was only identified at Stolford. There, two fishers were setnetting over mud mainly for brown shrimps, *C. crangon*. To the east of Hinkley Point, two fishermen maintain ranks of fixed stowe or stake-nets on the Steart Flats, catching shrimps, mullet, rays and sole from July to October (Ref. 19.150), and molluscs are gathered by hand.

19.4.142 Many of the commercial fishing vessels operating out of the north Somerset and South Wales coastal areas are under 10m in length and operate on a part-time basis supplementing income with charter angling trips, especially for cod which have remained relatively abundant in the area. The under 10m fishing fleet is not required to submit logbooks to Defra detailing catch levels. However, under the Commission Regulations (EC) No 1077/2008, an audit trail is now established to track all landings from first point of sale, although no data are as yet available from this process.

19.4.143 There are three <10m vessels working part time from the Usk at Newport, using small beam trawls for flatfish and brown shrimps which are also taken in Cardiff Bay (Ref. 19.150). There are two part-time boats operating out of Minehead, setting pots and taking out angling parties with several part-time boats also setting pots and nets close inshore between Highbridge and Burnham-on-Sea. Two angling charter boats operate from Watchet Harbour, taking regular inshore angling trips along the coast between Blue Anchor and Stert Flats. It would appear from the available data that trawling and drift netting are no longer being practiced by anyone in the waters off Hinkley Point.

19.4.144 Marine Management Organisation (MMO, formerly the Maritime and Fisheries Agency, MFA) landings statistics cover the relevant ICES statistical rectangle (31E6), a summary of which is presented in **Table 19.16** (taken from Ref. 19.27).

19.4.145 **Table 19.16** shows the average landed weight (kg) per year for certain species and their value in pounds sterling. The species with the greatest value per kilogram is sole, followed by sea bass and then cod. When actual catches are looked at, sea bass is most valuable, followed by crab and then plaice. Overall, sea bass is considered the more commercially important species, followed by sole and crab. The catches and price of the other species make them profitable, but not the main area of focus. These data are well reflected in the types of gear used in the area, driftnets and fixed nets to catch sea bass and cod, pots to catch crabs and trawling for sole and plaice.

19.4.146 The data represent the landings for the whole of statistical rectangle 31E6, and they cover a large area, including some commercially active ports such as Swansea and Port Talbot. Therefore, the actual level of commercial fishing around Hinkley Point cannot be calculated accurately.

Table 19.16: Average Annual (between 2004 and 2008) Weights (kg) and Values (£) of Fish Landings by ICES Statistical Rectangle

ICES Rectangle 31E6	Sea Bass	Cod	Conger	Crab	Herring	Plaice	Sole	Sprat	Whiting
Weight (kg)	6,335	1,342	168	4,847		1,450	1,427		153
Value (£)	34,585	2,992	136	6,401		2,692	12,298		111
Value (£/kg)	5.74	1.93	0.75	1.51	0.59	1.38	7.75	0.41	0.60

Note: *Values are either the actual value at the time of sale or, where this was not available, an estimate based on average prices maintained locally by MMO.*

19.4.147 Consultation with the MMO and local fisheries officers has corroborated the view that commercial activity in the Hinkley Point area is very limited. There have been no industry observer trips out of Watchet or Minehead, because there is no large-scale fishing activity there, and the only port nearby with commercial-scale landings is Ilfracombe.

19.4.148 The North Devon Fishermen's Association (NDFA) stated that none of its members operated as far up the Channel as Hinkley Point and they have no large-scale commercial activity east of Lynmouth; there are no trawlers or potters from the NDFA that work that ground. It was also stated that, because of the extremely strong tidal currents around Hinkley Point and further up the Bristol Channel, there would be little if any commercial trawling or drift netting.

19.4.149 The South Wales Sea Fisheries Committee (SWSFC) said that boats do use a lot of the Channel but would not operate as far up as Hinkley Point on any large scale.

iii. Migratory Fisheries

19.4.150 Fisheries for migratory species are of significant economic value, particularly in rural areas. However, overall salmon and sea trout netting is declining, in response to the phasing out of mixed stock fisheries and falling demand for wild salmon. Eel and elver net fishing in recent years has fluctuated in response to market forces.

19.4.151 Migratory species that are targeted commercially in the Severn Estuary and surrounding rivers include salmon, sea trout and eels. Both allis and twaite shad are also present in the Severn Estuary and were formerly fished commercially before numbers declined and the fishery collapsed. In the middle of the 19th century the value of shad rivalled that of salmon and in the River Severn, shad made up about one third of all catches.

19.4.152 Many of the net fishing methods used to target migratory species on the Severn Estuary are unique to the area and have a long history, notably lave netting (using a 'Y' shaped net and 'stalking' or 'cowering' in the shallows to catch the salmon migrating), and putcher nets (rows of baskets which use the ebb tide to trap salmon).

iv. Salmon and Sea Trout

19.4.153 The Estuary fisheries exploit mixed stocks of salmon originating from at least seven rivers entering the Estuary, most notably the Severn, Wye and Usk. Net licences issued for catching salmon also allow the fishermen to take sea trout. Hence, it is impossible to distinguish the allocation of effort between salmon and sea trout fishing. Sea trout are found in 26% of all rivers, and their distribution across England and Wales is very irregular. Wales has the widest distribution, with sea trout present in 49% of rivers. The licensed fishery in the Severn Estuary in 2007 comprised two seine nets, 20 lave nets and four fixed engines (e.g. putchers); see **Table 19.17**.

Table 19.17: Allowable and Utilised Effort for the Principal Salmon Net Fisheries in 2007

River/Fishery	Method	No. of Licences	Allowable Effort Net Days	% days Utilised	Av. Day/lic.
Severn	Putchers	4	304	79	60
Severn	Seine	2	312	0	0
Severn	Lave	20	1,560	15	12
Wye	Lave	7	553	24	19

Note: *adapted from Salmonid Stocks and Fisheries in England and Wales, 2007 (after Ref. 19.154).*

19.4.154 Salmon caught before 1st June must be released, with catches continuing from then until August. In 2000, local interests bought out drift netting in the mouth of the Usk, in Newport Bay and the putcher rank just upstream of Uskmouth which accounts for the lack of reported salmon net catches in the Usk after 1999 (**Table 19.8**). The breakdown of the net catches in the rivers Severn, Wye and Usk by gear type from 1999 to 2006 indicates that fixed engines or putchers account for the highest numbers of salmon taken. There are salmon putchers at the south-west and north-east ends of the Severn Bridge, at Aust and Beachley, and at Alvington below Lydney Lock (Ref. 19.154).

19.4.155 The total provisional figures for net and rod catches taken for the Midlands (River Severn) and Welsh (all rivers) regions in 2007 are described in Ref. 19.152 (see **Table 19.19**). The catches from these regions made up 21% of the total catches for England and Wales in 2007. Catch figures indicate the importance of the recreational rod and line fishery in Welsh rivers (especially the rivers Wye and Usk) with reported catches seven times higher than those of the net fishery. These figures do not take account of catches of salmon which go unreported (including those taken illegally), and it is estimated that there may have been a total of 22,000 additional fish caught in 2007 (Ref. 19.153).

Table 19.18: Summary of Salmon Net Catches Numbers Landed, 1999-2006

River	Method	1999	2000	2001	2002	2003	2004	2005	2006
Severn	Seine nets	35	41	5	20	38	43	25	13
	Lave nets	190	228	186	116	295	380	135	138
	Fixed engines	764	704	836	1054	1207	346	778	713
Wye	Lave nets	3	11	2	6	6	8	7	6
Usk	Drift nets	726	0	0	0	0	0	0	0

Note: *adapted from Salmonid and Freshwater Fisheries Statistics for England and Wales, 2006 (after Ref. 19.154).*

Table 19.19: Provisional Net and Rod Salmon Catches (including released fish) by Region for the 2007 Season

Region	Net Catch		Rod Catch		Total Catch	
	No.	Weight (kg)	No.	Weight (kg)	No.	Weight (kg)
Midlands	676	3,184	261	1,112	937	4,296
Welsh	613	2,022	4,488	16,239	5,101	18,261

v. Eels

19.4.156 Eels are found in all European countries bordering or connected to the North Atlantic. They are caught as elvers (juveniles returning from the sea) or adults in a variety of fisheries each with different levels of exploitation. Over the past two decades, catch data from across Europe show glass eel populations declining rapidly from the high levels of the 1970s, while 2001 produced a record minimum of just one percent of previous peak levels, and most recent data show a continued decrease and no significant recovery from the 2001 all time low.

19.4.157 Only hand-held dip nets are permitted for the capture of glass eels or elvers, and fishing is concentrated where the fish are plentiful and easy to catch, principally in estuaries of the Severn and other rivers draining into the Bristol Channel, such as the Parrett. Catch returns from these fisheries have been compulsory over the past few years and provide a good indication of the trend in eel recruitment. The fishing season is short, coinciding with the elvers entering rivers on spring tides in April and May (Ref. 19.154).

19.4.158 The number of licenses issued to fish for glass eel/elver in the Severn Estuary and Bristol Channel ranged from 487 to 577 between 2002 and 2004. Elvers are known to be targeted during their landward migration between November and March using dipnets within the area just seaward of Bridgwater Bay. The national 2007 catch was 2,051kg of which the Severn Estuary and Bristol Channel are estimated to represent 95% equating to a catch of 1,948kg. Based on an average individual weight per elver of approximately 0.5 g this would equate to 3,896,000 individuals. Only a small proportion of elvers caught are for domestic consumption, the majority are sold for re-seeding eel farms in Asia.

19.4.159 Eels are caught commercially in a number of locations and by a variety of instruments including fyke nets, putcheons and weir traps. The level of eel fishing effort is measured as the number of licensed instruments of all types. Licence sales in England and Wales have fluctuated between 1,500 and 2,700 (per year,) most likely in response to market price fluctuations. Many rivers throughout the Severn Estuary catchment support eel fyke net fisheries between spring and autumn. Fyke nets fished on the Wye take yellow eels in spring and summer and silver eels in autumn.

19.4.160 Between 2002 and 2004 the number of licenses issued for this fishery reduced from 80 to 47 although catches in fact rose over this period from 156kg in 2002 to 980kg in 2003 followed by a slight decline in 2004 to 569kg. The 2007 annual adult eel catch for Wales, South-West England and the Midlands was 2,396kg (data provided by the Environment Agency). The 2004 catch indicates that the Severn Estuary represents approximately 12% of this regional catch. As such, the 2007 adult eel catch for the Severn Estuary is estimated at approximately 288kg. Based on empirical data, there is presumed to be a 20:1 ratio of male to female eel in the Severn Estuary. Male and female eel reach maturity and migrate at different ages and, as such, will vary in weight. Taking an average weight of 90 g however for male silver eel of 90g and 580g for females (based on the most common ages at maturity), the adult eel catch for the Severn Estuary and Bristol Channel would equate to 3,040 males and 24.8 females.

vi. Recreational Fishing

19.4.161 Recreational angling accounts for the highest amount of fishing effort within the Severn Estuary and Inner Bristol Channel. Anglers fish from the shores along much of the Inner Bristol Channel targeting cod in the winter and sea bass in the summer, with other species such as whiting, flounder, eels, rays, sole and conger also caught. Angling is also carried out from charter vessels, and both forms represent an important recreational use of the Estuary, even though the quantities and values of fish taken are small compared to commercial fisheries.

r) Marine Mammals

19.4.162 A desk-based review of available data on marine mammals within the Severn Estuary and Bristol Channel was conducted. Subsequently, following the publication of guidance from by the Joint Nature Conservation Committee (JNCC) (Ref. 19.155), a network of acoustic sensors was deployed off the site.

19.4.163 A study of the Welsh shore of the Bristol Channel (around the Gower Peninsula and Swansea Bay) during the early 2000s documented regular occurrences of the harbour porpoise (*Phocoena phocoena)*, as well as occasional sightings of the common dolphin (*Delphinus delphis)* (Ref. 19.156).

19.4.164 Aside from this study, there is little available information regarding cetacean activity in the areas of the Inner Bristol Channel and Severn Estuary, although common dolphin *(D. delphis)*, bottlenose *(Tursiops truncatus)* and Risso's *(Grampus griseus)* dolphins, as well as grey seals *(Halichoerus grypus)* have been recorded in the wider Bristol Channel area in the past (Ref. 19.157).

19.4.165 The BEEMS programme has initiated an acoustic monitoring programme to assess cetacean site usage in relation to potential HPC construction impacts (Ref. 19.57). Recording devices have been deployed at two locations around the proposed temporary jetty and the cooling water intake and outfall structures, and a further three locations on a depth transect from the front of the station around 25km westwards into the Bristol Channel (**Figure 19.15**). These record cetacean 'clicks', the vocalisations used as a means of navigation and prey location (Ref. 19.156). The devices have been *in situ* for approximately since early 2011.

19.4.166 Harbour porpoise have been recorded at each of the five locations, including the vicinity of the proposed jetty and intake/outfall structures; see **Figure 19.15**. The initial dataset suggests a strong depth-preference, with the number of days on which porpoise were recorded increasing along the gradient from the existing station towards the open waters of the Channel (**Table 19.20**). The data on dolphin clicks have yet to be analysed, so the occurrence of these species in the area remains unclear, but initial inspection of the data suggests they are also found in the area.

Table 19.20: The Number of Days of Porpoise Recordings at the BEEMS Acoustic Recording Stations around Hinkley Point (from Ref. 19.57) during Initial Survey Period of 77 Days

Station	Location	Approximate water depth (m)	No. of days when porpoise clicks were recorded	Percentage of total recording days when porpoise clicks were recorded
1	Vicinity of proposed jetty	3.4	7	9
2	Vicinity of proposed intake/outfall	5	10	13
3	Inner transect, north-west of station	12	30	39
4	Mid-transect	12	20	37
5	Outer transect	20	51	66

19.4.167 Information on site fidelity and temporal patterns in the Channel's cetaceans is scarcer than that on their occurrence. It is unclear if the harbour porpoise recorded in the area are local residents or visitors, though workers involved in the Welsh study suggest they may be resident (Ref. 19.156). There is no clear evidence of significant seasonal patterns in the Welsh porpoises, although there is some indication of seasonal aggregations in the Carmarthen area (during November; see Ref. 19.156).

19.5 Scope of Assessment

a) Existing Baseline Condition

19.5.1 Section 19.4 above describes the existing baseline condition, in terms of the observed character of the local marine ecological interests, against which the assessment developed within this chapter is then undertaken. That baseline incorporates the presence and function of the existing HPB station. Where the impacts of HPB operations are isolated in the assessment below this is solely for the purposes of supporting, as a surrogate, understandings and predictions of the likely impacts of HPC beyond that baseline condition.

19.5.2 In recent years the HPB station has been obliged to maintain a lower operational load, meaning that reduced volumes have been abstracted and a reduced thermal output has been put to sea. These reduced volumes have been taken into account in characterising the impingement rates observed at that station and elaborated upon in predicting catches for HPC. Likewise, the development of numerical hydrodynamic models in support of the HPC development over this period has been calibrated against the reduced plume signature.

19.5.3 For the purposes of this assessment, calculations of the baseline condition have presumed the HPB station to be operating at 100% load, this being what is permitted under that station's consent to operate. So, for example, all plume extents are mapped with HPB operating at full load and the starting point for any comparison with fishing mortality will include, as baseline, the predicted influence of that existing operation, again at full load.

19.5.4 The observed condition of the benthic fauna utilised in this assessment will have been representative of HPB at high load, given that load reductions began just before the surveys commenced.

b) Significant Elements of the HPC development

19.5.5 The elements of the proposed HPC power station development which could lead to potential effects on the marine environment are likely to be the construction and operation of the following:

- the temporary jetty;
- the seawall;
- land-based discharges; and
- the cooling water system.

19.5.6 For each of these a number of potential impacts have been identified. Generally, these impacts can be grouped into several broader categories (e.g. habitat loss and disturbance). The proposed Fish Recovery and Return system is considered in Section 19.8, Mitigation.

c) Temporary Jetty

19.5.7 A temporary jetty would be constructed and operated during the overall construction phase for the HPC project. As a temporary structure, the potential effects of jetty construction, operation and dismantling are considered as a part of the construction stage of the project. These activities have the potential to generate the following changes which could impact on marine habitats and species:

- intertidal and subtidal habitat loss and disturbance due to piling, construction and maintenance activities;
- physical disturbance to habitats due to alterations in longshore current patterns caused by both the jetty structures themselves and dredging (including maintenance dredging) of the berthing pocket;
- alterations in water quality due to run-off from the jetty and its constituent materials during construction and dismantling;
- noise and vibration due to piling and vessel movements; and
- artificial lighting during construction and operation.

d) Construction of the Seawall

19.5.8 A new seawall will be constructed for coastal protection purposes on the line of the existing cliffs fronting the HPC Development Site, at the top of the intertidal shore. These activities have the potential to generate the following changes which could have an impact on marine habitats and species:

- loss of upper shore habitat and modification to slope of intertidal zone;
- physical disturbance to the upper shore during construction (machinery access and trampling by people);
- water quality alterations on the shore via run-off from works and other potential contaminant release;
- noise and vibration caused by operation of machinery and rock removal; and
- artificial lighting during 24 hour construction of the seawall.

e) Land Based Discharges

19.5.9 Construction and operational activities on the main site have the potential to create discharges, which could generate changes in water quality that have an impact on marine habitats and species.

f) Cooling Water System

i. Construction of the Vertical Shafts Offshore

19.5.10 The construction of the cooling water system, involving the construction of vertical shafts approximately 1.8km offshore for the placement of outfall structures and 3.3km offshore for intake structures, has the potential to generate the following changes which could impact on marine habitats and species:

- temporary and permanent loss of seabed habitat;
- physical disturbance to the seabed around each drilling site;
- water quality alterations due to discharges from dewatering activities and from platforms and support vessels, waste materials, chemicals associated with drilling operations;
- water quality alterations due to sediment disturbance and potential contaminant mobilisation;
- noise and vibration associated with both pile driving (for anchorage of platforms) and vessel movements; and
- artificial lighting if offshore construction works continue during the hours of darkness.

ii. Construction of the Horizontal Tunnels

19.5.11 The main cooling water tunnels connecting the power station itself to the cooling water intakes, via the shafts described above, will be drilled beneath the intertidal shore and seabed from land. All waste arisings will thus be managed, at least initially, onshore. These activities have the potential to generate the following changes which could impact on marine habitats and species:

- water quality changes due to discharge of waste water from tunnel drilling. If mud-assisted drilling is used this could contain suspended solids (including bentonite), organic polymer, and waste salts following control of pH; and
- vibration and noise.

iii. Operation of the cooling water systems

19.5.12 The operation of the cooling water systems at HPC will involve the abstraction and subsequent discharge of approximately 125 $m^3.s^{-1}$ on a virtually continuous basis over the full generating lifetime of that station. The principle impacts of abstraction will be: the impingement of fish and other marine life on screens; the entrainment of smaller organisms through these screens, their passage through the plant, subjection to stresses of pressure, increased temperature and potential chlorination and their subsequent return to sea; and any influence caused by the thermal plume arising and any associated residual biocides associated with the discharge.

19.5.13 Although the decision was made from the outset to incorporate relevant best practice mitigation into the design of the HPC cooling water system, no allowance for these features has been made in completing the initial assessments that follow below. Best practice measures include: the offshore location of intakes; use of low velocity side entry (LVSE) intake design; use of a behavioural cue at these intakes to deter fish; and use of a means of fish recovery from the screens in order to return fish and crustacean to sea in good condition.

19.5.14 This approach has permitted a direct translation of observed (and unmitigated) impingement levels at HPB across to predictions at HPC. The benefits of applying best practice in terms of mitigation are then considered in Section 19.8 of this chapter.

g) Accidents and Incidents

19.5.15 There is the risk of impact due to accidents occurring during construction (e.g. water quality changes due to chemical spillages and surface water discharges containing spilled/leaked contaminants) and, to a lesser degree, during operation. It is not possible to assess the potential impact of such incidents/accidents as they could vary significantly in scale, location and type with variable outcomes on potential receptors.

19.5.16 The implementation of best practice management measures during construction and operation will be the mechanism by which the potential risk of accidents occurring is managed and any consequential impacts are either eliminated or minimised.

19.6 Assessment of Impacts

a) Introduction

19.6.1 As a result of the very high suspended sediment concentration of the Inner Bristol Channel, the marine waters and the physical habitats and assemblages associated with them have a particularly low sensitivity to localised disturbances to the sediment regime. Similarly, as described in **Volume 2 Chapter 17**, the extremely dynamic nature of the Inner Bristol Channel (i.e. an extreme hyper-tidal range, associated with high current speeds), its physical scale and the level of temporal and spatial variance that are already the norm, due primarily to the tidal regime, strongly suggest that in order for any significant change to occur a human intervention in the system would, itself, have to be very significant. Within this context, the main marine infrastructure components considered as a part of this development are, in comparison, either of a very small scale (e.g. the intake-outfall structures) or designed so as to offer little hindrance to coastal processes (e.g. the temporary jetty). There are clear exceptions however, most obviously the issue of *Corallina* turf habitat discussed below.

19.6.2 With specific reference to the operational phase, whilst the scale of cooling water abstraction and discharge may appear from an anthropocentric perspective to be large, the physical scale and the level of temporal and spatial variance described above mean that the actual influence of these activities tends to be subtle and, even with considerable effort, difficult to discern. This is certainly the case for the thermal plume that will be associated with HPC. The plume will be characterised by localised increases in sea temperature and residual traces of contaminants, both of which will diminish with time and distance from the outfall and depth through the water column. The dynamic behaviour of this plume will be dictated by a combination of the effluent's low relative density and the ebb and flood tidal currents. The result is a relatively widespread but nonetheless subtle area of influence.

19.6.3 These physical processes not only lend themselves to numerical modelling but also, given the thermal signature of any existing plume's presence and the appropriate level of care, provide a means of calibration and validation of these models which then in turn permits a high level of confidence in their predictions. These predictions can extend to the outer reaches of that plume's influence. An ensemble of such predictive tools have been employed extensively in support of the assessment that follows within this chapter. The development of the models used in support of the HPC assessment is described within **Volume 2 Appendix 18A** of this ES.

19.6.4 Just as these issues of scale and variance are highly significant for any consideration of HPC within the context of the physical environment of the waters off Hinkley Point, any consideration of the ecology of these same waters is subject to the same conditions in terms of the biological response to these same conditions. In the simplest terms, the ecology is driven by and responsive to the scale and variance of the physical environment it inhabits. One of the consequences of that environment around Hinkley is that many of the species involved are highly resilient to variations in salinity, temperature and high levels of suspended solids. Many are also, through either reproductive or dispersal strategies, their migratory behaviours (both seasonal and tidal), and their form and habit, resilient to the degree of physical disturbance and tidal displacement which represent, in this hypertidal environment, the norm.

19.6.5 Whilst these attributes of the local marine and estuarine ecology are significant in considering the effects of construction-related disturbance and the potential impacts of the thermal plume, density dependence can also be significant when considering the potential impacts of impingement and entrainment. The general principle of density dependence is that increasing population size reduces available resources, limiting population growth. So when numbers of young fish are caught by either fishing activities or a power station this same principle suggests that survival and growth amongst the remainder of the population involved will increase. Due to the high level of complexity involved, density dependant factors such as this cannot be taken into account in the assessments completed below but, where this applies, it lends an additional level of precaution to the estimates used.

19.6.6 Having stated that elements of the physical environment are open to high levels of predictability, there are also significant elements of uncertainty fundamental to the assessments that follow. Populations of individual species will rise and fall within years and between years in a complex manner. This is most obviously the case for species that are well studied, such as commercial fishery stocks, but it will also be true for those not subject to this level of scrutiny. The baseline characterisation studies described above, and the population or stock size estimates utilised in the assessment that follows, provide reasonable understandings of the present day condition and are considered to be sufficient to need in this instance, but they are also subject to constant change. In sum, however, the functional components of that ecology will tend to track the physical regime, so although specific components of that ecology (such as an individual species population) will tend to increase and decrease in a complex fashion, the functionality and attributes of the assemblage as a whole will tend to behave more conservatively. This means that assessments made today, on the basis of good knowledge should, with care and maintenance of that assessment, remain relevant over time.

b) High value receptors

19.6.7 A number of receptors considered in this assessment are recognised as being of high value in conservation terms. For the purposes of predictions of impacts, however, the technical assessment has been developed on the basis of their sensitivity to the specific pressure or ‘stressor’ under consideration. Examples of where this approach has been used include the reef-building polychaete worm *Sabellaria alveolata* and the algal turf forming species *Corallina*. Despite this approach, the value of the receptor has nevertheless not been ignored in final determinations.

c) Potential Impacts during Construction

i. Habitat Loss and Change

19.6.8 A number of components of the construction works and activities will lead to small-scale habitat loss and/or change in existing habitat conditions. This section covers those activities that will lead to permanent loss of marine habitat (intertidal and subtidal) and/or permanent change. Temporary disturbance to habitat during construction is covered under the section on physical disturbance.

19.6.9 The location of the proposed temporary jetty in relation to the intertidal area is shown in **Figure 19.16**. The installation of piers to support the jetty would result in direct habitat loss in the intertidal area. Some 52 piers would be installed across the intertidal area and the footprint of these piers would cover an area of approximately 34m^2. These piers across the intertidal area would be installed by using a balance of land-based plant gaining access across the shore, and marine engineering plant, such as a jack-up barge or rig, working from seaward.

IMPACT: Intertidal Habitat Loss as a Result of Construction of the Temporary Jetty

19.6.10 The Hinkley intertidal area supports communities that, in terms of species composition, may be considered typical of such coastlines around much of the UK. The fucoids *Fucus spiralis* and *Fucus vesiculosus* in particular are typical of sheltered to moderately exposed shores and occupy much of the intertidal at Hinkley Point. These species are widespread in their distribution and are not species of conservation concern. With the exception of the *Corallina* habitat, this intertidal area is thus considered to be of medium value.

19.6.11 The *Corallina* swards are of significance as they have been identified as a notable community of the hard substrate habitat which is a sub-feature of the SAC.

19.6.12 There are no areas of intertidal or subtidal *Sabellaria* reef in close proximity to the proposed jetty location; this was confirmed both by an acoustic seabed survey and subsequent ground-truthing carried out to check this understanding locally (Ref. 19.35). The nearest area of *Sabellaria* reef is a small section within the intertidal >500m to the east (in front of HPA) and a wider area some 500m to the west. As no *Sabellaria* reef habitat is located close to the jetty no impact is anticipated for this receptor.

19.6.13 Thus whilst it is clear that some small-scale habitat loss would occur, the footprint of the jetty piles is negligible in relation to the area of the intertidal zone (**Figure 19.16**) and the magnitude of the effect on that intertidal area as a whole is, therefore, considered to be low. In addition the majority of the habitats represented within the intertidal area are common and the species involved are widely dispersed across the Hinkley Point intertidal and throughout the UK, suggesting medium value. Taking these factors into account, the impact of this small-scale loss is considered **minor adverse** with regard to the majority of the intertidal communities present. The presence of *Corallina* turf in the area, however, merits further consideration.

IMPACT: Loss of Corallina as a Result of Construction of the Temporary Jetty

19.6.14 The *Corallina* biotope is considered to be of high value. The locations of channels with *Corallina* and associated run-offs were mapped and are shown in relation to the proposed jetty in **Figure 19.17**. It can be seen that the jetty will be located in the vicinity of the western extent of the channels supporting *Corallina* but has been deliberately positioned between, rather than over, mapped areas of cross-channel features that are heavily colonised by this species (and can be described as maintaining *Corallina* turf).

19.6.15 Given the proposed siting of the temporary jetty, the scale of this habitat loss would be very small and it is likely that *Corallina* would only be present in parts of the habitat lost. In addition, recolonisation will occur after the removal of the jetty. Hence, the magnitude of this effect is predicted to be very low and the significance of the impact is assessed to be **minor adverse**.

IMPACT: Intertidal Habitat Change as a Result of Construction of the Seawall

19.6.16 The upper area of the shore where the seawall would be constructed is effectively unoccupied by marine species and dominated by cobble/shingle material associated with both washout from the cliff and storm-driven longshore transport. The biotope is classified as 'barren littoral shingle', as shown by **Figures 19.8-10**. Within the construction area itself, **no impact** upon marine fauna or flora would thus occur.

IMPACT: Subtidal Habitat Loss as a Result of the Construction of the Vertical Shafts for the Cooling Water System

19.6.17 Habitat loss would occur due to excavation of the seabed for the construction of vertical shafts connecting to the horizontal (intake and outfall) tunnels. Habitat loss/modification would be permanent for the area of the estuary bed required for the vertical shaft openings. It would be temporary at the anchoring locations (wet drill operation) and for the area around the vertical shaft opening.

19.6.18 The benthos of the area surrounding both the intake and outfall structures is typical of the extensive muddy plain that makes up most of the local seabed. Population densities are low due to the extreme tidal conditions. The most prevalent species around the proposed vertical shaft sites are the oligochaete *Tubificoides amplivasatus* and the polychaete *Nephtys*. All species identified are commonly found at a national level. The biotope concerned is '*Nephtys hombergii* and *Macoma balthica* in infralittoral sandy mud', also described as 'Mobile circalittoral sandy mud supporting a sparse faunal compliment', a biotope which covers approximately 76km^2 out of the total of 94km^2 surveyed locally – see **Figure 19.18** (Refs. 19.14 and 19.25). The habitat type which is likely to be lost is thus locally common and widespread as well as being common throughout estuaries in the UK.

19.6.19 The vertical intake shafts in total would represent a loss of subtidal habitat of approximately 58m^2. The area of the opening of the outfall vertical shafts would be approximately 39m^2. This represents significantly less than 0.1% of the area of the '*Nephtys hombergii* and *Macoma balthica* in infralittoral sandy mud' within Bridgwater Bay. In addition, during wet drilling, there would be temporary loss of habitat around the anchor sites, which would again probably be in the region of 0.1% of the area of the dominant biotope in Bridgwater Bay. The percentage of this habitat lost due to construction of the vertical shafts in relation to its local extent is considered to be small and, therefore, the magnitude of this effect is assessed as very low. The sensitivity of the receptor to impact is low and, thus, the significance of the impact is predicted to be **negligible**.

IMPACT: Indirect Impact to Subtidal Fauna as a Result of the Construction of the Vertical Shafts for the Cooling Water System

19.6.20 The predominant epifauna within the area is the brown shrimp *Crangon crangon*. As with other mobile epifaunal species, *C. Crangon* would be able to move away from the area to seek suitable nearby habitat and would be less affected by the habitat loss. In the areas of disturbance around the shafts a typical faunal assemblage would very quickly become re-established due to tidal mobilisation of surface sediments. Even in less dynamic systems the evidence from studies of recovery rates in subtidal benthic communities of the type present within the footprint of the works clearly demonstrates that soft-sediment, bivalve-annelid dominated communities are able to recover from disturbance events within one to two years (Ref. 19.161). As a result, the sensitivity of this habitat is considered to be low.

19.6.21 Overall, given that rapid recovery of affected areas within the construction footprint would be expected, the impact of this activity would be predominantly related to the small-scale habitat loss (as described above). The loss of this area of habitat would have a **negligible** impact upon the extent and functioning of the affected subtidal communities.

19.6.22 The small loss of subtidal habitat that would occur during construction of the shafts would not be expected to have any impact on prey availability for fish.

IMPACT: Sabellaria as a Result of the Construction of the Vertical Shafts for the Cooling Water System

19.6.23 Subtidal *Sabellaria* may be present at the vertical shaft sites, however, given the local habitat type involved, it is not anticipated that any reef formations would be present. Therefore, it is considered that there would be **no impact** on *Sabellaria* reef through construction of the vertical shafts.

IMPACT: Subtidal Habitat Change due to Capital and Maintenance Dredging

19.6.24 As noted in **Volume 2**, **Chapter 17**, the operating face of the jetty head will be aligned with the direction of ebb/flood tidal currents in the vicinity. A berthing pocket immediately associated with that operational area will be dredged in order to allow safe delivery of materials across a range of tidal conditions. This dredged area is estimated to be 160m in length and 27m in width with sediments removed to a uniform depth of around 3.5m below the existing seabed (4.5m below Chart Datum (CD)).

19.6.25 Given the uniform nature of the substrate with depth (Ref. 19.26) and the dominance of the tidal regime and the associated processes of sediment suspension, mobilisation and deposition, any physical habitat loss due to dredging within this chronically disturbed environment is expected to be of short duration, and given the dominant sedient transport regime a typical subtidal assemblage is likely to become re-established quickly thereafter.

19.6.26 Again, the benthos of this area is typical of the extensive muddy plain that makes up most of the local seabed. Population densities are low due to the extreme tidal conditions. All species identified are commonly found at a national level. The biotope concerned is *'Nephtys hombergii* and *Macoma balthica* in infralittoral sandy mud', also described as 'mobile circalittoral sandy mud supporting a sparse faunal compliment', a biotope which covers approximately 76km^2 out of the total of 94km^2 surveyed locally – see **Figure 19.18** (Refs. 19.14 and 19.25). The habitat type which is likely to be affected in this instance is thus locally common and widespread. Hence the magnitude of the effect is predicted to be low.

19.6.27 As with the area around the cooling water headworks, the predominant epifauna within the area is the brown shrimp *C. crangon*. As with other mobile epifaunal species, *C. crangon* would be able to move away from the area to seek suitable nearby habitat if need be. In the areas of disturbance both within the berthing pocket area itself and around its margins, a typical faunal assemblage would very quickly become re-established due to tidal mobilisation of surface sediments. Even in less dynamic systems the evidence from studies of recovery rates in subtidal benthic communities of the type present within the footprint of the works clearly demonstrates that soft-sediment, bivalve-annelid dominated communities are able to recover from disturbance events within one to two years (Ref. 19.161). As a result the sensitivity of this habitat is considered to be low.

19.6.28 On this basis, the significance of the impact has been assessed as **minor adverse**.

ii. Physical Disturbance

IMPACT: Disturbance to Intertidal Habitats during Construction of the Temporary Jetty

19.6.29 Several activities associated with the construction of the jetty may cause disturbance to the intertidal area within and adjacent to its footprint, including piling, dredging and the use of construction plant and materials. The impacts of dredging are discussed in Paragraph 19.6.42 below. Piling works (the drilling/piling and use of jack-up rigs) has the greatest potential to cause disturbance, along with the machinery movements required to emplace the jetty infrastructure. These activities may lead to the generation of debris (e.g. from drilling), channel blocking, smothering and the abrasion of rock surfaces supporting intertidal communities.

19.6.30 Plant and vehicles working on the intertidal shore itself will be deliberately constrained within narrow construction corridors no more than 20m wide to either flank of the jetty structure itself, and a similarly constrained 10m wide route along the top of the intertidal area (above MHWS) in order to provide landward access to the works. A wider corridor (75m to either flank of the line of the jetty) will limit the deployment of marine engineering plant, such as a piling barge.

19.6.31 The volumes of fine sediment generated during drilling and through disturbance by machinery on intertidal sediments are likely to be very low in comparison to the existing high sediment loadings present in the water column. The sensitivity of local habitats is considered to be medium, and the significance of this impact is therefore predicted to be **minor adverse**.

IMPACT: Disturbance to Sabellaria due to Construction of the Temporary Jetty

19.6.32 There is no observed occurrence of intertidal or subtidal habitat supporting *Sabellaria* reef within 500m of the jetty and therefore the likelihood of this receptor being directly impacted by the jetty construction works is considered highly unlikely. Although there is the potential for some sediment disturbed during construction to be transported into intertidal areas supporting *Sabellaria* reef, it is considered that the overall volumes would be negligible in the context of the high volumes of sediment routinely present in the water column. As such, **no impact** on *Sabellaria* reef is predicted in terms of this aspect of the temporary jetty construction works.

IMPACT: Disturbance to Corallina due to Pile Driving and Plant Movements

19.6.33 Disturbance to intertidal habitat in the vicinity of the jetty would be unlikely to affect the continuing presence of many of the intertidal species present (e.g. fucoid dominated communities). Given the species involved, the recolonisation of any disturbed areas would be expected to be relatively rapid (one to two years). No long-term effects would thus be expected.

19.6.34 However, as stated previously, *Corallina* turf is considered to be of importance as it provides a habitat for many other organisms; it is also, for this reason, recognised as a notable community of the hard substrate habitat which is a sub-feature of the SAC. It is, therefore, considered to be of high value. On the basis of the mapping work, the *Corallina* biotope intermittently occurs within an area of some 500m x 50m.

19.6.35 An additional factor is that the longshore drainage channels upon which the *Corallina* run-offs themselves depend tend to flow from east to west across the shore, implying that any disturbance to one of these channels may have an impact on habitat areas to the immediate west of the construction area. The jetty will be located towards the western end of the extent of the known distribution of *Corallina* (see **Figure 19.17**) and the alignment deliberately avoids the mapped *Corallina* spillways. Even if the construction area activities were to extend further than 20m from the actual alignment of the jetty itself, this suggests that in total an area of less than 4% of *Corallina* biotope area (*c*. 118,800m^2 within the vicinity of Hinkley Point) would be present within the footprint of the works, although this area would increase if a longshore drainage channel were to be compromised. This would nonetheless represent a relatively small area and indicates that even if all of the *Corallina* biotope within this wider area were disturbed, which would be highly unlikely, this change would be of very low magnitude, resulting in a **minor adverse** impact.

IMPACT: Intertidal Habitats due to Scour Associated with Jetty Piers

19.6.36 An expert assessment of the level of sediment scour (see **Volume 2, Chapter 17** for further information) that would be associated with the jetty piles due to waves and tidal streams has shown that soft sediments would be scoured to a depth of no more than 1.3m in the immediate vicinity of the piers themselves.

19.6.37 The top width of a scour hole in non-cohesive sediments is a function of the scour depth and the angle of repose of the sediment involved. As a conservative measure, the angle of repose associated with a loose fine sand would be in the order of 26-28°

which translates into an area around each pier foot, in soft sediment, of no more than a couple of metres.

19.6.38 This impact on sediment distribution would be limited to the length of the jetty that extends across the muddy seabed. The extent of this disturbance feature around the piers themselves is predicted to be very low and would be confined to a habitat type (i.e. soft sediment) that is subject to continual remobilisation due to tidal forces, and thus of very low sensitivity. The sediment transport processes associated with scour are normal to this hypertidal (>6m tidal range) habitat and the impact associated with this element of disturbance is, thus, assessed as **negligible**.

19.6.39 The effect described above would not occur in association with the piers introduced across the exposed rocky platform of the intertidal shore or the exposed rock that the line of the jetty will cross in the near subtidal area. Shear forces around the foot of these structures will be increased and could result in a loss of fauna and flora in the immediate area around each. Again, the extent of this disturbance feature around the piles themselves is predicted to be very limited and any loss of associated flora and fauna of very low magnitude. The impact associated with this element of disturbance is thus assessed as **negligible**.

19.6.40 **Volume 2**, **Chapter 17** discusses the potential impact of construction works on the superficial geology of the cross-shore rock platform flanking the jetty, and recognises that a moderate adverse impact may occur due to the high sensitivity of the receptor but relatively low magnitude of the effect involved.

IMPACT: Intertidal Disturbance Associated with Construction of the Seawall

19.6.41 Under the existing coastline configuration, the alignment of the proposed seawall places it above the Mean High Water Mark.

19.6.42 The construction works would require that machinery for the excavation works and actual placement of the seawall have access to the upper intertidal area, either on a permanent or temporary basis depending on whether tidal conditions permit. Given that rock from the upper intertidal area would be removed during excavation (this impact is covered under the section on habitat loss/change, see above), further disturbance would therefore be limited to any additional effect that machinery operating along the upper shore would have on existing intertidal communities.

19.6.43 There is also the potential for some sediment release during the excavation and construction of the seawall. The volume of sediment released is anticipated to be minimal and is unlikely to result in any noticeable increase in sedimentation on the intertidal area either in isolation or in combination with other construction activities.

19.6.44 A 30m wide construction zone will be established fronting the HPC Development Site and all works on the sea wall confined to this zone. **Figure 19.35** shows the extent of that zone in relation to intertidal habitat distribution (Ref. 19.55). The biotopes that would be involved within the footprint of this zone are (areas rounded to nearest 10 m^2 and indications of recoverability from MarLIN database: http://www.marlin.ac.uk/):

- Eunis A1.32; 1,200 m^2; 'Fucoids on variable salinity rock'; high recoverability (full recovery within about 5 years).
- Eunis A1.321; 4,530 m^2; '[*Pelvetia canaliculata*] on sheltered variable salinity littoral fringe rock'; moderate recoverability (full recovery up to 10 years).
- Eunis A1.322: 1,710 m^2; '[*Fucus spiralis*] on sheltered variable salinity upper eulittoral rock'; high recoverability (full recovery within about five years).
- Eunis A1.421: 430 m^2; 'Green seaweeds [*Enteromorpha spp.*] and [*Cladophora spp.*] in shallow upper shore rockpools'; very high recoverability (full recovery within at most 6 months).
- Eunis A2.111: 17,880 m^2; 'Barren littoral shingle'; no intolerance to disturbance.

19.6.45 This 30m zone would not encroach into the area that supports the local *Corallina* turf interest and, at is nearest point, would be some 40m from the habitat supporting that interest.

19.6.46 The works would be temporary and no permanent loss of habitat would occur.

19.6.47 The biotopes directly involved in these temporary works, and listed above, would recover within a reasonable timespan from the disturbance generated by the works. Each is widespread locally and typical of this part of the Bristol Channel.

19.6.48 Whilst the loss of some areas of biotope would occur while this construction zone is in use, given the relatively short duration of the works and the generally high level of recoverability involved, this suggests that sensitivity is low. Given that a frontage of approximately 750m long will be disturbed, the magnitude of the effect is considered to be medium. A **minor adverse** impact is thus predicted.

IMPACT: Disturbance to Corallina due to Construction of the Seawall

19.6.49 The observed distribution of the *Corallina* biotope shows that the nearest occurrence is approximately 75m from the site of the proposed seawall. Given the distance between the seawall and the presence of *Corallina* it is considered unlikely that the seawall works would have the potential to impact upon this interest. As a consequence, **no impact** on *Corallina* as a result of the construction works for the seawall is anticipated.

IMPACT: Intertidal Disturbance Associated with Delivery of Rock Armour for Sea Wall

19.6.50 Two layers of rock armour (total thickness 2.5m, nominal rock diameter 1.35m, median rock mass 6.54t) will be placed at the toe of the sea wall in order to protect that toe from scour and beach lowering. This armour will be placed along a frontage of approximately 760m. Rock armour would be delivered by barge directly to the Hinkley frontage and temporarily placed seaward of the works area to provide protection during sea wall construction.

19.6.51 Vessels grounding on the shore as the tide falls may cause some physical damage to that shore but this will be limited to localised abrasion on initial grounding and the subsequent presence of that passive mass over the surface over the low tidal period. Damage to physical and ecological receptors would generally be minor, with one potential exception: if the activity were to occur over areas of *Sabellaria* colony, loss of localised elements of reef within the berthing footprint involved may occur.

19.6.52 Unloading and transport of materials will involve the movement of vehicles across the shore. If this were to involve the areas of limestone/shale platform, compaction and subsequent erosive loss of the area could be presumed. If this were to involve areas of *Sabellaria* reef, loss of that reef within the affected area could be presumed. Again if this activity were to extend within the limestone shale platform areas, an impact on the *Corallina* interest could be presumed, both through direct loss or compromise to the longshore drainage channels which support that particular interest (for each of these interests, see Ref.19.55 and **Figure 19.36**).

19.6.53 To avoid physical disturbance to sensitive habitats due either to the grounding of barges or the passage of vehicles, a graphical analysis was been completed in order to constrain the berthing activity to a relatively insensitive intertidal area. The need was to avoid interference with both physical features (most obviously the widely distributed cross-shore rock platforms that are typical of the Hinkley Point frontage) and the potentially sensitive biotopes (both the *Corallina* interest associated with these same rock platforms plus *Sabellaria* reef – see Ref. 19.55), whilst also finding an area of the shore whose topography and surface would be suitable for the operation involved.

19.6.54 **Figure 19.36** shows the intertidal area selected. The barge landing area is largely coincident with the historical graving dock associated with the construction of the substantial HPA/B cooling water intake structure currently positioned offshore. It would be limited at its eastern and western boundaries by rock platform habitat, and on its downshore boundary by *Sabellaria* reef. As a precautionary measure, no vessel would be permitted to come to ground outside an inner perimeter set back 50m from each of these boundaries. This would permit flat bottomed barges to be brought close to shore during a high tide, permitting them to ground over the subsequent low water period and be unloaded, without damaging potentially sensitive receptors.

19.6.55 The biotopes associated with this area (inner zone only) are (areas rounded to nearest 10 m^2 and indications provided of recoverability from MarLIN database: http://www.marlin.ac.uk/):

- Eunis A1.32; 1,757 m^2; ‘Fucoids on variable salinity rock’; high recoverability (full recovery within about 5 years).
- Eunis A1.321; 248 m^2; ‘[*Pelvetia canaliculata*] on sheltered variable salinity littoral fringe rock’; moderate recoverability (full recovery up to 10 years).
- Eunis A1.322; 1,368 m^2; ‘[*Fucus spiralis*] on sheltered variable salinity upper eulittoral rock’; high recoverability (full recovery within about five years).

- Eunis A1.323/A1.326; 4,668 m^2; [*Fucus vesiculosus*] on variable salinity mid eulittoral boulders and stable mixed substrata/[*Fucus serratus*] and [large *Mytilus edulis*] on variable salinity lower eulittoral rock; high recoverability (full recovery within about 5 years).
- Eunis A1.46; 415 m^2; 'Barren rock' or 'hydrolittoral soft rock'; no intolerance to disturbance.
- Eunis A2.111; 3,255 m^2; 'Barren littoral shingle'; no intolerance to disturbance.
- Eunis A2.431; 3,097 m^2; Barnacles and [*Littorina spp.*] on unstable eulittoral mixed substrata; high recoverability (full recovery within about five years).

19.6.56 In practice, the actual area of impact will be very much more limited than the areas above suggest, determined by the actual berthing location chosen within this barge landing area on the basis of navigational practicability, and the route taken by vehicles between the sea wall construction zone and the grounded barge. The most likely berthing area within the restricted zone is characterised as Eunis A1.46, described by MarLIN as having no intolerance to disturbance.

19.6.57 Whilst the loss of some areas of biotope will occur while this barge berthing area is in use, the relatively short duration of the works and the generally high level of recoverability involved suggests that sensitivity is low. Given that, as a worst case, a moderate area of the intertidal shore may potentially be disturbed, the magnitude of the effect is considered to be medium. A **minor adverse** impact is thus predicted.

IMPACT: Disturbance to Subtidal Habitats during Construction of Vertical Shafts for the Cooling Water System

19.6.58 Drilling of the shafts would physically disturb sediment on the estuary bed. The method of anchoring during a wet drill approach would result in varying degrees of disturbance; for example, simple anchors would result in a lesser impact than those requiring piling, and the drilling of these would disturb bottom sediments.

19.6.59 The level of seabed sediment scour around the construction-site is likely to be sufficient to remove the 2m of silt overlying the rock surface locally. Given the existing tidal and sediment transport regime this impact, in sediment transport terms, will be of little consequence.

19.6.60 The main impact of this disturbance would be a localised alteration in habitat type away from soft mud to exposed rock. The scale of this disturbance in relation to the widespread nature of the existing muddy plain that extends widely around this location would be inconsequential and, thus, its magnitude would be very low. Given the continual process of tidally driven suspension, deposition and re-suspension normal to the local muddy plain, the sensitivity of the receptor is also very low; resulting in an impact of **negligible** significance.

IMPACT: Disturbance to Subtidal Habitats due to Increased Suspended Sediments Associated with the Construction of the Vertical Shafts

19.6.61 It is considered highly unlikely that the drilling works would produce levels of suspended solids or bedloads that would, beyond a distance at most a few hundred meters downstream of operation, be greater than levels that occur under natural conditions. For both the local infauna and epifauna as well as the estuarine fish populations, already selected by the prevailing conditions of extreme turbidity, this suggests both a low magnitude effect and very low sensitivity. As a consequence a **negligible** impact is predicted.

IMPACT: Subtidal Habitat Disturbance due to Capital and Maintenance Dredging

19.6.62 As noted in **Volume 2**, **Chapter 17**, the operating face of the jetty head will be aligned with the direction of ebb/flood tidal currents in the vicinity. A berthing pocket immediately associated with that operational area will be dredged in order to allow safe delivery of materials across a range of tidal conditions. This dredged area is estimated to be 160m in length and 27m in width with sediments removed to a uniform depth of around 3.5m below the existing seabed (4.5m below CD).

19.6.63 The benthos of this area is typical of the extensive muddy plain that makes up most of the local seabed. Population densities are low due to the extreme tidal conditions. All species identified are commonly found at a national level. The biotope concerned is *'Nephtys hombergii* and *Macoma balthica* in infralittoral sandy mud', also described as 'mobile circalittoral sandy mud supporting a sparse faunal compliment', a biotope which covers approximately 76km^2 out of the total of 94km^2 surveyed locally (**Figure 19.18**, Refs. 19.14 and 19.25). The habitat type which is likely to be affected in this instance is thus locally common and widespread with no protected species; as a result the magnitude of the effect would be low.

19.6.64 Given the existing tidal regime and the associated processes of sediment suspension, mobilisation and deposition, any observable impact due to dredging in this chronically disturbed environment is expected to be of short duration.

19.6.65 As with the area around the cooling water headworks, the predominant epifauna within the area is the brown shrimp *C. crangon*. As with other mobile species, *C. crangon* would be able to move away from the area to seek suitable nearby habitat if need be. In the areas of disturbance both within the berthing pocket area itself and around its margins, a typical faunal assemblage would very quickly become re-established due to tidal mobilisation of surface sediments. Even in less dynamic systems the evidence from studies of recovery rates in subtidal benthic communities of the type present within the footprint of the works clearly demonstrates that soft-sediment, bivalve-annelid dominated communities are able to recover from disturbance events within one to two years (Ref. 19.161). As a result the sensitivity of this habitat to disturbance is considered to be low.

19.6.66 On this basis the significance of the impact is assessed as **minor adverse**.

iii. Changes in Water Quality

IMPACT: Subtidal Habitats due to Spread of Contaminants during Dredging

19.6.67 Capital and, potentially, maintenance dredging, will be required at the seaward end of the jetty to establish and maintain a berthing pocket. Dredging will mobilise sediments and re-suspend particulates in the water column, leading to a temporary and localised increase in suspended solids concentrations and a potential reduction in water quality. Information on existing contaminant loadings within the sediment to be dredged (see **Volume 2**, **Chapter 18**) indicates that there would be a negligible effect on water quality through the mobilisation of this material and thus a **negligible** impact on the local ecology.

IMPACT: Corallina due Changes in Water Quality Associated with Dredging

19.6.68 Although this dredging activity will occur in relatively close proximity to the low water mark and the *Corallina* run-off areas of the lower shore, given the existing tidal regime, any suspended solids in excess of normal levels would largely be advected by the tides and carried elsewhere. A very low magnitude effect would be expected on the *Corallina* run-off feature (i.e. it is expected that the receptor would experience little or no degradation and disturbance is likely to be within the range of natural variability). The sensitivity of the receptor can be regarded as high, on a precautionary basis, given that it is a notable community under the SAC designation. However, given the intermittent presence of the identifiable habitats and their distance from the works, and the fact that *Corallina* is locally selected by the prevailing turbidity regime, in this case its sensitivity is judged to be low. Consequently, the significance of this impact would be **negligible**.

IMPACT: Sabellaria due to Changes in Water Quality Associated with Dredging

19.6.69 Advice provided in Section 5 under Regulation 33(2)(a) of the Habitats Regulations (Ref. 19.114) identifies that *Sabellaria* reef has a moderate level of vulnerability to changes in concentrations of suspended solids. As with *Corallina*, however*, Sabellaria* is locally selected by the prevailing turbidity regime.

19.6.70 The site of the berthing pocket is located greater than 500m away from any areas of intertidal *Sabellaria* reef. Hence, the likelihood of *Sabellaria* being impacted by an increase in suspended solids that would be sufficient to have an adverse effect upon this species is considered very low. The receptor value is nevertheless high as *Sabellaria* reef is an Annex I Habitat, although it's sensitively is considered to be low in this environment. Overall, given the lack of *Sabellaria* in close proximity to the jetty, a **negligible** impact is predicted.

IMPACT: Subtidal Habitats due to Drilling of the Vertical Shafts for the Cooling Water System

19.6.71 During drilling the excavated materials will be mixed with seawater prior to being separated at the water surface. Cuttings with particles larger than 100 microns will be diverted to a barge and sludge re-injected until it reaches a limiting density, at which point this will be diverted to a sludge treatment barge. Filtering would separate solids and seawater, with the seawater being recycled and then released back into the Bristol Channel.

19.6.72 During the drilling works, some sediment from beneath the mobile sediment layer may potentially be disturbed and re-suspended. The volume of sediment likely to be mobilised in this manner is expected to be negligible within the context of existing suspended sediment and bedload concentrations.

19.6.73 The available data show that contaminant levels within the area are relatively evenly spread due to the dynamic tidal flow conditions and regime of continuous re-suspension. This understanding is described in **Volume 2**, **Chapter 18** on Marine Water and Sediment Quality. In this context, and given the low volumes that would be involved, it is anticipated that the impact of any remobilised contaminants on water quality would be negligible. Thus the consequence for the local marine ecology would be a low magnitude effect, set against a very low sensitivity, likewise suggesting an impact of **negligible** significance.

IMPACT: Discharges Associated with the Drilling of the Cooling Water and Fish Recovery Return Tunnels

19.6.74 A variety of discharges will arise from the construction-site, as described below. An offshore discharge location will only become available when the HPC cooling water (CW) system is commissioned; until that time an alternative temporary discharge route has been identified. The impact of commissioning discharges is not described here, but is considered later within this Chapter in the context of the Operational Impacts. The sections below summarise the waste streams involved (greater detail can be found in **Volume 2**, **Chapter 18**) and concludes with an assessment of the consequence of use of the temporary discharge route for marine ecological receptors.

19.6.75 Three main cooling water tunnels will be driven from the land under the seawall, intertidal shore and seabed using dedicated Tunnel Boring Machines. In addition, a further shorter and narrower tunnel will be driven, again from landward, under the seawall and intertidal shore in order to provide a discharge route for the proposed Fish Recovery and Return (FRR) system (described in detail in **Section 19.8** below on mitigation measures).

19.6.76 Some detail of the waste arisings from the cooling water tunnelling operation are described here but quantifications are not yet available for the similar, but very much smaller, FRR operation. For the purpose of this assessment it is taken that the waste arising from that smaller but immediately local operation will be dealt with in precisely the same manner as the cooling water tunnel arisings and will thus not alter the assessment outcome below.

19.6.77 Tunnelling arisings will be recovered to land where they will be treated to separate waste solids from waste water and drilling fluids.

19.6.78 In practice, bentonite-based drilling mud will only be used if geological conditions prove difficult. Consequently a precautionary approach has been taken here which assumes use of the mud-assisted drilling method.

19.6.79 The volume of extracted material in drilling these tunnels would be approximately 577,000m^3 to 650,000m^3 depending on the expansion factor used. While the tunnel machine digs, any bentonite slurry would be sent to the cutting face, become loaded with materials and would then be returned to a separation unit where it would be treated to remove drill cuttings. Dilution water would need to be added to any bentonite and the volume needed for this would be about 60m^3 per hour for the three tunnels, therefore a similar quantity would need to be discharged. This drilling waste could include release of drilling compounds such as bentonite and other chemicals (e.g. organic polymer and residual salt compounds following pH control). Current estimates are that such waste water would contain up to 1,000mg.l^{-1} suspended solids (including 5% bentonite) and 0.7ppm of organic polymers.

19.6.80 These discharges would go to sea via the discharge structure established at the top of the intertidal area. Design studies have considered a number of potential single and multiple outfall configurations and these were tested using a hydraulic model in order to investigate their possible impact on the intertidal shore. The configuration that was selected through that modelling exercise was a single outlet that would result in a relatively confined effluent stream discharge route across the intertidal shore, to the eastern flank of the one-time HPA/B graving dock. This routing will avoid any cross-shore spillage intersecting with sensitive features, such as the longshore drainage routes associated with *Corallina*.

19.6.81 Thus at no point will this discharge route intersect with the *Corallina* interest either directly or via long-shore drainage channels. As noted in Appendix 19A, the influence of suspended solids would have **no impact** on the local *Corallina* and *Sabellaria* interests, and any fresh water input involved would have **no impact** upon the local *Corallina* interest and have **negligible** impact upon *Sabellaria*.

IMPACT: Sewage, Dewatering and Surface Drainage

19.6.82 Sewage and associated wastes associated with the construction workforce will be treated to a tertiary level via package treatment plant prior to discharge, providing a high quality of effluent at point of discharge to the shore. Further details are provided in **Volume 2**, **Chapter 18**.

19.6.83 Surface drainage from the site together with dewatering effluent from the HPC Development Site will also, further to interception, be put to the cross-shore discharge. The base characteristics will be low salinity water plus suspended solids. Again, further details are provided in **Volume 2**, **Chapter 18**.

19.6.84 The discharge of these various waste waters has the potential to impact upon intertidal ecology via their variable salinity, suspended solids composition, and volume.

19.6.85 The high suspended sediment concentration could potentially cause smothering as a result of accretion of fine sediment. Data from existing sources indicate that suspended sediment concentrations in surface waters in the nearshore zone are typically in the order of 250mg/l but can be as high as 1,000mg/l – see **Volume 2**, **Chapter 18**.

19.6.86 As noted above, these discharges would go to sea via the discharge structure established at the top of the intertidal area. Design studies have considered a number of potential single and multiple outfall configurations and these were tested using a hydraulic model in order to investigate their possible impact on the intertidal shore. The configuration that was selected through that modelling exercise was a single outlet that would result in a relatively confined effluent stream discharge route across the intertidal shore, to the eastern flank of the one-time HPA/B graving dock. This routing will avoid any cross-shore spillage intersecting with sensitive features, such as the longshore drainage routes associated with *Corallina*. **Figure 19.19** shows the course of that modelled effluent stream discharge route in relation to biotope mapping, and **Appendix 19A** provides further information on the range of options examined and the allied assessments of impact upon the local marine ecology.

19.6.87 **Figure 19.19** shows both the modelled cross-shore drainage from HPB and a modelled flow pattern associated with the planned discharge structure. At times of low water, the existing discharge, entirely of surface water run-off, crosses a variety of intermediate intertidal biotopes before reaching the lower shore and percolating through an extensive downshore slope of low grade *Sabellaria* reef. The proposed discharge will flow downslope further to the east, firstly across 'barren littoral shingle' biotope then, in turn, '*Pelvetia* on sheltered variable salinity littoral fringe rock', '*Fucus spiralis* on sheltered variable salinity upper eulittoral rock', 'barnacles and *Littorina* spp. on unstable eulittoral mixed substrata', 'hydrolittoral soft rock', and then finally 'a limited downshore extent of '*Sabellaria* reefs on sand-abraded eulittoral rock' – an eastward extension of the same area of low-grade reef currently influenced by the existing surface water drainage.

19.6.88 At no point will this discharge route intersect with the *Corallina* interest either directly or via long-shore drainage channels. As noted in Appendix 19A, the influence of suspended solids would have **no impact** on the local *Corallina* and *Sabellaria* interests, and the fresh water input involved would have **no impact** upon the local *Corallina* interest and have **negligible** impact upon *Sabellaria*.

IMPACT: Corallina due to Discharges Associated with the Drilling of the Cooling Water and Fish Recovery Return Tunnels

19.6.89 Baseline studies have shown that *Corallina* is present within distinctive channels and run-offs along the lower intertidal area, and since any cross-shore discharges could potentially enter these channels and remain there at low tide, a smothering impact is possible. More significantly, a discharge flow might run directly across the *Corallina* run-offs. One of the reasons for the success of the rare *Corallina* run-off biotope on the Hinkley intertidal is the presence of water cover during low tide exposure also allowing high light levels on the alga, a situation not present elsewhere in this region. Excessively high turbidity in discharged water may, if it were to flow towards the *Corallina* run-offs, cause harm. Alterations in salinity, in pH, in turbidity and the presence of organic polymers as well as increased rates of water flow (erosion) are all potentially significant adverse effects on the *Corallina* run-offs. The sensitivity of the algal turf receptor is considered high, but given the mitigation already in place in terms of deliberate placement of the discharge point so as to avoid this particular receptor, the magnitude of any effect is predicted to be very low and the significance of the impact **minor adverse**.

IMPACT: Sabellaria due to Discharges Associated with the Drilling of the Cooling Water and Fish Recovery Return Tunnels

19.6.90 Habitat that supports low grade *Sabellaria* reef of low to medium ‘reefiness’ is present on the lower intertidal area and so there is some potential for discharge from the upper shore to affect this area. **Figure 19.19** shows that the existing surface water drainage discharge already flows into a wider area occupied by that species. On the basis of this observation together with an understanding of estuarine habit and the turbidity regime to which that species is adapted, the sensitivity of this receptor is considered low. The discharged waters would encroach upon lower intertidal habitat only around the time of low tide, reducing the magnitude of the effect to low and leading to an impact of **minor adverse** significance.

IMPACT: Intertidal due to Sedimentation Associated with Discharges

19.6.91 The volumes and suspended solids involved in this discharge may alter the pattern of sedimentation within the modelled area of flow across the intertidal shore. This influence will compete with those of wave and tide, which will in turn rework any materials added or displaced. As the biotope map shows, a significant part of the route of flow will be over rock and shingle and only a limited area involves ‘mixed substrata’ – predominantly limestone cobbles mixed with mud and sandy mud. The impact of variable flow plus suspended solids is thus considered to be of low magnitude and the biotopes involved of low sensitivity; suggesting that a **minor adverse** impact would arise.

IMPACT: Intertidal due to Salinity Associated with Discharges

19.6.92 The discharge will be of variable salinity. Surface water drainage and dewatering water will be of low salinity whilst waste water arising from the tunnelling activities is likely to be variable. As noted above, the existing biotopes which will be crossed by this discharge are frequently described as of ‘variable salinity’ – or are bare rock or barren shingle; the lower shore is occupied by *Sabellaria*, the potential impact on which has already been discussed. On this basis, the sensitivity of the wider intertidal fauna and flora that might be harmed in this instance is considered to be low, and the magnitude of the effect is predicted to be low; hence a **minor adverse** impact is predicted.

IMPACT: Fish due to Increased Suspended Solids Associated with Discharges

19.6.93 Any increase in local suspended solids concentrations associated with these discharges will have the potential to decrease water quality in the vicinity. This could affect fish that may be present in the water column. As discussed previously, the fish assemblage is inevitably well adapted to the existing high turbidity regime and any such alterations to this regime would thus appear to be inconsequential.

19.6.94 While the suspended solids levels associated with the discharge may at times be above background levels, dispersion to background levels would occur over a relatively short distance, suggesting a low magnitude effect. Given that fish are also mobile and would be able to move rapidly out of any waters that are of poor quality, their sensitivity is regarded to be low. Hence the significance of the impact would be **minor adverse**.

IMPACT: Corallina due to Construction of the Seawall

19.6.95 During construction of the seawall there are a number of activities and processes that may lead to a reduction in water quality (as a result of the discharge of potentially contaminated water across the intertidal). The excavation footings for the foundation of the seawall may need to be dewatered and discharge onto the upper intertidal area is likely to be the main route of disposal. This discharge and the excavation works may lead to a localised increase in suspended sediment concentrations.

19.6.96 The location of the seawall works on the uppermost part of the shoreline and largely above MHWS, suggests that the potential for any significant effect on water quality and in turn on the local ecology in the nearshore zone is unlikely. Under high tide conditions, any discharges from the construction area, even if containing relatively high suspended sediment concentrations, would be rapidly dispersed and it is anticipated that background conditions would be achieved close to the points of discharge.

19.6.97 Under low tide conditions, discharges across the upper intertidal area are likely to infiltrate the existing substrates (as they are permeable) and any fine sediment would be anticipated to be washed into the upper beach fabric or deposited in existing areas of mud. Although this depends on the volume of the discharges, it is considered unlikely that they would be of sufficient strength to reach the *Corallina* community present on the lower-mid shore. Even if the discharge were to reach this area and the drainage collected in channels containing *Corallina*, very similar events are understood to occur naturally with rainwater draining off the intertidal area. With the effects of tidal shear these materials would quickly be re-suspended and dispersed. Little impact is thus envisaged on the wider ecology of the shore.

19.6.98 Taking these aspects into consideration, the magnitude of the effect on intertidal communities, and in particular *Corallina*, is thus predicted to be very low. *Corallina* is known (MarLIN) to be moderately well adapted to the periodic natural exposure to extreme salinity variations. It is, however, considered to be of high value in conservation terms. Consequently, the significance of the impact is assessed to be **minor adverse** for this receptor.

IMPACT: Sabellaria due to Construction of the Seawall

19.6.99 Extents of low to medium ‘reefiness’ grade *Sabellaria* reef are present on the lower intertidal several hundreds of metres away from the proposed seawall construction area on the upper shore (**Figures 19.8-10**). It is thus unlikely that any discharge from the seawall construction works would reach the lower intertidal areas supporting *Sabellaria*; even should it do so any such discharge would be diluted or greatly dispersed. **No impact** on this conservation interest feature is thus expected (potential in-combination effects are considered in **Section 19.7** below).

IMPACT: Fish due to Construction of the Seawall

19.6.100 While fish may be present in the vicinity of the discharged waters, it is not anticipated that they would be affected by the discharges as they are fully mobile and able to respond rapidly to an adverse increase in either suspended sediment concentration levels and/or contaminant levels. Given their mobility, **no impact** with respect to fish populations is anticipated.

iv. Noise and Vibration

d) Introduction

19.6.101 A number of construction activities have the potential to generate a significant increase in background noise and vibration levels in marine waters. These aspects of the construction works include: the drilling works for the intake and outfall shafts, construction, operation and dismantling of the temporary jetty and construction of the seawall. No noise and vibration is likely to be caused by land based drainage.

19.6.102 The potential marine receptors are fish and marine mammals, both of which are known to be sensitive to noise disturbance. As a result, both the sensitivity of fish to noise and the scale of noise that might be involved have been reviewed (Ref. 19.56) and as described earlier in this chapter, following recent guidance from JNCC (Ref. 19.155), an array of underwater acoustic sensors has been established both local to the site and on a transect offshore in order to characterise the cetacean interest (Ref. 19.57).

19.6.103 During construction of the shafts for the intake and outfall tunnels the main sources for the generation of noise and vibration will be any piling works and vessel movements around the construction areas themselves. There is no information currently available regarding the types of piling expected to be used (e.g. impact, rotary or vibro piling) so for the purposes of this assessment, as a worst case, it is assumed that percussion piling will be used. Vessel movement noise will be generated regardless of whether piling is used or not.

19.6.104 For the temporary jetty, piling works as well as general construction works would be the main sources of noise and vibration during construction and vessel noise during construction. Details of the construction methodology for the temporary jetty are presented in **Volume 2**, **Chapter 3**.

19.6.105 General activities, including the re-profiling of the cliff face, will generate noise during construction of the seawall. However, given that these works would occur above MHWS the potential for causing an effect to marine species sensitive to acoustic disturbance within the water column is considered negligible. As such the potential impact of noise generated during construction of the seawall is not considered any further in this assessment. The potential effect of noise disturbance on birds that may be utilising the intertidal area during construction of the seawall and the aggregate jetty is covered in **Volume 2**, **Chapter 20** on Terrestrial Ecology and Ornithology'.

Piling Noise – Intake and Outfall Structures and Temporary Jetty

19.6.106 No specific values for the predicted noise levels which could be generated by pile driving during the construction phase for the proposed HPC are yet available as this depends on the technique and equipment to be used. However, a number of previous studies have examined noise levels during construction of coastal developments requiring pile driving. Pile driving has been found to generate sound pressures significantly greater than 192dB re: 1µPa (Ref. 19.162) (Note: the SI unit for the measurement of sound in water is decibels relative (dB re:) to a reference pressure (1µPa)). The level of sound generated can vary in relation to different factors including the size of piles and the scale of the operation (Ref. 19.163).

19.6.107 Studies reported in Ref. 19.164 measuring the sound levels associated with percussive piling found variation in peak to peak pressure changed from 195dB at the pile driver, to approximately 152dB at a distance of about 240m, with a linear decline in sound pressure with distance (measured in metres). 150dB is considered the safe threshold for no physical effects.

19.6.108 The same study (Ref. 19.164) found that at a distance of about 400m from the source of the sound no signal of vibratory piling could be detected, as it was drowned by shipping noise. It also found no evidence that trout reacted to vibro-piling at even a close range of less than 50m. It is probable that the lack of behavioural responses was largely due to the sound energy from the piling being at frequencies at which the fish were relatively insensitive.

Noise Associated with Drilling Works

19.6.109 As described in **Volume 2**, **Chapters 2** and **3** of this ES, a series of three cooling water tunnels will be dry bored from land under the seawall and seabed, in the dry, and two vertical shafts will be wet drilled offshore to meet each of these. In addition a single shorter tunnel to service the FRR discharge will be bored, again from land, to exit in the near subtidal.

19.6.110 No explicit information is available on the level of sound that might be associated with the wet drilling operation, but it is expected that the sound levels involved will be similar to those associated with allied piling activities, and thus have a range of influence of a few hundred meters at most (Ref. 19.56).

19.6.111 The three main cooling water tunnels will be bored by dedicated Tunnel Boring Machines at a depth of between 20 and 40m below the seabed, through a solid rock geology. As a result very little noise is expected to reach the marine environment.

19.6.112 The FRR tunnel will be bored at depth under the seawall and intertidal shore; again, very little if any noise would be expected to reach the marine environment.

Vessel Noise during Construction of the Cooling Water System, Dredging Works for the Temporary Jetty and Operational Traffic using the Temporary Jetty

19.6.113 The construction of the vertical shafts for the intake and outfall structure is likely to require a variety of vessels to move platforms and associated equipment into place, collect discharges, collect and transport drill cuttings and other waste materials, and supply plant and personnel to site.

19.6.114 Capital dredging and possibly maintenance dredging will be required for the berthing pocket at the end of the temporary jetty.

19.6.115 Very large tankers and container ships can generate sound levels in the range 180-190dB re: 1µPa at 1m which is similar to that generated by pile driving (Ref. 19.165) although for smaller vessels the potential impact is greatly reduced. **Table 19.21** shows the sound frequencies and source levels produced by various vessels that may be required during the construction of the proposed development.

Table 19.21: Vessel Sound Frequencies and Source Levels

Vessel	Frequency (Hz)	Source level (dB re 1µPa @ 1m)
Supply vessel	20 – 1,000	110 – 135 (without thrusters) 121 – 146 (with thrusters)
Fishing boat	250 – 1,000	151
Tug (pulling empty barge)	37 – 5,000	145 – 166
Tug (pulling loaded barge)	1,000 – 5,000	161 – 170
Twin diesel work boat	630	159

19.6.116 Ref. 19.165 provides a review of underwater noise in relation to marine dredging and construction activities. Generally, noise generated by dredgers depends on the type of vessel and the activity that is being undertaken. A study by Cefas (Ref. 19.166) of sound levels generated during aggregate dredging found that sound pressure levels were generally found to fall below the ambient noise level (100dB re 1~Pa) within 25km, however some dredging vessel activities were found to emit strong tonal sounds which were detectable at distances greater than 25km. Low frequency sounds were found to be generated by the dredger maintaining its position. Higher frequency sounds (>2kHz) were generated by full dredging activities whilst maintaining position.

19.6.117 Large vessels can cause an aural and potentially a visual disturbance for fish. Generally, vessel noise can elicit avoidance or attraction responses in fish at very low or very high frequencies (Ref. 19.167). Some behavioural changes have been observed in fish in relation to vessel noise such as forming tighter formations, avoiding noise sources and increasing swimming speeds (Ref. 19.168). Experimental studies have shown that avoidance occurs at 118dB within the range of 60 – 3,000 Hz (Ref. 19.169).

19.6.118 There are already large vessels operating within the Severn Estuary/Bristol Channel and fish and marine mammals are likely to have become accustomed to a background level of underwater noise resulting from these activities. In addition, fish and marine mammals have the ability to move away from the sources of vessel noise. As the UK BAP species are all marine migrants moving through the Hinkley Point area from the Bristol Channel, Irish Sea and further afield it would be expected that they would be frequently exposed to vessel noise during their lifetime. Young-of-the-year migratory Annex II species (Atlantic salmon, twaite shad, allis shad, river lamprey, sea lamprey) passing through the estuary, however, would be less acclimatised to vessel noise because of their age.

Effect of Construction Noise on Fish

19.6.119 In order to assess potential impacts of noise on fish an understanding of the hearing abilities of fish is required (see **Table 19.22**). Fish use three organs to detect sound:

the lateral line, the ear and the swim bladder. The presence/absence and characteristics of these organs determine the hearing abilities of fish species which can be considered to be hearing non-specialists, specialists or generalists (Ref. 19.170 and 19.171). Non-specialist fish are those with no swim bladder e.g. lamprey, plaice, dab and sole. Clupeiformes (e.g. sprat, herring and shad) fall within the specialist category and as such can hear sounds over a far greater range than other species (e.g. Ref. 19.172). Species of conservation importance which are considered to be hearing generalists, and are potentially present near the study area, include salmon and eel.

Table 19.22: Hearing Frequency Range for Fish Species of Conservation Importance in the Area around Hinkley Point (Ref. 19.164)

Common Name	Legislative Protection	Hearing Category	Frequency Range (Hz)	Hearing Threshold Range over this Frequency Range (dB re 1µ Pa)
Atlantic salmon, *Salmo salar*	Annex II and V (Habitats Directive) UK BAP	Generalist- swim bladder	30-350	95-130
Shad – Twaite shad, *Alosa fallax*	Annex II (Habitats Directive) UK BAP	Specialist	30,000-60,000	190-198
River lamprey, *Lampetra fluviatilis*	Annex II and V (Habitats Directive) UK BAP	Generalist- no swim bladder	Unavailable	Unavailable
Sea lamprey, *Petromyzon marinus*	Annex II (Habitats Directive) UK BAP	Generalist- no swim bladder	Unavailable	Unavailable
Sea trout, *Salmo trutta morpha trutta*	UK BAP	Generalist-swim bladder	30-350	95-130
Common or Sea Sturgeon, *Acinpenser sturio*	Annex IIa and IVa (Habitats Directive), UK BAP Bern Convention Appendix III, CITIES Appendix I, WCA Sch. 5	Potential specialist	100 – 2000	Unavailable
Eel, *Anguilla anguilla*	UK BAP	Generalist- swim bladder	10-300	Unavailable
Cod, *Gadus morhua*	UK BAP	Generalist- swim bladder	10-500	65-140; /75-110; /95-120
Herring, *Clupea harengus*	UK BAP	Specialist	20-4,000	75-135
Dab,	UK BAP	Generalist- no	30-200	90-105

Common Name	Legislative Protection	Hearing Category	Frequency Range (Hz)	Hearing Threshold Range over this Frequency Range (dB re 1µ Pa)
Limanda limanda		swim bladder		
Sole, *Solea solea*	UK BAP	Generalist- no swim bladder	Unavailable	Unavailable
Plaice, *Pleuronecte s platessa*	UK BAP	Generalist- no swim bladder	Unavailable	Unavailable
Whiting, *Merlangius merlangus*	UK BAP	Generalist – swim bladder	Unavailable	Unavailable

***Note:** Where species data are lacking, data for those of similar physiology are presented where possible.*

19.6.120 In addition to auditory problems, more severe impacts could include the perforation of swim bladders by high-energy underwater noises (Ref. 19.173) which can cause fish to sink, lose the ability to orientate themselves, or lead to internal bleeding and fatality. Noise levels within 5m of pile driving operations can exceed levels that can harm or kill fish, with peak values quoted at around 218dB. The sound pressure levels which may cause harm to fish differs between species and is largely dependent on the presence or absence of a swim bladder. Underwater noise may also create disturbance to local fish populations, although fish will rapidly acclimatise to background noise (Ref. 19.56).

19.6.121 Audiograms (see **Table 19.22**) indicate hearing ranges for some of the species of conservation importance known to be present within the Severn Estuary/Bristol Channel (Ref. 19.164).

19.6.122 Of particular importance in the Severn Estuary are populations of migratory salmon and shad that may be migrating through the estuary during the works. Salmon are only sensitive to low frequency sound and do not react to frequencies above 380 Hz. The lowest response threshold and presumably the frequency of greatest sensitivity are between 100 and 160 Hz. Above this sensitivity rapidly declines. Vibratory piling produces sound within the range of frequencies detectable by salmon.

19.6.123 Shad are clupeids (a family of fish also including herring, sardine and menhaden), and as such it could be considered that they are morphologically very similar to the Atlantic herring (*Clupea harengus*). Studies on American shad *Alosa sapidissima* found shad could detect sound from 200 Hz to over 180,000 Hz, although the two regions of best sensitivity ranged from 200 to 800 Hz and the other from 25 to 150 kHz (Ref.19.174), with the lower bandwidth similar to that reported in herring by Ref. 19.175. It has been suggested that there are subtle differences in the ears of Clupeinae and Alosinae that may provide a mechanical explanation for why only the shads are able to detect ultrasound (Ref. 19.172).

19.6.124 Data on the response of allis shad to sound are limited, however data on the closely related twaite shad indicate noise levels of 158dB and a ramped frequency range of

100 to 500 Hz caused fish to undertake avoidance reactions at 138dB, which was >40dB above ambient noise levels (Ref. 19.176).

19.6.125 Comparing data on vessel noise generation (**Table 19.21**) with the hearing capabilities of the fish species (**Table 19.22**) it can be seen that supply vessels, fishing boats and tugs (pulling empty barges) can generate sound within the hearing frequency range of most species, the only exception being twaite shad. A tug pulling a loaded barge however, can generate sound at much higher frequencies (1,000 to 5,000 Hz) which lies outside the range of the majority of fish species (salmon, twaite shad, sea trout, eel, cod, dab). Similarly the frequency of sound generated by a twin diesel work boat is outside the hearing range of these species.

19.6.126 For fish species to hear the vessels and demonstrate an avoidance reaction, both the frequency and noise level indicated in **Table 19.21** would need to be within the range of a particular species. However, attenuation of sound means that as distance from the vessel increases, noise levels would reach values less than those indicated to be source noise levels in **Table 19.21**.

19.6.127 The impact associated with vessel noise would be expected to be smaller than that associated with pile driving even though vessel noise may be more of a continuous nature. While it might be anticipated that there could be a greater effect due to the combination of vessel plus piling noise, it is considered unlikely that the significance of this cumulative effect would be any greater than for piling alone. This is again due to the fact that any fish within the zone of influence would no longer be present in the affected area or would avoid it while noise levels were raised.

19.6.128 Dredging would only be undertaken for around four weeks during the construction phase and mobile organisms can evade the noise source if required. Consequently, noise impacts associated with dredging are not expected to affect mobile marine ecology receptors.

IMPACT: Generalist (no swim bladder) due to Noise Associated with Piling

19.6.129 Lacking swim bladders, flat fish are deemed to be least likely to be impacted by piling works owing to their weak auditory capacity (restricted to particle motion). Although it is possible that individual fish may be impacted in the immediate vicinity of piling activity, flat fish found around Hinkley Point are widespread and unlikely to be impacted negatively at a population level. The receptor value in this case is considered to be low. The magnitude of the effect is also predicted to be low due to (a) the existing noisy intertidal environment, (b) the fact that at any one time only a very small proportion of the overall population of any one fish species would be likely to be within close proximity to the piling works, (c) the adoption of soft start piling (a gradual increase in noise levels), and (d) the ability of larger fish to swim away from the noise source. The impact significance is therefore predicted to be **negligible**.

IMPACT: Generalist (no swim bladder) due to Noise and Vibration Associated with Dredging

19.6.130 In terms of vessel movements and dredging activities, fish would be present in the vicinity of the dredging for the jetty and therefore, would be directly affected by the noise and vibration associated with the operation of the dredger, which would be temporary. The receptor value is considered to be low, while the magnitude of the effect is predicted to be very low (i.e. it is expected that the receptors would experience little or no degradation as they are generally habituated to vessel noise and disturbance is likely to be within the range of natural variability and limited to areas within and adjacent to the development). The impact of significance is therefore assessed as **negligible**.

IMPACT: Generalist (no swim bladder) due to Noise and Vibration Associated with Construction of Horizontal Tunnels

19.6.131 With regard to drilling noise during the construction of the horizontal tunnels, the depth of the drilling within the bedrock (40-20m depth) suggests that the propagation of sound waves into the water column would be limited. Flatfish, which are sensitive to vibration and low frequency sound, are likely to be able to feel the vibration from the approach of drilling activity through the seabed and would, therefore, have the opportunity to move from the area before noise levels increased. Any avoidance reaction in fish would be likely to be confined to the immediate corridor above the tunnel and it is considered that there would be a very low/negligible sound level within the water column at a distance of >1km from the source.

19.6.132 Thus, for generalist fish species, a low sensitivity combined with low magnitude of effect would have no more than a **minor adverse** impact.

IMPACT: Generalist (swim bladder) due to Noise and Vibration Associated with Piling

19.6.133 There is still considerable uncertainty about the effects of piling noise on migratory fish species, although the available data suggests that levels sufficient to cause serious injury or death are unlikely to occur at distances of greater than 5m from the source, and at greater than 400m it is unlikely that salmon or trout would react at all to vibratory piling. Based on salmonid and clupeid hearing it could be anticipated that migratory fish in the vicinity of piling activities would be expected to show avoidance behaviour to noise levels above 90dB depending on the intensity of background noise.

19.6.134 Anadromous species migrating seaward are unlikely to be prevented from migrating by noise impacts as the size of seaward migrating salmon (smolts), shads and lamprey means that their swimming speeds are typically lower than tidal stream velocities. The movements of juveniles of anadromous species will thus be determined by tidal transport, which means that individuals will tend to pass the area of disturbance fairly rapidly. In the case of salmon smolts, the utilisation of the fastest flowing portion of the estuary would ensure animals are rapidly conveyed past any area subject to disturbance impacts.

19.6.135 The Severn Estuary is a known migratory route and given the designated status and importance of the migratory fish populations the disturbance and potential physical impact of piling could be considered to be of moderate significance. However, given that the Inner Bristol Channel is approximately 20km wide at the point of disturbance and that it is unlikely that elevated noise levels that would lead to avoidance would extend beyond 400m there would be sufficient space for any displaced migratory fish to continue migration. Given the relatively small area of the Inner Bristol Channel that would be impacted during the construction and piling phase it is, therefore, considered that the magnitude of the effect would be low (on a receptor of low sensitivity) and that there would thus be a **minor adverse** impact.

IMPACT: Hearing specialists (swim bladder) due to Noise and Vibration Associated with Piling

19.6.136 The potential impact of noise generated during pile driving would vary depending on the species/assemblage of fish considered. For non-migratory, resident species within the range of the works it is certain that an effect would occur, but that, based on hearing range and sensitivity only species such as herring would be likely to be sensitive to the generated noise levels. For such species, within the immediate vicinity of the piling it would be expected that some disturbance would occur and potentially if fish were within very close proximity to the piling (i.e. within a couple of metres), physical damage could occur. The sensitivity for these species would therefore be high.

19.6.137 It may be presumed that without mitigation individuals would be open to harm if in close proximity to the operations themselves. If percussive piling were to be used without mitigation, the magnitude of the effect would be medium, and the sensitivity of the receptor also medium, with a consequential impact of **moderate adverse** significance.

IMPACT: Effect of Construction Noise on Marine Mammals

19.6.138 As discussed in the baseline section, there is evidence from acoustic monitoring that marine mammals visit the area, however they are not commonly observed and are unlikely to be present on a regular basis in the vicinity of Hinkley Point. For the purpose of this assessment they have been assumed to be intermittently present. The receptor value is considered to be high, as it includes Annex II species of international importance. Impacts are predicted to be direct and temporary, however, due to the limited presence of marine mammals, the adoption of a soft-start approach and their ability to avoid areas of disturbance, the magnitude of the effect is assessed to be very low. Therefore, it is predicted that the impact significance for marine mammals from noise associated with the construction works would be **minor adverse**.

i. Artificial Lighting

19.6.139 The construction works may require that night time working is undertaken, in which case powerful artificial lighting will be needed. This may apply to the drilling works for the intake and outfall shafts, construction and dismantling of the temporary jetty and construction of the seawall. For the purposes of assessment it is presumed that lighting will be required. Lighting will also be required for the temporary jetty during its operation.

19.6.140 The effect of artificial lighting has been considered in relation to two broad habitat types and the species that utilise these habitats – namely intertidal areas and the water column.

IMPACT: Lighting Effects on Intertidal Areas

19.6.141 This effect only applies with regard to the temporary jetty. While it is possible that lighting may be used during construction of the seawall (tidal conditions permitting) there are no intertidal communities of significance (e.g. *Corallina* turfs) within 100m of the location for the seawall.

19.6.142 The invertebrates and plants present on the intertidal are likely to be tolerant to exposure from artificial light as clearly these communities are subject to intense light levels on a daily basis. Artificial lighting would also only have an effect during low tidal conditions, which effectively means that due to attenuation through the water column, communities would not be subject to a 24 hour increase in light levels. Potential impacts on birds are considered in **Volume 2**, **Chapter 20**, Terrestrial Ecology and Ornithology.

19.6.143 Of the *Corallina* dominated biotope present on the Hinkley intertidal only a relatively small area falls within the footprint of the temporary jetty. Within this small area it can also be stated that potential lightfall from artificial lighting would only affect a proportion of the *Corallina* biotope present, as light levels would rapidly drop off away from the source. Although an increase in light levels could potentially promote growth of *Corallina*, it is highly unlikely that the increase that some isolated areas of *Corallina* might be subject to would promote growth such that it was of significance or potentially interfere with other physiological processes. Hence **no impact** is anticipated.

IMPACT: Lighting Effects on the Water Column

19.6.144 In the case of the construction phase, lighting of the works for drilling of the vertical shafts for the intake/outfall structures and for the temporary jetty may influence the water column. Light penetration into the water column will also occur during operation of the temporary jetty.

19.6.145 The key variable to take into account when assessing light attenuation through water is the suspended sediment load of the water. Due to the very high turbidity levels within this area of the Inner Bristol Channel there would be limited penetration of the artificial light into the water column, and it is considered that light levels would be negligible after 1-2m of passage though water. Consequently, only organisms near the water surface may potentially be affected by this night time lighting and benthic organisms on the estuary bed would not be expected to be influenced.

19.6.146 Light is known to have a strong influence on fish behaviour, with photoperiod acting as an environmental cue in relation to reproduction, and also as a factor determining migration. Changes in natural reproductive development rates as a result of artificial light regimes have been demonstrated for a range of fish species. However, this has generally been where the light environment experienced by fish is overwhelmingly determined by that artificial source (e.g. in aquaria, laboratories or fish farm facilities).

19.6.147 Light has also been demonstrated to influence fish migration, with species such as salmon and sea trout migrating predominantly at night rather than day. Similarly, various species have been demonstrated to either be attracted to or repelled by light, with the majority being repelled.

19.6.148 While it is possible that some fish species may be present within the area affected by artificial light, the potential magnitude of change associated with this effect (for the reasons given above) is considered to be very low. Given that it is likely that only a very small percentage of the Inner Bristol Channel would be affected, for both the temporary jetty and the shaft drilling works, and that many species, including migrating fish, would avoid any lit areas and thus be of low sensitivity, the overall effect on fish movement is anticipated to be **negligible** for the construction phase (drilling works and jetty) and operational phase for the temporary jetty.

e) Potential Impacts during Operation

i. Introduction

19.6.149 This section covers the range of impacts that would occur as a result of operational activities. The key aspects and the receptors that these could affect are listed below in **Table 19.23**.

Table 19.23: Key Operational Impacts and Receptors

Receptor	Phytoplankton	Zooplankton	Epifauna	Benthic flora	Subtidal invertebrates	Intertidal habitats (including Sabellaria)	Fish	Marine mammals
Thermal plume impacts			✓	✓	✓	✓	✓	
Chemical plume impacts			✓	✓	✓	✓	✓	
Entrainment and impingement impacts of abstraction on intake screens	✓	✓	✓	✓	✓		✓	

ii. Thermal Discharges

Allied Assessments

19.6.150 The issue of the proposed thermal discharges from HPC is discussed in **Volume 2**, **Chapter 18**. That chapter deals with matters of compliance against specific temperature and allied water quality criteria set down in both regulations and existing guidance. Discussions within this chapter focus solely on the implications of the thermal fields involved on the marine ecology of the system.

Numerical Modelling of Thermal Plumes

19.6.151 The supply of cooling water is fundamental to the operation of any thermal power station and the requirements of a nuclear station are not significantly different from to those using conventional fuels (e.g. coal, oil). HPC is situated on the coast in order to utilise the large volumes of seawater available. In such circumstances the areas potentially most vulnerable to any excess temperature will be the intertidal and shallow water seabed.

19.6.152 The Inner Bristol Channel is subject to both variable freshwater inputs from river estuaries and a variable temperature regime. There may be periods of constant high or low temperature and low salinity during river floods, depending on the season. Therefore, any biological impact will be dependent on a combination of salinity and temperature conditions. More open coastal locations may not be affected by such large salinity and temperature variations, but will be more prone to the effects of weather, wind and waves. For the purposes of both appropriate engineering design and environmental assessment the first step is to secure an understanding of the existing baseline condition over which any proposed discharges will be superimposed.

19.6.153 For HPC, operational requirements determine that at full operating load the cooling water will be discharged at 10 to 12°C above intake, and at full load the cooling water volume involved across both European Pressurised Reactor (EPR) units will be approximately $125m^3.sec^{-1}$.

19.6.154 A continuous supply of cool water is a primary operational requirement. In order to ensure this supply the relative positions of the intakes and outfalls are chosen with considerable care so as to avoid the recirculation of heat during the full range of tidal and meteorological conditions that might be expected. To this extent the needs of the power station operator and the local marine ecology are identical i.e. stable conditions within a limited mixing zone area with efficient loss of excess heat to atmosphere from the sea surface.

19.6.155 To simulate this wide range of hydrodynamic, meteorological and geomorphological conditions the GETM thermal outputs have been used, unless stated otherwise. This model is considered to overestimate water temperature outputs (by approximately 0.5 to 0.75°C); while it is considered that the Delft model was underestimating the extent of the plume. The upper local sea water range temperature of 20.4°C (98 percentile based on 32 years of Cefas data for Hinkley Point) was also used as the basis for a precautionary assessment.

19.6.156 Details of the models employed in support of the HPC development may be found in Refs. 19.59, 19.65, 19.38 and 19.67. A summary of model development is included as **Appendix 18A** to this ES.

19.6.157 Hourly model outputs against a selected set of variables were used to produce time series means and averages. The basic modelling scenarios that were tested, Runs A-E, are described in **Table 19.24**. The runs were used to produce detailed thermal predictions to establish baseline conditions (i.e. HPB operating alone) and to represent a range of potential operating conditions in the future.

19.6.158 In order to establish baseline conditions and validate the model, Runs A and B represent HPB operating at 70% and 100%. The reasons for running variations on the HPB operating scenario relates to a reduction in HPB operating output during the modelling verification and calibration stage. It should be noted that it is not envisaged that operation of HPB at 70% reflects long term operating conditions at HPB. Modelling of HPB between 70% and 100%, however, does provide the ability to assess a range of conditions under which the station could operate both now and in the future (i.e. it reflects a range of current baseline conditions).

19.6.159 Run C calculates the thermal plume conditions in relation to the operation of HPC only (i.e. the effects of HPB are removed). This reflects conditions that would occur in the future when HPB ceases generation.

19.6.160 Run D reflects a time whereby HPC is operating at full capacity and HPB is operating, but potentially below consented maximums (as described above). Run D thus provides the opportunity to assess impacts on the potential lower range of HPB operation.

19.6.161 Run E is considered to represent the upper limit of potential combined operation, i.e. both HPC and HPB are operating at maximum consented levels. For the purposes of the assessment included within this chapter, a five year overlap with HPC is assumed (based on the potential extension of the operational life of HPB).

19.6.162 In summary, Runs A and B are considered to reflect the current baseline conditions experienced at Hinkley Point; while Runs C, D and E reflect potential operating conditions in the future and therefore form the basis of the impact assessment in this chapter, as well as the allied HRA.

Table 19.24: Calculated Thermal Plume Areas at the Bed, for Particular Excess Temperatures

Run	**Total plume area km^2 at the bed at particular mean excess temperatures The 2nd value indicates the equivalent plume area once corrected for the time that cells are dry**					
	≥0.75°C	**≥1.0°C**	**≥1.25°C**	**≥1.5°C**	**≥2°C**	**≥3°C**
Run A Hinkley B (70%)	8.99 4.31	5.88 1.67	4.04 0.56	2.8 0.20	0.71 0.02	0.0 0.0
Run B Hinkley B (100%)	13.58 8.51	9.62 4.71	7.10 2.34	5.18 1.01	3.06 0.20	0.31 0.01
Run C Hinkley C (100%)	51.50 43.7	37.4 27.9	25.77 16.4	18.22 9.54	5.31 2.17	0.0 0.0
Run D Hinkley C (100%)+B (70%)	60.21 54.4	46.26 40.1	35.8 28.7	27.78 19.7	17.95 8.5	3.6 0.20
Run E Hinkley C (100%) + B (100%)	63.83 57.71	49.01 43.38	38.65 32.32	30.50 23.45	19.90 11.17	7.65 0.77

19.6.163 The extent of the thermal mixing zones associated with HPB (which defines the existing baseline) and HPC are illustrated in **Figures 19.20** to **22**.

IMPACT: Thermal Regime Change on Non-migratory Fish

19.6.164 An understanding of the fish assemblages likely to be present in the vicinity of the predicted mixing zone have been obtained from sampling at sea (e.g. Ref. 19.33), from intertidal fish surveys (e.g. Ref. 19.177) and from impingement data collected at HPB (e.g. Ref. 19.36). The dominant species recorded include sprat, whiting, herring, sole and flounder. Both the sampling at sea and the impingement data reveal a wide range of fish species including a number of commercially important species.

19.6.165 Potential impacts on fish assemblages attributable to the discharge of thermal effluent have been comprehensively reviewed by the BEEMS Expert Panel (Ref. 19.21). These may include changes to spawning season, reproductive capacity (Ref. 19.178), feeding behaviour changes and recruitment impacts.

19.6.166 Responses of fish to changes in temperature have been extensively studied in the past, particularly in relation to commercially important species and protected species and in relation to community changes in response to regional climate change (Refs. 19.21 and 19.179). Egg and embryonic life stages may be most at risk from increases in temperature and the significance of this risk will depend in a large part upon their relative abundance within the area and the significance of these larval stages in terms of recruitment, as well as the degree to which they are actually exposed. In practice, recent ichthyoplankton studies carried out off Hinkley Point (Ref. 19.33 and 19.34) suggest that local fish egg and larval abundances are chronically low. Adults would be expected to move away from an area of higher temperature, therefore, reducing the likelihood of exposure.

19.6.167 While fish will undoubtedly be present within the area affected by the thermal plume, the overall effect is difficult to quantify due to the composition of the fish assemblage. Whatever the level of effect on different species it is obvious that fish have the capacity to move in and out of the thermal plume and thus no direct mortality would be expected. It is known that certain species, such as sea bass, congregate near thermal plumes, suggesting that the presence of the thermal plume may be beneficial for this species. Increased temperature may also be beneficial for other Lusitanian (warmer-water) species present in the Inner Bristol Channel, but potentially of some detriment for species nearer the southern extent of their range (Arctic-Boreal or cold-water species) e.g. cod (Ref. 19.21). Given that the predicted warming would cover a relatively small area of the Inner Bristol Channel, the magnitude of the effect is considered to be low. It is apparent that no large-scale changes in the fish assemblage as a result of the predicted temperature change would occur.

19.6.168 There are likely to be small-scale changes in the composition of the epibenthic fish assemblage within the footprint of the thermal plume. But again, as the vast majority of the species present are tolerant to temperature variations within the range predicted for the thermal plume (Ref. 19.14), it is unlikely that any shift in the composition of the assemblage would be significant either within the confines of the affected area itself and certainly not at the Bridgwater Bay-Inner Bristol Channel level. The sensitivity of non-migratory species is therefore low.

19.6.169 Taking the above points into account, whilst it is possible that some small-scale changes to the fish fauna within the footprint of the plume may occur, overall the fish assemblage would retain its existing composition. Only through an Inner Bristol Channel alteration in water temperature would the composition of the fauna be likely to change, as evidenced by the long-term data series collected from the intake screens at HPB (described earlier in this chapter), and such temperature change would not occur as a result of the thermal discharge into a relatively localised area. The conclusion is thus that although temperature sensitivities exist among the fish fauna, the predicted extent and magnitude of the thermal discharge would not lead to significant change in either species composition or population levels in the estuary and, overall, a localised, long-term but **minor adverse** impact would be anticipated.

IMPACT: Thermal Regime Change on Migratory Fish

19.6.170 Migratory fish may be influenced by thermal change through a number of potential pathways (as for other, resident fish), but it is perhaps the potential for migratory behaviour to be affected that is of greatest importance (Ref. 19.21). For those species for which the Severn Estuary is of importance, the following aspects of are significance:

- River lamprey migrate from estuaries to spawn in rivers when water temperature reaches 10 - 11ºC, usually in March and April (Refs. 19.21 and 19.180), however spawning may continue at higher temperatures (Ref. 19.181).
- Sea lamprey usually migrate from the sea and spawn in British rivers in late May or June, when the water temperature reaches at least 15ºC (Ref. 19.182). Adult sea lamprey have been shown to survive in a wide range of temperatures from 4-20ºC (Refs. 19.21 and 19.183).
- Migration of shad from the sea to estuaries appears to be triggered by temperature (Ref. 19.182). Temperature requirements for both twaite and allis shad migration have been shown by a number of workers to be similar and range from 10 - 16ºC (Refs. 19.21 and 19.182). Allis shad eggs have been shown to be sensitive to water temperatures below 16 - 18ºC, therefore it has been hypothesised that climate change may make some British rivers more favourable for allis shad than in the past (Ref. 19.182). Temperature has been shown to affect larvae development and year- class strength, in that temperatures at the higher end of the range have encouraged spawning activity and enhanced subsequent larval survival and growth (Ref. 19.182). Temperature preferences for larvae are dependent on size to some degree with preferences between 17 and 21.5ºC identified by Ref. 19.184 in the Elbe estuary. Overall, an increase in temperature may be beneficial for warm-water species such as shad and lampreys and of some detriment to cold-water species such as salmon (Ref. 19.21).
- Fish are known to migrate into and out of thermal effluent discharges, and it is reported that greater fish abundances can be found at outfall locations than at adjacent locations, however this is influenced by seasonal migrations (Refs. 19.21 and 19.185). The presence of thermal effluent discharges could potentially locally exclude some species with low tolerance to temperature, which may result in local changes in species composition and community structure (Ref. 19.185). The author of Ref. 19.73 demonstrated that salmon migrating at sea and eels in estuaries use temperature fronts, however there appears to be little evidence to suggest that thermal effluent discharges can interrupt migration (Refs. 19.21 and 19.73). The authors of Ref. 19.186 reviewed evidence of thermal barriers to fish and were unable to find firm evidence of the reality of thermal barriers in rivers and estuaries, except near to the lethal limit. There remains potential, however, for avoidance behaviour within some species when undesirable temperatures are encountered, for example sea trout smolts are known to avoid temperature increments of >6°C thermal effluents (Ref. 19.187).

- Sea trout smolts are known to avoid thermal interfaces where the temperature rise is above 6℃ (Ref. 19.237).

19.6.171 Possible thermal occlusion of migratory pathways thus remains one of the primary considerations when assessing thermal effluent effects on diadromous fish. Temperature increases affecting migratory fish species and thermal standards for marine environments are discussed in Ref. 19.21. A maximum uplift of 2^{o}C is recommended for the edge of mixing zones within SACs which include sensitive species such as salmonids; and an uplift of less than or equal to 3^{o}C is recommended for other status classes.

19.6.172 The best practice guidelines for prevention of thermal barriers to fish migration state that no more than 25% of the cross-sectional area of an estuary or river should exceed a temperature of 2℃ above ambient for more than 5% of the year (Refs. 19.31 and 19.186). Hence predicted excesses above ambient were analysed for each of the Transects A to D (**Figure 19.23**) for each GETM Model Run A to E (**Table 19.25**). Analysis of the annual results show that only Transects B (Stolford to Burnham-on-Sea) and C displayed potential failures (**Table 19.25**) (Refs. 19.59, 19.63 and 19.65). However, in both cases there were only a few annual events and neither transect indicated breaches of the criteria for more than 5% of the time and, therefore, neither of the transects failed the criteria.

19.6.173 In the interests of understanding the system and with a view to extending the logic to future climate scenarios when specific meteorological conditions may become more frequent, Transects B and C (**Figure 19.23**) were analysed in more detail. On this basis (see Ref.19.59) the future conditions most likely to produce barriers to fish migration are warm, summer conditions, on spring tides with moderate winds from the west. Even so they are unlikely to exist for more than one or two hours on each tide and only occur on spring tides. It is therefore considered unlikely that the thermal cross sectional area criteria will be breached during the lifetime of HPC.

Table 19.25: Incidence of Hourly Intervals of Occlusion of Estuarine Cross Sectional Area >25% from Annual Analysis (Ref.19.59)

No of Excess Temperature Events where the cross sectional area at >2C is > 25% of the transect						**Breach Annual %**
Transect	**Run A**	**Run B**	**Run C**	**Run D**	**Run E**	**Run E**
A	0	0	0	0	0	
C	0	0	0	7	28	0.39%
B	0	0	0	0	4	0.05%
D	0	0	0	0	0	
No of Excess Temperature Events where the cross-sectional area >= 2C is in the range 0.1% - 25% of the transect						
Transect	**Run A**	**Run B**	**Run C**	**Run D**	**Run E**	
A	0	0	0	0	0	
C	0	0	0	26	54	
B	157	715	75	766	1461	
D	0	0	0	0	0	

19.6.174 Migratory fish passage is thus not predicted to be hindered in the Inner Bristol Channel, Bridgwater Bay area or the River Parrett and both these water bodies are predicted to remain passable at all states of the tide.

19.6.175 While it is thus possible that the predicted thermal change could lead to an alteration in the behaviour of migratory fish, it is not considered likely that this would have any significant effect on either their ability to migrate or would influence their cues for migration. The expected temperature change would not be sufficient to block migratory pathways through the Inner Bristol Channel towards the Severn Estuary or rivers draining into the estuary (e.g. the Parrett, Wye, Usk). It is clear that the migratory fish populations (both from a conservation and fisheries perspective) are of importance. However, given their overall tolerance to temperature change, their ability to select their preferred temperatures and the relatively localised nature of the predicted >2℃ change, it is considered that the potential magnitude of change is low, and the sensitivity of migratory species is medium. Hence, overall, the impact would be **minor adverse**.

IMPACT: Thermal Plume on Corallina and Sabellaria

19.6.176 Where the thermal plume impinges upon intertidal or shallow subtidal areas, there is likely to be a shift in the zonation of benthic macrofaunal communities as a result of their differential tolerance to temperature rise, upper shore species being more tolerant than lower shore or shallow-subtidal species (Refs. 19.72 and 19.189). Species and communities of the deeper subtidal would not experience temperature rises of an extent likely to have any adverse impact, as they will not suffer any direct contact with the plume-water.

19.6.177 The intersection of the thermal plume with the seabed and intertidal areas, as modelled by GETM, is shown in **Figures 19.24** to **19.26**.

19.6.178 The benthic communities or habitats occurring within the vicinity of the HPC plume include four species that might be of concern if sensitive to an increase in temperature:

- The bivalve *Macoma balthica* on the intertidal flats, as a potentially significant food resource for littoral-feeding birds or demersal fish or decapods.
- The shrimp *Crangon crangon*, a significant food resource for birds and fish, and a significant predator on the intertidal.
- The *Corallina* run-off biotope, as it is both rare in this region (and in the UK) and itself provides a habitat for many other species.
- *Sabellaria alveolata*, a common species but one that produces biogenic reef habitat (again to the benefit for other species) along the lower shore.

19.6.179 Both *Corallina* run-offs and *Sabellaria alveolata* tubes and reefs are present across the Hinkley Point intertidal. *S. alveolata* is a Lusitanian species restricted in its distribution in the UK by winter cold temperatures, and indeed shows the greatest development of reefs within the outflow of the existing Hinkley Point Power Stations. *Corallina officinalis* agg. is naturally tolerant of warmer (and colder) waters than those in Bridgwater Bay, occurring from Norway to Morocco, as well as in mid- to low-shore permanent rock-pools which can be subject to extremes of temperature at low tide.

19.6.180 The modelling outputs predict that the extent of the thermal plume for HPC alone will have no greater influence on the Hinkley shore than that of HPB – see **Figures 19.24** to **19.26** and **Figure 19.27**. This suggests that both existing *Corallina* and *Sabellaria* communities would not be subject to an increase in thermal load and, consequently, **no impact** with regard to these ecological interests is anticipated. While a simultaneous operation of HPC and HPB would result in some increase in average temperatures on the Hinkley frontage, available data on both *Corallina* and *Sabellaria* (e.g. see Refs. 19.14 and 19.73) suggest that such an increase would be unlikely to have any ecological consequence for these species.

IMPACT: Thermal Plume on Macoma balthica

19.6.181 The bivalve *Macoma balthica* is dominant in both intertidal and subtidal infaunal communities at Hinkley Point (Refs. 19.23 and 19.28). This species is also considered to be an important prey item for birds and benthic fish and crustacean species (Ref. 19.14). *M. balthica* has a wide geographic range, with southern limits on the coasts of the Bay of Biscay, although local populations will be adapted to the ambient temperature regime. For example, studies on populations in the Wadden Sea (Ref. 19.190) and in the Baltic Sea (Ref. 19.191), both colder waters than are found at Hinkley, recorded reduced population sizes and increased offshore migration in response to raised temperatures, in the former case over the longer term (possibly a result of climate change) and in the latter case in response to a thermal discharge of 10ºC ∆T.

19.6.182 Studies conducted as part of BEEMS contrasted the condition of *M. balthica* populations across a geographical temperature gradient, finding no relationships between latitude and condition, age or structure of the populations (Ref. 19.50). However, a wealth of literature has shown warmer winter temperatures are associated with reductions in fecundity, recruitment, condition and earlier recruitment (Ref. 19.14).

19.6.183 Growth of *M. balthica* is reported to cease at 15ºC (Ref. 19.192) and its growth period in the Wadden Sea is limited to between the time of first spawning in early spring and the point at which mean temperatures reach 15 ºC. A reduction in growth period may occur with limited food availability and increased summer temperatures. Increased temperatures as a result of the thermal plume could be expected to bring forward the 15ºC growth threshold.

19.6.184 Ref. 19.14 suggests that under an operational scenario of HPB and HPC running together at full capacity a worst case reduction in growth period of approximately five days would occur. Slightly less than half of Stert Flats would be affected by a change in the *M.balthica* growing period for the most extreme scenario (HPB + HPC at full load), whilst Berrow Flats would experience a reduction of 1 day only (2% of its growth period) – see **Figures 19.24** to **19.26**.

19.6.185 Initial studies (Ref. 19.23) were carried as part of the BEEMS programme into the characterisation of populations outside and within the HPB plume. It was found that there were no significant differences in biomass, length or condition between stations inside and outside the area of influence of the thermal plume for any of the survey datasets. However, the surveys upon which this initial finding were based contained only a few sites within the expected intersection of the HPB plume.

19.6.186 Potential impacts of the HPB thermal plume on the Stert Flats *M. balthica* populations were investigated using more detailed seasonal measures of abundance, biomass and size from 2010 (Ref. 19.249). Data from 15 stations across the flats were gathered in April, July and October 2010 and January 2011. Mean and standard deviation of *M. balthica* abundance, shell and tissue ash-free dry-weight (AFDW), length and juvenile Tellinacea abundance were utilised in a cluster analysis for each season. With this analysis each cluster represents a distinct population 'type' distributed across the flats. The cluster groups were overlaid on a map, **Figure 19.38**, showing the current estimation of the HPB thermal plume extent (calculated from water and sediment temperature sensor measurements taken across Stert Flats during spring and summer 2011; the map has been drawn using night-time temperatures, in order to reduce the influence of naturally-occurring changes in sediment temperature caused by solar irradiance).

19.6.187 Nine sites in the Severn Estuary, including Hinkley Point, were identified as likely habitats for *Macoma*. The sites were visited to identify the occurrence of *Macoma* and, if present, quantify population parameters over the high and/or mid-shore levels (Ref. 19.249). Individual length and age data (obtained by counting growth rings) were then processed for five sites between Hinkley Point, in the south, and Clevedon, in the north (Hinkley Point, Weston-Super-Mare, Kewstoke, Wick-Saint-Lawrence and Clevedon).

19.6.188 The results of this investigation (Ref. 19.249) showed that there was no clear correspondence between *M. balthica* population 'types' (cluster groups) on Stert flats and thermal uplift from HPB for any of the four seasonal surveys undertaken in 2010. The cluster groups did not appear to correspond to the thermal uplift contours. Nor did they clearly correspond to shore level or distance from the River Parrett. Based on this assessment, there was no apparent signal of contemporary thermal impacts on the intertidal *M. balthica* populations in the study area.

19.6.189 This same study (Ref. 19.249) confirmed that *M. balthica* populations are present elsewhere in the Severn Estuary. The presence of the species has been confirmed at each of intertidal sites between Hinkley Point and Clevedon and also further up-river of this point. The data showed that there are significant differences in both size and age between the various sites visited. These data also showed that the *M.balthica* population close to Hinkley Point and the area of influence of the HPB plume did not have the smallest or youngest individuals in the Severn; they show other populations with different or the same size and age characteristics, with the Hinkley Point population being within the measured range of variability and not at one extreme. The presence of other populations in the vicinity of Stert Flats suggests that any potential local thermal plume impacts could be mitigated by recruitment to these flats from elsewhere in the estuary.

19.6.190 The conclusion of these studies is that the current weight of evidence does not support the proposition that the HPB plume is affecting the structure of *M.balthica* populations in Bridgwater Bay.

19.6.191 In considering the impact of HPC alone (with the influence of HPB being the existing baseline), where HPC will contribute thermal inputs over a relatively small spatial extent of Stert Flats, the magnitude of this effect is considered to be low (involving a very low level of change). The moderate sensitivity of this species combined with its high value provides a combined receptor sensitivity and value of medium. The resultant impact associated with HPC would thus be of **minor adverse** significance.

IMPACT: Thermal Plume on Benthic Communities on Stert Flats

19.6.192 Other benthic species that have a significant functional role on Stert Flats, such as the small but highly abundant gastropod *Hydrobia* and the polychaetes *Hediste* and *Nephtys*, are not regarded as particularly temperature sensitive. Aside from being prey to other species, *Macoma* has an additional value within this system as it contributes to the bioturbation of superficial sediments. The other species present, however, also contribute to this processing suggesting that any reduction of *Macoma* in this role would be of little significance. Overall, the ecological functioning of the intertidal area exposed to the HPC plume is expected to be unchanged, with the receptor being of low sensitivity and the effect of low magnitude, and any impact thus of **minor adverse** significance.

IMPACT: Thermal Plume on Subtidal Benthic Habitats

19.6.193 The subtidal soft sediments off Hinkley Point and Stert Flats will experience very little of the thermal plume (see **Figures 19.24** to **19.26**), suggesting a low magnitude effect. The thermal sensitivity assessments (Ref. 19.33) have found all species to have between low and moderate thermal sensitivity, rated overall as low, leading to an impact of **minor adverse** significance.

IMPACT: Thermal Plume on Microphytobenthos

19.6.194 The microphytobenthos that probably contribute the bulk of the primary productivity within this system are predicted to be unaffected by the thermal plume as their photosynthetic optimum typically falls between 20-30°C (Ref. 19.194). As many of the microphytobenthic species are found across coastal waters in most of Europe, a 3°C increase should be within the tolerance of the assemblage and so **no impact** is expected.

IMPACT: Thermal Plume on Crangon Crangon

19.6.195 The shrimp *C. crangon* is the most abundant epifaunal species around Hinkley Point (Ref. 19.33) and is a major food resource for demersal fish and intertidal birds, as well as having a significant influence on the benthic community as it's also a major predator. The wide distribution of this species extends south to the Moroccan coast of Africa and into the Mediterranean. *C. crangon* is considered to have a high tolerance to increased temperature (Refs. 19.33 and 19.193) and thus regarded as very low sensitivity to impact in this instance. In the colder waters of the Wadden Sea, shrimp abundance is higher after mild winters, and laboratory experiments have shown a temperature optimum above 20°C (Ref. 19.193).

19.6.196 The *C.crangon* populations at Hinkley Point show a slight increase in abundance over time, suggesting there is no detrimental effect of the current discharge from

HPB (Ref. 19.102) but perhaps minor benefit. The magnitude of the effect that would be associated with HPC is thus considered to be very low, and the significance of any impact would be **negligible**.

IMPACT: Thermal Plume on Adequacy of Intertidal Invertebrate Prey Resource

19.6.197 Seasonal increases in the population size of *C. crangon* might be expected to increase predation on recently-settled and juvenile *Macoma balthica*, but in practice predation in the May and June period is the most important factor in *M. balthica* spat survival, i.e. the period when the shrimp population has been shown not to be increasing, while seasonal increases in the shrimp population will relate to juveniles too small to exploit *M. balthica* as a prey species.

19.6.198 As waterfowl are primarily a terrestrial/coastal feature, the direct impacts from HPC are dealt with in **Volume 2**, **Chapter 20**, Terrestrial Ecology and Ornithology, of this ES. The indirect effects of food availability on birds as result of the thermal plume are discussed briefly below.

19.6.199 The distribution of *M. balthica* is not uniform, with greater levels of biomass being present on the lower shore. On the mid and upper shores of Stert Flats species such as *Hediste diversicolor*, *Hydrobia ulvae* and *Nephtys hombergii* provide a significant amount of the prey biomass present (see **Figure 12** in Ref. 19.51). Despite these distributional differences in prey composition the distribution of waterbirds does not mirror this pattern (see **Appendix 20B**); this suggests that the individual birds present within the area affected by the thermal plume are more generalist feeders. As *M. balthica* represents between 30% to 90% of the biomass in various areas of Stert Flats, the reduction of up to 11% of this resource, based on HPC + HPB at 100% (i.e. 3.3% to 9.9% of biomass), is relatively small and is unlikely to significantly reduce the prey resource available to the birds present. Given that there is no detectable effect on *M. balthica* due to the current HPB plume (as found above), the real-world effect is also likely to be lower than is predicted by the model.

19.6.200 Provisional outputs of a trophic model (known as the MORPH model) support the conclusions drawn above (Ref. 19.51). Initial runs of this model show that the prey resource available is adequate to support the number and types of birds recorded in the area, as individuals are able to switch to different types of prey as *M. balthica* biomass declines.

19.6.201 The evidence available suggests that potential effects on the survival and/or body condition of birds feeding on the intertidal due to changes in the invertebrate prey resource are unlikely to be discernible. Their sensitivity to the effect is thus considered to be very low and the magnitude of the effect associated with HPC alone would be low. Hence the significance of any impact would be **minor adverse**.

iii. Chemical Discharges

Introduction

19.6.202 During the operational phase a number of non-radiological waste water discharges will be made. These will be primarily due to:

Whilst commissioning (via cross-shore drain and main cooling water outfall)

i conditioning of the cooling water system and other plant; and

ii treated sewage and surface drainage.

Post commissioning (via main cooling water outfall)

iii antifouling measures in the sea water cooling system;

iv effluent from site services (demineralisation plant, laundry etc.);

v treated sewage and site drainage; and

vi hydrazine.

19.6.203 Cooling water will be abstracted from a series of near-seabed intakes some 3.3km offshore. During normal operation, seawater will be abstracted at approximately $65m^3.sec^{-1}$ for each unit and subsequently discharged at the same rate through a pair of outfall head-works, again mounted on the seabed, some 1.8km offshore. The locations of the intake and outfall tunnels are shown in **Figure 19.6**.

19.6.204 Detailed information on non-radioactive discharges during construction, commissioning and operation of HPC is provided in the **Volume 2, Chapter 18** 'Marine Water and Sediment Quality' of this ES.

IMPACT: Corallina and Sabellaria via Commissioning Wastes Discharged via Cross-Shore Discharge

19.6.205 Commissioning waste streams arise as the integrity and function of various areas of plant are tested, or established areas of plant are taken out of storage and the need arises to discharge conditioning volumes. All such discharges are of water, together with solids disturbed by the flow. These tests are classified as 'cold flush' and 'hot flush', with effluents from the latter incorporating ΔT.

19.6.206 Only 'cold-flush' tests will result in effluents being put to the temporary cross-shore discharge route described under 'Construction Impacts' above; 'hot flush' tests will await the availability of the operational cooling water discharge route and associated sea water pumping capacity.

19.6.207 The potentially sensitive receptors to effluents arising via this route due to construction have already been described. There will be an overlap in the use of the cross-shore discharge for both construction and commissioning purposes, as surface water, dewatering water and treated sewage will continue to be discharged via the cross-shore discharge until other means become available.

19.6.208 As with the construction discharges by the same route, management of the various waste streams involved will ensure that all EQS requirements are met at the point of discharge from the sea wall, and that levels of solids are controlled to the median ambient level of $250mg.l^{-1}$.

19.6.209 Given the nature of the biotopes involved (all variable salinity in character) a low sensitivity to this impact and low magnitude result in a predicted impact of **minor**

adverse. Equivalent impacts on the *Corallina* biotope and the *Sabellaria* interest (as described in Appendix 19A) are of **no impact** and **negligible** impact respectively.

IMPACT: Subtidal Habitats via Commissioning wastes discharge

19.6.210 Only once the main cooling water system is complete (cooling water pumps plus associated offshore intake and outfall infrastructure) will hot-flush testing commence, and once that plant is available no further commissioning discharges will be put to the cross-shore discharge route.

19.6.211 The availability of the main cooling water (CW) plant will permit both increased initial dilution of effluents and their discharge offshore, a distance removed from potentially sensitive habitats. As a consequence, in terms of the marine ecological interest, the resultant impact of these discharges will be of low magnitude and involve receptors of low sensitivity, resulting in an impact of **minor adverse** significance.

Operational Waste Streams: Residual biocide

19.6.212 Where the biological fouling of marine cooling water circuits by the planktonic larvae of bivalves and barnacles, or tube-building worms such as *Sabellaria*, and the adult organisms that subsequently develop, presents a risk, a means of control has to be applied by the plant operator. A variety of means of control are available (Refs. 19.196 and 19.198) but principal amongst these is low level chlorination. Under this approach a low level of oxidant, produced either by the electrochlorination of seawater or through the addition of sodium hypochlorite solution, is dosed into the cooling water stream either on a continuous or intermittent basis. An appropriate level of chlorine in the circulating cooling water controls both macrofouling (settlement bivalves and barnacles) and the build up of microfouling (biofilms) (Refs. 19.196 and 19.198).

19.6.213 The preferred option described in the GDA (Refs. 19.246 and 19.247) is therefore to select an approach based on self-cleaning bar screens at the intake and chlorination of the cooling water prior to the condensers if/as required.

19.6.214 The need for dosing is that of exercising control on a precautionary basis so as to retard biological growth within the cooling water circuit. In practice it is unhelpful to apply a lethal dose of a biocide as this will tend to release larger organisms or aggregations of organisms within the cooling water flow, readily resulting in the plant blockage the operator seeks to avoid. As a result, current best practice is to apply a chronic rather than acute toxicant which is effective within the cooling water system itself, but having little or no impact beyond the point of discharge. The use of oxidant chemistry offers an additional advantage in that the base chemistry of seawater exercises a level of demand, significantly compounding the reduction in levels of residual oxidant remaining as the discharged cooling water effluent is dispersed and diluted.

19.6.215 In variance from the GDA it is considered that dosing to $0.5 mg.l^{-1}$ of active chlorine once every 30 minutes per cooling channel will not be required. This is because operational experience at HPA and HPB suggests that the risk of biofouling is likely to be low at HPC. This long term operational experience at the site is thought to be due primarily to the extreme turbidity regime normal to the nearshore waters of Bridgwater Bay as:

- The very high turbidity levels in the waters around the seabed intake will prevent biofouling by algae.
- Flow rates within the cooling system will typically be $2m.s^{-1}$, and in combination with these high turbidity levels this will tend to discourage successful settlement.
- The very high suspended solids levels of the water extracted from Bridgwater Bay and their low available organic carbon content are understood to greatly limit the 'scope for growth' (i.e. a negative energy balance where energy used to filter food from the suspended sediment is greater than that assimilated from the filtered particles) of species such as the common blue mussel *Mytilus*.

19.6.216 Although the likelihood of biofouling is expected to be low at HPC there may be occasions when cooling water flows are reduced, such as during major outages, when organisms will be able to colonise the cooling system more readily. This is less significant at the Forebay but fouling in the water box next to the condenser is potentially serious as it could result in the blockage of condenser tubes. Reef forming *Sabellaria* is very tolerant of high turbidity and extreme disturbance and could therefore become a problem at Hinkley Point.

19.6.217 It is therefore considered important that the HPC site has the ability to chlorinate the cooling system, should this prove to be necessary, albeit not at the levels or frequency described in the GDA. When chlorination is undertaken the dosing will take place prior to the condensers but after the drumscreens, thus avoiding any dosing of the Fish Recovery and Return system (see discussion of this particular need later in this Chapter).

19.6.218 As described above, the GDA for the EPR design identifies that under normal conditions worst case chlorination will involve injecting $0.5mg.l^{-1}$ of active chlorine, applied sequentially once every 30 minutes per cooling channel to achieve a Total Residual Oxidant (TRO) level of $0.2mg.l^{-1}$. This would only be applied when the sea temperature exceeds 10°C. However, in variance from the GDA, under most circumstances at HPC it is expected that chlorination will not be required. The water quality modelling utilised in this ES (see **Volume 2**, **Chapter 18**) is based on the maximum concentration of residual oxidants downstream of the condensers being $0.2mg.l^{-1}$ if both UK EPR units are being dosed and $0.1mg.l^{-1}$ if only one UK EPR unit is being dosed.

19.6.219 The following proven approach will be adopted to minimise the amount of chlorination required:

- A strategy will be implemented based on "Cooling water management in European power stations: Biology and Control of Fouling" and best practice used by EDF Energy Nuclear Generation (formally British Energy) for its existing fleet of nuclear power stations as set out in their strategy document, Ref. 19.245. This involves the maintenance of a site specific risk based protocol to prevent biofouling. This is an important difference from the general approach described in the GDA.

- The strategy described in Ref. 19.245 describes the fouling control hierarchy as involving screening, cleaning and dosing in that order of preference. Effective screening is the first line of defence, so appropriate plant and practices will be put in place at HPC to achieve this. Screening and filtration help prevent systems becoming fouled but eventually the systems will need to be cleaned. Chemical dosing is a means of limiting fouling but is only carried out in conjunction with screening and cleaning and will not be relied on as the sole means of preventing fouling.
- Identifying the need for chlorination will be closely linked to monitoring protocols for fouling, including monitoring of the condenser efficiency, examination of growth in circuits and monitoring populations of organisms on surrounding shores.

19.6.220 The dosing strategy that will be maintained at HPC will be a risk based intermittent dosing regime that will respect both the operational needs of the plant and local environmental sensitivities.

IMPACT: Subtidal Habitats due to Chorine Discharge

19.6.221 Although it is anticipated that chlorination will be required only infrequently at HPC, the ability to chlorinate is regarded by the operator as a necessary precautionary measure. At some point in the life of the station, changed conditions (e.g. brought about gradually via climate change, or more suddenly via tidal barrage construction), chlorination might become necessary, perhaps at short notice. As a result the effects of a chlorinated discharge need to be discussed here.

19.6.222 Whether added as either sodium hypochlorite solution or produced in situ by electro-chlorination of sea water, the chlorine reacts rapidly by oxidation with the bromide (and to a lesser extent ammonia) in sea water to produce a complex mixture of mainly brominated compounds, dominated within the cooling water circuit itself by hypobromous acid, which provide the active disinfectant. Collectively these disinfecting (oxidising) compounds are known as Total Residual Oxidant (TRO), expressed as a chlorine equivalent (Ref. 19.197).

19.6.223 To provide effective antifouling control within the cooling water circuit the standard chlorine dose applied results in a TRO of $0.2mg.l^{-1}$ at the condensers. The Environmental Quality Standard (EQS) is $0.01mg.l^{-1}$ TRO requiring dilution or decay of 20x.

19.6.224 To describe the mixing zone that would be associated with HPC, the GETM model was used to predict TRO levels in the receiving water (Ref. 19.60). Simulations were run for an April to May period to represent the most typical time when chlorination might be applied (see **Figure 19.28** and **Figure 19.29**). The results indicate that the area of exceedance of the EQS (standards derived under the requirements of the Dangerous Substances Directive) associated with HPC will not extend to the ecologically sensitive areas of the intertidal habitat (se **Volume 2, Chapter 18**). On the basis of the EQS, the sensitivity of the receptor may be considered to be medium, the magnitude of effect low, and the impact significance **minor adverse**.

IMPACT: Intertidal Habitats due to Chlorine Discharge (Chronic)

19.6.225 To test whether or not the key intertidal species on the Hinkley Point mudflat might vary in their resistance of chronic TRO effects, further studies were carried out. Provisional toxicity testing with three abundant species in that area is summarised in Ref. 19.53. A conservative view of the data arising from this effort suggests the potential for some chronic toxicity to sensitive species, and in particular *Macoma*. A precautionary screening level (SL), considering the potential for sublethal effects of TRO exposure in the form of reduced feeding by *Macoma*, 0.001mg.l^{-1} TRO has thus been suggested (see Ref. 19.14). The extent of the mixing zone allied with that SL is shown in **Figure 19.28** and **Figure 19.29**.

19.6.226 Allied predictions of plume extent in relation to habitat type, assuming that both HPB and HPC are chlorinating simultaneously, are provided in **Figure 19.30** and **Figure 19.31**.

19.6.227 On the basis of the suggested SL, and presuming the application of continuous chlorination at both HPB and HPC (noting that such chlorination has not been applied at HPB for many years), the sensitivity of the receptor may be considered to be medium, the magnitude medium, and the significance of the impact **moderate adverse**.

IMPACT: Subtidal Habitats due to Chlorination By-Products Discharge

19.6.228 The acute oxidants formed by chlorination are short lived and are not persistent in natural waters. The residual complexity is the consequent production of numerous more persistent compounds formed by reaction between chlorine (bromine) and other mineral or organic constituents of natural waters. Collectively these compounds are known as chlorination by-products (CBPs) (Refs. 19.198 and 19.199). Given their intimate dependency on local seawater characteristics the actual 'fingerprint' of CBPs produced varies from site to site.

19.6.229 Bromoform is invariably the most common CBP in seawater cooled power station effluents, but other trihalomethanes, haloacetic acids, haloacetonitriles and halophenols are also found (Ref. 19.199). Given that chlorination has not occurred at the Hinkley Point site for many years the likely level of CBP production, and particularly bromoform production (although this will most probably fall into the range already documented for a range of other sites (Ref. 19.200) of 1-43µg.l^{-1} at the cooling water outfall itself), is unknown.

19.6.230 Extensive monitoring around existing nuclear power plants whilst confirming the presence of many CBPs, has shown the concentrations of CBPs measured in the cooling water outfalls to be approximately 1,000 times lower than the acute toxicity thresholds known for each. These CBPs are not bio-magnified in the food chain and are not considered a health risk (Ref. 19.200).

19.6.231 On this basis, receptor sensitivity to exposure to the plume can be regarded as low and the magnitude of the effect medium, resulting in an impact of **minor adverse** significance.

IMPACT: Intertidal and Subtidal Habitats due to Hydrazine Discharge

19.6.232 The potential use of hydrazine and the extent of any chemical plume is described in **Volume 2, Chapter 18**.

19.6.233 GETM modelling at HPC (Ref. 19.60) shows that the acute PNEC is exceeded at the surface in the immediate vicinity of the discharge and the chronic PNEC is exceeded also in the surface water (only), due to the thermal buoyancy of the plume, up to 2km from the discharge. **Figure 19.32** illustrates the extent of intersection with the bed.

19.6.234 The annual mean hydrazine concentrations are not predicted to exceed the chronic PNEC across any areas of the intertidal, so **no impact** is expected on this receptor.

19.6.235 The chronic PNEC will be exceeded for a small subtidal area around the outfall structures themselves. The sensitivity of the subtidal biotopes is considered to be low and the magnitude of impact also low, suggesting an impact of **minor adverse** significance. Further details are provided in **Volume 2**, **Chapter 18**.

IMPACT: Subtidal Habitats due to Ammonia Discharge

19.6.236 Ammonia exists as an equilibrium between free ammonia and ionised ammonium hydroxide: NH_3 + H_20 ⇆ NH_4+ +OH^{-}. The equilibrium is altered by changes in temperature, pH and salinity. Free (unionised) ammonia is the toxic form, so changes in general water quality as well as total ammonia concentration will affect the potential toxicity of the discharge.

19.6.237 The EQS for unionised ammonia is 21µg.l^{-1} NH_3-N.

19.6.238 With current water quality conditions and using the plume as a guide to mixing area (20m deep, 10km wide 20km long), and assuming no decay after discharge, the annual HPC Nitrogen discharge would lead to an average uplift in unionised ammonia levels in the plume of about 2.5µg.l^{-1}. This would be less than 1% of the background level of 360µg. l^{-1} (95th percentile) and so the magnitude is considered to be very low. The sensitivity of the receptor is low given the baseline conditions and the impact on marine ecological receptors is considered to be **negligible**.

iv. Impingement of Fish and Shrimp

19.6.239 The routine abstraction of approximately 125$m^3.s^{-1}$ of cooling water from the Bridgwater bay area of the Inner Bristol Channel for the proposed HPC will carry with it the risk of fish impingement and entrainment resulting in the loss of fish from estuarine populations. Although the cooling water intakes will be protected by coarse bar screens at their entrance to prevent the intake of larger fish and debris, a significant number of organisms (fish and crustaceans, and plankton) will inevitably enter with the cooling water.

19.6.240 Owing to their high relative abundance within local inshore waters and their relative lack of mobility in comparison to adults, the majority of fish abstracted by power station intakes are the egg, larval and juvenile lifestages.

19.6.241 The larger of these organisms (fish and crustaceans >25mm length) will be impinged and removed by fine-meshed drum-screens (currently 10mm at HPB, but 5mm for HPC), before the cooling water enters the power station cooling system, in order to prevent them blocking the condenser tubes.

19.6.242 The smaller organisms (mostly the eggs and larvae of fish and crustaceans) that pass through the drum screens will be entrained in the cooling flow and continue on through the power station cooling system to be returned via the thermal discharge back to the Bristol Channel. As noted below, significant proportions of these entrained organisms are expected to survive the entrainment process to re-enter the estuarine ecosystem.

19.6.243 A small proportion of the incoming cooling water ($12m^3.s^{-1}$ across both EPR units out of the total of around $125m^3.s^{-1}$ maximum) is filtered via separate band-screens sited adjacent to the main drum screens, supplying essential cooling supplies for auxiliary and back-up systems. This has a low duty and minimal impact compared with the main cooling water circuit and therefore, is not discussed further.

19.6.244 Comparison of data from the fish trawling sites surveyed during 2008 to 2009 suggests that, when taking the full catch across surveys as a whole, there was little difference in terms of the fish catch between offshore and nearshore zones (Ref. 19.202). Thus, impingement records from HPB provide a satisfactory basis for predicting abstraction effects for HPC. Entrainment data from HPB are sparser and plankton surveys indicate more variability between nearshore and offshore areas (Ref. 19.33), therefore HPB is not a good model and the studies supporting this ES have thus estimated impingement effects from plankton survey data alone.

19.6.245 Ref. 19.202, together with Refs 19.27 and 19.43, summarise and assess abstraction effects data from HPB and predict impingement and entrainment rates for HPC without and with proposed abstraction mitigation measures. The means of mitigation and the consequential residual impacts are discussed later in this chapter of the ES; the discussion that follows here is constrained to a consideration of unmitigated impacts.

19.6.246 Impingement predictions for HPC are based primarily on a Comprehensive Impingement Monitoring Programme (CIMP) carried out over 12 months from February 2009 to February 2010 (Ref. 19.36) and ichthyoplankton surveys off the Hinkley Point area undertaken quarterly in 2008 and again in May 2009 (Ref. 19.33). Where suitable and appropriate biological data are available, these predictions are put into the context of local commercial landings and local fish populations (spawning-stock biomass (SSB)).

Assessment of Impingement Loss (without mitigation)

19.6.247 CIMP surveys carried out during 2009 and 2010, and analyses of raw impingement catch data, followed best practice procedures set out in Ref. 19.9. This requires a sampling intensity of at least forty 24 hour impingement samples per year, collected according to a strict protocol.

19.6.248 The assessment work undertaken and detailed below has been based upon the following assumptions for an unmitigated abstraction design:

- intake design similar to HPB;
- no chlorination at the intake, within the intake tunnels;
- continual low dose chlorination into the cooling water flow from the pumping station onwards;
- 5mm drum-screen mesh; and
- no FRR system.

19.6.249 Estuarine waters contain a high proportion of juvenile fish, and around 90% of the impingement catch at HPB comprises fish of <20cm total length. Although mostly of no direct value to commercial fisheries, these individuals are important features of the populations both in terms of the protected status of some species and the subsequent potential contribution of all species to the adult fish assemblage. Egg, larval and juvenile lifestages do, however, exhibit high natural mortality rates and relatively few of the individuals lost as a result of impingement and entrainment would have been be likely to survive through to adulthood. To give an indication of the relative value of juvenile life stages to the adult population, the authors of Ref. 19.203 and 19.204 developed a measure known as 'equivalent adult value' (EAV), defined as "*the fraction of the adult lifetime fecundity of an adult that has just reached maturity which is required to replace that juvenile*" (Ref. 19.205). On this basis the author of Ref. 19.206 developed this technique for application within the assessment of power station impact assessment. This approach is further explained in Ref. 19.207, where the authors applied the method for the analysis of Sizewell power station impingement data.

19.6.250 There are a number of limitations associated with the use of EAV. Their calculation is based on the development of life-tables containing detailed information on life-history data, such as age-specific mortality, fecundity and growth rates, which are not available for all species or geographic stocks. Also, the EAV method does not take into account density-dependent factors in population dynamics. It is generally accepted, therefore, that the EAV method represents a worst-case in terms of likely lost production.

19.6.251 The predicted impingement losses for HPC described in Ref. 19.43 are scaled from recent HPB screen surveys. Predictions in this report are primarily based on the BEEMS Comprehensive Impingement Monitoring Programme (CIMP) carried out over 12 months from February 2009 to February 2010 (Ref. 19.36). For a few species, where suitable and appropriate biological data are available, these predictions have been put into the context of local commercial landings and local fish populations (spawning-stock biomass, SSB).

19.6.252 Predicted impingement rates for HPC do not take account of the difference in screen mesh size, which will be 5mm on HPC compared with 10mm on HPB. The HPC screens will therefore retain some smaller fish that would have been entrained into the cooling water system at HPB. There is no reliable method of accounting for this difference. Impingement estimates for HPC will therefore be underestimated, and entrainment rates overestimated.

19.6.253 Data from CIMP were available for up to 64 species of fish and up to 14 species of crustacean. For many of these species the predicted impingement is based upon very small numbers of individuals caught on the screens of existing power stations during limited (40 x 24 hr) sampling intervals at an abstraction rate of $30m^3.s^{-1}$. The predicted impingement has been calculated by scaling the numbers up to a full year at the proposed cooling water abstraction rate of $125m^3.s^{-1}$. For example, only two Allis shad *(Alosa alosa)* were caught, but after scaling up, this leads to a predicted impingement of 68 individuals per year. Such impingement predictions for species caught infrequently are subject to more uncertainty.

19.6.254 For some species of commercial and/or conservation importance, sufficient data are available to make an assessment of stock data and the impact of predicted impingement on the local fish populations in the Bristol Channel and Severn Estuary areas. **Table 19.26** lists the 15 species that constitute about 88% (by number) of the total numbers of fish and shrimp impinged at HPB, providing a prediction of the HPC catch without mitigation. **Table 19.27** shows predicted HPC catch in the context of spawning stock biomass (SSB) or stock size (numbers), as appropriate.

Table 19.26: Predicted Total Annual Impingement (numbers of fish as, EAV, and total number of shrimp) of Key Species at HPC and HPB for Selected Species for an Abstraction Rate of $125m^3.s^{-1}$ via HPB-type Intake Structures, Without Mitigation (Data from Ref. 19.43)

Species: Common Name	EAV Annual Impingement at HPC, Current (HPB) Intake Design	EAV Annual Impingement at HPB
Sprat (largest numbers)	3,380,850	936,386
Whiting (BAP)	288,078	79,253
Sole (BAP)	32,429	8,599
Cod (BAP)	32,063	8,733
Herring (BAP)	44,792	12,570
Plaice (BAP)	493	129
Blue whiting (BAP)	160	46
Eel (Eel management plan)	1,304	351
Twaite shad (SAC designated)	2,276	646
Allis shad (SAC designated)	68	22
Sea lamprey (SAC designated)	207	42
River lamprey (SAC designated)	82	18
Salmon (SAC designated)	0	0
Sea trout (SAC designated)	0	0
Brown shrimp (*Crangon crangon)* – the main crustacean impinged	Estimated annual impingement (no.) 19,135,756	Estimated annual impingement (no.) 4,911,592

Commercial Species

19.6.255 **Table 19.26** shows impingement rates for key, commercial fish species recorded at HPB and rescaled values for HPC, calculated as Equivalent Adult values (EAVs). The rescaled numbers assume replication of the HPB intake design, with no mitigations. Impingement rates of individual species are considered below in the context of known stock data (Ref. 19.43).

19.6.256 **Figure 19.33** shows the distribution of the ICES statistical rectangles referred to in the analysis that follows.

IMPACT: Sprat due to Impingement

19.6.257 Until recently there has been little information on sprat in the Bristol Channel. From 2003, regular biannual Environment Agency (unpublished data) multi-method surveys in the Estuary above Weston-super-Mare have shown sprat nurseries off Cardiff and Penarth.

19.6.258 It seems likely that the sprat encountered at Hinkley Point are part of a population that is limited to the Bristol Channel and, given the lack of any assessment for the species, it is considered that the most useful comparison for sprat is between impingement data at Hinkley Point power station and landings data reported for UK vessels fishing in the Bristol Channel; ICES statistical rectangles (see **Figure 19.33**) 32 E5–E7, 31 E5–E7 and 30 E5 (sprat = 190kg).

19.6.259 Based on the scaled-up CIMP dataset, the total annual estimated impingement of sprat at HPC, assuming a constant abstraction rate of $125m^3.s^{-1}$, would be about 3.38 million fish. Owing to a lack of biological and population data, it is not possible to derive an EAV for sprat, but, as adult sprat are comparatively small, an Equivalent Adult Value of unity is assumed, although this is likely to be a conservative assumption. With the current cooling water intake design, the Equivalent Adult numbers of sprat likely to be impinged annually at HPC without mitigation is approximately 26.4t.

Table 19.27: Equivalent Adult Value (EAV) of Predicted Annual Fish Impingement at Hinkley Point C Power Station at Maximum Cooling Water Demand of 125m^3.s^{-1}, Without Mitigation

Species	Estimated Annual Impingement at HPC (no. of fish)	EAV Annual Impingement at HPC (no. of fish)	EAV Annual Impingement at HPC (biomass - t)	Est. local spawning stock biomass (2004-8) (biomass - t)	EAV Annual Impingement at HPC (% local SSB)	Local Annual Landings (t)	EAV Annual Impingement (% Local Annual Landings)	Impact Assessment (without mitigation)
Sprat	3,380,000	3,380,000	26.40			0.19	13,894.0	Moderate
Whiting	2,100,000	288,078	51.28	1,613.00	3.18	33.48	153.0	Moderate
Sole	602,776	32,429	7.43			263.00	2.8	Minor
Cod****	371,097	32,063	140.40	975.00	14.40	65.17	215.0	Moderate
Herring	90,526	44,792	5.64			119.40	4.7	Moderate
Plaice	5,383	493	0.23	952.00	0.02	84.00	0.3	Minor
Blue whiting	1,166	160	0.02	*37,900.00	5.28×10^{-5}			Minor
Sea bass								Minor
Twaite shad	2,276				Approx. 1.24% local pop.			Moderate
Eel	1,304		0.08	133.40	0.06	26.00	0.3	Moderate
River lamprey	82				<0.07% pop.			Moderate
Sea lamprey	207				1.36% pop.			Moderate
Salmon	0			**58.62 million eggs (Min spawning stock level)		***2482 fish (comm/ recr angling)		Negligible

Notes: *Figures are given as a percentage of spawning stock biomass (SSB) and local annual landings (data from Ref. 19.43). The impact levels are as discussed in the text. SSB is a mean estimate for years 2004 to 2008, inclusive. Local annual landings refer to data from vessels fishing in the Bristol Channel, using ICES statistical rectangles. Based on the scaled-up CIMP dataset.*

* *Combined stock in ICES Subareas VIII and IX and Divisions VII d-k (the "southern areas")*

** *Conservation limit for the Rivers Severn, Wye and Usk combined.*

*** *Mean annual catch (2004-08) in the Severn Estuary net fishery combined with rod catches on the Rivers Severn, Wye and Usk (whether returned to the water or not).*

**** *Cod assessment has subsequently reappraised to account for bias caused by an exceptional spike in recruitment during the period of sampling upon which this assessment was based, in 2009; the ratio of annual catches 2008:2009 was 5.8% and that for the mean of 2004-2008:2009 was 7.3% (Ref. 19.260).*

19.6.260 As the catch of sprat in the local fishery is small (0.19t currently, not as a targeted fishery but incidental), this impingement is almost 140 times that of the local fishery. As no stock assessment is made for sprat, it is not possible to assess the impact of impingement on local populations.

19.6.261 Given that little information is available on the sprat population, a precautionary assessment suggests an impact of **moderate adverse** significance, based on medium magnitude and medium value.

IMPACT: Whiting due to Impingement

19.6.262 Although the basic biology of whiting is well known, it has proved difficult to estimate its abundance and to follow the dynamics of the different populations around the UK (Ref. 19.43). Part of the problem may be related to distribution and stock structure, and the extent of mixing between areas. However, it is well established that there has been an overall decline in abundance of whiting to very low levels in many areas (Ref. 19.209).

19.6.263 There have been sufficient uncertainties in the data used in exploratory assessments for the Celtic Sea whiting (Divisions VIIe–k) stock that ICES is currently unable to provide estimates of fishing mortality or SSB, although SSB shows a decreasing trend and recent recruitment is low (note that survey results indicate that the 2007 year- class may be stronger than the recent average).

19.6.264 The Environment Agency (unpublished data) has shown whiting nurseries to be present on both the English and Welsh coasts of the Bristol Channel and Severn Estuary. It seems likely that the whiting encountered at Hinkley Point are part of a population that occupies the Bristol Channel and Celtic Sea, with some limited mixing with whiting in the Irish Sea. The most useful comparison is between impingement data at Hinkley Point and landings data reported for UK vessels fishing in ICES statistical rectangles (**Figure 19.33**) 32 E5–E7, 31 E5–E7 and 30 E5 (= 33.48t, mean 2004–08). At a population level, an indicative comparison is with the SSB estimate for Divisions VIIe–k, weighted by the ratio of the above landings to total UK landings for VIIe-k. The average UK landings from this stock from 2004 to 2008 were 529t, and the average annual SSB is estimated at 25,492t (corresponding to international landings of 9,240t, as estimated by ICES). Therefore, the estimated "local" SSB = 25492 x (33.48/529) = 1613 t.

19.6.265 Based on the scaled-up CIMP dataset, the total annual estimated impingement of whiting at a new power station at HPC, assuming a constant abstraction rate of $125m^3s^{-1}$, would be about 2.1 million fish. Using the relationship between total numbers, EAV numbers and EAV weights provided by the Expert System PISCES 2009 to re-scale the impingement estimates derived from the CIMP data, and with the current cooling water intake design, the Equivalent Adult number of whiting predicted to be impinged annually at HPC without mitigation is 288,078 fish (51.28t). This equates to approximately 153% of the local whiting fishery (33.5t) and 3% of the "local" SSB (1613t).

19.6.266 On this basis, without mitigation, a **moderate adverse** impact is predicted, based upon medium magnitude and medium value.

NOT PROTECTIVELY MARKED

IMPACT: Sole due to Impingement

19.6.267 Sole stocks have shown substantial variations in abundance over the past 50 years, largely as a result of fishing and variability in breeding success (Ref. 19.210). In the more northern regions, the abundance of sole also fluctuates naturally as a result of severe mortality during very cold winters, such as in 1963. The Environment Agency (unpublished data) has shown sole nurseries to be present on the English coast off Clevedon and the Welsh coast off Peterstone, extending up the M48 crossing. The analytical age-based assessment for the sole stock in the Bristol Channel and Celtic Sea (Divisions VIIf and VIIg, **Figure 19.33**) is based on landings, two commercial catch per unit effort (CPUE) series and one survey index. There is also a confirmatory short UK Fisheries – Science Partnership time-series for this and an adjacent area available to the authors of this assessment. The general trends in the estimates of stock numbers, fishing mortality and recruitment have been similar in recent assessments. The stock is currently considered by ICES to be fished sustainably and to have full reproductive capacity (Ref. 19.209). SSB in 2008 (2200t) is estimated to be above the precautionary biomass limit set by ICES to protect fish stocks. The average (2003–2007) total annual international catch in VIIf, g (not including discarding) was 1,114 t; UK landings were 263 t; and the SSB estimate was 3,240 t.

19.6.268 The sole at Hinkley Point are part of a population that occupies the Bristol Channel and Celtic Sea, with relatively limited mixing with adjacent sole populations. The most valid comparison for sole is between impingement data for the Hinkley Point and landings data reported for UK vessels fishing in the Bristol Channel and Celtic Sea (Divisions VIIf and VIIg), and with the SSB estimate for this stock. Comparison with a more locally restricted fishery or population, in ICES statistical rectangles 32 E5–E7, 31 E5–E7 and 30 E5, say, would ignore the extensive mixing of early life-stages of sole throughout the Bristol Channel and Eastern Celtic Sea.

19.6.269 Based on the scaled-up CIMP dataset, the total annual estimated impingement of sole at a new power station at HPC, assuming a constant abstraction rate of $125m^3.s^{-1}$, would be 602,776 fish (Appendices B2 and B3). Using the relationship between total numbers, EAV numbers and EAV weights provided by the Expert System PISCES 2009 (Ref. 19.43) to re-scale the impingement estimates derived from the CIMP data, and with the current cooling water intake design, the Equivalent Adult numbers of sole likely to be impinged annually at HPC without mitigation is 32,429 fish (7.43t). This equates to approximately 3% of the local sole fishery (263t) and 0.23% of the VIIf,g SSB (3,240t).

19.6.270 On this basis, without mitigation, a **minor adverse** impact is predicted, based on medium magnitude and low value.

IMPACT: Cod due to Impingement

19.6.271 The assessment for cod in ICES Divisions VIIe–k (Western English Channel, Celtic Sea and Bristol Channel) is based on commercial landings, three surveys and four commercial CPUE series. Discard data are not included in the assessment, although a correction for high-grading for the years 2003 to 2005 in the French fisheries has been made. The main uncertainties in this assessment are partial information available on recent quota-induced changes in discarding, and under-reporting and area misreporting of landings. The results of the 2008 assessment are broadly consistent with those of 2007 in terms of trends in fishing mortality, SSB and recruitment, although there was a change in the perception through an upward revision via the fisheries assessment process of the 2005 and 2006 year- classes by 74% and 67%, respectively, and an upward revision of SSB in 2007 by 14%.

19.6.272 Ref. 19.209 considers cod in Divisions VIIe–k (**Figure 19.33**) to be overfished, but currently harvested sustainably. The stock has had a truncated age structure over several decades, and its dynamics have been strongly recruitment-driven, i.e. the stock increased in the past in response to good recruitment and decreased rapidly during times of poor recruitment. Fishing mortality has been very high since the mid-1980s, but has declined since 2002 and is now below the precautionary level of fish mortality set by ICES to protect fish stocks at Fpa (0.68). SSB has been below the absolute biomass limit (beyond which, there are considered too few spawning adults for the population to recover) set by ICES, Blim (6,300t) since 2004, but most recently was estimated to be slightly above the limit. Recruitment since 2002 has been well below the long-term average. The average (2003 to 2007) total annual international catch in VIIe–k (including a high-grading estimate) was 4,175t; UK landings were 343t; and the estimated SSB was 5,133t.

19.6.273 The thermal tolerance of cod is not well known, but scientific evidence (Ref. 19.248) points to the species being cold-adapted, i.e. it prefers lower sea temperatures to warmer ones, especially during its spawning season. Indeed, the Celtic Sea stock management unit of cod lies at the southern limit of the known distribution of cod in the North Atlantic and environs. Very recent data on cod (from eight of the stocks in the NE Atlantic) tracked with electronic data-storage tags (Ref. 19.251) indicate that climate warming will mainly affect cod populations at their early life-history stages and also the prey species on which cod depend, but that cod can exist in a thermal range of -1.5 to 19°C (a much narrower 1-8°C in their spawning season). Such ranges would mark cod down as remarkably thermo-tolerant, but the results of other analyses, despite high levels of uncertainty in the basic data, suggest that some of the southern cod stocks might well disappear within the current century if general predictions of climate warming translate to reality. Ref. 252, for instance, evaluated the likely response of all known and managed cod stocks to climate change (warming) in the period up to 2100 and, although it stresses that oceanographic variables other than temperature (e.g. plankton production, prey and predator fields, and industrial fishing) will play a role in future trends of the cod stocks, its prognoses for the southern stocks of cod such as the Celtic Sea stock are not positive.

19.6.274 Ref. 19.43 states that the cod found at Hinkley Point are part of a population that occupies the Bristol Channel and the eastern Celtic Sea and that has limited mixing with adjacent cod populations. The international stock assessment for cod in this region is for ICES divisions VIIe-k (Western Channel, Celtic Sea and Bristol Channel) and therefore includes cod in the western English Channel and Irish coastal waters, which are thought by some scientists to comprise largely separate stocks from those in the Bristol Channel and eastern Celtic Sea.

19.6.275 The international annual catch estimate for cod in ICES Areas VIIe-k was an average of the 2003-2007 data of 4175t, of which the UK's share was 343t, compared with an

NOT PROTECTIVELY MARKED

estimated VIIe-k spawning stock biomass (SSB, i.e. mature fish, not the sizes being impinged at Hinkley Point) of 5133 t for the same period.

19.6.276 The 'local' UK catch in 2004-2008 was 65.2t ('local' being as recorded from rectangles 32E4-E7, 31E4-E7, 30E4-E5, and 29E4, i.e. from Fishguard in the north to the entrance to the English Channel in the south, and west to west of both Lands End and the western landfall of Wales). The 'local' catch takes place well outside the Bridgwater Bay area, which functions as a nursery for 0-group fish that will not join the adult stock until they much older.

19.6.277 Ref. 19.43 assumed that the stock in the local area could be approximated by the ratio of the UK catches in the local area to the whole VIIe-k area i.e. the "local" SSB would be of the order of 5133*65.2/343t or 975t. Without independent stock assessments of the various areas independently, this is the considered best assumption that can be made.

19.6.278 The SSB estimate was based on analyses back-calculated from catches and survey data up to 2010, but the same data already show that there was a major recruitment spike of the 2009 cod year class (spawned February-April 2009), already possibly seen as being the second highest recruitment in that stock of cod in the historical time-series (Ref. 19.260). The long term time-series maintained at HPB tends over the years to mirror the spikes in cod recruitment observed through fisheries management studies fairly well, and the CIMP data for 2009/10 (Ref. 19.36, which includes an analysis of length frequencies) clearly show those juvenile cod being impinged in large numbers at that time. It is inappropriate to base future impingement prediction likelihood on data collected solely at the time of this clear spike (Ref. 19.260). A revised SSB reflecting the impact of the 2009 recruitment on the overall Celtic Sea cod stock would not be viewed as scientifically sound until those cod started to appear in the commercial catches in large numbers, which will not be until 2012. Prior to 2009 the last cod recruitment spike in both the long term HPB data and the national fisheries database was in 2000, but the total cod numbers impinged in that (also good recruitment) year were only 37% of those in 2009.

19.6.279 In order to use datasets that are synchronous in time with the catch and stock assessment data, this assessment should ideally be using either 2008 or earlier impingement data or an average for the period 2004-2008 to predict future HPC impingement of juvenile cod. On the basis of monthly time-series of cod numbers impinged at HPB for the periods January 2003 to March 2010, the ratio of annual catches is as follows:

- 2008:2009 : 5.8% of 2009 catch;
- Mean 2004-2008:2009 : 7.3%.

19.6.280 Taking the worst case figure of 7.3%, the HPB and HPC catches are reduced to:

- HPB: 0.29% of local SSB;
- HPC: 0.24% of local SSB;
- HPB+HPC: 0.51% of local SSB.

19.6.281 On this basis, without mitigation, a **minor adverse** impact is predicted based upon low magnitude and the medium value of the receptor.

IMPACT: Herring due to Impingement

19.6.282 Except where a fishery exploits spawning herring (e.g. at Llangwm in Milford Haven), larval surveys are the main tool to locate and assess inshore spawning populations, but insufficient numbers of small larvae have been found to assess the status of these small spawning groups of herring. Only MMO landings statistics from local fisheries are available.

19.6.283 It seems likely that the herring encountered at Hinkley Point are part of a population (or populations) that is limited to the Bristol Channel and adjacent inshore waters and, given the lack of any assessment, it is considered that the most useful comparison is between impingement data for the Hinkley Point and herring landings data reported for UK vessels fishing in ICES statistical rectangles (**Figure 19.33**) 32 E5–E7, 31 E5–E7 and 30 E4–E5 (119.4t, mean for 2004 to 2008).

19.6.284 Based on the scaled-up CIMP dataset, the total annual estimated impingement of herring at HPC, assuming a constant abstraction rate of $125m^3.s^{-1}$, without mitigation, would be about 90,526 fish. Using the relationship between total numbers, EAV numbers and EAV weights provided by Expert System PISCES 2009 to re-scale the impingement estimates derived from the CIMP data, and with the current cooling water intake design, the Equivalent Adult number of herring likely to be impinged annually at Hinkley C is 44,792 fish (5.64t). This equates to approximately 5% of the local herring fishery (119.4t). As no stock assessment is carried out for herring in the area, it is not possible to assess the impact of impingement on local populations.

19.6.285 On this basis, without mitigation, a **moderate adverse** impact is predicted based upon medium magnitude and medium value.

IMPACT: Plaice due to Impingement

19.6.286 Ref. 19.209 advises that the plaice stock in the Celtic Sea (Divisions VIIf,g) had reduced reproductive capacity and was overfished. SSB peaked in the period 1988 to 1990, following a series of good year- classes, then declined rapidly and, since 2002, has been below or around the biomass limit (1,100t). There have been some very weak year- classes since the late 1990s. The average (2003 to 2007) total annual international catch in VIIf,g (not including discarding) (**Figure 19.33**) was 461t; UK landings were 84t; and the SSB estimate was 952t.

19.6.287 Plaice encountered at Hinkley Point are part of a population that occupies the Bristol Channel and Celtic Sea, with some limited mixing with plaice in the Irish Sea. The Environment Agency (unpublished data) has shown plaice nurseries to be present off Cardiff Flats. However, given that ICES conducts separate assessments for ‘stocks’ in VIIf,g and VIIa (Irish Sea), Ref. 19.43 considers that the most useful comparison for plaice is between impingement data for the Hinkley Point and landings data reported for UK vessels fishing in the Bristol Channel and Celtic Sea (Divisions VIIf and VIIg), and with the SSB estimate for this stock. Comparison with a more locally restricted fishery or population, in ICES statistical rectangles 32 E5–E7, 31 E5–E7

NOT PROTECTIVELY MARKED

and 30 E5, say, would ignore the extensive mixing of plaice life stages throughout the Bristol Channel and Eastern Celtic Sea, and with adjacent plaice populations.

19.6.288 Based on the scaled-up CIMP dataset, the total annual estimated impingement of plaice at HPC, assuming a constant abstraction rate of $125m^3.s^{-1}$, would be about 5,383 fish (Appendices B2 and B3). Using the relationship between total numbers, EAV numbers and EAV weights provided by the Expert System PISCES 2009 to re-scale the impingement estimates derived from the CIMP data, and with the current cooling water intake design, the Equivalent Adult numbers of plaice likely to be impinged annually at HPC without mitigation is 493 fish (0.23t). This equates to approximately 0.3% of the local plaice fishery (84t) and 0.02% of the Celtic Sea SSB (952t).

19.6.289 On this basis, without mitigation, a **minor adverse** impact is predicted, based upon a medium magnitude of effect and low value.

IMPACT: Blue Whiting due to Impingement

19.6.290 The ICES assessment of the stock status of blue whiting is based on an analysis of catch-at-age data from commercial fisheries from 1981 to 2009, and three acoustic surveys that between them cover the distributional area of the spawning stock (Ref. 19.43). These show that recruitment of the 2005 to 2009 year classes has been low (following ten years of above average recruitment) and there has been a significant decrease in SSB since 2004, although the estimated abundances for recent years have changed greatly with successive annual assessments. For example, the SSB estimate for 2009 is estimated in 2010 to be about 42% lower than the estimate made in 2009. The Ref. 19.43 assessment values (which have built on previous work) are used here.

19.6.291 There is no evidence that blue whiting in the Bristol Channel and Celtic Sea are discrete from the population that occupies the whole of the west coast of North-West Europe (including the Norwegian Sea), which ICES treats as a single stock for assessment purposes. It is considered that the most useful comparison is between impingement data at Hinkley Point and landings data reported for all vessels fishing the combined stock in Subareas VIII and IX, and Divisions VIId-k (the " southern areas") (= 37,900t, mean 2004 to 2008). At a population level, the mean SSB estimate for the whole stock in the years 2004 to 2008 was 5,360,000t, which is near the long-term mean for the stock.

19.6.292 Based on the scaled-up CIMP dataset, the total annual estimated impingement of blue whiting at HPC, assuming a constant abstraction rate of $125m^3.s^{-1}$, without mitigation, would be about 1,166 fish. Using the relationship between total numbers, EAV numbers and EAV weights for whiting (which we have assumed will be similar for blue whiting) provided by the Expert System PISCES 2009 to re-scale the impingement estimates derived from the CIMP data, and with the current cooling water intake design, the Equivalent Adult numbers of blue whiting likely to be impinged annually at HPC is 160 fish (0.02t). This equates to <0.1% of the blue whiting fishery (37,900t) and <0.1% of the corresponding SSB (5,360,000t).

19.6.293 On this basis, without mitigation, a **minor adverse** impact is predicted based upon medium magnitude and a low value.

IMPACT: Sea Bass due to Impingement

19.6.294 Environment Agency (unpublished data) surveys have shown sea bass nurseries extending from Cardiff Flats eastwards to Arlingham, near Gloucester. However, few sea bass are taken on the HPB screens.

19.6.295 On the basis that the magnitude of impact is very low and a receptor of medium value, the significance of any impact is considered to be **minor adverse**.

IMPACT: Crustacean (including C. crangon) due to Impingement

19.6.296 The coastal areas (out to six nautical miles) off the North Devon coast and off the South Wales coast west of the River Rhymney come under the jurisdiction of the Devon and the South Wales Sea Fisheries Committees (SFC), respectively. The sea area of the Bristol Channel east of the Devon and Somerset border around to the mouth of the River Rhymney in South Wales falls outside the geographic boundaries covered by any SFC and, consequently, is an area where fishing activity remains largely unknown. It is suspected that there may be some artisanal crustacean fisheries, for example stake-netting or push-netting for brown shrimps, because healthy populations are known to exist, but the absence of any fisheries authority in the area suggests that it is of relatively little importance from a fisheries perspective. The South Wales SFC suggests that there is little or no potting activity east of Porthcawl on the Welsh coast, and Devon SFC is similarly unaware of any significant potting or trawling activity east of its border.

19.6.297 The official reported landings of shellfish, as recorded by the MMO (Ref. 19.27), show no brown or pink shrimps from this area in recent years (from 2000). The same data since 2005 show that reported annual landings of brown crab from the Bristol Channel area (as defined by ICES rectangles 30E5, 31E5–E7 and 32E5, **Figure 19.33**) are typically of the order of 200t, but less than 11t (in 2007) was taken in rectangle 31E6, the eastern portion of which is in the area adjacent to the Somerset coast and in the vicinity of Hinkley Point. The level of spatial resolution described by an ICES rectangle prevents us from specifying whether these crabs were taken close to the power station or, more likely, in the extreme west of the area off the North Devon coast. Reported annual landings of velvet swimming crabs *(Necora puber)* and common prawns from the Bristol Channel as a whole since 2005 are 3.5t and <200kg respectively, with just 30kg of velvet swimming crabs (in 2009 only), and no common prawns coming from rectangle 31E6. Most of the landings of these crustaceans in the Bristol Channel area are made into Devon and Cornwall, or to Welsh ports on the Pembrokeshire coast. A population estimate for the brown shrimp and the adjacent Stolford mudflats ($20km^2$) in the 1980s (Ref. 19.100) put the stock level at between $3x10^6$ to $5x10^7$ individuals (approximately 3-50t biomass).

19.6.298 In a national context, the reported landings of these crustaceans into England and Wales in 2008 were: brown crabs, 11,403t; velvet swimming crabs, 332t; common prawns, 33t; brown shrimps, 861t; shore crabs, 21t; and pink shrimps, 13t.

19.6.299 The annual shrimp *(C. crangon)* catch for HPC is predicted to be 19,135,756 individuals (**Table 19.26**), equivalent to around 19t.

NOT PROTECTIVELY MARKED

19.6.300 On this basis, without mitigation, a **moderate adverse** impact is predicted based upon medium magnitude and medium value.

Specifically Designated Conservation Species

IMPACT: Salmon due to Impingement

19.6.301 Although estimates of the upstream run of adult salmon are obtained using electronic fish counters or upstream traps on a number of catchments in England and Wales, there are no such data available for rivers entering the Severn Estuary. However, estimates of spawning escapement (numbers of spawning adult fish) are obtained from catch data and exploitation rates, and these are used to assess individual river stock status against conservation limits (CLs: the minimum spawning stock level below which further reductions in spawning numbers are likely to result in significant reductions in the number of juvenile fish produced in the next generation). The CL for each river is defined in terms of eggs deposited.

19.6.302 The River Severn CL is 12.85 million eggs, and the egg deposition estimated for 2008 was 16.56 million, 120% of the CL (mean 131%, 2004 to 2008). The River Wye CL is 35.66 million eggs, and the egg deposition estimated for 2008 was 22.58 million, 63% of the CL (mean 61%, 2004 to 2008). The River Usk CL is 10.11 million eggs, and the egg deposition estimated for 2008 was 21.36 million, 211% of the CL (mean 189%, 2004 to 2008). From these values we can estimate the number of smolts produced, using average egg-to-smolt survival data.

19.6.303 The mean annual catch (2004 to 2008) of salmon from the Severn Estuary net fishery was 837 fish (the long-term average is approximately 3,000 fish), with rods taking an average of 336, 682 and 987 fish from the Rivers Severn, Wye and Usk, respectively.

19.6.304 For the purposes of evaluating the impact of impingement of salmon smolts or adult fish on the intakes at Hinkley Point, data on catches or estimates of abundance for the Severn Estuary and its major rivers, the Severn, Wye and Usk, cover the overwhelming majority of salmon that might be vulnerable. Over the five-year period of 2004 to 2008, the mean annual catch of salmon from the commercial net fishery in the Severn Estuary was 837 fish, and recreational anglers caught an annual average of 2005 salmon from the Rivers Severn, Wye and Usk combined. Although 55% of salmon reported caught by anglers on these rivers were released alive, any impact of power station mortalities should be compared with the total catch (not fish killed), because recreational fisheries are valued per salmon caught.

19.6.305 No salmon were recorded in the long-term impingement monitoring programme at Hinkley Point between 2005 and 2009 and none were recorded in the CIMP (see Ref. 19.27).

19.6.306 On this basis, without mitigation, the predicted impact is considered to be **negligible**.

IMPACT: Twaite Shad due to Impingement

19.6.307 Spawning populations of twaite shad are confined to four rivers in the UK, namely the Rivers Tywi, Usk, Wye and Severn (including its tributary the River Teme). The twaite shad is a protected species, but there is only sparse population data for them in the Severn Estuary, so the potential for the estimation of shad stock sizes from current sampling techniques is limited and, as such, few estimates have been made. However, as part of the recent Severn Tidal Power Feasibility Study Strategic Environmental Assessment, an attempt has been made to estimate shad population size and age distribution using a simplified age-structured matrix model (Ref. 19.212).

19.6.308 The model described in Ref. 19.212 applies a matrix incorporating life-history parameters (adult survival rates; sex ratio; fecundity at weight/age; spawning propensity; and density-dependence) to predict the number of adult female shad within the River Severn RBD. The model incorporates a density-dependent egg deposition function based on a stock–recruitment relationship derived by M. Aprahamian (pers. comm., cited in Ref. 19.212) for adult females aged six years and applies forecasting and hindcasting methods using documented life history parameters to predict adult population size in a given year. For the purposes of this study, adults are considered to be aged between three and nine years old.

19.6.309 The model estimate indicates an average population size of approximately 92,000 female shad. Given a sex ratio of 1:1, the total mean population of twaite shad aged between three and nine years in the Severn RBD is therefore estimated to be 184,000, although variation in year-class strength may result in estimates ranging between 112,000 and 596,000.

19.6.310 Based on the scaled-up CIMP dataset, the total annual estimated impingement of twaite shad at a new power station at Hinkley Point, assuming a constant abstraction rate of $125m^3.s^{-1}$, without mitigation, would be about 2,276 fish (Ref. 19.43). As it is not currently possible to derive an EAV for twaite shad because of the absence of the necessary life history data, we have not rescaled the impingement estimates derived from the CIMP data. Therefore, with the present cooling water intake design, the equivalent adult numbers of twaite shad likely to be impinged annually at HPC (2,276 fish) equates to approximately 1.24% of the estimated local twaite shad population (184,000 adults).

19.6.311 On this basis, without mitigation, a **moderate adverse** impact is predicted, based upon a medium magnitude of effect and medium receptor value.

IMPACT: Eel due to Impingement

19.6.312 The Environment Agency monitors fish populations extensively within the Severn River Basin District (RBD), although the (mostly) multispecies electric fishing surveys used may underestimate the true density of eel (Ref. 19.213). The data suggest that eels are currently well distributed throughout the lower and middle parts of the catchments, and the Environment Agency has concluded that the eel population in the Severn downstream from Worcester has shown little change since the early 1980s, over the period when average recruitment to Europe has declined substantially (by 95% or more; Ref. 19.214).

19.6.313 The density and the biomass of eel in the middle reaches of the Severn and Warwickshire Avon catchments were low during the 1980s, but have not been

NOT PROTECTIVELY MARKED

surveyed in recent years. Similar survey data for the Bristol Avon catchment and Somerset rivers within the Severn RBD indicate a general decline in densities and biomasses between 1991 and 1993, and 1994 and 2006, by 37% and 48%, respectively.

19.6.314 A modelling approach to estimate the proportional impact of estuarine glass eel fisheries on the population is available (see Ref. 19.215 and 19.216) and, although it could be used here, it requires extensive sampling of glass eels during spring, when they enter the estuary.

19.6.315 In the absence of data on historical production of eel in England and Wales, a standard production rate of 16.9kg per hectare has been applied by the Environment Agency in estimating historic production and hence setting the 40% escapement biomass target (6.76kg per hectare) required under the European Eel Regulation 110/2007. This production rate was selected with reference to estimated production rates for the Bann (Northern Ireland) and Loire (France) catchments, reported by Ref. 19.217. Using the Environment Agency's Probability Model (Ref. 19.218), silver eel output from the Severn RBD is estimated to be about 8.4kg per hectare, which equates to about 133.4t of silver eel per year (Ref. 19.219). As such, the Severn RBD is tentatively assessed as exceeding its management target for silver eel production at this time. Note, however, that this model estimate is based on estimates of local yellow eel densities for 109 sites in the Severn catchment, extrapolated to the entire wetted area and converted to silver eel equivalents using a "silvering index", and therefore has a high degree of uncertainty.

19.6.316 Given Hinkley Point's location on the south coast of the Inner Bristol Channel seawards of the River Parrett, the potentially susceptible population consists of glass eels/elvers migrating upstream to freshwater, silver eels migrating downstream from freshwater, and any yellow eels living in the marine environment of the local area. Comparisons of glass eel and yellow/silver eel mortalities through impingement with population estimates are theoretically possible, but the models to permit this are still being developed and it is uncertain anyway which are the relevant 'populations'. The European eel is currently considered to comprise a single reproductive stock throughout its distribution range (and spawns in the Sargasso Sea off the Gulf of Mexico), and individual river and adjacent coastal marine populations appear to mix considerably.

19.6.317 The most useful indicator of impact is a comparison between impingement data for eels (although these are not differentiated by life stage) at Hinkley Point and estimates of the reported catch of each life stage 2005 to 2008 in the Severn Estuary RBD. A total of 774kg of glass eels was declared as caught in the Severn RBD in 2005, 684kg in 2006 and 1254kg in 2007. The declared annual catches of yellow eels in the years 2005 to 2007 were 4,088, 2,785 and 892kg respectively, and 419, 968 and 133kg of silver eels.

19.6.318 Based on the scaled-up CIMP dataset, the total annual estimated impingement of eels at HPC, assuming a constant abstraction rate of $125m^3.s^{-1}$, would (without mitigation) be about 1,304 fish, equivalent to 0.08t of adult eels. As it is not currently possible to derive an EAV for eels because of their complex life history, the impingement estimates derived from the CIMP data are not rescaled. With the present HPB cooling water intake design, the equivalent adult numbers of eels likely to be impinged annually at HPC (i.e. 0.08t) equates to <0.3% of a potential eel fishery (26t) and <0.06% of the local SSB (133.4t).

19.6.319 On this basis, without mitigation, a **moderate adverse** impact is predicted, based upon a low magnitude effect and the high sensitivity of the receptor. The impact of entrainment is considered separately below.

IMPACT: River and Sea Lamprey due to Impingement

19.6.320 More than half the UK SAC designations for the presence of either one or both of river and sea lamprey are situated on the Welsh coast, including the Rivers Wye and Usk. The most recent condition assessment round in 2007 classified all but the River Usk as unfavourable for river lamprey and all but the River Wye as unfavourable for sea lamprey. Stock status information is restricted to SAC rivers and is primarily in the form of ammocoete (larval lamprey) densities and distribution. The River Usk has the greatest *Lampetra* spp. ammocoete population across all British SAC rivers, and the River Wye has the greatest sea lamprey ammocoete population (Ref. 19.220).

19.6.321 Although river and sea lamprey are believed to spawn and reside within the River Severn, no assessment has been undertaken of their stock. However, as part of the Severn Tidal Power Feasibility Study Strategic Environmental Assessment, an estimate of lamprey population size and age distributions was derived (Ref. 19.212) using measurements of life-history traits collated from the literature to construct a generic life table for sea lamprey and river lamprey. Lampreys were assumed to represent one discrete population, given the species' capacity to disperse, as evidenced by their lack of homing and wide juvenile movement within several rivers throughout the UK. The life cycle of lamprey was represented by a stage-structured model and constructed with vital rate data and information on: average age at metamorphosis (ammocoete and parasitic juvenile); average ammocoete density per m^2 of optimal and suboptimal habitat; metamorphosis success (ammocoete to parasitic juvenile); ammocoete survival; and sex ratio.

19.6.322 Markov Chain Monte Carlo (MCMC) simulations were used to estimate the mean population size from the model output and provide a likely average population size of adult lamprey in the Rivers Usk and Wye. These estimates have been based on best guesses of available habitat of 1% per metre length of river for both optimal and suboptimal habitat. The population estimates are shown in **Table 19.28** (Ref. 19.212).

Table 19.28: Population Estimates of Lamprey (Mean ± s.d.) (Ref. 19.212)

	River Lamprey	Sea Lamprey
Usk	27,667 ± 4,696	3,069 ± 455
Wye	88,442 ± 14,326	12,200 ± 1,836
Total	116,109	15,269

19.6.323 Based on the scaled-up CIMP dataset, the total annual estimated impingement of river and sea lamprey at HPC, assuming a constant abstraction rate of $125m^3.s^{-1}$, without impingement, would be about 82 and 207 fish (Ref. 19.43), respectively. As it is not currently possible to derive an EAV for lamprey because of their complex life

NOT PROTECTIVELY MARKED

history, the impingement estimates derived from the CIMP data have not been rescaled. Therefore, with the present HPC cooling water intake design, the numbers of lamprey likely to be impinged annually at HPC equate to <0.07% of the river lamprey population and 1.36% of the estimated sea lamprey population.

19.6.324 On this basis, without mitigation, a **moderate adverse** impact is predicted based upon low magnitude and the high sensitivity of the receptor.

IMPACT: Fish Assemblage due to Impingement

19.6.325 The range of fish species assessed in some detail above is reasonably representative of the fish assemblage as a whole. In sum, a medium sensitivity and medium magnitude of effect may be assigned resulting, without mitigation, in an impact upon the local estuarine/marine fish assemblage of **moderate adverse** significance. See Ref. 19.14 for further discussion.

v. Entrainment

19.6.326 The aquatic organisms at risk of passing through the filtration system fall into three categories:

- Holoplankton representing those organisms that permanently exist within the plankton which are dominated by copepods within the Bristol Channel as with many other estuaries in the UK.
- Meroplankton representing those organisms which temporarily reside within the plankton including decapods, molluscs, echinoderms, annelids, shrimps, eggs and larvae (fish and invertebrate).
- Juvenile fish of a size small enough to allow them to pass through the drum screen mesh.

Assessment of Entrainment Loss (without mitigation)

19.6.327 The estimation of entrainment impacts associated with HPC (Ref. 19.27) has been carried out in accordance with best practice guidance contained in Ref. 19.18. Assumptions on cooling water system design are as for the Assessment of Impingement Losses, above.

19.6.328 The six anadromous species designated under the Severn Estuary, River Wye and River Usk SACs are: Atlantic salmon, twaite shad, allis shad, river lamprey, sea lamprey and sea trout. Being anadromous, the early life stages of the SAC species salmon, and the BAP species, sea trout are not likely to be vulnerable to entrainment as they will remain within freshwater during this life stage.

19.6.329 In addition, the juvenile life stages of these species present within the Inner Bristol Channel will be of sufficient size to avoid their passage through the 5mm drum screen mesh and would thus be subject to impingement mortality instead (Table 19.29) and likewise be subject to any means of mitigation associated with that impinged catch (see below). Lamprey transformers, glass eel, elvers and juvenile shad could however be vulnerable to entrainment as they may be present in the area at a size small enough to allow them to pass through a mesh size of either 5mm.

Table 19.29: Smallest Sizes of Various Fish Species Excluded by a 5mm Screen Mesh (Ref. 19.238)

Species	Smallest Size Excluded (Length, mm)
Eel, lamprey, pipefishes	100
Herring, salmon, common goby, sand-smelt, poor cod, whiting, sprat, grey mullet	40
Sea bass, shad, pouting	35

19.6.330 The previous entrainment studies at HPB and plankton studies within the vicinity of the site suggest that the eggs and larvae of the following key species are potentially at risk of being entrained through the cooling water system: sea bass, cod, eel, flounder, haddock, herring, lemon sole, plaice, pout, sole, sprat, gobies and whiting.

19.6.331 Entrainment estimates were determined on the basis that fish eggs and larvae would be entrained in direct volumetric proportion to their densities within the Bristol Channel within the vicinity of Hinkley Point (ICES rectangles 29E4, 30E4, 31E4, 30E5, 31E5 and 31E6, **Figure 19.33**). This assumption may be over-pessimistic. Ref. 19.221 found that the densities of fish larvae in Southampton Water were greater than those entrained from the entire water column, indicating that larvae were able to avoid entrainment and that actual entrained numbers were significantly lower than would be expected from offshore plankton surveys. At Bradwell Power Station on the Blackwater Estuary in Essex, entrainment monitoring for sole eggs and fry sampled just a single egg during seven weeks on-site. Whether the differences observed in this study or the previous studies are a result of the sampling techniques or a result of patchy distribution of plankton is unknown, but it has been suggested that it may in part be due to stratification of larvae in the water column (Ref. 19.222).

Entrainment of Other Zoo- and Phytoplankton

19.6.332 Other types of plankton will enter with the cooling water and are not likely to resist entrainment, although patchiness and stratification may affect their susceptibility. BEEMS surveys at HPB indicate that crustacea form an important component of entrained holoplankton (e.g. the seasonal mysid *Schistomysis spiritus*). Phytoplankton levels, primarily comprised of diatoms, are low in the Bridgwater Bay area of the Bristol Channel, owing to high turbidities, and consequently zooplankton are limited. As noted earlier in this Chapter, copepods are the dominant zooplankton in the waters off Hinkley Point.

19.6.333 Aquatic organisms entrained through the travelling screen mesh and into the cooling water system are at risk of a number of mechanical, hydraulic, pressure, temperature and chemical related stressors during this passage. The survival of entrained individuals is dependent upon the species, their developmental stage and size, physiological condition and the design of the cooling water system.

IMPACT: Entrainment of Phytoplankton

19.6.334 In a series of experiments at Fawley power station the author of Ref. 19.250 demonstrated that, in the absence of chlorination, primary production was enhanced

NOT PROTECTIVELY MARKED

by increased water temperature up to a discharge temperature of 23ºC but thereafter was progressively inhibited. No significant net loss in phytoplankton productivity was found at discharge temperatures of up to 27ºC. The author concluded that the entrainment effects of mechanical damage and thermal shock on phytoplankton were negligible.

19.6.335 That same study found that primary productivity was reduced by approximately 60% with a chlorination level of 0.2mg.l^{-1} and a Δt of 10ºC. It was not clear if the phytoplankton cells were killed or temporarily inhibited. For experimental reasons cells had to be cultured in chlorinated water for 3 hours, which is not representative of the short exposures in a power station (e.g. 18 minutes for HPC). Such exposure may have increased the measured effects.

19.6.336 Ref. 19.250 describes results from laboratory experiments on the effects of thermal shock upon the diatoms *Phaeodactylum tricornutum* and *Gyrosigma spencerii*. Neither species were significantly affected when cultured at 12ºC or 16ºC by thermal shocks of up to 17ºC. Both species were killed at ambient temperatures of 24ºC and a Δt of 15ºC. Growth was inhibited at a Δt of 10ºC and Δt of 12ºC respectively. The LT50 (lethal temperature to 50% of the species) was 36.5ºC and 37ºC respectively.

19.6.337 The flagellate *Dunaliella tertiolecta* was more resistant and survived an exposure time of 40 minutes at a final discharge temperature of 41ºC; cell growth stopped for 5 days and then recovered to densities similar to the control within 12 days.

19.6.338 The 98%-ile predicted discharge temperature of HPC is 32.9°C (i.e. below the below expected LT50 values (Ref. 19.250)). No loss of productivity is expected at a discharge temperature of 31ºC. At 34ºC there is a possibility of a small reduction in growth, but this may not be noticeable in the enhanced productivity of the warmer receiving waters. In the absence of chlorination the thermal effects of entrainment on primary production are thus expected to be **negligible**.

19.6.339 If chlorination resulting in an in-circuit level of 0.2mg.l^{-1} TRO were employed by HPC, the available evidence (Ref. 19.250) suggests that an approximate 60% reduction in productivity would be expected in entrained phytoplankton. Making worst case assumptions that the effected cells were killed and that HPC extracts 1% of the available source (plume) volume per day (Ref. 19.27) within the zone of abstraction, then 0.7% of the phytoplankton cells in that plume volume would be killed per day. Assuming phytoplankton are uniformly distributed over the entire Inner Channel, HPC could kill 0.05% of the Inner Channel phytoplankton abundance per day. The overwhelming majority of phytoplankton production and consumption by copepod zooplankton takes place outside of the Inner Channel and outside of the influence of HPC (Ref. 19.255).

19.6.340 The predicted recirculation of the HPC discharge water into the intakes is slight (Ref. 19.38). Moreover the reduced phytoplankton abundance in the HPC discharge water would rapidly be restocked from phytoplankton cells from elsewhere in the Channel that are outside of the HPC abstraction zone. Under such circumstances the impact on phytoplankton productivity would be **negligible**.

IMPACT: Entrainment of Zooplankton (1) copepods

19.6.341 A comprehensive review of entrainment survival for over 20 power stations in the USA determined a mean survival rate for a range of aquatic organisms and lifestages of over 50% (Ref. 19.223). Survival rates were highest for macroinvertebrates (72 to 92%) and lowest for sensitive fish species such as herring (mean values approaching 25%). Effects from physical, temperature and chemical stressors differed between the species. As would be expected survival was lowest for the delicate early larval stages and highest in early juveniles. For clupeids survival rates of juveniles ranged from zero to 81.5% with an average of 25%. Similar survival rates were also observed for clupeid larvae ranging from zero to 70%.

19.6.342 Ref. 19.224 describes the development of an entrainment mimic unit (EMU) designed to mimic realistically the conditions of entrainment passage through the cooling water system of a coastal power station under laboratory conditions as a means of assessing likely mortalities of entrained organisms. The apparatus allows the assessment of the effects of the four key stressors of entrainment: temperature, pressure, biocide and mechanical effects, alone and in combination. Their original experiments on larvae of the Pacific oyster *(Crassostrea gigas)* gave a baseline comparison of the technique to a standard bioassay technique (the D-stage larval test) and demonstrated the suitability of the apparatus and experimental protocols to assess the impacts of power-station entrainment.

19.6.343 A study reported in Ref. 19.250 calculated that the natural mortality of the copepod *Eurytemora affinis* in the Inner Channel was approximately 33 yr^{-1} i.e. 8.6% per day. This value was not atypical for copepods found in similar temperatures. Annual mortality ranges for *Acartia* spp. were reported as 17-58 yr^{-1} with higher figures of up to 257 yr^{-1} reported for tropical latitudes.

19.6.344 As noted above, the dominant members of the plankton at Hinkley Point are members of the genus *Acartia* and an assessment of the likely impact upon this genus alone thus has value in terms of indicating the likely scale of impact on the local holoplanktonic assemblage as a whole. After Ref. 19.250, this assessment makes the following assumptions: 1.1% of plume volume entrained per day (Ref. 19.27); entrainment mortality 20% (from EMU experiments, Ref. 19.200); ratio of plume volume to volume of Inner Channel =7.2%; copepods uniformly distributed throughout the Inner Channel. The entrainment mortality in the summer at Hinkley Point will represent 0.016% of the Inner Channel population per day. Ref. 19.253 and further studies described by Ref. 19.250 show that the population of *Acartia* spp. is distributed over the entire Central and Inner Channels in the summer and, therefore, the percentage of the Bristol Channel population that will be killed by HPC is less than 0.004%. Given the natural productivity of the species this will cause a **negligible** impact.

IMPACT: Entrainment of Zooplankton (3) Sabellaria larvae

19.6.345 As noted earlier in this Chapter, reefs of the tube building worm, *Sabellaria alveolata,* are found to the west of Hinkley Point and along the low shore directly in front of the station, as well as on some low shore areas of Stert Flats.

NOT PROTECTIVELY MARKED

19.6.346 As described by Ref. 19.250, there is evidence from laboratory experiments that *S.alveloata* spawns briefly in July and the larvae spend a minimum of six weeks and a maximum of eight months in the plankton. Field observations on larval settlement have proved variable from year to year but peaks have been detected off the Cornish coast in September to November and December. On the French Atlantic coast peak larval densities have been reported from October to March and spawning has been reported in the Bay of Mont-Saint-Michel in early May with a settlement time of 12 weeks and then September with a settlement period in the 8ºC warmer water of four weeks.

19.6.347 Larvae settle principally on old colonies and detect the cement used by tube building worms of *S.alveolata* or *S.spinulosa*. Natural mortality has been estimated by field measurement to be 0.09 d^{-1} (range 0.089 to 0.097 d^{-1}). These values were in the range of marine invertebrate mortalities described elsewhere (Ref. 19.250) (mean of 23 species 0.23 d^{-1}, range 0.016 to 0.82). There is evidence for vertical migration with larvae moving towards the surface during the flood tide during the day as well as at night.

19.6.348 *S.alveolata* growth is promoted by high levels of suspended sediment and higher water temperatures. In the UK it is at or near the northern edge of its thermal range and it can suffer high mortalities in cold winters.

19.6.349 The planktonic life stage of *S. alveoloata* is the only stage vulnerable to entrainment. There are no published data on the entrainment mortality of *Sabellaria* larvae. Ref. 19.44 found no adult mortality for *S. spinulosa* after a 28 day exposure to chlorine at 0.1mg.l^{-1} at 15ºC ambient. Ref. 19.52 reports an EC50 for a 5min exposure at 0.3mg l^{-1} for the polychaete *Phragmatopoma californica* (temperature not specified). In the absence of more data a 50% mortality has been assumed for HPC with chlorination at 0.2mg l^{-1} TRO.

19.6.350 Modelling of the potential abstraction of *Sabellaria* larvae released from potential spawning areas in Bridgwater Bay by particle tracking in the HPC GETM model (Ref. 19.261) predicts a 0.05% chance of larval abstraction per day for four intakes. Assuming 50% entrainment mortality, the predicted worst case loss of *S.alveolata* larvae is 0.025% per day. Natural mortality is approximately 9% per day (Ref. 19.250). In practice the risk of abstraction will be less than calculated because no account has been taken of larval dispersion into the wider channel. The resultant increase in natural mortality from 9% to 9.025% is considered to be of **negligible** significance.

IMPACT: Entrainment of Zooplankton (4) mysids

19.6.351 From Refernece 19.250 the main mysids found in the Inner Bristol Channel and the Hinkley Point forebay have been observed to be (by % number): *Schistomysis spiritus*, 66%; *Mesopodopsis slabberi*, 20%; *Gastrosaccus spinifer*, 11%; *Neomysis integer*, 4%.

19.6.352 Mysids are part of the hyperbenthic community and are normally found within 1m of the seabed. Maximum concentrations are found just below the low water mark in summer and near to the 5 to 10m contour in winter. They indiscriminately feed on fine particulate matter including detritus, algae, zooplankton and sand grains. Mysids are good swimmers and can maintain 10 body lengths.s^{-1}. They can maintain their position even in strong currents by sheltering on the seabed. Mysids are an important part of the diet of *C.crangon* and fishes in the 3-15cm length category.

19.6.353 Ref. 19.250 reports very limited data availability on entrainment mortality for mysids and thus, as a precautionary measure, a 100% mortality rate is assumed in this instance. After Ref. 19.250, this assessment makes the following assumptions: 1.1% of plume volume entrained per day (Ref. 19.27); entrainment mortality 100%; ratio of plume volume to volume of Inner Channel =7.2%; mysids uniformly distributed throughout the Inner Channel.

19.6.354 On the basis of this assessment, the additional mortality in the Bristol Channel from entrainment losses associated with HPC will be 0.08% d^{-1} (predominantly to juveniles). The natural mortality of mysids is 4% d^{-1} (adults) to 6% d^{-1} (juveniles); hence there will be a **negligible** increase in mysid mortality due to entrainment.

IMPACT: Entrainment of Zooplankton (5) Crangon

19.6.355 Ref. 19.240 concluded that, in combination, the stresses of entrainment under standard power-station operating levels would result in approximately 20% mortality of brown shrimp larvae (from the combination of total residual oxidant (TRO), and rise in temperature (ΔT).

19.6.356 Using morphometric measurements a study reported by Ref. 19.250 determined that the Bristol Channel *C. crangon* population (east of the line Nash Point to Porlock Bay) is distinct from its south-western sea neighbour. *C. crangon* is impinged at HPB throughout the year with peak abundance in the period July to November and minimum abundance in April/May. At Bridgwater Bay *C. crangon* (mostly juveniles) migrate with the rising tide onto the high intertidal flats. At low water the population is concentrated near the low water mark and HPB catches are largest; typically 7 times those at high water. Spawning takes place twice a year in January and late spring/early summer; the females migrate offshore to the west to release their eggs. Mature males remain offshore to mate with returning females. The January spawning leads to egg hatching at the end of March/early April with metamorphosis and settlement on the intertidal area in early to mid May. The early May spawning hatches in early June with settlement in mid July.

19.6.357 *C. crangon* larvae are not been found in the monthly plankton sampling at HPB. This is in agreement with Ref. 19.253 who found highest density of *C. crangon* larvae in the Outer Bristol Channel. The size of the annual recruitment is therefore determined by environmental factors outside of Bridgwater Bay and not the influence of HPB or HPC. The lifecycle stages of *C. crangon* that are vulnerable to impingement and entrainment are thus juveniles and predominantly mature females that utilise the lower parts of Stert flats.

19.6.358 With a 10mm inlet screen mesh at HPB, approximately 38% of *C. crangon* that are drawn into the cooling water system have been estimated as being impinged and the rest are entrained and pass through the condensers (after Ref. 19.250; figures calculated using typical length frequency distribution of *C. crangon* and reported

NOT PROTECTIVELY MARKED

impingement probabilities). With the proposed 5mm drum screen mesh of HPC approximately 90% of the animals will be impinged and 10% entrained.

19.6.359 Bamber has produced results from EMU experiments using *C. crangon* larvae (Ref. 19.225). These experiments showed no effect from pressure, mechanical damage or direct effects for a ∆T of 12ºC or from chlorination. The work did show that elevated temperatures increased the animal's sensitivity to chlorine. Typical power station mortality with chlorination was estimated to be 25% (at a final discharge temperature of 23ºC).

19.6.360 No results from juvenile or adult *C. crangon* are available. Ref. 19.250 reports an estimated maximum temperature for *C. crangon* to survive of 30ºC based upon physiological considerations. However this estimate is not the same as the critical temperature for survival in a 20 minute entrainment exposure. Ref. 19.21 summarises thermal ULT for invertebrates as falling within the range 30-33ºC and for decapods as a mean of 32.9ºC. As a result, in the months of July or August, there may be some thermally induced mortality associated with HPC. The EMU derived 25% mortality applied to larvae, but *C. crangon* larvae are not abstracted at Hinkley Point. In principle it would be expected that juveniles and adults would be less sensitive to chlorine but in the absence of additional data the 25% mortality has been used in entrainment calculations for HPC with or without chlorination.

Table 19.30: *Crangon Crangon*: Annual Impingement and Entrainment Impact of HPC Options Compared with HPB.

Station	Impinged (m)	Loss (m)	Loss (t)	Entrained (m)	Loss (m)	Loss (t)	Total Loss (m)	Total Loss (t)
HPB	**4.9**	**4.9**	**3.6**	**12.9**	**0**	**0**	**4.9**	**3.6**
HPC 10mm mesh, No Cl	19.1	3.8	2.8	50.3	0	0	3.8	2.8
HPC 10mm mesh Cl at 0.2mg.l^{-1}	19.1	3.8	2.8	50.3	12.6	2.6	16.4	5.5
HPC 5mm mesh, No Cl	**43.0**	**8.6**	**3.9**	**26.4**	**0**	**0**	**8.6**	**3.9**
HPC 5mm mesh, Cl at 0.2 mg.l^{-1}	**43.0**	**8.6**	**3.9**	**26.4**	**6.6**	**0.4**	**15.2**	**4.3**

(m)=millions; (t)=tonnes

19.6.361 Ref. 19.250 provides an analysis of the annual impingement and containment impact of HPC (**Table 19.30**) and notes that the existing Bristol Channel population of *C. crangon* is density limited. Any reduction in local biomass due to HPC will rapidly be filled by a population that grows on average by 5% per day during the summer. The evidence from the HPB impingement surveys is that the production/biomass ratio has increased over the past 27 years.

19.6.362 Ref. 19.250 also notes that the estimated production at Stert flats is 1781kg.km^{-2}, i.e. the production from Stert/Berrow flats is 85 tonnes and the 200km^2 of the Bristol Channel inter-tidal flats is 356 tonnes. Estimated losses from HPB at present would thus amount to 1% of the annual production of *C. crangon* within the Bristol Channel, HPC with no chlorination 1.1% and with chlorination 1.2%.

19.6.363 There is therefore no significant difference between the total predicted losses from HPC (with its 5mm inlet mesh) and the existing HPB station. If HPC needs to chlorinate, losses could be further reduced from those shown above by adopting a 50:50% chlorination duty cycle. Under such circumstances the total losses would reduce to 1.1% of the Bristol Channel production.

19.6.364 On the basis of the findings described above, an impact of **minor adverse** significance upon *C. crangon* is predicted on the basis of very low sensitivity and a medium magnitude effect.

IMPACT: Entrainment of Zooplankton (6) ichthyoplankton

19.6.365 **Table 19.31** shows that entrainment survival rates for fish eggs may be high (80+%) and that survival rates for fish larvae are lower and more variable.

Table 19.31: Survival rates of entrained fish and crustacean from EMU cooling water passage simulation experiments (Ref. 19.225)

Species	Life Stage	Entrainment Survival Rate at 0.2ppm TRO and approximately10°C ΔT	Prime Causes of Mortality
Sole (*Solea solea*)	eggs postlarvae	93% 8%	pressure, thermal stress thermal stress and chlorine toxicity
Turbot (*Psetta maxima*)	eggs post larvae	93% 30%	pressure, thermal stress thermal, mechanical and pressure stress
Sea bass (*Dicentrarchus labrax*)	eggs larvae	54% 56%	thermal stress thermal stress and chlorine toxicity
Eel (*Anguilla anguilla*)	larvae*	52%	TRO
Shrimp (*Crangon crangon*)	larvae	75%	thermal stress and chlorine toxicity
Lobster (*Homarus gammarus*)	larvae	92%	mechanical stress

Note: **Eel tested at 2ppm TRO*

19.6.366 Ichthyoplankton varies spatially throughout the Bristol Channel, being highest for eggs in the spawning areas (particularly around Trevose Head, some 100 miles along the coast to the West of Hinkley Point, for most commercial species), and may also be high nearshore where larvae and post-larvae begin to recruit to nursery areas (e.g. for sea bass, see Ref. 19.226). In this respect, the water entrained at Hinkley Point will not be representative of other areas of the Bristol Channel, although the inner reaches of the Severn Estuary are well mixed. The Trevose Head spawning grounds are used here as a reference area.

NOT PROTECTIVELY MARKED

19.6.367 Ichthyoplankton surveys off the Hinkley Point area were undertaken quarterly in 2008 and again in May 2009 (Ref. 19.33). Eggs and larvae of just 14 species were detected in very low numbers (**Table 19.32** shows which species were detected during 2008/9). However, those surveys were designed to increase understanding of the subtidal ecology of the area and not just the ichthyoplankton community, so the timing of the surveys in 2008 were not optimal for the main fish spawning season.

Table 19.32: Presence (+) of Fish Eggs and Larvae Detected in Ichthyoplankton Surveys off Hinkley Point in 2008 and 2009

Species	Eggs	Larvae
Anchovy	+	
Dover sole	+	+
Rockling spp.	+	
Solonette	+	+
Sea bass	+	+

19.6.368 In order to obtain a better estimate of ichthyoplankton communities at the site, intensive monthly surveys were undertaken between February and June 2010 (Ref. 19.34). Despite this greatly increased sampling effort, the eggs and larvae of only 18 species were detected, although much better temporal and spatial density estimates were obtained. The 2010 surveys confirmed the findings of the 2008 and 2009 surveys that the Hinkley Point area has a very limited ichthyoplankton community and therefore the risk of entrainment loss is both low and is limited to a narrow range of species.

19.6.369 Although eggs and larvae of 18 species of fish were detected in the BEEMS intensive plankton survey off Hinkley Point in 2010 (Ref. 19.34), comparison with abundances at the Trevose spawning area have only been made for European sea bass, Dover sole, and sprat because these are the only ones of commercial interest identified during the BEEMS plankton surveys that can be compared with those species present.

19.6.370 The estimated entrainment of eggs and larvae over the period February to June 2010 given in **Table 19.33** has been made assuming:

- no exchange between the pool and adjacent sea areas;

- uniform distribution and abundance of ichthyoplankton throughout the water column; and
- the mean ichthyoplankton abundances from the 2010 surveys close to Hinkley Point power station occur within the identified 'pool'.

Table 19.33: Predicted Entrainment of Fish Eggs and Larvae between February and June 2010 at Hinkley Point C (based on the Ref. 19.34) in relation to the abundance in the Trevose spawning area

Species/ Species Group	Eggs	Larvae	A: Total**	B: Trevose	A/B
Sandeels		9,075,949	9,075,949		
Solenette	368,278	2,496,257	2,864,536		
Five-bearded rockling		333,687	333,687		
Herring		414,615	414,615		
European sea bass	47,282,931	41,981,786	22,051,122	29,206,261,000	0.11%
Rockling	18,546,479	799,420	19,345,899		
Gobies		10,351,234	10,351,234		
Butter fish		389,819	389,819		
European flounder		2,711,333	2,711,333		
European plaice		3,322,735	3,322,735		
Pilchard	2,891,002	386,310	3,277,311		
Dover sole	9,461,839	1,929,208	1,659,991	274,633,000,000	0.001%
Soles*	450,281	369,308	819,589		
Sprat		7,114,303	7,114,303	478,943,000,000	0.001%
Sea scorpion		474,262	474,262		
Unidentifiable fish	5,004,020	21,322,227	26,336,246		

NOT PROTECTIVELY MARKED

Species/ Species Group	Eggs	Larvae	A: Total**	B: Trevose	A/B
European anchovy	12,141,963		12,141,963		
Dragonets	383,685		383,685		

* *Indicates eggs and larvae that, due to damage, could not be confirmed as Dover sole, but were identified as belonging to the family Soleidae.*

** *For Dover sole and sea bass, the results have been adjusted so as to account for estimated survival based on EMU experiments.*

19.6.371 These entrainment estimates can be compared and put into context with the abundance of ichthyoplankton at the Trevose Head ground by examining the mean abundance of the same species in the Trevose spawning area (Ref. 19.227), ICES rectangles 29–31E4, 30–31E5 and 31E6 (**Figure 19.33**), assuming that:

- the mean abundances of eggs and larvae from the 1990 surveys were within the ICES rectangles 29–31E4, 30–31E5 and 31E6;
- the mean abundances of eggs and larvae from the 1990 surveys are still a reasonable approximation of the current situation; and
- the assumptions about the distribution and abundance of ichthyoplankton within the Trevose spawning area will be the same as that within the 'pool', i.e. uniform distribution and abundance throughout the water column.

19.6.372 Within the period February to June 2010, the predicted numbers of eggs and larvae of sea bass entrained by HPC are predicted to be <0.45% of the mean abundance within the Trevose spawning ground. For sole and sprat the numbers of entrained eggs and larvae over the same period are predicted to be <0.005% of the mean abundance within the Trevose spawning ground. Although the figures assume 100% mortality of all entrained organisms, previous EMU studies have indicated that this is not likely to be the case (but see the caveats above), in which case the impacts of entrainment mortality on local populations would be reduced further. Ongoing EMU trials under the BEEMS programme are investigating entrainment survival rates for relevant species and life stages and using exposure conditions based on the HPC cooling circuit design.

19.6.373 For certain species of conservation interest, such as shads (twaite and Allis) and lampreys (marine and river), that spawn and live as larvae in the freshwater tributaries of the Severn Estuary, entrainment of these early life history stages at HPC is expected to be negligible.

19.6.374 On the basis of the findings described above, an impact of **minor adverse** significance upon the ichthyoplankton is predicted on the basis of low sensitivity and low magnitude.

IMPACT: Entrainment of Zooplankton (7) glass eels

19.6.375 The majority of any glass eels abstracted by HPC will be entrained as they will be small enough to pass through the 5mm inlet screen mesh (Ref. 19.250). Glass eels enter the Bristol Channel in February to April and assuming the same efficiency as in the Gironde, the eels will migrate through the estuary at approximately 3 to 4km.d^{-1} using selective tidal stream transport.

19.6.376 The natural mortality of glass eels (i.e. excluding fishing mortality) has been estimated to be in the range 0.0233 – 0.0049 d^{-1}.

19.6.377 Glass eels entrained at HPC would be subject to mortality from:

- mechanical damage from the impellors n the cooling water pumps;
- thermal shock ; and
- exposure to chlorination for an 18 minute period inside the plant at 0.2mg.l^{-1} at the inlet to the condenser (If HPC uses chlorination).

19.6.378 Ref. 19.250 reports that the expected mortality from the temperature and chlorination regime described above would be negligible. HPC will employ cooling water pumps that are the same or close equivalents to those designed for Flamanville 3. These pumps were modelled in the STRIKER programme that has been widely applied to other pump mortality calculations (Ref. 19.225). The predicted mortalities ranged from 1.6% for a 70mm glass eel to 1.8% for an 80mm eel. The total entrainment mortality due to the cooling water pumps assuming a worst case 80mm eel is 1.8%.

19.6.379 After Ref. 19.250, this assessment makes the following assumptions: 1.1% of the plume volume is abstracted per day (Ref. 19.27); the mortality of entrained eels is 1.8% to 15%, i.e. the daily mortality is 0.02% to 0.165% of eels within the plume volume. Assuming that glass eels use the whole Channel to migrate, the daily mortality in the Inner Channel due to entrainment would be 0.0014% to 0.012%. Taking a mean value for natural mortality of 0.01 d^{-1} (or 0.995%), entrainment through HPC would increase the mortality of glass eels to within the range 0.996% to 1.007%. Such increases are considered to be of **negligible** significance.

19.7 Cumulative Assessment

a) Construction

i. Introduction

19.7.1 This section considers whether any of the identified effects associated with individual components of the HPC development could be additive or combine in such a manner that they could lead to a change (e.g. increase in effect or alteration in an area affected) that would be different to that determined for the individual components alone. The potential for cumulative impacts with other components of the HPC Project, namely Combwich Wharf, are considered in **Volume 11** Cumulative Effects. It should be recognised, however, that because of the spatial separation between the individual project components, their temporal extent and their localised effects on marine ecology, the potential for any interaction and therefore for such cumulative effects to occur is very limited.

NOT PROTECTIVELY MARKED

ii. Cross-shore Works

19.7.1 Works across the shore include: jetty construction, operation and removal; drilling of the horizontal tunnels for the cooling water structures; and seawall construction. The impacts of these activities will be additive in terms of the areas impacted, save where access corridors coincide.

19.7.2 During construction of the seawall, excavation works may lead to an increase in suspended sediments in the water column. However, the seawall is located on the uppermost part of the shoreline, above MHWS, and any discharges from the construction area, even if they contained relatively high suspended sediment concentrations, would be rapidly dispersed under high tide conditions. It is anticipated that background conditions would be achieved close to the points of discharge. Even under low tide conditions, it is not anticipated that the seawall works would contribute sufficient suspended sediment to reach the *Corallina* community present on the lower to mid shore. Should some discharge reach the area of *Corallina* it is likely to replicate events occurring naturally during rainfall events and the materials would be quickly re-suspended and transported elsewhere by the tide. Therefore, a combined impact due to the seawall construction with either the jetty piling works or the drilling of the horizontal tunnels (see below) is not predicted to occur.

19.7.3 Drilling of the horizontal tunnels is anticipated to take place during the operational stage of the jetty, and as such there would be no possibility for interaction between the construction stages. It is also anticipated that any discharge from the drilling works would occur over an area of the foreshore to the east of the jetty and would not impact upon the same intertidal area. Consequently, while a greater overall extent of foreshore supporting *Corallina* would be affected cumulatively, the same area of foreshore would be unlikely to be impacted by both activities. Following the end of the drilling works, the foreshore would not be disturbed again by activities until the dismantling of the jetty.

19.7.4 Overall it is concluded that while the foreshore at Hinkley Point may be subject to a number of construction related disturbance events, the totality of these events would be one of prolonging the overall period of effect across distinct parts of the foreshore, rather than intensifying impacts, such that a longer term loss or change in habitat function would occur. With the application of best practice described above and in **Section 19.8** below, specifically the use of constrained corridors for working and access, management of waste solids and liquids, appropriately designed roadbeds and use of appropriate vehicles to limit compaction of the cross-shore rock superficial limestone platforms (as also discussed in **Volume 2**, **Chapter 17**), the accumulated residual impact is predicted to be **minor adverse**.

iii. Sub-tidal Works

19.7.5 The offshore works which could result in cumulative impacts include the installation of jetty piles, dredging associated with the berthing pocket of the jetty, and the installation of the vertical shafts for the cooling water system.

19.7.6 The jetty will be in its operational phase during the installation of the vertical shafts and, hence, no cumulative impacts on marine life through increased suspended sediments or disturbance will arise. The capital dredging for the berthing pocket will also have been complete, but there is the potential for maintenance dredging of the berthing pocket to overlap with the installation of the vertical shafts.

19.7.7 Sensitive benthic habitats which could be impacted by this work include *Sabellaria spinulosa*, although there is no observed occurrence of this reef within 500m of the jetty. There is the possibility that some sub-tidal *Sabellaria* is present around the vertical shaft sites, however, given the habitat type involved this would not include any reef formations. It is therefore considered that, with the application of best practice, there will be **no cumulative impact** from increased suspended sediments on sensitive habitats due to the proposed sub-tidal works.

iv. Cross-shore Discharges

19.7.8 All cross-shore discharges will be via a single point of discharge specifically selected to avoid low water cross-shore flows intersecting with sensitive receptors.

19.7.9 The assessments included above relate to the cumulative effect of both construction and early commissioning discharges being passed via the same route. The accumulated residual impact, with mitigation, thus remains **minor adverse**.

b) Operation

i. Impingement and Entrainment

19.7.1 The AEV methodology applied in this instance has not involved the integration of impingement and entrainment losses for the very simple reason that ichthyoplankton have been found to occur at Hinkley only in very low numbers. As a result, the conclusion reached for the cumulative impact of impingement and entrainment remain identical, prior to mitigation, to those given above for impingement alone for each of the individual species considered.

19.7.2 As noted above, the larvae of the brown shrimp *C. crangon* do not occur locally so it is the consideration of adult and juvenile individuals alone that contribute to the impact of HPC on the population of this species.

19.8 Management Controls and Mitigation Measures

a) Introduction

19.8.1 The following sections contain a description of the specific mitigation measures considered to be appropriate, along with specific mitigation for each operation activity, where required, to reduce identified significant adverse impacts on marine ecology to acceptable levels.

19.8.2 As described in the **Construction Method Statement** which forms **Annexe 2** to this ES, a suite of Environmental Management Plans will be implemented to ensure that best working practices and required environmental mitigation measures are implemented. An Environmental Management and Monitoring Plan (EMMP) will provide the overall framework of environmental requirements and Construction

NOT PROTECTIVELY MARKED

Environmental Management Plans (CEMPs) will show how the contractor(s) will comply with the EMMP and any SSMPs.

19.8.3 Recognised best practice and regulatory guidance will apply wherever appropriate, for example by use of Environment Agency Pollution Prevention Guidance notes (PPGs).

19.8.4 In terms of the marine ecological sensitivities described earlier in this chapter, a clear example of the need to apply best practice will be in the control of works in the intertidal area, where appropriate means will be applied both to limit physical damage to fragile limestone pavement areas, and guard against the release of potentially polluting materials.

19.8.5 Likewise, the need to apply best practice will also apply to the management of offshore works.

19.8.6 The primary means of obtaining mitigation is through appropriate engineering design and subsequent management of plant. To accomplish this requires both a width of experience in building and operating such plant in a wide variety of circumstances over many years, together with a detailed multidisciplinary understanding of the environment into which new plant is to be introduced.

19.8.7 A significant element of HPC has been that precisely the same studies that have provided an understanding of potential environmental impacts have been employed in supporting considerations of detailed plant design where any element of that design or function encroaches upon, or depends upon, the structure and functioning of these marine systems.

b) Construction

i. Introduction

19.8.1 The primary means of mitigating impacts on the ecology of the local coastal environment during the construction of HPC will be appropriate engineering design combined with the application of best practice in terms of the management of construction and subsequently the plant itself.

ii. Habitat Loss and Change

19.8.2 Works on the seawall will be limited to a defined corridor along the top of the intertidal area and all associated works managed so as to prevent more widespread disturbance to the middle and lower intertidal areas and, in particular, the loss of control of any solid or liquid arisings from the works.

19.8.3 In bringing rock armour to the site by sea and landing these materials on the intertidal shore by barge, the following constraints would apply:

- barge deliveries would be limited to the within the inner perimeter shown by **Figure 19.36** (upslope of *Sabellaria* biotope, east of [*Fucus serratus*]/[*Ascophylum*] platform, west of [*Fucus serratus*]/[*Ascophylum*] platform); and

- unloading and transport of materials towards the sea wall construction zone will also be limited to that area.

At no point would vessels be permitted to ground against the intertidal shore outwith that inner perimeter.

19.8.4 There will be limited impact in terms of disturbance to the biotopes involved within the berthing area (hydrolittoral soft rock; [*Macoma*] and [*Arenicola*] in muddy sand shores; [*Fucus vesiculosus*] on variable salinity mid eulittoral boulders and stable mixed substrata/[Fucus serratus] and [large *Mytilus edulis*] on variable salinity lower eulittoral rock; [*Fucus spiralis*] on sheltered variable salinity upper eulittoral rock; [*Pelvetia calanaliculata*] on sheltered variable salinity littoral fringe rock; barren littoral shingle). These biotopes and habitats are widely distributed and common on local rocky shores and all would be expected to recover quickly from any superficial and localised loss of flora or fauna due to disturbance.

19.8.5 Unless managed sensitively, works to construct the temporary aggregate jetty will cause disturbance to the limestone and shale fabric of the cross-shore rocky platform which supports the *Corallina* turf interest. The extent of this damage will be limited by restricting the works to within a predefined corridor extending no further than 20m to either flank of the line of the jetty. There is also likely to be a need to make good the microtopography of the shore and reinstate longshore drainage channels should localised damage occur. As a consequence, piers will be introduced from seaward rather than landward as far as it is practicable to do so. Damage to the superficial geology will be limited by use of an appropriate temporary roadbed established within the access corridor, rendering the magnitude of impact low.

19.8.6 The use of jack-up rigs over the lower shore could cause similar damage to the rock surface, though over a much reduced area. Where works pass across the area of the limestone platform that dominates the middle and lower intertidal areas, any damage to the existing microtopography and the associated long-shore drainage routes will be restored after both construction and removal of the jetty, rendering the magnitude of effect very low.

19.8.7 The temporary aggregate jetty will be piered throughout its length with the express purpose of limiting hindrance to the passage of wave and tide. The open structure of the jetty means it will have a very limited effect on sediment transport on the foreshore and the subtidal and the associated ecological interests.

19.8.8 The FRR discharge line will not be driven across the shore surface but introduced by microtunneling from landward under the seawall and intertidal shore to reach a seabed outfall. Thus, aside from the temporary aggregate jetty, no cross-shore structures are to be introduced.

19.8.9 As described below, there will be a need to put construction and commissioning discharges across the shore from a discharge point at the head of the shore. In order to avoid areas of habitat that would be particularly sensitive to such flows, a number of possible outfall configurations have been tested in relation to biotope mapping. The location selected will not lead to flows entering the limestone platform

NOT PROTECTIVELY MARKED

drainage network leading to *Corallina*, and that flow will involve only limited areas of low sensitivity – see **Appendix 19.1** and **Figure 19.19**.

19.8.10 The connection between the HPC Development Site itself and the offshore cooling water intake and outfall headworks will be via tunnels bored under the shore and seabed from landward and, aside from these headworks themselves, there will be no structures on the seabed.

iii. Physical Disturbance

19.8.11 The mitigation measures for physical disturbance are the same as those outlined for loss of habitat above.

iv. Changes in Water Quality

19.8.12 Again, in terms of the potential for waste streams, the primary means of mitigating impacts on the ecology of the local coastal environment during the construction of HPC will be appropriate engineering design combined with the application of best practice.

19.8.13 Until such time as the cooling water system becomes available the intention is that construction and commissioning related effluents will be discharged across the intertidal area from a single dedicated discharge point. That discharge point has been selected on the basis of hydraulic modelling, which identified a location and route across the shore that avoided potentially sensitive and valuable biotopes – see **Appendix 19.1** and **Figure 19.19**.

v. Noise and Vibration

19.8.14 As noted in earlier sections, and for conservative purposes within this assessment, percussive piling is presumed for works associated with the aggregate jetty and the installation of cooling water headworks offshore.

19.8.15 Some risk of impact applies to both specific fish populations present in the immediate locality when such operations begin (particularly hearing specialists such as sprat and herring), and any marine mammals. The guidance provided by JNCC (Ref. 19.96) has been applied in terms of establishing a network of acoustic sensors offshore, but that guidance also suggests an appropriate ‘soft-start’ protocol for piling, and this will be adopted as a matter of precaution.

19.8.16 Soft-start is the incremental in crease in pile power over a set time period until full operational power is achieved. The soft start duration will be a period not less than 20 minutes. If there is a break in the piling operations for more than ten minutes, then the soft-start procedure will be repeated.

19.8.17 Once pile driving is initiated then the potential for physical damage effectively ceases as any fish within the zone of influence (ensonification) would move out of the area to avoid the increase in noise levels/pressure.

19.8.18 There are indications from initial use of the acoustic sensor network that porpoises are present in the area, albeit in low numbers. The decision whether or not to employ marine mammal observers during these works and apply the appropriate controls (Ref. 19.96) will be taken on the basis of further findings from this study in consultation with the relevant regulatory authorities.

vi. Artificial Lighting

19.8.19 The impacts predicted due to the presence of artificial lighting on the foreshore have been assessed as negligible and, therefore, no mitigation measures are required to minimise the impacts.

c) Operation

i. Introduction

19.8.20 The primary means of mitigating impacts on the ecology of the local coastal environment during the operation of HPC will be appropriate engineering design combined with the application of best practice in terms of the management of the plant itself.

ii. Thermal Discharges

19.8.21 As noted above, the primary means of mitigation is appropriate engineering design. In this instance, extensive oceanographic and ecological studies permitted the development and testing of a series of numerical hydrodynamic models (see **Appendix 18A to Volume 2, Chapter 18**) which, in turn, permitted the testing of a series of alternate intake and outfall configurations, shown in **Figure 19.7**.

19.8.22 By means of these tests an intake and outfall configuration was found that avoided recirculation of sea water from either the HPB or HPC outfalls, and accomplished a degree of separation of the two thermal plumes, thus limiting the compounding of any impacts on potentially sensitive areas, particularly the intertidal shores of Bridgwater Bay.

iii. Chemical Discharges

19.8.23 Although the impact of low level chlorination for the control of biological fouling within the cooling water circuits has been assessed as having a minor impact in relation to the EQS, a precautionary SL based upon provisional toxicity data suggests the need for a more conservative approach.

19.8.24 As a result, an application will be made for a permit to dose oxidant to the HPC cooling water systems but with an understanding that both the dose involved and the duration of the dosing period will be limited such in order to comply with the precautionary SL.

19.8.25 As the scope for growth of potentially fouling species such as the blue mussel *Mytilus* is already very limited, and that long-term experience at Hinkley Point suggests that the need for such dosing is infrequent, a limited dosing regime will prove operationally sufficient should the need ever arise.

NOT PROTECTIVELY MARKED

iv. Impingement of Fish and Shrimp

Regulatory Guidance

19.8.26 Environment Agency (best practice) guidance for mitigation of abstraction impacts at nuclear new build sites is given in Ref. 19.229; earlier material supporting this most recent guidance is Ref. 19. 230. This guidance is not mandatory, but adherence to it establishes common ground between the regulator and developer and helps to avoid development of unsuitable designs which might be damaging to marine/estuarine biota or might delay permitting of the project. The conservation agencies, NE and CCW, were also party to the development of the intake screening guidance and thus its application it is intended to meet their conservation objectives also.

19.8.27 For large, direct-cooled plant, the guidance recommends the following cooling water intake design features:

- Location of the cooling water intake away from fish spawning grounds.
- Maintenance of low velocities (target ≤$0.3 m.s^{-1}$) at all tidal states (see next paragraph) via low velocity side entry (LVSE) intake design.
- A cap ('velocity cap') across the top of the intake to prevent vertical intake currents, which fish find it difficult to avoid.
- Fish deterrent system fitted to the cooling water intake structure to provide avoidance cues.
- Fish Recovery and Return (FRR) system to intercept and return any fish not repelled by the intake fish deterrent system (e.g. hearing-insensitive species).

19.8.28 On the low velocity criterion, the guidance proposes a default value of $0.3 m.s^{-1}$ but allows higher values subject to a risk assessment based on fish swimming performance data provided within the guidance documents themselves. Such an assessment has been completed for HPC, as described below.

Intake Water Velocity

19.8.29 The offshore locations of the four HPC cooling water intake structures are not in the proximity of any known fish spawning grounds (Ref. 19.43). The intake design has been developed along the principles outlined in Environment Agency guidance, referenced there as the 'low-velocity side-entry' (LVSE) intake design (see **Figure 19.34**). Such a design has not previously gone beyond small-scale laboratory testing and the design developed for HPC has had to take account of factors other than fish protection, including the need for seismic qualification, harmonic stability and constructability, and hydraulic performance. Using numerical hydraulic modelling, the design adopted for HPC (see **Figure 19.34**) was tested against the LVSE concept-design and shown to offer more uniform low-velocity profiles and therefore to perform better than the LVSE reference design (Ref. 19.231).

19.8.30 The low-velocity intake design developed for HPC provides substantially lower velocities around the tidal cycle than the open-all-round cooling water intake structure of the HPA and HPB. Ref. 19.232 considered the effect of tidal stream velocities adding to pumped intake velocities at this type of offshore intake and showed that at Sizewell A, fish impingement peaked at maximum flood and ebb tidal velocities. At Hinkley Point, tidal stream velocities reach at least 1.5m.s^{-1}, and velocities for fish escape may exceed this value with the pumping effect added. An analysis of the effect of intake velocity differences between the proposed HPC low-velocity design and the HPB 'baseline' case on the ability of different species of fish to escape showed that, for the same 1.5m.s^{-1} tidal velocity, the EA LVSE reference design would result in velocities that would allow a further 16.1% of the fish impinged to escape (i.e. could reduce the impingement by 16.1%), while the HPC design would increase this reduction of impingement to a value of 52.2% (**Table 19.34**). These figures are given per unit of cooling water flow.

Table 19.34: Analysis of the HPB Impingement Catch showing % of Fish that would Remain Vulnerable to Capture with the Reduced Intake Velocities Modelled for the EA's LVSE Design and the Proposed HPC Intake Design

Intake Design	Tidal Velocity m.s^{-1}	% of Hinkley 'HPB' Fish below Escape Velocity						
		Shad	Sea bass	Sole	Whiting	Herring	Cod	All Six Species
HPC	1.5	41.8	27.8	38.5	50.9	30.6	49.8	47.8
EA LVSE Reference Design	1.5	79.5	54.2	77.9	85.8	79.6	85.0	83.9

Note: *Values were calculated using published swimming performance data and modelled velocities (Ref.19.231). Figures for 'All Six Species' are weighted according to annual catches at HPB.*

Acoustic Fish Deterrence

19.8.31 Acoustic fish deterrents (AFDs) will be fitted either to or near each of the four intake heads as the primary mitigation against fish entrapment. Environment Agency guidance (Ref. 19.229) advocates the fitting of AFDs at such cooling water intake structures to repel hearing-sensitive fish. These include pelagic species such as herring, sprat and shads, and moderately hearing-sensitive demersal fish such as cod and whiting. Epibenthic species, including flatfish, eels and lampreys are less sensitive and little influenced by AFDs, so the main mitigation against capturing these species will be through an onshore FRR system (see below).

19.8.32 The AFD system at HPC will be of the sound-projector-array (SPA) type (Ref. 19.230). The number and positioning of sound projectors will be determined by acoustic modelling using PrISM™ software, as per Environment Agency guidance (Ref. 19.230). This will also ensure that the soundfield will be confined to the immediate area of the intake head, avoiding the risk of any acoustic disturbance in the wider estuarine environment.

19.8.33 AFD underwater sound frequencies will be in the 20-500Hz hearing-sensitive range of most fish (Refs. 19.233, 19.234 and 19.235). Clusters of sound projectors may be deployed on vertical rails or piles, allowing them to be raised above water level periodically for replacement and servicing. Additional sound projectors would be installed to provide a level of redundancy which will allow for any sound projector failures between service events. The condition and sound output status of the AFD

NOT PROTECTIVELY MARKED

system would be continuously monitored and logged remotely via an offshore telemetry link.

19.8.34 Performance data for AFDs are summarised by Ref. 19.230 and include data for estuarine and coastal power stations. AFD efficiency values taken from this source are shown in **Table 19.34** for key fish species found at Hinkley Point. Figures range from 0.95 (95%) for sensitive clupeids to 0.16 (16%) for insensitive flatfish. In all cases, these efficiency values were obtained from trials at power stations such as Hartlepool and Doel (Belgium) that do not benefit from having low-velocity intake designs, so improvements would be expected where lower velocities allow more fish to escape.

19.8.35 In practice the design and establishment of a system such as an offshore AFD deployment is a complex procedure involving a degree of uncertainty, requiring appropriate management. Both the necessary design tools (the underwater acoustic modelling capability coupled to a detailed understanding of fish behaviour) and the technology (the sound projectors) are readily available. A technical working group has been established within EDF in order to evolve the initial conceptual design towards the final installation and the outputs from this group will be discussed with the regulators involved as that effort progresses.

19.8.36 Any such system will require commissioning, and experience to date suggests that this commissioning process allied with appropriately designed trials is a key step to securing the required standard of performance

Fish Recovery and Return System

19.8.37 Drum screens within the onshore cooling water pumphouse area are designed primarily to exclude debris that might clog the steam condensers within the turbine hall. The drum screen system selected for HPC is suitable for FRR and will follow or improve upon the detailed Environment Agency guidance on FRR system design. In particular, it will include the following features:

- smooth-finish 5mm drum screen mesh;
- fish bucket design suitable for retention of eel, lamprey and other fish and crustacean species;
- continuous screen rotation at an elevation rate at least 1.5m per minute;
- low- (<1 bar) followed by high-pressure (usually >3 bar) backwash sprays;
- hopper geometry to minimise the risk of fish recycling within the screenwell; and
- smooth-finish troughs with horizontal and vertical bend radius ≥3m.

19.8.38 After considering various options, including a variety of cross-shore routes and return via the main cooling water outfall tunnel, the chosen route for fish return to the subtidal estuary will be via a dedicated bored tunnel driven from landward, under the seawall and intertidal shore, to a specific point on the tidally scoured rock exposure below LAT but above the subtidal muddy plain. In selecting this position there has been a need to balance a series of requirements, not least that the relatively small outfall structure does not become clogged due to progressive siltation with relative sea level rise over the design life of HPC.

19.8.39 A number of additional factors have been taken into account (Ref. 19.236) including:

- the need for an exit point that will permit a discharge line and outfall design that will not entrain solids from seaward, or block over periods of outage;
- the need for a location that will be sustainable over the life of the site, given trends in relative sea level and possible landward encroachment of the subtidal muddy plain;
- the length of the discharge tunnel;
- the risk of re-impingement of discharged fish by the HPB intake;
- avoidance of the HPB thermal plume; and
- potential predation by sea birds, fish or marine mammals.

19.8.40 The fish return tunnel will discharge continuously at a point approximately 550m offshore, some 150m beyond and 1m below the LAT mark, as shown on **Figure 19.37**.

19.8.41 Ref. 19.236 estimates <1% risk of fish re-entering a cooling water intake on a single ebb-flood tide. A relatively short simulation was used as it was considered that animals which survived any longer will have responded and will start to exhibit their own behaviour; animals not exhibiting near normal behaviour within this time are likely to have been predated.

19.8.42 Ref. 19.236 also considered the effect on migratory fish that are drawn in from an intake point 3km offshore and discharged further inshore, showing that fish discharged from the release point quickly re-disperse offshore.

19.8.43 Ref. 19.230 gives typical survival rates for FRR systems ranging from <10% for delicate pelagic species such as herring, sprat and smelt, to between 50 and 80% for demersal species such as cod, whiting and gurnards and >80% for epibenthic fish such as flatfish, gobies, rocklings and crustacean. Lampreys and eels would also fit into this last category, whereas shads would fall into the pelagic group. The values given assume that screens are fitted with FRR fish buckets, low-pressure fish backwash sprays in advance of the high pressure backwash units and are rotated continuously, in line with EA guidance. These values are incorporated within **Table 19.35** below.

19.8.44 Ref. 19.230 advises against addition of biocides upstream of the fish return point or in the fish return water supply, to preclude the potential toxicity risk. Otherwise, where biocides need to be used for operational reasons, a toxicity risk assessment would need to be carried out to ensure that the fish being returned will not be subjected to acute or sublethal toxic risk. It is not envisaged that biocides will be used routinely at HPC but should the need arise, their use will be managed in order to prevent toxic impact within the FRR itself.

NOT PROTECTIVELY MARKED

19.8.45 In addition to the main cooling water system drum screens, band-screens will be also be installed in the cooling water pumping station to screen the auxiliary cooling supply. Although these band screens will put materials to the FRR, the likelihood is that the condition of any returned fish or shrimp by that route will not be as high as via the drum screens. Against a total volume flow of approximately $125m^3.sec^{-1}$, these band screens would be responsible for screening no more than $12m^3.sec^{-1}$.

Combined Effect of Intake Mitigation Measures

19.8.46 **Table 19.35** lists the factors used in calculating mitigation performance. Where mitigation factors are not given in Environment Agency guidance, they have been taken from other referenced studies, or values from the nearest similar species (e.g. blue whiting based on whiting, plaice based on flounder values). In the case of FRR mitigation factors, survival rates given in Environment Agency guidance as "<10%" or ">90%" have been allocated mitigation factors of zero and 90% respectively; where, for demersal fish, these have been given a range of survival values of between 50 and 80%, a mitigation factor of 0.5-0.8 has been used. The HPC low velocity side entry intake (LVSE) mitigation factors are taken from Ref. 19.43.

Table 19.35: Assumed Proportional Effects of Intake System Mitigations (Mitigation Factors)

Species	AFD Efficiency F_{AFD}	Catch Reduction with Low Velocity Side Entry (LVSE) Intake F_{LVI}	Survival through FRR F_{FRR}
Sprat (largest numbers)	0.88	0.34	0.00
Whiting (BAP)	0.55	0.49	0.50 -0.80
Sole (BAP)	0.16	0.36	0.80
Cod (BAP)	0.55	0.51	0.50 -0.80
Herring (BAP)	0.95	0.34	0.00
Plaice* (BAP)	0.16	0.76	0.80
Blue whiting* (BAP)	0.55	0.49	0.50 -0.80
Eel (Eel management plan)	0.16	1	0.80
Twaite shad* (SAC designated)	0.88	0.383	0.00
Allis shad* (SAC designated)	0.88	0.383	0.00
Sea lamprey* (SAC designated)	0.06	1	0.80
River lamprey** (SAC designated)	0.06	1	0.80
Salmon (SAC designated)	n/a	n/a	n/a
Crangon	0.00	1	0.80

19.8.47 The order in which the mitigation factors are applied is important. The AFD is the first mitigation experienced by approaching fish (crustaceans are assumed not to be sensitive to the AFD) and this factor is therefore applied first. The effect of reduced velocity is then applied to reduce the number of fish entering the intake. Finally, the mitigation factor for survival rate in the FRR system is applied to give an overall estimate of losses associated with cooling water abstraction.

19.8.48 The AFD and FRR mitigation factors described in **Table 19.34** have been incorporated in the assessments that follow and, in aggregate, describe the minimum performance standard that the operator would expect to meet through implementation of these measures at HPC.

19.9 Residual Impacts

a) Introduction

19.9.1 Following implementation of the proposed mitigation and management measures, impacts have been re-assessed, where appropriate, to determine the residual impact. These are outlined below for each of the described impacts.

b) Construction

i. Habitat Loss and Change

19.9.2 Following implementation of the proposed mitigation measures above, the impacts of physical construction in terms of habitat loss will be reduced to a very low magnitude, with a **minor adverse** residual impact remaining where sensitivity (most obviously in terms of the *Corallina* swards) is high.

ii. Physical Disturbance

19.9.3 The impacts associated with physical disturbance to marine ecology, following the implementation of mitigation measures, will be constrained to **minor adverse** significance.

iii. Changes in Water Quality

19.9.4 Following mitigation measures outlined above, the residual impacts of construction and commissioning discharges on local marine ecological interests will be constrained to a **minor adverse** level of significance, with a low magnitude and extent affecting only habitats of low sensitivity,

iv. Noise

19.9.5 The residual impact of underwater noise on sensitive receptors during construction, following the implementation of mitigation measures, will be constrained to one of **minor adverse** significance.

v. Artificial Lighting

19.9.6 **No impacts** to marine ecology were identified during construction from artificial lighting and, therefore, the residual impact is unchanged.

NOT PROTECTIVELY MARKED

c) Operation

i. Chemical Discharges

19.9.7 On the basis that appropriate limits may be set on any application of a dosing regime, by constraining the magnitude of the impact to low whilst retaining the understanding of medium sensitivity, the residual significance of the impact concerned will reduce from moderate to **minor adverse**.

ii. Impingement of Fish and Shrimp

19.9.8 **Table 19.36** summarises estimates of fish and crustacean losses attributable to HPB and HPC cooling water abstraction for the key commercial and conservation species and for shrimps. Predicted entrainment rates (**Table 19.33**) are considered to be too small in relation to Bristol Channel stocks to merit further consideration.

19.9.9 The great majority of fish caught at Hinkley Point are juveniles. This assessment thus depends upon a calculation of Adult Equivalent Value (EAV) based upon known fisheries-related or conservation-related estimates of population and age structure in order to scale the level of impact involved.

Table 19.36: Predicted Total Annual Impingement (numbers of fish, EAV) at HPC and HPB for Selected Species assuming an Abstraction Rate of 125m^3.s^{-1} via Current Intake Structures and via Low-Velocity Side Entry (LVSE) Intake Structures with AFD and with a FRR System (data from Ref. 19.43)

Species: Common Name	HPC, Current (HPB) Intake Design	HPB	HPC with Low-Velocity Intake and AFD (increase from current HPB)		HPC with Low-Velocity Intake and AFD and FRR (increase from current HPB)	
Sprat (largest numbers)	3,380,850	936,386	405,702	-(57%)	405,702	-(57%)
Whiting (BAP)	288,078	79,253	129,635	(64%)	64,818	-(18%)
Sole (BAP)	32,429	8,599	27,241	(218%)	5,448	-(36%)
Cod (BAP)*	32,063	8,733	14,428	(65%)	7,214	-(17%)
Herring (BAP)	44,792	12,570	2,240	-(82%)	2,240	-(82%)
Plaice (BAP)	493	129	414	(221%)	83	-(36%)
Blue whiting (BAP)	160	46	72	(55%)	36	-(22%)
Eel (Eel management plan)	1,304	351	1,304	(272%)	261	-(26%)
Twaite shad (SAC designated)	2,276	646	273	-(58%)	273	-(58%)
Allis shad (SAC designated)	68	22	8	-(63%)	8	-(63%)
Sea lamprey (SAC designated)	207	42	207	(398%)	41	(0%)
River lamprey (SAC designated)	82	18	82	(355%)	16	-(9%)
Salmon (SAC designated)	0	0	0	(0%)	0	(0%)

Species: Common Name	HPC, Current (HPB) Intake Design	HPB	HPC with Low-Velocity Intake and AFD (increase from current HPB)		HPC with Low-Velocity Intake and AFD and FRR (increase from current HPB)	
Sea trout (SAC designated)	0	0	0	(0%)	0	(0%)
Brown shrimp (*Crangon crangon* – the main crustacean impinged	19,135,756	4,911,592	19,135,756	(290%)	3,827,151	-(22%)

* *Cod assessment has subsequently been reappraised to account for bias caused by an exceptional spike in recruitment during the period of sampling upon which this original assessment was based, in 2009; the ratio of annual catches 2008:2009 was 5.8% and that for the mean of 2004-2008:2009 was 7.3% (Ref. 19.260).*

Sprat

19.9.10 With the AFD and LVSE intake design, the numbers of adult sprat impinged annually at HPC could be reduced to approximately 3.16t, which is about 17 times the local fishery. Sprat are delicate bodied species and as a result the FRR system is unlikely to reduce impingement mortality. With mitigation, the residual impact of cooling water abstraction on sprat populations is considered to be **minor adverse**.

Whiting

19.9.11 With the Acoustic Fish Deterrence (AFD) and low velocity side entry (LVSE) intake design, the reduction in annual impingement numbers of whiting is reduced to approximately 23t and 1.4% of the local standing stock biomass (SSB). The Fish Recovery and Return (FRR) system is expected to reduce mortality of this species by 50% and as a result the post- -mitigation residual impact is considered to be **minor adverse**.

Sole

19.9.12 The mitigation measures discussed above are likely to reduce annual impingement numbers to 6.24t, as a demersal species the FRR system could reduce impingement by about 96% (Ref. 19.241), but using a more conservative figure of 80% the residual impact would be reduced to **minor adverse**.

Cod

19.9.13 Under the current assessment, based on CIMP data in 2009-10, AFD and the LVSE intake design could reduce impingement numbers of this species to approximately 63.1t which is about 6.48% of the local SSB. As a demersal species the FRR could reduce impingement mortality by about 94% (Ref. 19.241). However, the cod assessment has recently been reappraised to account for bias caused by an exceptional spike in recruitment during that particular period of sampling. The ratio of annual catches at HPB over 2008:2009 was 5.8% and that for the mean of 2004-2008:2009 was 7.3% (Ref. 19.260). Thus, on a worst case basis, the HPC catch prior to mitigation would be 0.24% of the local SSB. As a result, with mitigation, the magnitude of impact is estimated as very low. In combination with a receptor value/sensitivity of moderate this suggests an impact of **minor adverse** significance.

NOT PROTECTIVELY MARKED

Herring

19.9.14 The AFD and low velocity intake is likely to reduce impingement mortality of herring by approximately 0.24t equating to about 0.24% of the local fishery, the FRR is unlikely to bring any benefit to this delicate bodied species. Taking into the consideration the AFD and LVSE mitigation measures the residual impact on this species post-mitigation is considered to be **minor adverse**.

Plaice

19.9.15 Equivalent adult numbers of plaice impinged annually at HPC could be reduced to around 00.19t with the use of AFDs and the low velocity intake, with the FRR impingement mortality could be reduced by a further 80%, the residual impact on this species is therefore considered to be **minor adverse**.

Blue whiting

19.9.16 With the AFD, the EAV of blue whiting is reduced to 72 fish equating to <0.1% of the blue whiting fishery. Due to a lack of information on the swimming speed of this species it is not possible to assess the impact of the low velocity intake. Assuming the effectiveness of the FRR is similar to whiting, a very similar species, the FRR could reduce impingement mortality by up to 50%, meaning the post-mitigation residual impact is assessed to be **minor adverse**.

Eel

19.9.17 Eels are unlikely to benefit from the low velocity intake, however they are considered to be a robust fish and the FRR could reduce impingement mortality by up to 100%. Assuming a more conservative estimate of 80%, the residual impact on this species post-mitigation is **minor adverse**.

Shad

19.9.18 The AFD and LVSE intake design impingement mortality of twaite shad could be reduced to approximately 273 fish, about 0.15% of the local estimated population. As a delicate bodied species similar to herring and sprat, the FRR is unlikely to reduce impingement mortality further and the post-mitigation residual impact is expected to be **minor adverse**.

Lamprey

19.9.19 Lamprey are unlikely to benefit from the AFDs and low velocity intake design, however they are considered to be a robust fish and a suitable FRR could reduce impingement mortality by up to 100%. Assuming a more conservative estimate of 80%, the residual impact on lamprey post-mitigation is considered to be **minor adverse**.

Shrimp Populations

19.9.20 Impingement rates of C. crangon at HPB are very high. It is known that *C. crangon* feed on the intertidal mudflats at high tide. As the tide recedes they migrate to the shallow subtidal and are found in a concentrated band in the shallow subtidal

(Ref. 19.102). Thus, the natural behaviour of *C. crangon* is likely to concentrate it in the vicinity of the intake structure at certain times. Other intertidal mudflat will be found much further away from the intake. The HPC intake structures are also being constructed further offshore than those at HPB. Overall the magnitude of the impact has been assessed as medium.

19.9.21 Even though *C. crangon* cannot actively avoid entrainment and impingement, the literature suggests that the larvae will have high survival rates following entrainment. (Ref. 19.240). Impingement rates of *C. crangon* are predicted to be reduced with the use of FRR.

19.9.22 Such species are both highly fecund and mobile so recolonisation rates following disturbance are typically rapid. Recent data suggests that numbers observed via SEDS at HPB have been increasing which suggests the current abstraction activities are not affecting the mudflat communities (Ref. 19.102). These understandings suggest a high degree of resilience. Sensitivity is thus considered to be very low.

19.9.23 With low sensitivity and medium magnitude of impact, a **minor adverse** impact is predicted.

Fish Assemblage

19.9.24 The proposed HPC has been specified with low velocity side-entry (LVSE) intake structures and a Fish Recovery and Return system. If these proposed impingement mitigation measures function as designed, the impingement losses at HPC are calculated to be similar to those of the existing HPB.

19.9.25 The resulting HPC impingement losses will have a negligible effect on the spawning stock of the protected migratory species that use the Severn Estuary and have been captured on the intake screens of HPB (European eel, sea lamprey and twaite shad). The catches of Allis shad and salmon on the HPB intake screens are too small to allow a reliable impingement loss to be calculated.

19.9.26 The impact on the commercially important fish species that represent the majority of the existing impingement losses (sprat, whiting, sole, plaice, herring and blue whiting) is considered to be negligible. For whiting, sole, plaice and blue whiting the impingement losses will have a negligible effect on the spawning stock. Sprat is the dominant (>97%) clupeiform fish impinged at HPB and the population trend for this group since 1981 has remained stable. As HPC (with mitigation) will only impinge 28% more that the current HPB, the conclusion is that HPC (with mitigation) is unlikely to have any significant impact on local sprat population.

19.9.27 For herring the impingement losses are less than 2% of the local fishery and will therefore have negligible impact on the local population.

19.9.28 The impact on cod will represent 0.24% of the local SSB (Ref. 19.260). This level of loss is equivalent to 0.06% of the Total Allowable Catch of cod recommended by ICES for 2011 for Divisions VIIe-k (3,420t) and is unlikely to have any detectable effect on the local cod population when considered against the background natural variability in SSB. The predicted losses of cod from a mitigated HPC are 12%

NOT PROTECTIVELY MARKED

greater than those currently caused by HPB. HPB has had no measurable effect on the local abundance trend for cod since 1981.

19.9.29 The predicted impingement losses on crustaceans (as represented by the impact on the brown shrimp *C. crangon* the main crustacean impinged) are also expected to be similar to those of HPB.

19.9.30 On the basis that impacts on all species examined above are predicted to be minor, and that these species provide a reasonable cross section of the local fish assemblage as a whole, the residual impact on the fish assemblage as a whole as a result of HPC operations is also assessed as **minor adverse**.

iii. Entrainment

19.9.31 Predicted entrainment rates (**Table 19.31**) are considered to be too small in relation to Bristol Channel stocks to merit further consideration. The residual impact following the implemented of mitigation is assessed as **minor adverse**.

19.10 Proposed Monitoring Measures

a) Introduction

19.10.1 Monitoring will be undertaken to inform the need for adjustment to the mitigation measures applied and check the continuing validity of assumptions.

19.10.2 The listing below is indicative; detailed surveillance and allied contingency protocols will be subject to further development.

b) Technical Review Procedure

19.10.3 In consultation with the relevant regulatory bodies EDF Energy will establish and maintain a technical working group to:

- maintain active stewardship of the objectives involved in the monitoring described both above and described in **Volume 2**, **Chapters 18** and **19**;
- advise upon the appropriate level of detail of these efforts, and
- review outcomes, advising on any necessary consequent action.

19.10.4 The technical working group will be made up of a number of recognised technical specialists, an independent chairman, and be supported by a secretariat, all operating under agreed Terms of Reference. An interface with regulatory technical nominees will be maintained throughout and their active involvement as observers of the technical review process encouraged.

19.10.5 The group will report to EDF Energy. It is envisaged that this technical review procedure will continue to operate throughout the period of HPC construction and into the early years of generation.

c) Construction

i. Corallina run-offs

19.10.6 Considerable care will be required in order not to compromise the cross-shore rock platform physics of the habitat upon which the *Corallina* run-offs depend. Thus, as stated within **Volume 2 Chapter 17**, to guard against untoward effects on the longshore drainage regime and the sensitive habitats associated with these, monitoring will assess both the establishment of the remedial measures involved and the longer term consequence of these activities.

ii. Cetaceans and Noise

19.10.7 Although the numbers would appear to be low, especially close to the site itself, recent evidence from acoustic monitoring in the Hinkley Point area contradicts previous assumptions that small cetacea do not frequent the area.

19.10.8 Acoustic monitoring will thus be continued both to secure the local baseline and, subsequently, to test for the relative presence or absence of small cetacea over the periods of construction when significant noise disturbance (from percussive piling) is likely. The acoustic array will not be maintained beyond the construction period.

19.10.9 Expert advice will be obtained on whether or not, with the acoustic monitoring network already in place, and data on seasonal and spatial distribution available, any further measures will be necessary to manage these works through active surveillance of cetacean presence, as implied by current guidance (Ref. 19.155).

iii. Discharge to Intertidal Area

19.10.10 All construction and some commissioning discharges will be put to a single cross-shore discharge. Although hydraulic modelling has shown that this combined discharge will be constrained both in terms of route and width and that the impacts are predicted to be minor, these understandings will be confirmed through periodic monitoring of the intertidal area involved.

iv. Scour

19.10.11 A limited degree of seabed scour will be associated with the offshore components of the temporary aggregate jetty, the cooling water intake structures, the cooling water outfall structures, and the discharges arising from these latter structures. Likewise, there is the possibility of linear bathymetric features developing in association with the jetty berthing pocket.

19.10.12 The aerial extent of scour associated with these structures and features will be monitored by sidescan and swathe sonar survey following station commissioning, and the need to revisit this effort reviewed on the basis of initial findings. Associated ground truthing (grab sampling) will permit mapping of the resultant habitat and biotope distributions in the immediate vicinity will be appropriate.

NOT PROTECTIVELY MARKED

d) Operation

i. Numerical Modelling

19.10.13 There has inevitably been is a very considerable dependency, within the assessment developed both in this Chapter and **Volume 2**, **Chapter 18**, upon the outputs of numerical hydrodynamic models.

19.10.14 Whilst the primary hydrodynamic models have been subject to considerable challenge over the course of their development, and as a fully validated and calibrated ensemble represent current best practice in terms of constraining uncertainty, they are nonetheless estimates of reality rather than observations.

19.10.15 As a result, and in accord with Environment Agency guidance for NNB (Ref. 19.68), it will be appropriate to conduct field investigations in two circumstances: when a single EPR unit is fully operational and once both units are operating together. The standard for such investigations is set by Ref. 19.20 and 19.68. This monitoring will capture the behaviour of the thermal plumes under known tidal and meteorological conditions, allowing comparison of the results with previous estimates. Additional model runs may prove necessary in order to replicate the field conditions found at the time.

19.10.16 There will be a need to gather a sufficient body of empirical data on these operations before it becomes possible to validate certain of these models. Until that point only observational data will be available.

19.10.17 **Appendix 18A** to **Chapter 18** describes the development of the existing numerical hydrodynamic models and the extent of compliance with current Environment Agency guidance appropriate to considerations of New Nuclear Build in the UK (Ref. 19.68), That guidance also requires that the models will continue to be 'available for use over the period of at least 10 years from the date of commissioning of the power station, and beyond that for as long as there is (are) no suitable alternative)s) available'.

ii. Efficacy of Fish Protection Measures

Acoustic Fish Deterrence (AFD)

19.10.18 Precautionary estimates have been used is assessing the mitigaiton benefit of the acoustic fish deterrent (AFD) systems that will be deployed around the HPC cooling water intakes.

19.10.19 There will be a need to prove that the minimum performance standard, based upon these estimates, has been met early in the operational life of the station. Thus, trials defined by current guidance on best practice (Ref. 19.19) will be carried out at that time and any adjustments made to the AFD systems and the trials then extended system should this prove necessary.

19.10.20 Such trials would carried out over a period of weeks or a few months and involve the enumeration and identification of fish impinged on the CW screens. Over this period the AFD systems would be switched on and off on alternate days. The trials would cease only once specific statistical criteria on the difference between 'AFD on' and 'AFD off' days, for a range of species, have been met.

19.10.21 The nature of the AFD deployment, as a series of active instrument packages requiring routine maintenance, means that instrumented monitoring of the performance of this equipment would be needed for the life of the plant, coupled with a routine maintenance cycle. Once initial proving trials have been secured, this requirement would be limited to confirming the appropriate underwater sound field is being maintained via telemetry from the offshore instrument packages themselves. If any unexpected deterioration is observed that might hazard the minimum performance standard, this would bring forward the maintenance cycle on the AFD system involved.

Low Velocity Side Entry (LVSE) Intake Design and Position

19.10.22 The HPC intake design is novel, although with a strong basis of understanding from both previous trials, numerical modelling studies, and expert advice. The intakes are also, following advice on best practice for fish protection (Refs. 19.229 and 19.230), located well offshore.

19.10.23 In practice, given the fixed nature of the installations, it will not be possible to discriminate the actual benefits of the HPC LVSE intake design from any benefit of offshore location, but the sum of that benefit may become apparent through maintaining fish impingement monitoring of the HPB drum screens over the period of the AFD trials described above, both on 'AFD on' and 'AFD of' days, either for their full duration or until specific statistical criteria are met.

Fish Recovery and Return (FRR) Efficacy

19.10.24 As with the AFD, a precautionary estimate of system efficacy has been incorporated in the assessments mentioned earlier in this chapter.

19.10.25 There will be a need to prove that the minimum performance standard, based upon these estimates, has been met early in the operational life of the station. Thus trials defined by current guidance on best practice (Ref. 19.19) and based on previous experience (Ref. 19.207 and 19.241) will be carried out at that time and any adjustments then made to the system in order to secure that standard, should this prove necessary.

iii. Fish Monitoring Programme

19.10.26 A fish impingement/entrainment programme will be developed and implemented, using best practice developed through BEEMS and elsewhere. This will include tests of the AFD system, such as those described above, to define the benefits of both the AFD system itself and the LVSE intake design and location against the HPB base, should HPB still be operating. This will inform enhanced operation of the AFD and FRR systems as necessary as well as informing sustainable decision making at other sites.

NOT PROTECTIVELY MARKED

19.10.27 The comprehensive impingement monitoring programme (CIMP), utilised to estimate likely impingement catches of HPC for this ES, will be re-established for a single annual period at HPC in order to confirm these previous estimates.

iv. Chlorination

19.10.28 The primary means of constraining the operational need to control biological fouling through oxidant dosing is via continuing surveillance both of local intertidal shores and for the presence of epifaunal growth within the cooling water circuits themselves.

19.10.29 Such surveillance is currently maintained by HPB and elements of this, adapted as appropriate given the difference in plant design (primarily the offshore position and low flow nature of the HPC intake design), will be adopted by the HPC operator.

v. Trends and Variance in Local Populations

19.10.30 There will be an advantage both to the operator and others in furthering medium to long-term so as to maintain an understanding of key populations.

Invertebrate Populations on Stert Flats

19.10.31 The existing baseline of seasonal studies of *Macoma* and other key invertebrate species on Stert Flats will be extended in order to elaborate on the existing understanding of within-year and between-years variance. After an initial three year period a reduced sampling strategy will be implemented in order to track longer term trends in these populations.

vi. Severn Estuary Data Set (SEDS)

19.10.32 By the end of 2011 there will be a time series of fish impingement data based upon 31 years of continuous monthly sampling at Hinkley Point.

19.10.33 This database was instigated within the CEGB with an understanding that only with the establishment of at least one such long-term database in the UK would the scientific community and plant operators be able to describe the baseline of longer term change against which developments such as HPC might best be understood.

19.10.34 Although the use of fish protection measures at HPC, which in combination will reduce the catch per unit volume to one a third of that experienced at HPB, will mean that a like for like continuation of this exercise on the new station will not strictly be possible, there will be considerable value in continuing such sampling for the longer term. The implementation of the CIMP programme described above will, should the two stations operate in parallel, will provide a means of calibration between the different station catch rates.

19.11 Summary of Impacts

a) Introduction

19.11.1 Impacts have been assessed after taking into consideration aspects of project design and management and generic mitigation measures which would be required as part of the development. Following this approach the vast majority of impacts have been predicted to be of negligible to minor significance, although some are considered to be of moderate significance before mitigation. In these instances specific mitigation has been identified, as discussed in the previous sections of this Chapter. The predicted residual effects as they stand are presented in **Table 19.37** and **Table 19.38** below.

b) Construction

19.11.2 A summary of the potential impacts on marine ecology associated with the construction of HPC, setting out impacts prior to mitigation, the mitigation proposed, and the subsequent residual impacts is presented in **Table 19.37**.

NOT PROTECTIVELY MARKED

Table 19.37: Assessed Impacts of Significance during the Construction Phase

Sensitivity	Significance Pre-mitigation	Reason	Mitigation	Residual Significance
Habitat Loss and Change				
Intertidal habitats: general	Minor	Jetty construction and removal	Best practice in managing works on the shore	Minor
Corallina biotope	Minor	Jetty construction and removal	Best practice in managing works on the shore	Minor
Intertidal habitats	No Impact	Seawall construction	Best practice in managing works on the shore	No Impact
Subtidal habitats	Negligible	Vertical cooling water shaft construction	Best practice in managing works offshore	Negligible
Subtidal fauna	Negligible	Vertical cooling water shaft construction	Best practice in managing works offshore	Negligible
Sabellaria reef	No Impact	Vertical cooling water shaft construction	Best practice in managing works offshore	No Impact
Subtidal habitats	Minor	Capital and maintenance dredging	Best practice in managing works offshore	Minor
Physical Disturbance				
Intertidal habitats	Minor	Jetty construction and removal	Best practice in managing works on the shore	Minor
Intertidal habitats	Minor	Sea wall construction	Restricted working corridor; best practice in managing works on the shore	Minor
Intertidal habitats	Moderate	Barge delivery of rock armour to shore	Restricted landing area	Minor
Sabellaria reef	No impact	Jetty construction and removal	Jetty alignment is remote from reef areas	No impact
Corallina biotope	Minor	Due to pile driving activity and plant movement on the intertidal	Best practice in managing works on the shore (constrained corridor, avoidance of compaction of surface) coupled with restoration of microtopography	Minor

Sensitivity	Significance Pre-mitigation	Reason	Mitigation	Residual Significance
Subtidal habitats	Negligible	Scour allied with jetty piers	Impacts are highly localised with very limited ecological consequence	Negligible
Intertidal habitats	Minor	Introduction of waste materials and particulates from seawall construction	Best practice in managing works on the shore	Minor
Seawall: *Corallina* biotope	No impact	Introduction of waste materials and particulates from seawall construction	Best practice in managing works on the shore; seawall is remote from Corallina run-off areas	No impact
Subtidal habitats	Negligible	Vertical cooling water shaft construction	Best practice in managing works offshore	Negligible
Subtidal habitats – suspended sediments	Negligible	Vertical cooling water shaft construction	Best practice in managing works offshore	Negligible
Subtidal habitats	Minor	Capital and maintenance dredging	Best practice in managing works offshore	Minor
Changes in Water Quality				
Subtidal habitats	Negligible	Capital and maintenance dredging	Best practice in managing works offshore	Negligible
Corallina biotope	Negligible	Capital and maintenance dredging	Isolated due to tidal regime	Negligible
Sabellaria reef	Negligible	Capital and maintenance dredging	Best practice in managing works offshore	Minor
Subtidal habitats	Negligible	Vertical cooling water shaft construction	Best practice in managing works offshore	Negligible
Corallina biotope	Minor	Construction site discharges: composition	Appropriate discharge location selected on basis of intertidal biotope distributions; additional mitigation by effluent treatment	Minor
Sabellaria reef	Minor	Construction site discharges: composition	As above	Minor

NOT PROTECTIVELY MARKED

Sensitivity	Significance Pre-mitigation	Reason	Mitigation	Residual Significance
Intertidal habitats	Minor	Construction site discharges: composition	As above	Minor
Intertidal due to sedimentation	Minor	Construction site discharges: scour	Appropriate discharge location selected on basis of intertidal biotope distributions; additional mitigation by effluent treatment	Minor
Intertidal due to salinity changes	Minor	Construction site discharges: variable salinity	As above	Minor
Fish	Minor	Construction site discharges: suspended solids	Best practice in managing works on the shore	Minor
Corallina biotope	Minor	Seawall construction	Best practice in managing works on the shore	Minor
Sabellaria reef	No impact	Seawall construction	Best practice in managing works on the shore	No impact
Fish	No impact	Seawall construction	Best practice in managing works on the shore	No impact
Noise and Vibration				
Fish: hearing generalist minus swim bladder (lampreys, dab, sole, plaice)	Negligible	Percussive pile driving generating underwater noise which can cause avoidance reactions or physical injury to fish	Use of 'soft start' approach to piling	Negligible
Fish: hearing generalist minus swim bladder (lampreys, dab, sole, plaice)	Negligible	Noise and vibration associated with dredging	Best practice in managing works offshore	Negligible
Fish: hearing generalist minus swim bladder (lampreys, dab, sole, plaice)	Minor	Noise and vibration associated with construction of horizontal tunnels	Best practice in managing works offshore	Minor
Fish: hearing generalist plus swim bladder (salmon, sea trout, eel, cod,	Minor	Percussive pile driving generating underwater noise which can cause avoidance reactions	Use of 'soft start' approach to piling	Minor

Sensitivity	Significance Pre-mitigation	Reason	Mitigation	Residual Significance
whiting)		or physical injury to fish		
Fish – hearing specialists (shads, sturgeon, herring, sprat)	Moderate	As above	Use of 'soft start' approach to piling	Minor
Marine mammals	Minor	As above	As above	Minor
Artificial Lighting				
Intertidal habitats	No impact	Lighting on aggregate jetty during construction and/or operation	N/A	No impact
Water column	Negligible	As above, plus offshore construction works for the placement of cooling water headworks	N/A	Negligible

c) Operation

19.11.3 A summary of the potential impacts on marine ecology associated with the operation of HPC, setting out impacts prior to mitigation, the mitigation proposed, and the subsequent residual impacts is presented in **Table 19.38**.

Table 19.38: Assessed Impacts of Significance during the Operational Phase

	Significance Pre-mitigation	Reason	Mitigation	Residual Significance
Thermal Discharges				
Non-migratory fish	Minor	Thermal regime change	Majority are tolerant to temperature variations	Minor
Migratory fish	Minor	Thermal regime change plus thermal occlusion of migratory pathways	Selected intake/outfall configuration	Minor
Benthic habitats: *Corallina* biotope and *Sabellaria* reef	No impact	Intersection of thermal plume with intertidal and shallow subtidal areas	As above	No impact
Benthic habitats: *Macoma balthica*	Minor	As above	As above	Minor

NOT PROTECTIVELY MARKED

	Significance Pre-mitigation	Reason	Mitigation	Residual Significance
Benthic habitats: ecological functioning on Stert Flats	Minor	As above	As above	Minor
Benthic habitats: subtidal	Minor	Intersection of plume with subtidal areas	As above	Minor
Microphytobenthos	No impact	Intersection of thermal plume with intertidal areas	As above	No impact
Crangon crangon population	Negligible	Thermal plume	As above	Negligible
Adequacy of intertidal invertebrate prey resource to avifauna	Minor	Intersection of thermal plume with intertidal areas	As above	Minor
Chemical Discharges				
Intertidal habitats: *Corallina* biotope and *Sabellaria* reef	Moderate	Commissioning waste streams via cross-shore discharge	Appropriate positioning of discharge location. Effluent sentencing and pre-treatment	Minor
Subtidal habitats	Minor	Commissioning waste streams via cooling water system outfall	Effluent sentencing and pre-treatment	Negligible
Chlorine EQS (acute)	Minor	Operational discharge of residual biocide	Selected intake/outfall configuration	Minor
Site specific Screening Level (chronic)	Moderate	Operational discharge of residual biocide	Selected intake/outfall configuration. Constrained dosing regime	Minor
Chlorination by-products	Minor	Operational discharge of residual biocide	Selected intake/outfall configuration. Constrained dosing regime	Minor
Subtidal habitats and water column immediately around outfall headworks	Minor	Operational discharge of hydrazine	Hydrazine discharges will be constrained	Minor
Subtidal habitats and water column immediately around outfall headworks	Negligible	Operational discharge of morpholine	Low toxicity	Negligible
Subtidal habitats and water column immediately around outfall headworks	No impact	Operational discharge of ethanolamine	Low toxicity	No impact

	Significance Pre-mitigation	Reason	Mitigation	Residual Significance
Trophic functioning	Negligible	Operational discharge of nitrogen and phosphorous	Very low volumes to be discharged	Negligible
Subtidal habitats and water column immediately around outfall headworks	Negligible	Operational discharge of ammonia	Very low volumes to be discharged	Negligible
Impingement of Fish and Shrimp				
Sprat	Moderate	Population mortality	AFD + low velocity intake design	Minor
Whiting	Moderate	Population mortality	AFD + low velocity intake design + FRR	Minor
Sole	Minor	Population mortality	FRR	Minor
Cod	Minor	Population mortality	AFD + low velocity intake design + FRR	Minor
Plaice	Minor	Population mortality	FRR	Minor
Blue whiting	Minor	Population mortality	AFD + low velocity intake design + FRR	Minor
Sea bass	Minor	Population mortality	AFD + low velocity intake design + FRR	Minor
Crustaceans incl. *Crangon crangon*	Moderate	Population mortality	FRR	Minor
Salmon	Negligible	Population mortality	AFD + low velocity intake design + FRR	Negligible
Twaite shad	Moderate	Population mortality	AFD + low velocity intake design + FRR	Minor
Eel	Moderate	Population mortality	FRR	Minor
River and sea lamprey	Moderate	Population mortality	FRR	Minor
Fish assemblage	Moderate	Population mortality; functioning	AFD + low velocity intake design + FRR	Minor
Entrainment				
Ichthyoplankton	Minor	Population mortality	5mm mesh limits entrainment forcing diversion to FRR	Minor

NOT PROTECTIVELY MARKED

	Significance Pre-mitigation	Reason	Mitigation	Residual Significance
Other zooplankton including mysids	Minor	Population mortality; functioning	5mm mesh limits entrainment forcing diversion to FRR	Minor
Phytoplankton	Minor	Population mortality; functioning	5mm mesh limits entrainment forcing diversion to FRR	Minor

Notes: AFD: Acoustic Fish Deterrence System; FRR: Fish Recovery and Return System

19.12 Conclusions

19.12.1 An extensive series of marine ecological studies, calling upon longer term efforts and project-specific investigations, has secured a good understanding of the marine environment local to the Hinkley Point site.

19.12.2 Early design considerations carried out using numerical modelling tools developed on the basis of these marine studies have enabled the consideration of a variety of cooling water intake and outfall configurations. Subsequently, these same studies have been utilised in optimising finer detail of the cooling water system designs, leading to a series of means of mitigating potentially untoward impacts, as described above.

19.12.3 In summary, with appropriate design and management of HPC construction and operation, all impacts upon marine ecological receptors can be rendered limited to no greater than minor adverse significance.

CHAPTER 20: TERRESTRIAL ECOLOGY AND ORNITHOLOGY

CONTENTS

TABLES

FIGURES

APPENDICES

20. TERRESTRIAL ECOLOGY AND ORNITHOLOGY

20.1 Introduction

20.1.1 This chapter of the Environmental Statement (ES) provides an assessment of the potential impacts on terrestrial and freshwater ecology, and on ornithology (collectively referred to as biodiversity within this Chapter) arising from the construction and operation of Hinkley Point C (HPC – the proposed development) and associated highway improvement works (see **Chapter 2** of this volume of the ES for a detailed description of the proposed development). Although it assesses impacts on freshwater ecology, impacts upon coastal and marine ecology are assessed separately in **Chapter 19** of this volume of the ES. Where required, mitigation measures are identified to prevent, reduce and where possible off-set any potential adverse impacts that are identified to be of significance.

20.2 Scope of Assessment

20.2.1 The scope of the assessment has been determined through a formal Environmental Impact Assessment (EIA) scoping process undertaken with the Infrastructure Planning Commission (IPC). It has also been informed by ongoing consultation with statutory consultees (including Natural England (NE), the Environment Agency (EA), Sedgemoor District Council (SDC), West Somerset Council (WSC) and Somerset County Council (SCC)), Somerset Wildlife Trust, the local community and the general public in response to the Stage 1, Stage 2, Stage 2 Update and M5 Junction 24 and Highway Improvements consultations.

20.2.2 The assessment of impacts on biodiversity has been undertaken adopting the methodologies described in Section 20.4 of this chapter.

20.2.3 The baseline conditions, against which the likely environmental impacts of the proposed development are assessed, have been determined through desk-based data collection and field surveys, and are described in Section 20.5 of this chapter.

20.2.4 Section 20.6 of this chapter sets out the assessment of the impacts on biodiversity arising from the proposed development. The development has been designed, where possible, to incorporate measures that will prevent, reduce or off-set potential adverse impacts. No other measures are proposed as mitigation in relation to the impacts of the development on biodiversity that are identified in this ES. However, a series of additional good practice measures has been identified (see Section 20.7), which will contribute to reducing impacts that are of no more than minor adverse significance and hence that do not require mitigation.

20.2.5 The impacts of the development are summarised in Section 20.8 of this chapter.

20.2.6 The objective of this chapter is to meet the requirements of the Infrastructure Planning (Environmental Impact Assessment) Regulations 2009 (Ref. 20.1) in relation to flora and fauna and for the:

- collection of baseline information on biodiversity;
- identification of biodiversity receptors that could be significantly affected by the proposed development, and the definition of these potential impacts (i.e. 'scoping');
- assessment of the magnitude and significance of the potentially significant impacts of the proposed development incorporating design measures that have been devised in response to the findings of the assessment (but that are not dealt with separately as mitigation measures);
- identification of mitigation measures that would avoid or reduce adverse impacts and measures that offset adverse impacts; and
- assessment of residual impacts (i.e. after the implementation of the proposed mitigation measures).

20.3 Legislation, Policy and Guidance

20.3.1 This section identifies and describes legislation, policy and guidance of relevance to the assessment of biodiversity impacts associated with the construction, operation and post-operational phases of the proposed development.

20.3.2 As stated in **Volume 1, Chapter 4** of this ES, the Overarching National Policy Statement (NPS) for Energy (NPS EN-1) (Ref. 20.2) when combined with the NPS for Nuclear Power Generation (NPS EN-6) (Ref. 20.3) provides the primary basis for decisions by the IPC on applications for nuclear power generation developments that fall within the scope of the NPSs.

20.3.3 Notwithstanding this, the IPC may consider other matters that are both important and relevant to its decision-making. This could include Planning Policy Statements (PPSs), Planning Policy Guidance Notes (PPGs), and regional and local policy documents. However, if there is a conflict between these and the NPS, the NPS prevails for the purposes of IPC decision making.

20.3.4 Further, the Planning Act 2008 provides that the IPC must, in making its decision on an application, have regard to any Local Impact Report (LIR) prepared by relevant local authorities. It is anticipated that the LIRs will rely in part on PPSs, PPGs, and regional and local policy to provide a context for their assessment. On this basis, regard has been given to these documents (where they are relevant to the technical assessment), since they are likely to inform the LIRs prepared by the relevant local authorities.

a) International Conventions

i. The Convention on Biological Diversity 1992 (Ref. 20.4)

20.3.5 The Convention on Biological Diversity (the Convention) focuses on the conservation of all species and ecosystems. It requires the development of national strategies, plans or programmes for the conservation and sustainable use of biodiversity. In accordance with this, the UK has developed Biodiversity Action Plans (BAPs), which provide guidance for the conservation and management of biodiversity. In 2010, the parties to the Convention agreed the Nagoya Protocol. This provides a transparent legal framework for the effective implementation of one of the three objectives of the Convention, namely the fair and equitable sharing of benefits arising out of the utilisation of genetic resources.

20.3.6 At Nagoya, the parties to the Convention adopted the Strategic Plan for Biodiversity 2011-2020 (Ref. 20.5) with the purpose of inspiring broad-based action in support of biodiversity over the next decade by all countries and stakeholders. The Strategic Plan, which includes 20 targets, known as the Aichi Targets, serves as a flexible framework for the establishment of national and regional targets, and promotes the coherent and effective implementation of the three objectives of the Convention on Biological Diversity.

ii. The Convention on Wetlands 1971 (Ref. 20.6)

20.3.7 The Convention on Wetlands (commonly referred to as the Ramsar Convention) originally focused on the conservation and wise use of wetlands, primarily as habitat for waterbirds. However, the scope of implementation of the Convention has been broadened to cover all aspects of wetland conservation in recognition of the importance of wetland ecosystems for biodiversity conservation. Under the Convention, each country is required to designate sites (‘Ramsar sites’) that meet the Criteria for Identifying Wetlands of International Importance, which are based on Article 2.2 of the Convention.

b) European Legislation

i. Council Directive 2009/147/EC on the Conservation of Wild Birds (the European Union (EU) Birds Directive) (Ref. 20.7)

20.3.8 The EU Birds Directive requires Member States to take the requisite measures to maintain the population of all species of naturally occurring wild birds in the States’ European territory at a level that corresponds to various requirements. Member States shall take special conservation measures concerning the habitat of species mentioned in Annex I of the Directive, and shall take similar measures for regularly occurring migratory species that are not listed in Annex I. Under the Directive, the most suitable areas for the conservation of these species (whether on land or at sea) are classified as Special Protection Areas (SPAs). In England and Wales the Directive is implemented under the Wildlife and Countryside Act 1981 (as amended) (Ref. 20.8) and the Conservation of Habitats and Species Regulations 2010 (Ref. 20.9).

ii. Council Directive 92/43/EEC on the Conservation of Natural Habitats and of Wild Fauna and Flora (the EU Habitats Directive) (Ref. 20.10)

20.3.9 The EU Habitats Directive requires Member States to maintain or restore, at favourable conservation status, natural habitats and species of wild fauna and flora of Community interest (i.e. those listed in Annexes I, II, IV and/or V of the Directive). Member States are also required to contribute to a coherent European ecological network of protected sites by designating Special Areas of Conservation (SACs) for the natural habitat types listed in Annex I and habitats of the species listed in Annex II.

20.3.10 Under the Directive, the conservation status of a habitat is defined as favourable when: its natural range, and the areas it covers within that range, are stable or increasing; the species structure and functions which are necessary for its long-term maintenance exist and are likely to continue to exist for the foreseeable future; and the conservation status of its typical species is favourable. The conservation status of a species is defined as favourable when: population dynamics data indicate that it is maintaining itself on a long-term basis as a viable component of its natural habitats; its natural range is neither being reduced nor is likely to be reduced for the foreseeable future; and there is, and would probably continue to be, a sufficiently large habitat to maintain its populations on a long-term basis.

20.3.11 In England and Wales, the Directive is implemented through the Conservation of Habitats and Species Regulations 2010 (Ref. 20.9).

c) National Legislation

i. The Conservation of Habitats and Species Regulations 2010 (the Habitats and Species Regulations) (Ref. 20.9)

20.3.12 The Habitats and Species Regulations, which replace the Conservation (Natural Habitats, &c.) Regulations 1994 (Ref. 20.11), are the principal means by which the EU Habitats Directive and EU Birds Directive are transposed into national law for England, Wales and the territorial seas. The Habitats and Species Regulations, *inter alia*, provide for the designation and protection of European sites, and the protection of European protected species.

20.3.13 Under the Habitats and Species Regulations, a person who does any of the following in respect to a European protected animal species (those listed in Schedule 2) is guilty of an offence:

- deliberately captures, injures or kills any wild animal of a European protected species;
- deliberately disturbs wild animals of any such species;
- deliberately takes or destroys the eggs of such an animal; or
- damages or destroys a breeding site or resting place of such an animal.

20.3.14 It is also an offence under the Habitats and Species Regulations deliberately to pick, collect, cut, uproot or destroy a wild plant of a European protected species (those listed in Schedule 5).

20.3.15 However, these actions can be made lawful through the granting of licences by the appropriate authorities. Licences may be granted for a number of purposes (such as science and education, conservation, preserving public health and safety), but only after the appropriate authority is satisfied that there are no satisfactory alternatives and that such actions would have no detrimental effect on the maintenance of the conservation status of the species concerned.

ii. The Wildlife and Countryside Act 1981 (the WCA) (Ref. 20.8)

20.3.16 The WCA (as amended, including by the Countryside and Rights of Way Act 2000 (Ref. 20.12)) strengthens provisions under the National Parks and Access to the Countryside Act 1949 (Ref. 20.13) to designate, protect and manage Sites of Special Scientific Interest (SSSIs) and to establish National Nature Reserves (NNRs) in England and Wales. These sites can be established on land down to the low water mark. SSSIs and NNRs can be designated for their flora, fauna or geological interests.

20.3.17 The WCA (subject to specified exceptions) makes it an offence to:

- intentionally kill, injure or take any wild animal included in Schedule 5;
- intentionally or recklessly:
  - damage or destroy any structure or place which any wild animal specified in Schedule 5 uses for shelter or protection; or
  - disturb any such animal while it is occupying a structure or place which it uses for shelter or protection or;
  - obstruct access to any structure or place which any such animal uses for shelter or protection;
- intentionally:
  - kill, injure or take any wild bird; or
  - take, damage or destroy the nest of a wild bird included in Schedule ZA1; or
  - take, damage or destroy the nest of any wild bird while that nest is in use or being built; or
  - take or destroy an egg of any wild bird.
- intentionally or recklessly:
  - disturb any wild bird included in Schedule 1 while it is building a nest or is in, on or near a nest containing eggs or young; or
  - disturb dependent young of such a bird.
- intentionally pick, uproot or destroy any wild plant included in Schedule 8.

iii. Protection of Badgers Act 1992 (Ref. 20.14)

20.3.18 Under the Protection of Badgers Act, it is an offence (subject to specified exceptions) to:

- wilfully kill, injure or take, or attempt to kill, injure or take, a badger; or
- cruelly ill-treat a badger; or
- interfere with a badger sett by doing any of the following things:
  - damage a badger sett or any part of it; or
  - destroy a badger sett; or
  - obstruct access to, or any entrance of, a badger sett; or
  - cause a dog to enter a badger sett; or
  - disturb a badger when it is occupying a badger sett.

iv. The Hedgerows Regulations 1997 (Ref. 20.15)

20.3.19 The Hedgerows Regulations make it an offence to remove or destroy certain hedgerows without the permission of the local planning authority.

v. The Natural Environment and Rural Communities (NERC) Act 2006 (Ref. 20.16)

20.3.20 Section 40 of the NERC Act sets out a requirement for every public authority (including local authorities), in exercising their functions, to have regard, so far as is consistent with the proper exercise of those functions, to the purpose of conserving biodiversity.

20.3.21 Section 41 of the NERC Act requires the Secretary of State to publish a list of habitats and species which are of principal importance for the purpose of conserving biodiversity in England. The list, which includes 56 habitats and 943 species, has been drawn up in consultation with NE, as required by the NERC Act.

vi. Countryside and Rights of Way (CRoW) Act 2000 (Ref. 20.12)

20.3.22 The CRoW Act provides for public access on foot to certain types of land, amends the law for public rights of way, increases protection for SSSIs, strengthens wildlife enforcement legislation and provides for better management of Areas of Outstanding Natural Beauty (AONB).

d) National Planning Policy

i. Planning Policy Statement 1: Delivering Sustainable Development (PPS1) (2005) (Ref. 20.17)

20.3.23 PPS1 was published in 2005 and sets out the Government's overarching planning policies on the delivery of sustainable development through the planning system.

20.3.24 Paragraph 5 states that planning should facilitate and promote sustainable and inclusive patterns of urban and rural development by, amongst other things: protecting and enhancing the natural and historic environment, the quality and character of the countryside, and existing communities.

ii. Planning Policy Statement 9: Biodiversity and Geological Conservation (PPS9) (2005) (Ref. 20.18)

20.3.25 PPS9 was published in 2005 and sets out planning policies on the protection of biodiversity and geological conservation through the planning system. The broad aim of the policies is to ensure that planning, construction, development and regeneration should have minimal impacts on biodiversity and enhance it wherever possible.

20.3.26 Key objectives of PPS9 include (page 2):

- *"to promote sustainable development by ensuring that biological and geological diversity are conserved and enhanced as an integral part of social, environmental and economic development, so that policies and decisions about the development and use of land integrate biodiversity and geological diversity with other considerations.*
- conserve, enhance and restore the diversity of England's wildlife and geology by sustaining and where possible improving the quality and extent of natural habitat and geological and geomorphological sites; and to conserve, enhance and restore the diversity of England's wildlife and geology by sustaining, and where possible improving, the quality and extent of natural habitat and geological and geomorphological sites; the natural physical processes on which they depend; and the populations of naturally occurring species which they support."

20.3.27 Paragraph 8 states that, where a proposed development on land within or outside an SSSI is likely to have an adverse effect on an SSSI (either individually or in combination with other developments), planning permission should not normally be granted. Where an adverse effect on the site's notified special interest features is likely, an exception should only be made where the benefits of the development, at this site, clearly outweigh both the impacts that it is likely to have on the features of the site that make it of special scientific interest and any broader impacts on the national network of SSSIs.

20.3.28 Paragraph 9 states that sites of regional and local biodiversity and geological interest, which include Regionally Important Geological Sites, Local Nature Reserves and Local Sites, have a fundamental role to play in meeting overall national biodiversity targets; contributing to the quality of life and the well-being of the community; and in supporting research and education.

20.3.29 Paragraph 10 states that planning authorities should not grant planning permission for any development that would result in the loss or deterioration of ancient woodland, unless the need for, and benefits of, the development in that location outweigh the loss of the woodland habitat.

20.3.30 Paragraph 12 states that networks of natural habitats provide a valuable resource and should be protected from development, and, where possible, strengthened by or integrated within it.

20.3.31 Paragraph 16 states that planning authorities should ensure that protected species are protected from the adverse effects of development and refuse permission where harm to the species or their habitats would result, unless the need for, and benefits of, the development clearly outweigh that harm.

iii. Consultation Paper on a New Planning Policy Statement – Planning for a Natural and Healthy Environment (2010) (Ref. 20.19)

20.3.32 In its final form, it is intended that this PPS will replace PPS9. The draft PPS contains policies to maintain and enhance, restore or add to biodiversity and geodiversity through the planning system. It includes policies to promote opportunities for the incorporation of beneficial biodiversity and geological features within the design of development, and to maintain networks of natural habitats by avoiding their fragmentation and isolation.

20.3.33 A key objective of this PPS is to bring together related policies on the natural environment and on open space and green spaces in rural and urban areas to ensure that the planning system delivers healthy, sustainable communities which adapt to and are resilient to climate change and gives the appropriate level of protection to the natural environment (page 10).

iv. The UK BAP (Ref. 20.20)

20.3.34 The UK Government signed the Convention on Biological Diversity at the Earth Summit in Rio de Janeiro in 1992 (Ref. 20.4). Following this, the Prime Minister announced an eight point plan for the UK which included the production of the UK BAP. The UK BAP identifies the means by which the UK should contribute to the global conservation of biodiversity over the following 20 years. As part of the UK BAP, a list of priority species and habitats was developed, the conservation of which requires specific actions to be implemented.

e) Regional Planning Policy

20.3.35 The Government's revocation of regional strategies was quashed in the High Court on 10 November 2010. However, on that same date the Government reiterated in a letter to Chief Planners its intention to revoke regional strategies through the Localism Bill. This letter was also challenged but, on 7 February 2011, the High Court held that the Government's advice to local authorities that the proposed revocation of regional strategies was to be regarded as a material consideration in their planning development control decisions should stand. The decision of the High Court was upheld by the Court of Appeal on 27 May 2011. Therefore, the regional strategies remain in place but in the case of development control decisions it is for planning decision-makers to decide on the weight to attach to the strategies (see **Volume 1, Chapter 4** of this ES for a full summary of the position regarding the status of regional planning policy).

i. Regional Planning Guidance 10 for the South West 2001-2016 (RPG10) (2001) (Ref.20.21)

20.3.36 RPG10 sets out the broad development strategy for the period to 2016 and beyond. Policy EN1 (Landscape and Biodiversity) seeks the protection and enhancement of the region's internationally and nationally important landscape areas and nature conservation sites. The protection and, where possible, enhancement of landscape and biodiversity should be planned into new development.

ii. The Draft Revised Regional Spatial Strategy (RSS) for the South West Incorporating the Secretary of State's Proposed Changes 2008-2026 (July 2008) (Ref. 20.22)

20.3.37 The draft Revised RSS for the South West looks forward to 2026 and sets out the Government's policies in relation to the development of land within the region. Chapter 7 deals with Enhancing Distinctive and Cultural Life. Policy ENV1 (Protecting and Enhancing the Region's Natural and Historic Environment) states the following:

> *"The quality, character, diversity and local distinctiveness of the natural and historic environment in the South West will be protected and enhanced, and developments which support their positive management will be encouraged. Where development and changes in land use are planned which would affect these assets, Local Authorities will first seek to avoid loss of or damage to the assets, then mitigate any unavoidable damage, and compensate for loss or damage through offsetting actions. Priority will be given to preserving and enhancing sites of international or national landscape, nature conservation, geological, archaeological or historic importance. Tools such as characterisation and surveys will be used to enhance local sites, features and distinctiveness through development, including the setting of settlements and buildings within the landscape and contributing to the regeneration and restoration of the area."*

20.3.38 Policy ENV4 (Nature Conservation) states the following:

> *"The distinctive habitats and species of the South West will be maintained and enhanced in line with national targets and the South West Regional Biodiversity Action Plan. Local Authorities should use the Nature Map to help map local opportunities for biodiversity enhancement in LDDs, taking into account the local distribution of habitats and species, and protecting these sites and features from harmful development. Priority will be given to meeting targets for maintenance, restoration and recreation of priority habitats and species set out in Appendix 1, focusing on the Nature Map areas identified in Map 7.3. Proposals which provide opportunities for the beneficial management of these areas and habitats and species generally, should be supported, including linking habitats to create more functional units which are more resilient to climate change."*

iii. Somerset and Exmoor National Park Joint Structure Plan Review 1991-2011 (2000) (Policies 'saved' from 27th September 2007) (Ref. 20.23)

20.3.39 The Somerset and Exmoor National Park Joint Structure Plan was adopted in 2000, with relevant policies saved from 27 September 2007. All policies have been saved with the exception of Policy 53, which is unrelated to impacts on biodiversity. The Plan provides a strategic base for all land use planning within the plan area for the period up to 2011.

20.3.40 Policy STR1 (Sustainable Development) states that development in Somerset and the Exmoor National Park should, amongst other things, conserve biodiversity and environmental assets, particularly nationally and internationally designated areas.

20.3.41 Policy 1 (Nature Conservation) states that the biodiversity of Somerset and the Exmoor National Park should be maintained and enhanced. The greatest protection will be afforded to nature conservation sites of international and national importance. In addition, Local Plans should include policies to maintain and enhance sites and features of local nature conservation importance including landscape features which provide wildlife corridors, links or stepping stones between habitats.

iv. The South West Biodiversity Implementation Plan (SW BIP) (Ref. 20.24)

20.3.42 The SW BIP sets out a framework of policies, priorities and actions to assist in achieving a more integrated approach to the delivery of biodiversity aims within the South West. It contributes towards the Biodiversity Strategy for England (Ref. 20.25) and aims to influence regional strategies, plans and policies.

20.3.43 The overall aims of the SW BIP are to:

- help to meet biodiversity targets for priority habitats and species in the South West;
- ensure regional strategic plans incorporate biodiversity issues for the South West;
- provide a strategic framework for the work undertaken by regional and local biodiversity partnerships in conserving biodiversity and promoting the sustainable use of biological resources; and
- develop wider support and active engagement by increasing awareness and understanding of the importance of biodiversity to the region’s health, quality of life and economic productivity.

v. Wild Somerset – The Somerset Biodiversity Strategy 2008-2018 (the Somerset Biodiversity Strategy) (Ref. 20.26)

20.3.44 The Somerset Biodiversity Strategy is intended to represent a long term blueprint for successful biodiversity conservation in Somerset. It proposes a vision for biodiversity conservation locally and sets out a series of objectives and actions aimed at making significant progress towards achieving them. It also identifies those organisations that are best placed to implement the actions, either through their own endeavours or working in partnership with others.

vi. Somerset Local BAP (LBAP) (Ref. 20.27) and West Somerset LBAP (Ref. 20.28)

20.3.45 The Somerset LBAP has been produced in conjunction with the Somerset Biodiversity Strategy and identifies targets and actions for the following biodiversity receptors across Somerset:

- ditches and ponds;
- gardens and urban greenspace;
- hedgerows and hedgerow trees;
- road verges and green lanes;
- traditional orchards;
- water and wetlands;
- wood pasture, parkland and veteran trees;
- bats;
- otter (*Lutra lutra*); and
- lapwing (*Vanellus vanellus*).

20.3.46 The West Somerset LBAP (2008) incorporates targets and actions identified in the Somerset LBAP and specifies the following ecological receptors as requiring particular biodiversity targets within West Somerset:

- coastal and marine;
- long-eared owl (*Asio otus*);
- native wildflowers of arable land;
- waxcaps; and
- woodland.

f) Local Planning Policy

i. West Somerset Local Plan (2006) (Policies 'saved' from 17 April 2009) (Ref. 20.29)

20.3.47 The West Somerset Local Plan forms part of the development plan for West Somerset. The Local Plan was adopted in April 2006 (with relevant policies ‘saved’ from 17 April 2009).

20.3.48 The Proposals Map indicates that the north-eastern corner of the development site adjacent to Hinkley A lies within a County Wildlife Site (Policy NC/3). The foreshore, which lies just outside of the northern boundary of the development site, is designated as an SSSI (Policy NC/1) and National Nature Reserve (Policy NC/1). The SSSI designation also abuts the eastern boundary of the development site. SPA and Ramsar site designations affect the foreshore ('unsaved' Policy NC/2). The development site lies outside of the defined development boundary.

20.3.49 The following saved policies are considered to be potentially relevant:

20.3.50 Policy NC/1 (Sites of Special Scientific Interest) states that development proposals which may, directly or indirectly, adversely affect SSSIs will not be permitted unless: there are no alternative means of meeting the development need, and the reasons for the development clearly outweigh the value of the development site and the national policy to safeguard the nature conservation value of the national network of such sites.

20.3.51 Policy NC/1 also states that, where the site is a National Nature Reserve (NNR) or a site identified under the Nature Conservation Review or Geological Conservation Review, particular regard will be paid to the site's national importance. Where development is permitted, the use of conditions or planning obligations to ensure the protection and enhancement of the site's nature conservation interest will be considered.

20.3.52 Policy NC/3 (Sites of Local Nature Conservation and Geological Interest) states that planning permission will not be granted for development which has a significant adverse effect on local nature conservation/geological interests or integrity of landscape features, unless the importance of the development outweighs the value of the substantive interests present.

20.3.53 Policy CO/1 (The Coastal Zone) states that development proposals in any part of the Coastal Zone, including those areas of existing developed coast, will only be permitted where: the development and its associated activities are unlikely to have an adverse effect, either directly or indirectly on heritage features, landscape character areas, nature conservation interests, including sub-tidal and marine habitats, and residential amenities; the development is unlikely to have an adverse effect on the character of the coast and maintains and where possible, enhances, improves or upgrades the environment particularly in derelict and/or despoiled coastal areas; the development requires a coastal location.

ii. West Somerset District Local Development Framework (LDF) Core Strategy (Options Paper) (January 2010)

20.3.54 The Core Strategy is at a preliminary stage of preparation and the Options Paper does not include any specific policies relating to terrestrial ecology or ornithology impacts at the development site.

iii. Supplementary Planning Guidance

20.3.55 West Somerset Council and Sedgemoor District Council have jointly prepared draft supplementary planning guidance in relation to the HPC Project. Public consultation on the Consultation Draft version of the HPC Project Supplementary Planning Document (the 'draft HPC SPD') (Ref. 20.30) commenced on 1 March 2011 and concluded on 12 April 2011. EDF Energy has submitted representations which object to the draft HPC SPD. **Volume 1, Chapter 4** of this ES provides a full summary of the position regarding the status of the draft HPC SPD.

20.3.56 With regards to the approach to masterplanning and design of the development site, Box 19 in the draft HPC SPD states, amongst other things, that appropriate mitigation measures for impacts on protected species or Biodiversity Action Plan Priority Species and nature conservation interests should be identified, including:

- Protecting the integrity of the European Natura 2000 sites (SACs and SPAs);
- Potential disturbance from the construction process leading to displacement of birds;
- Impacts on the Hinkley County Wildlife Site;
- The cumulative impacts with associated development, preliminary works, other applications for consent, and other projects, including for example, the Construction Centre, Bristol Container Port, Steart Coastal Management Project, and Oldbury power station; and
- Effects on water quality and migratory fish populations (page 37).

20.3.57 Further planning policy context is provided in the Legislative Planning Policy Context chapter (**Volume 1, Chapter 4** of this ES) and the introduction chapter (**Volume 2, Chapter 1** of this ES).

20.4 Methodology

a) Introduction

20.4.1 **Volume 1, Chapter 7** of this ES describes the generic assessment methodology for this EIA. The subject-specific methodology that has been used for the assessment in this chapter draws upon the Institute of Ecology and Environmental Management's (IEEM's) guidelines on ecological impact assessment (Ref. 20.31), but also reflects the standardisation of aspects of the assessment across all the topics that are covered in this ES. The main elements of this chapter's impact assessment methodology are listed in Section 20.2.5 of this chapter.

20.4.2 The remainder of this section outlines the methodologies that were adopted for baseline data gathering, consultation, scoping the assessment and the assessment methodology. The section concludes with information about limitations, constraints and assumptions.

b) Baseline Data Gathering

i. Desk Study

HPC Development Site

20.4.3 A desk study was undertaken in order to identify any requirement for further surveys and to inform the assessment process.

20.4.4 For the desk study, data were collected for the development site and a 3km[1] area around the development site (**Figure 20.1**). Data for this area had the potential to highlight notable species that could be present on the development site as well as indicating off-site ecological resources that could be affected by the proposed development. The desk study area was extended to 10km around the development site in relation to European nature conservation sites[2] and bat records.

20.4.5 During May 2009, information about statutory nature conservation sites within the 3km area (and 10km area for European sites) was obtained through the use of the following websites: www.magic.gov.uk; www.jncc.gov.uk; and www.naturalengland.org.uk. Also during May 2009, information about non-statutory nature conservation sites, and pre-existing biological records were obtained from the Somerset Environmental Records Centre (SERC). Information relating to designated sites was updated in April 2011. Of the large number of records received, only post-1990 records have been considered, as these are likely to be most relevant to the current conditions at the development site.

20.4.6 1:25,000 Ordnance Survey maps were studied in order to identify any water bodies located within 500m of the development site, given the possibility that any great crested newts (*Triturus cristatus*) that breed in such water bodies could utilise terrestrial habitats on the development site. The Great Crested Newt Mitigation Guidelines recommend that surveys of ponds up to 500m from a development may be required to determine the impact of the development on this species (Ref. 20.32).

20.4.7 The Nature Map created by Biodiversity South West (Ref. 20.33) was reviewed to determine if the development site lies within an identified Strategic Nature Area (SNA).

20.4.8 Information on active toad crossings (i.e. those that are known to be currently used by toads to access breeding ponds) within the study area was obtained from Froglife's Toads on Road project (Ref. 20.34).

20.4.9 Desk study data were also sought from the organisations and individuals listed in **Table 20.1**. This table also lists the data that were received.

[1] The study areas were defined to reflect the likely spatial scope of the impacts that would be caused by the proposed development, using information about the development proposals, knowledge of the local area and professional judgement. On this basis, the study area is larger for the development site than for the highway improvement sites.

[2] Under The Conservation of Habitats and Species Regulations 2010 (SI 2010 No. 490), European sites are defined as Special Areas of Conservation (SACs), candidate SACs, Sites of Community Importance and Special Protection Areas (SPAs). However, UK policy extends the requirements pertaining to European sites to include Ramsar sites and potential SPAs, and this would include proposed extensions or alterations to existing SPAs.

Table 20.1: Organisations and Individuals that Provided Ecological Baseline Data

Organisation/Individual	Data Requested	Data Received
NE	General biological information with follow-up specific request for invertebrate records	Contextual information received on nocturnal bird studies undertaken in other parts of the county, and on invertebrates on Wick Moor, located to the east of the development site.
Royal Society for the Protection of Birds (RSPB)	Contextual information	Paper on bird use of Bridgwater Bay and Steart Area (Ref. 20.35). General contextual information
British Trust for Ornithology (BTO)	Wetland Bird Survey (WeBS) data[3] (high and low tide)	WeBS core count data for years 04/05 – 08/09. Low tide count data were available for 2002/03 only.
Conservation Warden at Hinkley Point	Bird records for 'The Island' located at the mouth of the Huntspill River	As requested
Somerset Badger Group	Badger records for the study area	As requested
Somerset Bat Group	Bat records (and queries with regard to grey long-eared bat [*Plecotus austriacus*] records)	Confirmation that it holds no additional data to that received from SERC. Correspondence with Edward Wells (Chair of the SBG) with regard to specific queries. Bat survey data from the Quantocks (2010).
Somerset Ornithological Society	Bird information for the study area.	As requested
Somerset Otter Group	Otter information for the study area.	As requested
SCC Ecologists	Biological information	Great crested newt records. Information on bovine tuberculosis
SWT	General biological information relating to the study area	Confirmation that they hold no additional data to that received from SERC.
Bristol Ports Company and the Environment Agency	The findings of surveys undertaken to inform the EIA of a proposed coastal re-alignment scheme on the Steart Peninsula	Data provided in relation to bats

20.4.10 Baseline information has also been obtained from the following sources:

- Land Management Reports prepared by ADAS (Refs 20.36 and 20.37);
- West Hinkley Wind Farm Environmental Statement (Ref. 20.38);

[3] WeBS is the main scheme for monitoring the numbers of non-breeding waterbirds in the UK. The principal aims of WeBS are to identify population sizes, determine trends in numbers and distribution and to identify important sites for waterbirds. WeBS counts are predominantly undertaken by skilled volunteers.

- A history of the birds of Somerset (Ref. 20.39);
- Somerset bird reports (Somerset Ornithological Society, Refs 20.40, 20.41, 20.42, 20.43 and 20.44);
- The decommissioning environmental statement for Hinkley Point A (HPA) (Ref. 20.45);
- The National Biodiversity Network Gateway website (http://data.nbn.org.uk/); and
- National otter survey data (Ref. 20.46).

Highway improvement sites

20.4.11 Given the small size of the ten highway improvement sites, the areas for which desk study information was collected were limited to a 500m radius around each site[4].

ii. Extended Phase 1 Habitat Survey

20.4.12 An extended Phase 1 habitat survey of the development site and up to 100m beyond the boundary was conducted in May 2009, building on extended Phase 1 habitat surveys of smaller parts of the development site that were carried out in March 2007 and September 2008 (the scope of these surveys was smaller due to restricted access). The survey methodology was based on the Joint Nature Conservation Committee's (JNCC's) Phase 1 habitat survey methodology (Ref. 20.47). This involved habitats, together with notable features of biodiversity conservation interest, being identified and mapped; each notable feature of biodiversity conservation interest was described in a target note. The survey was extended (Ref. 20.48) to collect additional information on the presence/potential presence of legally protected and other notable species, and interest features such as hedgerows and water bodies. Details of the survey methodology are set out in **Appendix 20A.**

20.4.13 The same survey methodology was applied to the highway improvement sites, which were surveyed between the 1 and 5 August 2011. Based on the results of the desk study and the extended Phase 1 Habitat survey, it was concluded that no further surveys were required in relation to the highway improvement sites.

iii. Other Surveys

20.4.14 Based on the results of the desk study and the extended Phase 1 Habitat survey, it was concluded that further ecological surveys were required to inform the assessment of ecological impacts associated with the proposed HPC development. These are summarised in **Table 20.2,** with the detailed methods contained within **Appendix 20A-L and Q**.

[4] See footnote 1 for explanation of survey areas

Table 20.2: Summary of Ecological Surveys undertaken at the Development Site

Survey	Appendix Ref	Description
Hedgerow	Appendix 20A	An initial survey of hedgerows accessible at that time was undertaken in 2007, with repeat survey of all hedgerows within the development site undertaken in May 2009. All hedgerows that were likely to be at least 30 years old were assessed to determine if they met the criteria for being ecologically 'important' in respect to Paragraph 7 of Schedule 1 of The Hedgerows Regulations 1997 (Ref. 20.15).
National Vegetation Survey (NVC)	Appendix 20A	Areas of potential botanical interest within the study area (both within and adjacent to the development site) that could be affected by the works and that were identified through the extended Phase 1 habitat survey were subject to National Vegetation Classification (NVC) surveys in either 2007 or 2009. These surveys followed the standard NVC methodology (Ref. 20.49).
Woodland condition	Appendix 20A	A woodland condition survey was undertaken in May 2009. This involved collecting information about the height, naturalness, structure and diversity of each woodland compartment within, and adjacent to, the development site, in addition to a review of the management history and the production of a higher plant species list for each compartment. The survey was completed with reference to A Nature Conservation Review (Ref. 20.50)
River Corridor	Appendix 20A	A River Corridor Survey was completed for each watercourse within the development site following the guidance provided in the River Corridor Surveys – Conservation Technical Handbook (Ref. 20.51). The survey was undertaken in July 2009. During the survey, information on the physical and biological features of the aquatic, marginal, bank and adjacent land zones were recorded and mapped in order to characterise the watercourse. The River Corridor Survey also incorporated a detailed survey of the plant species present within and adjacent to the channel and identified culverts, bridges and other channel features.
Birds	Appendix 20B Appendix 20C Appendix 20Q	A breeding bird territory mapping survey, using an adapted version of the British Trust for Ornithology's Common Bird Census (CBC) methodology (Ref. 20.52), was carried out within and adjacent to the development site over four visits between April and July 2007. Additional surveys were also undertaken to determine whether any of the buildings within the development site are used by breeding barn owl (*Tyto alba*). This was completed initially using a pole-mounted camera in September 2009, to inspect the buildings for evidence that they had been occupied by barn owl during the breeding season (as a structural survey had determined that these buildings were not safe to access), followed by dusk emergence surveys in May and June 2010. Supplementary records of birds recorded outside the CBC survey (during other ecology surveys) were also used when compiling the final territory map, as was information supplied by Martin Sage of ADAS and Dick Best, EDF Energy's Hinkley Point Site Warden. Birds using inter-tidal areas and inshore marine waters in the vicinity of the development site were surveyed between April 2007 and March 2009. The surveys involved recording the locations, numbers and activities of birds present throughout the tidal cycle from observation points located along the frontage of the proposed development and to the east and west of the development site boundary. Data were recorded from five locations that overlooked areas referred to in this document as Count Sectors 1 – 5. In total 182 recording sessions were undertaken for each count sector.

Survey	Appendix Ref	Description
		In addition, further recording of birds using the inter-tidal habitats to the east of the existing Hinkley Point B (HPB) (i.e. on the Stert Flats) was undertaken between April 2010 and January 2011. From four vantage points, data were collected across a six hour period five times per month. Data were mapped using a 200 x 200m grid system. Birds foraging, loafing or roosting within agricultural fields within the survey area during daylight hours were surveyed by means of daytime field-by-field (walkover) surveys, which were undertaken between September 2007 and March 2009. In addition, surveys were undertaken to establish whether there was any nocturnal use of coastal fields within and adjacent to the development site during the passage and winter period. These surveys were conducted on a twice-monthly basis between December 2007 and May 2008, and again between August 2008 and March 2009. The behaviour of rafting shelduck was monitored in July and August 2011. Fourteen watches, each of six hours' duration, were completed from a vantage point on the shoreline close to the location of the temporary jetty.
Badger	Appendix 20D (Confidential due to information on sett locations)	Following an initial badger survey of the development site in 2007, extensive bait-marking studies (Ref. 20.53) were undertaken in 2008, 2009 and 2010 of the development site and land a minimum of 200m from the development site's boundary, to determine the use of the development site by badgers. Weekly surveys of the development site to record badger activity and active setts began in October 2010 and are on-going.
Bat	Appendix 20E Appendix 20F	A suite of bat surveys has been undertaken since 2007. All survey work has been undertaken with reference to the Bat Conservation Trust Guidance (Ref. 20.54) and has comprised the following: • bat activity transect surveys within the development site between summer and autumn 2007, in September 2008 and monthly between May and September in 2009; • bat activity transect surveys outside the development site boundary in 2010, specifically aimed at recording barbastelle (*Barbastellus barbastellus*) activity; • a winter roost assessment within the development site in early 2009 (predominantly of trees although buildings were externally assessed); • emergence and re-entry surveys of on-site buildings and woodlands containing trees with roosting opportunities, undertaken between June and August in 2009 and 2010, and during April 2011 (when only buildings were surveyed); • emergence and re-entry surveys of off-site woodland in summer 2010 specifically surveying for the potential presence of roosting barbastelle; • continuous deployment of two static Anabats (bat activity data loggers) at a range of locations between June and September 2009 (on-site), and between May and October 2010 (predominantly off-site and specifically to record barbastelle activity); • climbing inspections of trees with roost potential in 2009 and 2010; and • internal inspections of buildings using a pole-mounted camera in 2009.

Survey	Appendix Ref	Description
Dormouse (*Muscardinus avellanarius*)	Appendix 20G	Suitable habitat within part of the development site was surveyed for the presence of dormouse between June and November 2007, then continued (over a larger area when access was possible to the full development site) in 2008 and 2009. The survey methodology was designed with reference to the Dormouse Conservation Handbook (Ref. 20.55).
Otter	Appendix 20H	All water features (watercourses and water bodies) within the development site, and selected locations within approximately 5km of the development site, were surveyed for signs of otter in May 2009 (after an initial otter survey in August 2007). The survey methodology was designed with reference to Monitoring the Otter (Ref. 20.56).
Water vole (*Arvicola amphibius*)	Appendix 20H	All water features within the development site that had been identified during the extended Phase 1 habitat survey were surveyed for evidence of water vole in either August 2007 or September 2008, and again in May 2009. The survey methodology was designed with reference to the Water Vole Conservation Handbook (Ref. 20.57).
Great crested newt	Appendix 20I	In March 2009, a study was undertaken to identify all water bodies within, and within 500m of the development site. A screening assessment was then undertaken, whereby each water body identified was visited to assess its suitability to support breeding great crested newts, taking account of the Habitat Suitability Index (HSI) Guidelines (Ref. 20.58) and the connectivity between the water body and the development site. Where the screening assessment determined that a water body may provide suitable habitat for great crested newts, and it was determined that, if present, they could access the development site, then the water body was 'screened in' to a four visit presence/absence survey, which was undertaken between March and June 2009 using a methodology that was designed with reference to the Great Crested Newt Mitigation Guidelines (Ref. 20.32).
Reptiles	Appendix 20J	Areas of potentially suitable reptile habitat within and adjacent to the development site were surveyed in 2007, 2008 and 2009 to establish the presence/likely absence of reptiles and, where found to be present, to provide information for a population size class estimate. The survey methodology was designed with reference to guidance in Froglife's Advice Sheet 10 (Ref. 20.59) and additional guidance provided by the Herpetofauna Workers' Manual (Ref. 20.60) and Reptiles: Guidelines for Developers (Ref. 20.61).
Invertebrates	Appendix 20K Appendix 20L	A walkover survey in August 2008 and a freshwater invertebrate sampling visit in September 2008 were conducted to provide an initial assessment of the likely value of the development site to invertebrates. This survey work was then updated in 2009, when the watercourses within the survey area were further surveyed for freshwater invertebrates, and representative terrestrial habitats were surveyed for terrestrial invertebrates. In 2010 an invertebrate habitat assessment survey of the coastal zone was completed.

c) Consultation

20.4.15 Consultation has been undertaken throughout the EIA process and further information may be found in the Consultation Report. Consultation was undertaken with the organisations that are listed in **Table 20.3**, in order to discuss the scope of and approach to be taken to ecological surveys, the results of these surveys and the scope of any potential mitigation required.

Table 20.3: Consultation Undertaken to Inform the Assessment of Impacts on Biodiversity

Consultee	Date of Meeting	Primary Subject of Meeting
Natural England	07 June 2007	Scope of ecological surveys
	22 June 2009	
	05 March 2008	Scope of EIA (multi-disciplinary meeting)
	22 June 2009	Results of survey work, mitigation and other environmental measures
	07 October 2009	
	07 December 2009	
	23 March 2010	
	28 April 2009	Badger mitigation and licensing
	23 July 2009	
	27 October 2009	
	01 March 2010	
	23 March 2010	Mitigation and enhancement works, including development site restoration
	20 January 2011	Results of bat survey work
	24 January 2011	Mitigation and enhancement works, including restoration of the development site
	11 April 2011	Summary of work since Stage 2 consultation
	15 July 2011	Summary of ornithological data and of the assessment of disturbance and thermal effects, and discussions of modelling protocols
Somerset County Council	22 June 2009	Scope of ecological surveys
	22 June 2009	Results of survey work, mitigation and other environmental measures
	27 October 2009	
	07 December 2009	
	23 March 2010	Mitigation and enhancement works, including restoration of the development site
	24 January 2011	
	28 April 2009	Badger mitigation and licensing
	20 January 2011	Results of bat survey work
	11 April 2011	Summary of work since Stage 2 consultation
	15 July 2011	Summary of ornithological data and assessment of disturbance and thermal effects and discussions of modelling protocols
Environment	22 June 2009	Scope of ecological surveys

Consultee	Date of Meeting	Primary Subject of Meeting
Agency	05 March 2008	Scope of EIA (multi-disciplinary meeting)
	22 June 2009	Results of survey work, mitigation and other environmental measures
	07 December 2009	
	23 March 2010	Mitigation and enhancement works, including restoration of the development site
	15 July 2011	Summary of ornithological data and of the assessment of disturbance and thermal effects, and discussions of modelling protocols
Somerset Wildlife Trust	24 April 2009	Scope of ecological surveys
	01 October 2009	Results of survey work, and discussion of mitigation and conservation gain, and other environmental measures
	07 December 2009	
	23 March 2010	Mitigation and enhancement works, including restoration of the development site
	24 January 2011	
	20 January 2011	Results of bat survey work
Royal Society for the Protection of Birds	03 October 2007	Scope of ornithological surveys
	22 June 2009	
	09 February 2010	Results of survey programme, key findings, mitigation and HRA
	15 July 2011	Summary of ornithological data and of the assessment of disturbance and thermal effects, and discussions of modelling protocols
West Somerset Council (represented by Arup)	20 January 2011	Results of bat survey work
	24 January 2011	Mitigation and enhancement works, including restoration of the development site
	11 April 2011	Summary of work since Stage 2 consultation
	15 July 2011	Summary of ornithological data and of the assessment of disturbance and thermal effects, and discussions of modelling protocols

20.4.16 No surveys were required in relation to the highway improvement sites, other than the extended Phase 1 habitat survey (for which consultation was not required).

d) Scoping the Assessment

20.4.17 The first part of the assessment process was to undertake a scoping exercise. This involved differentiating the biodiversity receptors (i.e. designated sites, habitats and species' populations) that could be significantly affected by the proposed development and that therefore required more detailed assessment, from those receptors that are not likely to be significantly affected and did not require further assessment (i.e. they were 'scoped-out' of the assessment).

20.4.18 The first stage of the approach that was used for determining which receptors have the potential to be significantly affected by the proposed development involved using baseline data (collected by the desk study and field surveys) for the development site and up to 2km away (up to 10km away for European designated nature conservation sites)[5] to determine:

- which, if any of the species that have been recorded are legally protected or controlled (see **Appendix 20M**, Box 20M.2); and/or
- which, if any, sites, areas of habitat and species that have been recorded are of importance for biodiversity conservation, notwithstanding any legal protection that they may have (see **Appendix 20M**, Box 20M.1).

20.4.19 Use of these categories provides a robust and objective basis for focusing the assessment on receptors that are widely recognised to be important for the conservation of biodiversity in addition to those that are legally protected. It should be noted, however, that legally protected species may be protected for reasons other than for biodiversity conservation (e.g. badger, which is protected for welfare reasons).

20.4.20 For sites/habitats/species that are important for biodiversity conservation, the next stage of the scoping assessment was to determine whether the receptors are likely to be of sufficient 'value' that an impact upon them could be significant. In this context, value refers to a receptor being of sufficient quality (for sites and habitats) or size (for sites, habitats or species' populations). The distinction between importance and value can be illustrated by the great crested newt, which, as well as being legally protected, is important at a national level because it is a species of principal importance for biodiversity (Ref. 20.16). However, depending on the local abundance of this species, a small affected population might be anywhere between low or high biodiversity value.

20.4.21 The findings of the valuation of important receptors, together with information about whether receptors are legally protected, are set out in Table 20N.1 in **Appendix 20N**. For those receptors that are assessed as being of insufficient value for impacts to be significant, this appendix provides a justification for this conclusion.

20.4.22 Important receptors that are of sufficient value that an impact upon them could be significant, together with all legally protected species, were then taken through to the next stage of the scoping assessment. This involved identifying, for each receptor, any environmental changes that are likely to be caused by the proposed development, which have the potential to lead to a significant impact. Then the area was determined within which the environmental change could cause a significant impact on the receptor; this area is referred to as an 'ecological zone of influence'. The area where the receptor occurs was then compared with the ecological zone of influence. If the receptor occurs or is likely to occur within the zone of influence it was 'scoped in' to further assessment (Table 20N.2 in **Appendix 20N**).

20.4.23 The ecological zone of influence that is the most straightforward to define is the area affected by land take and land cover changes associated with the development. This zone is the same for all affected receptors. By contrast, for each environmental change that can extend beyond the area affected by land take and land cover

[5] There was also the possibility that other receptors could be identified as potentially being affected, based on the study team's experience of the local area.

change (e.g. changes in noise), the zone of influence may vary between receptors, dependent upon the receptors' sensitivity to the change and the precise nature of the change.

20.4.24 For example, one bird species might be unaffected by noise unless the noise is generated very close to where the bird nests, whilst another bird species might be disturbed at much greater distances; other species (e.g. of invertebrate) may be unaffected by changes in noise. A further complication is that the response of a receptor to a change associated with one development may differ to the response of the same receptor to a similar change on another development. This can occur as a result of the wide range of variables that influences the precise nature of any change (e.g. for noise this can include differing baseline noise conditions, specific magnitude, timing or other characteristics of the noise, and the effects of screening and topography).

20.4.25 In view of these complexities, the definition of the zones of influence that extend beyond the land take area was based upon professional judgement, informed by discussions with the technical specialists who were working on other chapters of the ES. These specialists provided information about the environmental changes that they assessed in their ES chapters. This information was then combined with available ecological information about different receptors' sensitivity to different environmental changes in order to define the extent of each ecological zone of influence. The potential outcome of this was that a zone of influence could be so extensive that a larger than expected species population or area of habitat could be affected, which in turn could lead to the potential for an impact to be significant when it was previously assessed that this would be unlikely. As a consequence, receptors that were initially scoped-out could be scoped back into the assessment.

20.4.26 Each relevant receptor (i.e. that is of sufficient value or is legally protected, as described above), which was located wholly or partly within one or more zones of influence, was then subject to further scoping assessment in relation to the relevant environmental change(s). The spatial extent of this assessment reflected the area occupied by the receptor. Thus, if part of a designated nature conservation site was located within a zone of influence, an assessment was made of the impacts on the site as a whole. A similar approach was taken for areas of notable habitat. For species that occur within an ecological zone of influence, an assessment was carried out on the total area that is used by the affected individuals of the species (e.g. for foraging or as a breeding territory).[6]

20.4.27 This final stage of the scoping assessment involved drawing upon available information about the magnitude and other characteristics of the environmental changes and the sensitivity of each relevant receptor to these changes, to arrive at a conclusion about the potential for a significant impact to occur. Where there was the potential for a significant impact, or contravention of protected species legislation, the receptor was taken forward for further 'post-scoping' assessment (see sub-section (d) below) as identified in the final column of Table 20N.2 in **Appendix 20N**.

[6] The affected individuals may, for example, be a pair of birds, a badger clan associated with a main sett or the population of great crested newts in a pond. Where appropriate, the area for which data were required was extended (e.g. to include other pairs of birds in a discrete subpopulation, or a metapopulation of newts).

20.4.28 In undertaking the sequence of steps that are described above, it was recognised that if the environmental changes could significantly affect biodiversity resources further than 2km from the development site (or 10km for European designed sites), the data-collection area would need to be extended. Further data collation would also be required if there were insufficient biological data for any receptor that could be significantly affected by the proposed development. However, neither scenario arose.

e) Assessment Methodology

20.4.29 The assessment of potentially significant biodiversity impacts in this ES draws upon:

- the results of desk study and field survey work;
- relevant published information on potential biodiversity receptors' status, distribution, biology and sensitivity to environmental changes (referenced in the text where used); and
- professional knowledge of ecological processes and functions.

20.4.30 Throughout the assessment process, the findings of the assessment were used to inform the design of the proposed development and identify requirements for any additional baseline data. As a result of this iterative process, environmental measures to avoid, reduce or offset impacts on potential biodiversity receptors were incorporated into the scheme design or identified as mitigation.

20.4.31 The remainder of this section outlines the approach that has been adopted to assessing the significance of impacts, which draws upon information about biodiversity value and the magnitude of impacts. It should be noted that the assessment has been undertaken in relation to each biodiversity receptor that could be significantly affected and/or that is legally protected (as identified in the final column of Table 20N.2 in **Appendix 20N)**, considering that the impact on each receptor could be the result of more than one type of environmental change caused by the development. For example, a receptor might be affected by land take and construction noise.

i. Value of Receptor

20.4.32 Sites, species' populations and areas of habitats have been valued as shown in **Table 20.4.** It should be noted that, in respect of species, the approach taken is to determine the value of the development site for the species under consideration, rather than the biodiversity conservation importance of the species itself (as discussed above in relation to scoping).

Table 20.4: Definition of Terms Relating to Biodiversity Value

Value Level	Value Guidelines
High	International/National designations – SACs, SPAs, Ramsar sites and SSSIs. Cited features of internationally/nationally designated sites. Species populations or habitat areas that are of major importance because of the quality/size of the habitat or the size of the species population in relation to the wider habitat resource/population – species/habitats are most likely to be species/habitats of principal importance under Section 41 of the NERC Act (and UK BAP priority habitats/species), species/habitats that are nationally rare and/or species that are legally protected. The regular occurrence of internationally/nationally important numbers of waterfowl (i.e. 1% or more of the relevant international or national population respectively).
Medium	County Wildlife Sites (CWSs). Features for which CWSs have been designated. Species populations or habitat areas that are of moderate importance because of the quality/size of the habitat or the size of the species population in relation to the wider habitat resource/population – species/habitats are most likely to be species/habitats of principal importance under Section 41 of the NERC Act (and UK BAP priority habitats/species), priority species/habitats in the Local BAP, species/habitats that are rare at the regional/county level and/or species that are legally protected.
Low	Other designated sites of district or local importance including Local Nature Reserves (LNRs), except where these have a higher additional designation. Species populations or habitat areas that are of some biodiversity value because of the quality/size of the habitat or the size of the species population in relation to the wider habitat resource/population – species/habitats are most likely to be species/habitats of principal importance under Section 41 of the NERC Act (and UK BAP priority habitats/species), priority species/habitats in the Local BAP, species/habitats that are rare at the district/local level and/or species that are legally protected species.
Very Low	Species populations or habitat areas that are of very low biodiversity value, typically because they are common and/or are not species/habitats of principal importance under Section 41 of the NERC Act, UK BAP priority habitats/species, priority species/habitats in the Local BAP, species/habitats that are rare at the district/local level and/or legally protected species.

ii. Magnitude of Impact

20.4.33 Using information about the way in which sites/habitats/species are likely to be affected by the proposed development, each impact that is assessed has been assigned a level of ‘magnitude’, based on the definitions that are set out in **Table 20.5.**

Table 20.5: Guidelines for the Assessment of Impact Magnitude

Magnitude of Impact	Criteria
High	The change permanently (or over the long-term) adversely affects the conservation status of a habitat/species, reducing the ability to sustain the habitat or the population level of the species within a given geographic area. Relative to the wider habitat resource/species population, a large area of habitat or large proportion of the wider species population is affected. For designated sites, integrity is compromised. There may be a decrease in the level of biodiversity conservation value of the receptor.
Medium	The change permanently (or over the long-term) adversely affects the conservation status of a habitat/species reducing the ability to sustain the habitat or the population level of the species within a given geographic area. Relative to the wider habitat resource/species population, a small-medium area of habitat or small-medium proportion of the wider species population is affected. There may be a decrease in the level of biodiversity conservation value of the receptor.
Low	The quality or extent of designated sites or habitats or the size of species' populations, experience some small scale reduction. These impacts are likely to be within the range of natural variability and there is not expected to be any permanent change in the conservation status of the species/habitat or integrity of the designated site. The change is unlikely to modify the evaluation of the receptor in terms of its biodiversity conservation value.
Very Low	Although there may be some impacts on individuals or parts of a habitat area or designated site, the quality or extent of sites and habitats, or the size of species populations would experience little or no reduction. Any impacts are likely to be within the range of natural variability and there would be no short-term or long-term effects on the conservation status of habitat/species receptors or the integrity of designated sites.
Beneficial	Improvement in the quality or extent of habitats, the size of species populations or the integrity of a designated site. This improvement must be achieved without compromising the integrity of the proposed development site or conservation status of the habitat/species that is present prior to development. Criteria for assessing the magnitude of beneficial effects can be derived from the definitions of adverse impacts.

20.4.34 The criteria in **Table 20.5** refer to the terms 'integrity' and 'conservation status'. The 'integrity' of a site, as referred to in **Table 20.5**, is defined as:

> *"the coherence of its ecological structure and function, across its whole area, that enables it to sustain the habitat, complex of habitats and/or the levels of populations of the species for which it was classified." (Ref. 20.31).*

20.4.35 Conservation status is defined differently for habitats and species (Ref. 20.31), as:

> *"For habitats, conservation status is determined by the sum of the influences acting on the habitat and its typical species, that may affect its long term distribution, structure and functions, as well as the long-term survival of its typical species within a given geographical area.*
>
> *For species, conservation status is determined by the sum of influences acting on the species concerned that may affect the long term distribution and abundance of its populations within a given geographical area."*

iii. Significance of Impacts

20.4.36 The significance of an impact is established with reference to Table 7.4 in **Volume 1, Chapter 7** of this ES, which sets out how, subject to moderation informed by professional judgement, the level of significance is derived from information about the magnitude of the impact and the value of the receptor. The only exception to this is for legally protected species, for which any contravention of the law is assessed as an impact of major significance irrespective of the magnitude of the impact or the biodiversity conservation value of the population that is affected.

iv. Cumulative Impacts

20.4.37 **Volume 1 Chapter 7** of this ES refers to the methodology used to assess cumulative impacts. Additive and interactive effects between impacts generated within the development site boundary and study area are assessed within this chapter. Cumulative impacts that consider activities and impacts generated at distance from the development site and study area are considered in **Volume 11** of this ES; this assesses the project-wide cumulative impacts and in-combination impacts with other proposed, or reasonably foreseeable projects.

f) Limitations, Constraints and Assumptions

20.4.38 No limitations, constraints or assumptions have been identified that would have a bearing on the assessment of likely significant impacts on biodiversity.

20.5 Baseline Environmental Characteristics

a) Introduction

20.5.1 Sub-section b below describes the biodiversity baseline of the study area (**Figure 20.1**), which includes desk study information obtained for a 3km radius around the development site (10km for European designated nature conservation sites and bat records), and field survey results from within the development site and the immediate surrounding 100m. The detailed results of each survey are described in the Baseline Reports in **Appendices 20A to 20L and 20Q**. A list of records of notable species (as defined in **Appendix 20M**), which was provided by SERC, is contained within **Appendix 20O**.

20.5.2 Information about the biodiversity baseline at the highway improvement sites is outlined in sub-section c below (and detailed in **Appendix 20P**). Given the small size of the highway improvement sites, desk study data were collected for 500m around each site and field survey data from within each site.

b) HPC Study Area Description

i. Designated Sites

20.5.3 The development site is located adjacent to five statutory designated nature conservation sites (see **Table 20.6** and **Figure 20.2**). There is one additional European designated nature conservation site within 10km of the development site (**Figure 20.3**). The development site is partially located within Strategic Nature Area 1169, Maritime Cliff and Slope, which extends along much of the coastline between Minehead and Bridgwater.

Table 20.6: Designated Statutory Nature Conservation Sites within 3km of the Development site (within 10km for European designated sites)

Site	Type of Designation	Location in relation to the development site	Reason for Designation
Severn Estuary	SPA	Adjacent to the development site	This site has been designated for its wintering populations of Bewick's swan (*Cygnus columbianus*), white-fronted goose (*Anser albifrons*), shelduck (*Tadorna tadorna*), gadwall (*Anas strepera*), dunlin (*Calidris alpina*) and redshank (*Tringa totanus*), and its wintering waterfowl assemblage.
Severn Estuary	SAC	Adjacent to the development site	This site has been designated for the following habitats and species: • estuaries; • intertidal mudflats and sandflats; • Atlantic salt meadows; • sandbanks; • reefs; and • three species of migratory fish: sea lamprey (*Petromyzon marinus*); river lamprey (*Lampetra fluviatilis*); and twaite shad (*Alosa fallax*).
Severn Estuary	Ramsar site	Adjacent to the development site	This site has been designated for the following habitats and species: • all SAC features (see above); • unusual estuarine communities associated with reduced productivity and diversity; • migratory fish, including sea trout (*Salmo trutta*), salmon (*Salmo salar*), Allis shad (*Alosa alosa*) and eel (*Anguilla anguilla*) in addition to the cited SAC species; • migratory birds in spring and autumn; • wintering waterfowl assemblage; and • internationally important wintering numbers of Bewick's swan, white-fronted goose, gadwall, shelduck, dunlin and redshank.

Site	Type of Designation	Location in relation to the development site	Reason for Designation
Bridgwater Bay	SSSI	Adjacent to development site	The site has been designated for the following habitats and species: • mudflats; • saltmarsh; • shingle beach; • grazing marsh; • internationally and nationally important numbers of wintering and passage wildfowl including (in addition to species cited in other designations) black-tailed godwit (*Limosa limosa*), teal (*Anas crecca*) and grey plover (*Pluvialis squatarola*); • a diverse invertebrate fauna of ponds and ditches; and • the ecological link to the Somerset Levels and the position of the area in the context of the Severn Estuary.
Bridgwater Bay	NNR	Adjacent to the development site	The site has been designated for its diverse habitats and plant communities, which support important bird populations.
Exmoor and Quantocks Oakwoods	SAC	5.2km to the south-west	The site has been designated for the following habitats and species: • old sessile oak woods in conjunction with heath; • alluvial forests with alder (*Alnus glutinosa*) and ash (*Fraxinus excelsior*); • barbastelle bat; • Bechstein's bat (*Myotis bechsteinii*); and • otter.

20.5.4 In addition to the bird species for which the Severn Estuary Ramsar site has been designated (under Criterion 6 of the Ramsar Convention), as set out in **Table 20.6**, other bird species occur at nationally important levels during the breeding season, passage periods and over-winter. These are herring gull (*Larus argentatus*), little egret (*Egretta garzetta*), ruff (*Philomachus pugnax*), whimbrel (*Numenius phaeopus*), curlew (*Numenius arquata*), greenshank (*Tringa nebularia*), wigeon (*Anas penelope*), shoveler (*Anas clypeata*), pochard (*Aythya ferina*), water rail (*Rallus aquaticus*) and spotted redshank (*Tringa erythropus*). Species identified on the Ramsar Information Sheet for possible future consideration under Criterion 6 are lesser black-backed gull (*Larus fuscus*), ringed plover (*Charadrius hiaticula*), teal and pintail (*Anas acuta*).

20.5.5 In relation to the SPA, the list in **Table 20.6** reflects the Natura 2000 Standard Data Form. Changes that have been suggested by the document, The UK SPA network: its scope and content (the 'SPA review') (Ref. 20.62) are the removal of white-fronted goose and gadwall (which no longer meet qualifying levels), and the addition of passage ringed plover and wintering curlew and pintail. The SPA Review has yet to be formally adopted, although, in practice, recommended additions are treated as SPA species.

20.5.6 One non-statutory designated site (County Wildlife Site – CWS) lies partially within the development site and a further seven are located within 3km (see **Table 20.7** and **Figure 20.4**).

Table 20.7: Designated Non-Statutory Sites within 3km of the Development site

Site	CWS Reference Number	Location in relation to the development site	Reason for Designation
Hinkley CWS	ST24/043	Partly within the development site boundary.	The site supports species-rich scrub, coastal grassland and broad-leaved woodland with ponds and areas of improved grassland. Designated specifically for the presence of Somerset County Notable vascular plant species, including grass vetchling (*Lathyrus nissolia*), pyramidal orchid (*Anacamptis pyramidalis*), Dyer's greenweed (*Genista tinctonia*) and yellow-wort (*Blackstonia perfoliata*).
Blue Anchor to Lilstock Coast CWS	ST24/051	0.1km to the west	Coastal cliffs, with unimproved calcareous grassland and scrub habitats from Blue Anchor to Lilstock
Cole Pool Field CWS	ST14/103	0.7km to the south south-west.	Field with unimproved neutral and marshy grassland and semi-improved areas
Mud House Copse CWS	ST24/003	1.2km to the south-east	Ancient semi-natural broad-leaved woodland
Honibere Wood CWS	ST14/046	1.3km to the west	A large tract of hedged, embanked and ditched ancient semi-natural woodland occupying very wet-lying ground on coastal strip of county (north of Stringson)
Wick Park Covert CWS	ST24/002	1.4km to the south-east	Ancient semi-natural broad-leaved woodland bisected by road
Martin's Wood CWS	ST14/070	1.4km to the south-west	A more or less square tract of ancient semi-natural woodland, with a hedge, ditch and embankment around its perimeter and with a small stream flowing eastwards along its southern edge
Monk Wood CWS	ST24/001	1.5km to the south-east	Broad-leaved ancient woodland
Fairfield House Park CWS	ST14/099	1.5km to the south-west	Parkland site marked on the 1st edition Ordnance Survey map, with an important assemblage of veteran trees
Cross Elms CWS	ST14/027	1.9km to the west	Small field of unimproved grassland and adjacent semi-natural broad-leaved woodland
Pophams Park CWS	ST14/045	2.1km to the south-west	Small area of deciduous woodland situated on flat ground
Fairfield Wood CWS	ST14/047	2.6km to the south-west	A large tract of high-forest, partly ancient woodland, straddling a stream which marks

Site	CWS Reference Number	Location in relation to the development site	Reason for Designation
			the boundary between Nether Stowey and Stringston parishes on essentially level and rather low-lying ground amidst arable and grassland
Quarry Copse CWS	ST14/054	2.8km to the south-west	A small copse of ancient woodland (tithe map) origin on relatively high ground north of Stringston
Claylands Corner Verge CWS	ST24/004	2.9km to the south-east	Roadside verge with species-rich unimproved neutral grassland supporting diverse invertebrate fauna, flanked by tall hedge/tree-belt and with advancing scrub
New Barn Wood CWS	ST24/017	2.9km to the south-east	Ancient semi-natural broad-leaved woodland with broad-leaved plantation

ii. Habitats

20.5.7 The results of the Phase 1 Habitat Survey are presented in **Figure 20.5** and summarised below. The habitats are described in detail in the Habitat Report in **Appendix 20A**.

Overview

20.5.8 The development site comprises open, gently rolling, mixed lowland farmland with hedgerows of variable quality, small scrubby woodlands and occasional standard trees. Although, much of the area is intensively managed, small areas of species-rich calcareous grassland occur along the cliff edge and the immediate vicinity of the existing Hinkley Point Power Station Complex. The latter form part of the Hinkley CWS, which also includes areas of woodland, scrub and other habitats. There is a lane with tall, species-rich hedgerows along much of its length aligned east-west along the low ridge across the approximate centre of the development site, this being referred to hereafter as ‘Green Lane’.

20.5.9 There is one water body within the development site boundary and two streams – the Holford Stream and HPC Drainage Ditch. The former flows west-east across the development site and connects to the Bridgwater Bay SSSI, whilst the latter discharges to the inter-tidal area to the north, which is also part of this SSSI, as well as being part of the Severn Estuary SAC, SPA and Ramsar site. A further watercourse forms the southern boundary of the development site (Bum Brook).

20.5.10 The northern boundary of the development site lies adjacent to Bridgwater Bay, from which it is separated by a low cliff, between zero and ten metres in height, which forms an escarpment between the land and sea. At low tide, the shore adjacent to the development site comprises a relatively narrow expanse of rock (extending to approximately 200m from the cliff and running parallel to it), interspersed with and fringed by muddy sand. Inter-tidal areas to the west include more extensive areas of mobile sand, while to the east, adjacent to the existing Hinkley Point Power Station Complex, the inter-tidal rock platforms, mud and sand extend up to 500m from the upper shore at low water (see **Chapter 19**, **Volume 2** of this ES).

Grassland

20.5.11 Most of the grassland within the development site is agriculturally improved and species-poor pasture dominated by perennial rye-grass (*Lolium perenne*) with abundant white clover (*Trifolium repens*). In a small number of fields, the sward is more structurally diverse and supports a greater range of species including creeping cinquefoil (*Potentilla reptans*), bulbous buttercup (*Ranunculus bulbosus*) and meadow vetchling (*Lathyrus pratensis*) (**Figure 20.5**, Target Notes [TNs] 1 and 3). A further area of grassland (around TN 2) is being managed, through a Countryside Stewardship agreement with NE, to gradually create a neutral to calcareous grassland community.

20.5.12 The four areas of grassland surveyed using the NVC survey methodology support a variety of species and grassland types, as described below.

- Grassland along and adjacent to the coastal footpath between the fence and the soft cliff edge: this calcareous grassland is generally only a few metres wide and has been narrowed in places by scrub invasion. It is species-rich, with notable species including adder's tongue (*Ophioglossum vulgatum*), bee orchid (*Ophrys apifera*) and carline thistle (*Carlina vulgaris*) (all of which are listed within the Somerset Notable Species Dictionary as 'uncommon'). This grassland community has closest affinity to the NVC community MG5(b) crested dog's tail (*Cynosurus cristatus*) – black knapweed (*Centaurea nigra*) grassland, lady's bedstraw (*Galium verum*) sub-community.
- Grassland along the western edge of the existing power station complex: grasses dominate the short (15 – 20cm) species-rich sward, within which notable species include grass-vetchling and dyer's greenweed. This grassland is intermediate between MG5 crested dog's tail-black knapweed grassland and MG1(e) false oat grass (*Arrhenatherum elatius*) grassland, black knapweed sub-community.
- Grassland associated with the young broad-leaved plantation (Bishop's Wood): the area is currently a young plantation, and the central part and the various tracks that radiate from it have a community that is classified as conforming to a mixture of MG6a perennial rye grass-crested dog's tail grassland and MG1 false oat grass grassland. However, the sward is moderately species-rich and has occasional common centaury (*Centaurium erythraea*), yellow-wort and pyramidal orchid, which suggest a slight calcareous influence.
- Grassland adjacent to Holford Stream: this is classified as MG10a Yorkshire fog – soft rush (*Holcus lanatus*-*Juncus effusus*) rush-pasture. The vegetation is generally very species-poor, although the northern part of the field is slightly more species-rich. The only notable species that has been recorded is grass vetchling, which is scattered throughout.

Woodland

20.5.13 There are seven areas of mature, semi-natural broad-leaved woodland within the development site, all of which are small, ranging in size between 0.1ha and 0.9ha. They are well connected to each other by the network of hedgerows, but none are adjacent to extensive areas of semi-natural habitat.

20.5.14 Although the structure and characteristic dominant species in each woodland varies slightly, all the woods, apart from Woodlands C and F (**Appendix 20A**), correspond broadly to NVC community W8 ash-field maple-dog's mercury (*Fraxinus excelsior – Acer campestre – Mercurialis perennis*) . Based on the species-poor ground flora in Woodlands A (Newclose Covet), D (Whitewall Brake), E and G (Govett's Copse), these show affinity with the ivy (*Hedera helix*) sub-community of W8. Woodland B supports few ash or field maple trees as it is dominated by English elm (*Ulmus procera*). Due to this dominance of elm, Woodland B (Haysgrove Brake) corresponds closer to the herb-Robert (*Geranium robertianum*) sub-community of W8, in which elm frequently occurs in varying abundance.

20.5.15 Woodlands C (Seaberton Brake) and F support little ash and field maple, whilst scrub species such as hawthorn (*Crataegus monogyna*) and blackthorn (*Prunus spinosa*) are dominant. Therefore, these woodlands correspond better with NVC community W21 hawthorn-ivy (*Crataegus monogyna – Hedera helix*) scrub. Again, due to the dominance of ivy in the ground flora, the ivy-common nettle (*Hedera helix – Urtica dioica*) sub-community fits best with the species present in both woodlands.

20.5.16 None of the woodlands within the development site are assessed as being ancient (i.e. they were not present prior to 1600AD) and many have only developed over the last 100 years. The recent development of the woodlands is likely to contribute significantly to their species-poor and structurally similar character.

20.5.17 In the southern part of the development site there are two areas of plantation woodland. The larger of these, Bishop's Wood (TN9 on **Figure 20.5**), was planted with native broad-leaved trees and shrubs in winter 1998/1999. Its ground flora contains a variety of grassland species including cowslip (*Primula veris*) and is moderately species-rich. The smaller area of plantation woodland (TN10) has also been planted with native broad-leaved species. However, tall ruderal vegetation, such as nettle (*Urtica dioica*) and creeping thistle (*Cirsium arvense*), dominates the ground flora.

Hedgerows

20.5.18 Of the 58 hedgerows within or directly adjacent to the development site, the survey concluded that 37 meet the criteria for classification as being ecologically 'important' under Paragraph 7 of Schedule 1 of the Hedgerows Regulations 1997 (Ref. 20.15). Seventeen of these hedgerows support seven or more woody species within each 30m section surveyed (although 25 of the hedgerows support seven or more woody species within their entire length). The maximum number of woody species recorded growing in a hedgerow was 12, with five other hedgerows supporting ten or 11 species.

20.5.19 Hawthorn and blackthorn are the commonest hedgerow species within the development site. The ground flora associated with all the hedgerows is species-poor and generally contains few of the woodland flora species that are listed on Schedule 2 of the Hedgerows Regulations (Ref. 20.15). Many of the hedgerows within the development site are located on banks or adjacent to ditches or both, but few of the hedgerows contain standard trees. Most of the hedgerows have gaps constituting less then 10% of their length.

20.5.20 Green Lane, which is located in the centre of the development site, is bounded along its entire southern boundary by a mature hedgerow located on a steep bank and dominated by elm, but also supporting blackthorn, elder (*Sambucus nigra*) and wild privet (*Ligustrum vulgare*). Along part of the lane, a mature hedgerow is also present to the north, which is species-rich and supports species such as wild privet, wayfaring tree (*Viburnum lantana*) and field rose (*Rosa arvensis*).

Watercourses

20.5.21 The two minor watercourses within the development site are poorly connected, seasonal or ephemeral, are encroached in places by ruderal vegetation and show signs of having been affected by agricultural activity.

20.5.22 The HPC Drainage Ditch is approximately 1km in length and varies in width between 0.5m and 1m. It has a steady flow of water during the wetter, winter months with an estimated depth of 0.2-0.3m, but the section upstream of Woodland A is dry for much of the year. The watercourse passes through three culverts and has earth banks (some of which have been re-profiled) along its entire course. Approximately 70% of the stream bed has a muddy substrate. The north-eastern section of the watercourse has sparse bank-side and channel vegetation limited to fool's water cress (*Apium nodiflorum*), hemlock water-dropwort (*Oenanthe crocata*) and bramble (*Rubus fruticosus* agg.). Within Woodland D (Whitewall Brake), the banks support a range of ruderal and marginal species, and mature trees, including crack willow (*Salix fragilis*) and hawthorn.

20.5.23 Holford Stream is between 0.5 and 1m wide and varies in depth between 0.1 and 1m. The watercourse passes through five culverts and under one stone bridge. The western section of the watercourse is ephemeral, and supports well established grassland and ruderal vegetation. The central section, which dries out during summer, is extensively cattle-poached. Freshwater plants in the channel are limited to fool's-watercress and brooklime (*Veronica beccabunga*). The eastern part of the watercourse is less cattle-poached.

20.5.24 Bum Brook, which runs along the southern boundary of the development site, is less ephemeral than the other watercourses on the site. It varies in width and depth, but along most of the section adjacent to the development site it was (at the time of survey) approximately 1m wide and 0.3-0.5m deep. The watercourse is shaded along its western section due to extensive bank vegetation, which includes bramble, nettle, Himalayan balsam (*Impatiens glandulifera*) and great willowherb (*Epilobium hirsutum*), with overhanging semi-mature crack-willow trees. Further downstream the watercourse is unshaded, with species on the banks including cow parsley (*Anthriscus sylvestris*) and hemlock water-dropwort, with branched bur-reed (*Sparganium erectum*) and fools water-cress within the channel. Further downstream, a hedgerow is present on the southern side of the watercourse which again shades the channel.

Water bodies

20.5.25 The single still water body within the development site is located within a wide hedgerow boundary adjacent to an arable field in the north-western part of the site. The pond has a mixture of willow and hawthorn growing in the centre and is prone to drying out (e.g. in July 2009), although it can be over 20m long by 8m wide in wet conditions. The pond supports few aquatic or marginal plants and, although there are areas of open water, the pond is heavily shaded by surrounding scrub and hedgerows.

iii. Birds

20.5.26 The following sections summarise the desk study data relating to birds and the results of the bird survey work. More detailed information about the desk study and survey findings is set out in **Appendix 20B, Appendix 20C** and **Appendix 20Q**.

Breeding Birds: Desk Study Information

20.5.27 Notable breeding bird species that have been recorded on or in the vicinity of the development site include lesser whitethroat (*Sylvia curruca*), which in Somerset is close to the western limit of its breeding range in the UK (Ref. 20.39), and nightingale (*Luscinia megarhynchos*), which has a restricted national distribution and breeds in small numbers that are of county-importance within the scrub to the south of the existing Hinkley Point Power Station Complex. Black redstart (*Phoenicurus ochruros*), which is protected under Schedule 1 of the Wildlife and Countryside Act 1981 (WCA), bred within the Hinkley Point Power Station Complex in 1996. Barn owl, which is another Schedule 1 species, has also nested on the development site. Other notable species that have been recorded include a number of farmland birds that have been subject to rapid population decline over recent years and, as a consequence, are listed as Species of Principal Importance under the NERC Act 2006 (Ref. 20.16) and/or are included in the Birds of Conservation Concern red list (Ref. 20.63).

Breeding Birds: Survey Data

20.5.28 The 2007 breeding bird survey recorded 28 species of breeding bird on the development site (see **Table 20.8**). Ten other species were recorded within 250m of the development site (which, on a conservative basis is used in this chapter as the area within which disturbance impacts are likely to occur – Ref. 20.64). In addition, independently of the survey, Cetti's warbler (*Cettia cetti*) was recorded off-site, but within 250m of it.

Table 20.8: Numbers of Breeding Bird Territories recorded in and within 250m of the Development Site

Species	Number of Territories Recorded within the Development Site Boundary	Number of Territories Recorded within 250m Buffer	WCA Schedule 1	Species of Principal Importance (NERC Act 2006)	Birds of Conservation Concern Red List
Buzzard	0	1			
Pheasant	4	2			
Moorhen	0	1			
Woodpigeon	8	8

***** *Cuckoo numbers are difficult to accurately census as they are highly mobile, vocal and have complex breeding ecology. Therefore, it is likely that the number of pairs of cuckoo has been overestimated.*

20.5.29 Cetti's warbler, which is also Schedule 1 listed, was recorded outside of the development site, to the south of the Hinkley Point Power Station Complex. No evidence was found that barn owl or nightingale breed on or within 250m of the development site and there is no further requirement to consider these species within this ES.

Inter-tidal Birds: Desk Study Information

20.5.30 The closest Wetland Bird Survey (WeBS) core count area (the areas counted at high tide annually as part of this national volunteer survey effort) is the large area of mud to the east of Hinkley Point (**Figure 3.1** in **Appendix 20C**); this area is known as Stert Flats and is referred to as 13411. This area regularly supports large aggregations of wading birds and wildfowl (referred to hereafter as waterbirds); peak counts of species that are interest features of the statutory nature conservation sites that adjoin the development site, are shown in **Table 20.9.**

Table 20.9: Selected WeBS High Tide Count Data 2003-2008

Species*	Peak Count (with month when peak count was recorded)					
	2003	2004	2005	2006	2007	2008
Black-tailed godwit	194 (November)	137 (October)	3 (September)	7 (November)	31 (November)	0
Curlew	1,330 (September)	1,380 (July)	1,550 (August)	1,480 (August)	1,450 (August)	425 (January)
Dunlin	8,900 (November)	8,300 (October)	9,300 (December)	11,000 (November)	5,500 (January)	3,500 (January)
Grey plover	170 (December)	190 (October)	146 (March and December)	520 (February)	138 (February)	190 (March)
Pintail	1 (September)	44 (September)	17 (November)	25 (October)	42 (November)	3 (March)
Redshank	583 (November)	950 (December)	380 (December)	580 (January)	469 (November)	680 (March)
Ringed plover	3 (September)	200 (August)	320 (August)	780 (August)	160 (August)	29 (March)
Shelduck	2,145 (September)	1,850 (October)	2,900 (August)	2,480 (September)	1,850 (August)	2,180 (June)
Shoveler	9 (December)	9 (January)	2 (January)	21 (March)	20 (November)	6 (January)
Teal	350 (December	1,800 (October)	720 (November)	1,350 (January)	820 (December)	1,350 (January)
Wigeon	240 (December	500 (November)	940 (November)	950 (January)	820 (January)	940 (January)

* *Bewick's swan, white-fronted goose and gadwall were not recorded during any of the WeBS High Tide surveys.*

20.5.31 The WeBS low tide count sectors BV695, BV696 and BV697 (**Figure 3.1** in **Appendix 20B**) cover all the count sectors included in the inter-tidal bird surveys. During low tide counts in winter 2002/03, the WeBS surveys recorded 13 species; these species and the peak counts recorded are shown in **Table 20.10.**

Table 20.10: WeBS Low Tide Count Data 2002/03

Species	BV695	BV696	BV697
Curlew	0	16	15
Dark-bellied Brent goose	0	0	11
Dunlin	0	10	0
Grey heron	0	3	2
Lapwing	90	4	0
Mallard	0	8	0
Oystercatcher	0	43	24
Pintail	0	30	0
Redshank	0	40	1
Shelduck	0	70	8
Teal	0	6	0
Turnstone	0	5	2
Wigeon	0	90	10

20.5.32 In general the peak numbers recorded were in BV696 which is to the east of the proposed development (approximately 950m away); BV697 that covers the frontage of the proposed development was shown to support relatively low numbers of waterbirds; this difference is expected given the distribution of intertidal habitats in the area.

20.5.33 Other inter-tidal survey data were collected from 2003-2006 in connection with the West Hinkley Wind Farm application (Ref. 20.38). The survey area comprised the inter-tidal area adjacent to the development site, extending to both the east and the west. The surveys found that the only wildfowl species that made regular use of the survey area were shelduck and wigeon and that these species were concentrated in inter-tidal habitat to the east of the existing Hinkley Point Power Station Complex. Amongst the waders that were recorded, curlew was found regularly during the surveys, with a peak count of 70. They ranged across the entire area surveyed, but favoured the inter-tidal mud to the east of the existing Hinkley Point Power Station Complex. Other cited species that were recorded in lower numbers were ringed plover, black-tailed godwit, grey plover and redshank. Non-cited wader species that were recorded included oystercatcher, purple sandpiper (*Calidris maritima*) and turnstone (*Arenaria interpres*).

Inter-tidal Birds: Survey Data

20.5.34 In total, each of five survey locations (see **Figure 2.4** of **Appendix 20C**) were visited on 182 occasions between April 2007 and March 2009. During the survey, 43 species of waders, waterfowl, gulls, terns and other seabirds were recorded. The majority of these species occurred in small numbers and/or sporadically. Fourteen species were recorded that are interest features of the Severn Estuary SPA and Ramsar site, or the Bridgwater Bay SSSI. **Table 20.11** shows summary data of peak counts and frequency of occurrence. **Figures 20.7-20.10** show a graphical representation of the data collected for species that occurred frequently.

Table 20.11: Summary Data from the Intertidal Bird Surveys

Area[1]	Species	No. of Survey Dates when Species was Recorded (and No. as a percentage of 182 survey dates)	SPA/SSSI Population[2]	Summed Peak Count[3]	% of SPA/SSSI Population	% Survey Dates >1%[4]

[1] The area has been separated into Count Sectors 1-3, 4 and 5 to coincide with the assessment of effects.

[2] Use has been made of the Severn Estuary SPA population of each species, this being the qualifying population (in the Natura 2000 Data Form or SPA Review) or, for assemblage species, the 5 year peak mean count for 2004/05 to 2008/09 inclusive, as shown in the 2008/09 annual WeBS report (Ref. 20.65). It should be noted that little egret, herring gull and black-tailed godwit are not designated features of the Severn Estuary SPA either as individual or assemblage species. This is evidenced by there being no mention of them within the Natura 2000 data form, SPA review or description of features by NE and the Countryside Council for Wales in the Severn Estuary European Marine Site Regulation 33 report (Ref. 20.66). Little egret and herring gull are described as species occurring in nationally important numbers on the Ramsar designation (but not as a qualifying features under any criterion), whilst black-tailed godwit appears as a cited feature for the Bridgwater Bay SSSI; the SSSI population has been taken to be the peak monthly count for the Parrett Estuary in 2009 (Ref. 20.44).

[3] The peak intertidal survey counts have been derived from the largest count of each species on any survey date in each area (for example, 25 curlew were counted in total across Count Sectors 1, 2, 3 on 14 September 2007).

[4] This figure shows the percentage of survey dates when the species count in the area concerned exceeded 1% of the SPA population. Intertidal surveys were undertaken on a total of 182 dates between April 2007 and March 2009 inclusive.

20.5.35 Other notable species recorded regularly were little egret, oystercatcher and herring gull. Little egret was recorded on 145 of 182 survey visits in numbers which peaked at six individuals but were usually between one and three birds. The majority of the activity was within Count Sectors 4 and 5, although little egret was recorded regularly in all 5 count sectors.

20.5.36 Oystercatcher was recorded on all 182 survey dates, with birds observed foraging, loafing and roosting within all five count sectors; the peak count was of 100 birds. The greatest level of roosting activity took place on the rocky platforms within Count Sectors 3 and 4; foraging birds were regularly recorded throughout the survey area.

20.5.37 Herring gull was noted on all survey dates and across all count sectors. A peak count of 350 birds was recorded. However, numbers fluctuated markedly between visits, as would be expected from this species, which ranges widely on a daily basis.

20.5.38 Data from the surveys undertaken within Stolford Bay and across Stert Flats (to the east of Hinkley Point) between April 2010 and January 2011 show that the number and frequency of occurrence of waterbirds across the mud flats to the east of Hinkley Point is greatly in excess of what was recorded in front of the existing HPB infrastructure and the development site. This is expected given the much greater foraging resource available in this area provided by the extensive mudflats.

20.5.39 Sixteen species of wildfowl, 19 species of wader and six additional species of seabird were recorded during the survey period. Twenty of these species occurred frequently and/or in high peak numbers (see **Table 20.12**).

Table 20.12: Peak Counts Recorded from Single Vantage Points on Stert Flats between April 2010 and January 2011

Species	No. of Survey Dates when Species was Recorded (from 123 Survey Dates)	SPA/SSSI Population or Severn Estuary/Somerset population[1]	Peak Count[2]	% of SPA/SSSI Population or Severn Estuary/Somerset population
Black-tailed godwit	27	172	160	93%
Curlew	122	3903	739	19%
Dunlin	99	44624	12590	28%
Grey plover	71	416	975	234%
Golden plover	10	17010	500	2.9%
Knot	51	3591	3575	100%
Lapwing	24	12056	412	3.4%
Mallard	84	3335	87	2.6%
Oystercatcher	117	803	504	63%
Pintail	67	599	158	26%
Redshank	56	2330	355	15%
Ringed plover	64	655	702	107%
Shelduck	123	3330	2049	66%
Shoveler	10	561	90	16%

Species	No. of Survey Dates when Species was Recorded (from 123 Survey Dates)	SPA/SSSI Population or Severn Estuary/Somerset population[1]	Peak Count[2]	% of SPA/SSSI Population or Severn Estuary/Somerset population
Teal	7	4709	27	0.6%
Turnstone	67	409	90	22%
Whimbrel	37	171	134	78%
Wigeon	37	8466	312	3.7%

[1] SPA/SSSI population figures are used for species that are interest features of the SPA/SSSI. For other species, Severn Estuary population levels were used (Ref. 20.62); if these were not available Somerset peak counts were used.

[2] Peak count numbers are from a single vantage point on a single date and are not summed across count sectors or dates.

20.5.40 **Table 20.12** shows that the peak numbers recorded from single vantage points during 2010/11 sometimes exceeded the population sizes of the Severn Estuary SPA; this reflects the highly mobile nature of wildfowl and waders in UK estuaries, which can be influenced by, for example, migratory and cold weather movements. The majority of records were of birds foraging and loafing on the mudflats – only a low level of roosting was recorded. Greatest levels of activity were noted on the mid- and high shore, which is likely to be due to the substrates in these areas being exposed for a longer period than on the lower shore.

20.5.41 Surveys of rafting shelduck in July and August 2011 recorded the majority of this species' activity at a considerable distance offshore (**Appendix 20Q**). Flocks were often diffuse and numbers regularly changed with individuals flying to/from flocks (demonstrating that not all birds that were present were in moult). A peak count of 1,100-1,300 birds was recorded, and the peak flock count that was recorded was of 450 birds, although the majority of flock counts numbered less than 100 individuals. Rafting birds spent most time drifting in the same direction as the tidal current but were seen to be able to swim against the tide, sometimes moving 100s of metres.

Birds using Agricultural Land: Desk Study Information

20.5.42 Data on birds recorded using fields within the development site were obtained from surveys that were undertaken to inform the West Hinkley Wind Farm application (Ref. 20.38). Records include small numbers of shelduck, teal and shoveler.

Birds using Agricultural Land: Diurnal Survey Data

20.5.43 The survey findings for species that are interest features of the statutory designated sites in the vicinity of the development site are set out in **Appendix 20B**. The maximum counts for these species within the development site boundary or within 250m of it were:

- shelduck – 20;
- mallard – 2;
- teal – 2;

- curlew – 20;
- redshank – 1;
- whimbrel – 3;
- little egret – 1;
- water rail – 1; and
- lapwing – 70.

20.5.44 Other species that were recorded in small numbers or infrequently included: golden plover (*Pluvialis apricaria*); snipe (*Gallinago gallinago*); peregrine (*Falco peregrinus*); merlin (*Falco columbarius*); and kingfisher (*Alcedo atthis*). Large flocks of some other non-cited species were recorded in some winter months. These species included skylark (*Alauda arvensis*), meadow pipit (*Anthus pratensis*), redwing (*Turdus iliacus*), fieldfare (*Turdus pilaris*) and linnet (*Carduelis cannabina*).

Wintering Birds on Agricultural Land: Nocturnal Survey Data

20.5.45 These surveys (see **Appendix 20B**) found that the fields within the development site that were surveyed and adjacent upper inter-tidal habitat were not being regularly used by large numbers of roosting or foraging birds, although there was consistent use of the coastal fields by small numbers of golden plover, a concentration of foraging snipe in Field 66 on one occasion and regular use of Count Sector 1 by moderate numbers of roosting oystercatcher (peak of 100 birds).

iv. Badger

Desk Study Information

20.5.46 Records held by SERC suggest that badgers occur throughout the survey area and that they are numerous in the district of West Somerset.

Survey Data

20.5.47 The bait marking study in 2010 identified 54 setts within the survey area including seven main setts (i.e. seven social groups), six annexe setts and 41 outlying setts. Of these, 30 were located within the development site boundary. These included five main setts, four annexe setts and 21 outlying setts. Since this survey, a further 23 outlying setts have been constructed within the development site boundary.

20.5.48 Disclosure of information about badgers (such as sett locations) cannot be included in public documents such as this ES. A confidential report (**Appendix 20D**) that sets out the survey findings has been provided to NE and will also be made available to the IPC and relevant consultees.

v. Bats

Desk Study Information

20.5.49 There are records of the following species from within the 3km study area:

- common pipistrelle (*Pipistrellus pipistrellus*);
- soprano pipistrelle (*Pipistrellus pygmaeus*);
- noctule (*Nyctalus noctula*);
- serotine (*Eptesicus serotinus*)
- *Myotis* sp.;
- long-eared bat (*Plecotus* sp.); and
- lesser horseshoe (*Rhinolophus hipposideros*).

20.5.50 Bat surveys completed to support previous development proposals (such as West Hinkley Wind Farm [Ref. 20.38]) found evidence that the barns in the western part of the development site were likely to be used by roosting bats. In the wider study area (which is 10km for bat records), there are also records of lesser and greater horseshoe (*Rhinolophus ferrumequinum*) bat maternity and hibernation roosts and brown long-eared (*Plecotus auritus*) bat roosts.

20.5.51 During 2010, a range of bat surveys was completed by Halcrow in support of the EA's Steart Realignment Project (Ref. 20.67), the location of which is approximately 2km to the east of the development site. The surveys were predominantly walked transects, with Anabats left out for single nights during the dusk and/or dawn surveys. At least nine species of bat were recorded during these surveys including common and soprano pipistrelle, noctule, serotine, long-eared, *Myotis* sp., lesser and greater horseshoe, and barbastelle. Barbastelle was only recorded from the Anabats (on seven of the 18 Anabat survey occasions (39% of the survey nights)), with the greatest number of passes recorded being on the 9 and 10 August 2010. During these peaks of activity, the passes were spread fairly evenly through the night, with short peaks of activity comprising a small number of calls close together, which were likely to be foraging bouts. Most of the activity was recorded in the western part of the Steart survey area (which is the closest part to the development site), with small numbers of passes along the River Parrett.

Survey Data

20.5.52 The surveys completed within the development site boundary between 2007 and 2009 recorded at least nine species of bat using the site (see **Appendix 20E**), namely:

- common pipistrelle;
- soprano pipistrelle;
- noctule;

- serotine;
- long-eared (likely to be brown long-eared);
- *Myotis* sp. (likely to be at least Natterer's (*Myotis nattereri*) and Daubenton's (*Myotis daubentoni*) based on call characteristics and habitats present);
- barbastelle;
- lesser horseshoe; and
- greater horseshoe.

20.5.53 The majority of the bat activity was recorded along the woodland edges and hedgerows, particularly along the well-hedged Green Lane. Both commuting and foraging behaviour were recorded.

20.5.54 The number of registrations and the location of these throughout the survey area indicate that all of the species recorded, apart from the horseshoe and long-eared bats, occur frequently throughout the development site. However, it is likely that the long-eared bats have been under-recorded (due to their quiet call). The occurrence of the lesser and greater horseshoe is no more than occasional and appears to be largely restricted to Green Lane.

20.5.55 The number of barbastelle records within the development site was much greater in 2009 than in previous survey years. The survey findings show that within the development site:

- there is regular usage of the woodlands and taller hedgerows in the northern part of the site – it is likely that barbastelle bats commute along a short stretch of the HPC Drainage Ditch in the northern part of the site (which provides no tree or hedge cover) to reach the northern woodland blocks;
- Green Lane is regularly used as a commuting (and possibly foraging) route for this species; and
- Benhole Lane is also regularly used by barbastelle.

20.5.56 The main findings of the, primarily off-site, bat survey work in 2010 in relation to barbastelle are summarised below (further detail is contained in **Appendix 20F**).

- During the off-site transect and emergence/re-entry surveys, barbastelle was recorded on four of the 15 survey nights (27% of the survey nights). To the east of the development site, a probable pass was recorded at Stolford and a definite pass was recorded at Wick Park Covert whilst, to the west of the development site, two passes were recorded at each of two sites to the north-west of Stringston (near Honibere Farm and at Great Plantation). The earliest pass was 26 minutes after sunset at Wick Park Covert in June, which is such a short period after the bat is likely to have left its roost that it may indicate that it was roosting in this woodland. The other records are likely to be indicative of commuting or brief foraging activity.

- The automated static Anabat surveys recorded barbastelle on 95 (27%) of the survey nights and at all but two of the survey locations. Based on available evidence, these records are most likely to be associated with commuting (i.e. a single pass in one night) than foraging behaviour (i.e. more than one pass over a period of time in one night).
- The highest levels of barbastelle activity were recorded where hedgerows are associated with watercourses or ponds. Barbastelle was also recorded occasionally in low numbers in very exposed locations along the coast.
- Whilst the Anabat surveys indicate regular usage of the landscape surrounding the development site by barbastelle, the level of activity recorded at each survey location and during each survey month varied greatly from a minimum of two passes up to a maximum of 305 passes per survey period. These results suggest that the land within the area surveyed is likely to be seasonally used by barbastelle, possibly in response to food availability. This is evidenced by the results at a survey location to the east of the development site, which is associated with a pond (East 2 – see **Appendix 20F**) where a high level of activity was recorded over a short period in May and very low or no activity was recorded in later survey months.
- The majority of the passes were recorded at least 60 minutes after sunset or before sunrise, suggesting that primary roosting sites (such as maternity roosts) are not in close proximity to the survey locations and that bats are travelling from a roost site to the survey area. However, the data provide no indication of the likely direction from which barbastelle bats were travelling to access the survey area.

20.5.57 All four of the derelict buildings within the development site support very small pipistrelle roosts (likely to comprise one or two bats only). Based on the activity survey results and the roosting opportunities offered by the buildings, there is also the potential for *Myotis* sp. and long-eared bats to use them. The buildings also provide conditions that could be suitable for hibernating bats. However, given the structural features present within the buildings it is likely that only small numbers of pipistrelles, *Myotis* sp. and long-eared bats would roost in the buildings during the winter.

20.5.58 One of the trees on the development site (a field maple at the eastern edge of Woodland F) has a 25cm deep cavity approximately 7m above the ground, within which a small number of bat droppings were found in 2009. Due to their location, these could not be collected for examination; they were therefore examined *in situ* using an endoscope. This confirmed that they were likely to be *Myotis* sp. droppings, although they could have been from barbastelle. Due to the speed with which bat droppings can decompose in the damp conditions within crevices, it is likely that this feature had been used during 2009. However, when the feature was inspected again in March 2010 and August 2010, no evidence of use by roosting bats was found, indicating that the feature is a very infrequently used roost.

20.5.59 Full details of the survey results are provided in **Appendix 20E and Appendix 20F**.

vi. Dormouse

Desk Study Information

20.5.60 There are no records of dormouse from within the study area. The nearest dormouse record is from approximately 6.5km to the south-west at Holford on the edge of the Quantock Hills (1994). There are three other dormouse records from the Quantock Hills, with further records on Exmoor to the west and Taunton to the south (from the NBN website [Ref. 20.68]).

Survey Data

20.5.61 No evidence of dormouse was found during the surveys that were undertaken to inform this ES (see **Appendix 20G** for more information about the survey findings). The survey effort score achieved equals 20 points and as such, in line with NE guidance (Ref. 20.55), it is reasonable to conclude that dormice are not present at this development site.

vii. Otter

Desk Study Information

20.5.62 There are no records of otter using the watercourses within or adjacent to the development site boundary. However, signs of otter are frequently found by EDF Energy's conservation warden at Hinkley Point on the watercourses to the east of the development site and an otter was seen on the 4 June 2011 at a large pond approximately 0.8km to the east of the site.

20.5.63 Otter survey work in the vicinity of the development site was undertaken on behalf of the Somerset Otter Group between 30 November 2010 and 22 January 2011, with four locations surveyed; three were along the coast north of Stolford (~1.8km east of the development site) and one was on Wick Moor Drove adjacent to the site. All of these locations showed evidence of use by otter, with recent evidence of activity recorded on between 22% and 50% of the survey visits.

20.5.64 In the wider area, otters occur on all the major watercourses including the River Parrett and its catchments to the east of the development site, and on smaller watercourses to the west such as those that discharge at Kilve and Williton (Somerset Otter Group, pers. comm.).

Survey Data

20.5.65 On the development site, the only evidence of otter presence was from three locations along the Bum Brook. In the wider area, evidence of otter was recorded in the following locations:

- a minor watercourse on Wick Moor (east of the development site);
- Great Arch, Stolford (east of the development site);
- Bum Brook (west of the development site); and
- Stogursey Brook (south of the development site).

20.5.66 With the exception of Bum Brook, the survey work found that water features within the development site offer limited commuting, foraging or resting/breeding opportunities for otter due to their lack of connectivity and ephemeral nature.

20.5.67 Full details of the otter survey results are provided in **Appendix 20H**.

viii. Water Vole

Desk Study Information

20.5.68 There are no records of water vole using the watercourses within or adjacent to the development site boundary. However, water vole has been sporadically recorded using ponds and watercourses to the east of the development site.

Survey Data

20.5.69 No water voles were recorded on watercourses within or adjacent to the development site during the surveys that were undertaken to inform this ES and, due to the poor habitat provided by the HPC Drainage Ditch and the Holford Stream, they are unlikely to occur in the future. The water vole survey results are provided in **Appendix 20H**.

ix. Great Crested Newt

Desk Study Information

20.5.70 There are no records of great crested newt from within the development site. Within the study area, there are records of this species from Pixies' Pond and another pond within Hinkley CWS to the east of the development site, which no longer exists. Populations of great crested newt are also known to occur approximately 1.5km to the east of the Hinkley Point Power Station Complex, in the Stolford area (all records provided by SERC).

Survey Data

20.5.71 One pond is located within the development site, with a further nine ponds identified within 500m of the development site boundary (with 500m being the maximum distance that great crested newts are generally considered likely to travel from their breeding ponds to utilise terrestrial habitats (Ref. 20.32)). Three of the ten ponds were screened out of further assessment on the basis that they were not suitable for breeding great crested newts or, if they were suitable, it was unlikely that any newts from these ponds would be able to access the development site.

20.5.72 A fourth pond, located off-site at Knighton Farm could not be accessed safely and, was therefore not included in the presence/absence surveys. However, as it is 335m from the development site and surrounded by good terrestrial habitat, it is unlikely that any great crested newts that occur in the pond would access the development site. Consequently this pond was also screened out of the need for further survey work.

20.5.73 The remaining six ponds were subject to presence/absence surveys that found no evidence of great crested newts (see **Appendix 20I** for more information about the survey findings).

x. Reptiles

Desk Study Information

20.5.74 The desk study did not locate any records of reptiles from within the development site. Grass snake (*Natrix natrix*) and slow-worm (*Anguis fragilis*) have been recorded from the eastern part of the Hinkley CWS and also from the nearby villages of Shurton and Stolford (records from SERC).

Survey Data

20.5.75 The surveys found small numbers of slow-worm using rough grassland located to the south of the woodland belt along Green Lane, with the maximum count being three adults. Based on guidelines in Froglife's Reptile Survey Advice Sheet (Ref. 20.59), this corresponds to the development site supporting a 'low' population of slow-worm. Both slow-worm and grass snake were recorded within the area of Hinkley CWS to the south of the existing Hinkley Point Power Station Complex, with maximum adult counts during one survey event of nine slow-worms and four grass snakes (see **Appendix 20J** for more information about the survey findings).

xi. Invertebrates

Desk Study Information

20.5.76 Invertebrates that have been recorded during the selective annual invertebrate monitoring that has been undertaken by EDF Energy (and previously British Energy) within Hinkley CWS since 1996 (focused primarily on butterflies and moths) include:

- chalkhill blue (*Polyommatus coridon*) recorded in 1999, but does not occur annually;
- populations of marbled white (*Melanargia galathea*) are a feature of the semi-natural grassland habitats;
- five UK Biodiversity Action Plan (BAP) priority butterfly species (which are also species of principal importance under the NERC Act) have been recorded – small heath (*Coenonympha pamphilus*), wall brown (*Lasiommata megera*), grayling (*Hipparchia semele*), dingy skipper (*Erynnis tages*) and grizzled skipper (*Pyrgus malvae*) (wall brown, dingy skipper and grizzled skipper are also Local BAP priority species);
- the moss carder bee (*Bombus muscorum*) has been recorded from the mosaic of habitat with the Hinkley CWS to the east of the development site; and
- the Nationally Scarce[7] beetle *Platyrhinus resinus* has been recorded adjacent to the development site within Branland Copse.

[7] Nationally Scarce species are defined as being recorded from 16-100 10x10km squares of the national grid.

20.5.77 In addition, SERC data list ten UK BAP priority moth species (which are also species of principal importance under the NERC Act) recorded from Hinkley/Hinkley Point. Another five UK BAP priority moth species (and species of principal importance) are listed within the Land Management Review Annual Reports (Ref. 20.37). In addition, Red Data Book (RDB) and Nationally Scarce water beetle species have been recorded from the ditches on Wick Moor (part of Bridgwater Bay SSSI) to the east of the development site.

20.5.78 The exact locations of the species seen during the historical surveys of Hinkley CWS are not provided in the Land Management Review Annual Reports (Ref. 20.37). However, based on their habitat preferences, all of the butterflies listed above are likely to occur within the development site, particularly along the coastal strip and within areas of calcareous grassland. Equally, the predominantly woodland or wetland habitat preferences of the moth species that have been recorded, mean that they are also likely to occur within the development site.

Survey Data

20.5.79 The aquatic invertebrate surveys within the development site boundary recorded common and widespread species of English watercourses with no nationally rare species identified. The only notable species recorded was the water beetle *Agabus congener*, which was found in the HPC Drainage Ditch. Holford Stream is generally more species-rich than the other watercourses sampled, being more faunistically similar to the watercourses on Wick Moor, although no notable species were recorded from it. The off-site sampling locations recorded three Nationally Scarce species, namely the hairy dragonfly (*Brachytron pratense*), the reed beetle *Donacia clavipes* and the anthomyzid fly *Anagnota bicolor*.

20.5.80 The terrestrial invertebrate surveys within the development site concluded that Whitewall Brake may be of value for invertebrates due to its semi-natural characteristics, structure and the maturity of some of the oaks. Two Nationally Scarce species were recorded here; the cranefly *Atypophthalmus inusta* and the snail-killing fly *Tetanocera punctifrons*.

20.5.81 The Nationally Scarce bombardier beetle, *Brachinus crepitans,* was found in the grassland on the coastal strip during the 2009 terrestrial invertebrate survey; another three Nationally Scarce species were then recorded in the 2010 survey of the cliff-top and foreshore habitats: the grey green bush cricket (*Platycleis albopunctata*), the scavenger beetle *Cercyon depressus* and the rove beetle *Heterota plumbea*. However, the habitat assessment of the cliff-top and foreshore habitats concluded that this area was unlikely to support important populations of invertebrates.

20.5.82 Full details of the invertebrate survey results are provided in **Appendix 20K** and **Appendix 20L.**

xii. Other Notable Species

20.5.83 SERC provided no other records of legally protected species from within the development site. In the wider area study area there are records of common toad (*Bufo bufo*), but there are no known active toad crossings within 2km of the site, with the nearest being 8.7km to the south. Records of hedgehog (*Erinaceus europaea*), 13 moth species and shepherd's needle (*Scandix pectens-veneris*), all of which are UK BAP priority species and species of principal importance under the NERC Act have also been recorded in the wider study area. Shepherd's needle is also an LBAP priority plant species; four other Local BAP (LBAP) priority plant species have also been recorded.

c) Highway Improvement Study Area Description

20.5.84 The results of the desk study and Extended Phase 1 Habitat Survey of the highway improvement sites are provided in **Appendix 20P**.

i. Designated Sites

20.5.85 Within 500m of the highway improvement sites, the only designated sites are 12 CWSs (**Table 20.13**).

Table 20.13: Designated Non-Statutory Sites within 500m of the Highway Improvement Sites

Site	CWS Reference Number	Location in Relation to the Site	Reason for Designation
C182 Farringdon Hill Lane Horse Crossing			
Mud House Copse CWS	ST24/003	Adjacent	Ancient semi-natural broad-leaved woodland
Wick Park Covert CWS	ST24/002	180m to the south-east	Ancient semi-natural broad-leaved woodland bisected by road
Junction Improvements at Claylands Corner			
Claylands Corner Verge CWS	ST24/004	Within site boundary	Roadside verge with species-rich, unimproved neutral grassland supporting a diverse invertebrate fauna, flanked by a tall hedge/tree-belt and with advancing scrub
Stockland Moor Wood CWS	ST24/016	140m to the south-east	Ancient semi-natural broad-leaved woodland with an area of swamp and invading carr woodland
New Barn Wood CWS	ST24/017	420m to the north-east	Ancient semi-natural broad-leaved woodland with broad-leaved plantation
A38 Taunton Road/Broadway			
Brownes Pond CWS	ST23/102	300m to the south-west	Pond supporting legally protected species
M5 Junction 23 (inc. Dunball Roundabout)			
South Hills Wood CWS	ST34/019	300m to the south-east	Ancient semi-natural broad-leaved woodland with species-rich grassland
Washford Cross Roundabout			
Furzy Ground Plantation CWS	ST04/027	500m to the north	Semi-natural broad-leaved woodland on tithe-map woodland site
Puthills Copse CWS	ST04/026	500m to the west	Ancient semi-natural broad-leaved woodland

Site	CWS Reference Number	Location in Relation to the Site	Reason for Designation
Cannington High Street			
Cannington Brook CWS	ST23/090	260m to the south	Site with legally protected species (designated for the presence of otter)
Huntworth Roundabout			
Junction 24 Embankment CWS	ST33/050	Within site boundary	Roadside verge/embankment which support Roesel's bush cricket (*Metrioptera roeselii*).
Stockmoor CWS	ST23/105	370m to the west	Interconnecting rhyne network containing legally protected species and nationally rare and nationally scarce invertebrates. Ponds support legally protected species.

ii. Desk Study Information

20.5.86 SERC held no records of legally protected or notable species from within the highway improvement sites. However, there are records of kingfisher adjacent to the A38 Bristol Road/The Drove site and of common pipistrelle adjacent to the Cannington High Street site. More distant records are of kingfisher from within 500m of two sites, brown hare within 500m of the A39 Sandford Corner site and the C182 Farringdon Hill Lane site, and otter recorded at the latter and within Cannington Village. Grass snake and slow-worm have also been recorded within 500m of the Cannington High Street site.

20.5.87 A cluster of existing species records (from SERC) is located approximately 400m to the west of the Huntworth Roundabout site. It appears that these records all relate to Stockmoor CWS but, based on the species they are unlikely to have all been recorded in this location. The records include various bat species, water vole, otter and great silver water beetle (*Hydrophilus piceus*). SERC also provided three records of barn owl within 500m of the site.

20.5.88 SERC also provided five records of Somerset Notable plant species within the study area.

iii. Extended Phase 1 Habitat Survey

Habitats

20.5.89 The majority of the highway improvement sites are dominated by hardstanding (roads and pavements) with adjacent areas of amenity grassland (e.g. gardens) and/or species-poor grassland, supporting species such as perennial rye grass, cock's-foot and white clover. At two of the sites (A39 Sandford Corner and Junction Improvements at Claylands Corner), there are small areas of more species-rich grassland with species present including agrimony, tufted vetch and bird's-foot trefoil.

20.5.90 Trees, scrub and hedgerows occur frequently within the highway improvement sites, with those sites located in urban areas (e.g. the centre of Bridgwater) tending to support ornamental non-native shrub species and planted native broad-leaved trees such as ash and lime, although scatted semi-mature field maple and sycamore trees also occur within a number of the site boundaries. Where scrub is present at any of the sites, it is species-poor and predominantly comprises bramble.

20.5.91 Hedgerows occur within four of the sites, with the majority supporting a limited range of woody species, restricted primarily to hawthorn, elder and hazel. None of the hedgerows are assessed as being ecologically 'important' under Paragraph 7 of Schedule 1 of the Hedgerows Regulations 1997 (Ref. 20.15).

20.5.92 One site (Wylds Road/The Drove) also supports a small area of ephemeral/short perennial vegetation growing on gravel, comprising buddleia (*Buddleja davidii*), scentless mayweed (*Tripleurospernum inordorum*) and perennial sow-thistle (*Sonchus arvensis*). The Perrymoor Brook flows through the A39 Sandford Corner site, although it is culverted underneath the A39 and a minor road, and is heavily shaded by scrub within the site.

Fauna

20.5.93 No evidence of legally protected or other notable fauna was found during the extended Phase 1 habitat surveys. However, some of the habitats that are present have the potential to support legally protected species, including breeding birds, which are likely to nest in the scrub, trees and hedgerows that occur on the majority of the sites. None of the trees within the highway improvement sites support features that are suitable for roosting bats, although the small extent of linear features within the sites (mainly hedgerows) could be used by commuting bats.

20.5.94 The rough grassland and scrub habitat at four of the sites has low potential to support small numbers of reptiles and/or great crested newts (the newts could be present as there are water bodies within 500m of these sites).

20.6 Assessment of Impacts

a) Introduction

20.6.1 The starting point in this section is to define those biodiversity receptors that could be significantly affected by the proposed development and/or are legally protected (as concluded in Table 14C.2 in **Appendix 14C**). In subsequent sections, these receptors are taken forward for assessment in relation to the construction and operational phases of the proposed development. The assessment reflects the following aspects of the proposed development that were incorporated as part of the iterative design process and that are relevant to the ecological impact assessment[8].

- The majority of the hedgerow that runs east-west across the centre of the development site (largely along Green Lane) and two strips of land to the north and south of the Green Lane would be retained throughout the development. The hedgerows associated with the Green Lane would be managed to increase their biodiversity value through a programme of removing of dead elm and replanting

[8] Some of these measures avoid or reduce impacts, but, as they form an integral part of the scheme, are not considered to be mitigation.

the resultant gaps with a species-rich mix of hedgerow shrubs and standard trees (**Chapter 22, Volume 2** of the ES).

- The north-south hedgerow along the development site's western boundary (eastern side of Benhole Lane) would also be retained and buffered from the construction activities by an approximately 30m wide strip of land between Benhole Lane and the security fence. This area (totally approximately 2.6ha) would be managed as a woodland/grassland habitat mosaic and would be partly planted with native broad-leaved trees.

- During 2009 and 2010, grass and wildflower seed was collected from areas of calcareous grassland located within that part of the Hinkley CWS that is within the boundary of the development site. This seed has been stored under controlled conditions in order to maintain its viability and would be used in combination with a locally sourced calcareous seed mix during the restoration of the construction area.

- Approximately 2.2ha of broad-leaved woodland planting, using a species-rich mixture of native whips and mature specimens, was planted in the south-west corner of the development site (broadly along the western part of Bum Brook) at the beginning of 2011.

- Approximately 1.4ha of broad-leaved woodland/scrub would be planted on a created bund along the north-western boundary of the development site at an early stage of the construction phase. This would be connected to Green Lane and Benhole Lane by a retained species-rich hedgerow.

- A woodland/grassland/wetland habitat mosaic would be created in the southern part of the development site during the beginning of the construction phase (see **Chapter 22**, **Volume** 2 of the ES). A mix of broad-leaved native tree species would be permanently planted in the southern part of this area using a mixture of whips and mature trees (a total of approximately 8.7ha). The northern part of the area would be seeded with a temporary native wildflower meadow mix (approximately 6.4ha), which would be lost during the restoration of the development site post-construction, but subsequently planted with trees as part of the restoration of the development site. A wetland area comprising ponds and reedbeds would be created adjacent to Bum Brook (approximately 0.2ha).

- A total of 15 buildings would be constructed with stonecrop (*Sedum* spp.) green roofs.

- A total of 25ha of arable land and/or improved pasture off-site would be seeded with a native wildflower mix.

- The management of the retained and created habitat features during construction and operation would be delivered through an Integrated Land Management Plan (ILMP) for the development site. This would detail the management objectives, and the prescriptions required to achieve these in relation to biodiversity and other topics (e.g. cultural heritage). The ILMP would also contain a management and monitoring programme.

- Appropriate fencing would be installed around all the created and retained habitat features within the construction area to protect them from direct impacts during development (see **Chapter 22** of this volume of the ES).

- A bat barn has been constructed along the development site's south-western boundary, adjacent to Benhole Lane) to provide alternative and enhanced roosting habitat for bats, to compensate for the barns removed as a result of the development. Bat boxes have been erected on trees within and adjacent to the development site, to compensate for the loss of the trees supporting features that are of medium and high potential value for roosting bats.

- The existing small, single storey barn located adjacent to the western boundary of the development site (see **Appendix 20E**) would be retained throughout the development.

- Green Lane would be crossed in two places by construction haul roads. The width of these crossing points would be minimised by a number of measures. Firstly, the vegetation clearance to allow construction of the haul road would be minimised. The areas where vegetation clearance is unavoidable to allow construction would then be replanted with tree stock 3-6m tall between the remaining Green Lane vegetation and the edge of the haul roads. Due to the residual width of the eastern haul road, a gantry-type structure would be installed above the haul road to provide a linear feature for commuting bats to follow (and also to provide them with some cover from predators).

- Prior to the completion of the permanent measures as described in the preceding bullet point, temporary structures would be put in place to provide connectivity across the gaps. This would be achieved using cut trees placed in barrels of sand and tied with mesh ribbon, to mimic leaves, as described in the Design Manual for Roads and Bridges (DMRB – Ref. 20.69). These barrels would be moved into position, approximately 2-3m apart, at the end of each working day for the period that they are required temporarily to bridge a gap in vegetation. These measures are unlikely to be required during the bat hibernation period between November and February.

- Once construction of the development is completed, the undeveloped construction areas would be restored. As described on the restoration plan **Chapter 22**, **Volume 2** of the ES) this would create an area of approximately 94ha[9] of semi-natural habitat, which together with Bridgwater Bay SSSI and the unaffected part of the Hinkley CWS would create a large area of semi-natural habitat around Hinkley Point.

- Vegetation clearance and habitat management would take place between September and March to avoid the breeding bird season. Where this is not possible, clearance would only be undertaken once surveys have shown that any breeding birds have fledged from the areas to be cleared.

- The EA's Pollution Prevention Guidelines (PPGs) would be adhered to and discharges into the Holford Stream and the Bum Brook would be managed to ensure compliance with greenfield run-off rates (see **Chapter 16** of this volume of the ES).

- The lighting strategy for the development site has been designed with reference to the Bat Conservation Trust's (BCT) Bats and Lighting publication (Ref. 20.70). It involves lighting being directional, with minimal upwards or backwards light spill

[9] See **Appendix 20R** – this figure includes an area for hedgerows, which are assumed to be 3m wide

and minimising light spill onto retained and created habitat features used by bats (such as tree lines).

- Measures have been incorporated into the scheme that are designed to avoid contravention of the legislation relating to legally protected species. These measures are outlined in Sections 20.6d and e of this chapter.
- Good practice measures would be implemented to minimise dust generation and road traffic emissions (see **Chapter 12** of this volume of the ES), polluted surface water run-off (see **Chapter 16** of this volume of the ES), changes in groundwater (**Chapter 15** of this volume of the ES) and noise (see **Chapter 11** of this volume of the ES).

b) Identification of Receptors that could be significantly affected

20.6.2 The method described in Section 20.4(d) of this chapter has been used to determine whether any of the designated nature conservation sites, habitat areas or species' populations that have been recorded within the study area could be significantly affected by the proposed development and therefore need to be subject to further assessment. The environmental changes that are likely to be caused by the proposed development, which have the potential to cause significant impacts are:

- land take/land cover change;
- noise and visual disturbance;
- lighting disturbance;
- hydrological changes (surface and groundwater);
- air quality changes; and
- thermal and chemical changes.

20.6.3 It should be noted that the latter five changes only apply outside the land take/land cover change zone. Within this zone, it is only necessary to assess impacts caused by land take/land cover change. This is because, although there would be other environmental changes within this zone, land take and land cover change are the dominant factors influencing biodiversity receptors.

20.6.4 For receptors of sufficient value and/or that are legally protected, **Appendix 20N** sets out the ecological zones of influence relating to these six changes. Based on these zones of influence, the following biodiversity receptors require further assessment because there is a mechanism by which they could be significantly affected by the proposed development and/or they are legally protected.

Habitats

- off-site ditches and grazing marsh (part of Bridgwater Bay SSSI);
- off-site wetland areas (part of Hinkley CWS);
- lowland calcareous grassland (within Hinkley CWS, along the coastal strip and within Bishop's Wood);

- woodland;
- hedgerows;
- watercourses;
- habitat networks;

Fauna

- breeding birds (in relation to legal protection only);
- declining farmland birds (on and up to 250m from the development site);
- lesser whitethroat;
- Cetti's warbler;
- inter-tidal wintering waterbirds that are SPA/Ramsar/SSSI qualifying features;
- inter-tidal passage waterbirds that are SPA/Ramsar/SSSI qualifying features;
- terrestrial wintering and passage birds (other than waterbirds);
- badger (in relation to legal protection only);
- barbastelle bat;
- greater horseshoe bat;
- lesser horseshoe bat;
- bat assemblage;
- otter;
- reptiles (in relation to legal protection only);
- great crested newts (in relation to legal protection);
- invertebrate assemblage;
- Somerset Notable plant species (on-site);

Designated sites

- Bridgwater Bay SSSI; and
- Hinkley CWS.

20.6.5 All the above receptors are relevant to the development site, other than great crested newt, which is only relevant to the highway improvement sites. Hedgerows, breeding birds, reptiles and great crested newts are also relevant to the highway improvement schemes.

20.6.6 Four of the above receptors require further assessment only because they are legally protected. They do not require further assessment in relation to biodiversity conservation value; because they are of insufficient value for impacts to be significant (see **Appendix 20O)**.

20.6.7 Exmoor and Quantocks SAC was identified in **Appendix 20N** as having the potential to be significantly affected by the proposed development but is not included in the above list as impacts upon it are assessed in the **Habitats Regulations Assessment**.

c) Valuation of Receptors

20.6.8 In order to inform the assessment of impacts, the biodiversity receptors that have been identified as requiring further assessment, excluding those identified as requiring assessment only in relation to legal protection, have been valued on the scale high, medium, low and very low according to the criteria that are set out in **Table 20.4**. The conclusions of this valuation are set out in **Table 20.14**.

Table 20.14: Summary Evaluation of Biodiversity Receptors

Receptor	Applicable Legislation	Policy Implications	Value	Rationale
Habitats				
Off-site ditches and grazing marsh (part of Bridgwater Bay SSSI)	WCA	N/A	High	SSSIs are by definition of national value. Whilst each of the qualifying features may not be of high value individually, in this instance, the ditches and grazing marsh within the SSSI are assessed as being of high value due to the invertebrate populations they support and the contribution this habitat type makes to the integrity of the SSSI.
Off-site wetland areas (part of Hinkley CWS)	Not applicable (N/A)	PPS 9 West Somerset Local Plan	Medium	The wetland areas within the CWS, comprising two ponds and associated reedbeds, form part of the CWS designation and contribute to the integrity of the CWS.
Lowland calcareous grassland	N/A	UK BAP Priority Habitat Habitat of Principal Importance for Biodiversity	Medium /Low	Calcareous grassland is scarce at the county level. The small areas within the development site that are located within Hinkley CWS and along the coastal strip contain a variety of species that are rare or uncommon at the county level. These areas are therefore of medium biodiversity value. Another area of calcareous grassland on-site has grown up in Bishop's Wood and a field adjoining Holford Stream. With management, this area could develop into a more species-rich and diverse calcareous sward. However, the area is being managed as developing woodland rather than grassland and, although a few scarce species are present, it currently represents calcareous grassland of low value.

Receptor	Applicable Legislation	Policy Implications	Value	Rationale
Woodland	N/A	N/A Habitat of Principal Importance for Biodiversity	Low	Parts of the woodland within the development site form part of the Hinkley CWS. Whilst the CWS as a whole is considered to be of medium importance, the woodland blocks within the CWS (and within the development site) are of relatively recent plantation origin and, due to their lack of established woodland ground flora and poor structural diversity, they are considered to be of low value.
Hedgerows	Hedgerows Regulations 1997	UK BAP Priority Habitat	Low	The majority of hedgerows within the development site are intact, but associated field margin communities, where present, lack diversity (due to agricultural improvement). 17 of the hedges within the area surveyed support seven or more woody species within each 30m section surveyed and therefore meet the criteria for classification as being important under the Hedgerows Regulations. A further 20 were found to meet one or more of the other criteria for classification as being important under the Hedgerows Regulations. Hedgerows are typical boundary features in West Somerset and, although species-rich, the hedgerows within the development site lack associated ground flora diversity. Despite this, based on the large amount of this resource within the development site, it has been concluded that hedgerows within the site are of value within the district. (See also habitat networks below).
Watercourses	N/A	N/A	Low	Watercourses within the development site are partially seasonal, show signs of agricultural improvement and support no protected species. The watercourse adjacent to the development site (Bum Brook) is only of marginally greater botanical interest.

Receptor	Applicable Legislation	Policy Implications	Value	Rationale
Habitat networks	N/A	PPS9	Low	The mainly intact hedgerows that are present throughout the development site provide good linkages to on- and off-site woodland and to the coast. The approach road to the Hinkley Point Power Station Complex presents a barrier to movement between the development site and the mosaic of habitats to the south of the, complex but this impact is likely to be relatively limited for most species. The level of use by bats (including nationally scarce species) and the indicative age of some of the hedgerows suggest that they are an important connective feature for protected species dispersal. The watercourses are of less value as habitat corridors than the hedges, and are only likely to complement the hedgerows to a minor degree. Their effectiveness as corridors is limited by their seasonality and lack of connectivity. There is little evidence of use of the watercourses by protected species.
Fauna				
Declining farmland birds (on and up to 250m from the development site)	WCA	Some species are: UK BAP[1] Species of Principal Importance for Biodiversity	Low	The farmland bird community (both breeding and non-breeding birds) is typical of the habitats present in the local area. Although many of the species that are present are declining across the UK, they still remain common and widespread on a county, regional and national level and, as such, the small number of pairs that occur on the development site are important at the district level and hence of low biodiversity value.
Lesser whitethroat	WCA	N/A	Low	Lesser whitethroat breeds on-site. It is notable because the three territories recorded within the development site boundary represent 4.6% of the Somerset population based on figures from the 2008 Somerset Bird Report (Ref. 20.43). However, within the wider breeding bird survey area, seven territories were identified suggesting that the Somerset Bird Report under-estimates the current County population size. As such, and given the extent of suitable habitat in the local area, the population of this species on the development site is assessed to be of low biodiversity value.

Receptor	Applicable Legislation	Policy Implications	Value	Rationale
Cetti's warbler	Schedule 1 WCA	N/A	Medium	Cetti's warbler breeds within 250m of the development site, but not on the site itself. No comprehensive survey of this species has been carried out in Somerset but records suggest there are less than 100 breeding pairs in the county (based on figures from 2008 Somerset Bird Report – Ref. 20.43) and the UK population is approximately 645 pairs (based on counts of singing males). Therefore, the population that breeds close to the development site is of medium biodiversity value.
Wintering waterbirds (including SPA/Ramsar/ SSSI qualifying features)	EU Birds Directive	Some species are: UK BAP Species of Principal Importance for Biodiversity	High	A number of wintering species forming the cited interest of the Severn Estuary SPA and Ramsar Site, and Bridgwater Bay SSSI regularly occur within 1km of the development site.
Passage waterbirds (including SPA/Ramsar/ SSSI qualifying features)	EU Birds Directive	Some species are: UK BAP Species of Principal Importance for Biodiversity	High	A number of passage species forming the cited interest of the Severn Estuary SPA and Ramsar Site, and Bridgwater Bay SSSI regularly occur within 1km of the development site.
Wintering and passage birds (other than waterbirds)	EU Birds Directive	Some species are: UK BAP Species of Principal Importance for Biodiversity	Low	Very low levels of use of terrestrial habitats (both diurnally and nocturnally) were noted by wintering and passage birds (e.g. flocks of wintering thrushes).

Receptor	Applicable Legislation	Policy Implications	Value	Rationale
Barbastelle bat	WCA Habitats and Species Regs. 2010	UK BAP Species of Principal Importance for Biodiversity Somerset Priority Species	High	Regular use of the development site by barbastelle was noted in July and August 2009, mainly from Anabats, with more sporadic records outside this period. The survey data indicates mostly commuting behaviour with occasional instances of foraging recorded within the development site and no confirmed roosts are present. Greater levels of barbastelle activity were recorded off-site in 2010, indicating the surrounding area is regularly used, although usage may be in response to seasonal food availability. Despite the lower amount of barbastelle activity on-site compared to the surrounding area, the development site is assessed as being of high biodiversity value for this species.
Greater horseshoe bat	WCA Habitats and Species Regs. 2010	UK BAP Species of Principal Importance for Biodiversity Somerset Priority Species	Medium	Greater horseshoe bats were recorded commuting infrequently both on and off-site during the bat surveys that were undertaken to inform this ES, indicating that the development site and surrounding area is unlikely to form part of a core territory for this species.
Lesser horseshoe bat	WCA Habitats and Species Regs. 2010	UK BAP Species of Principal Importance for Biodiversity Somerset Priority Species	Medium	Lesser horseshoe bats were recorded commuting infrequently both on and off-site during the bat surveys that were undertaken to inform this ES, indicating that the development site and surrounding area is unlikely to form part of a core territory for this species.

Receptor	Applicable Legislation	Policy Implications	Value	Rationale
Bat assemblage	WCA Habitats and Species Regs. 2010	Some species of bats are Species of Principal Importance for Biodiversity UK BAP and West Somerset BAP priority species	Medium	The development site supports four confirmed ephemeral common pipistrelle summer roosts. These buildings also have the potential to support winter roosts and could be used by brown long-eared and *Myotis* sp. bats. There is regular use of parts of the development site by two pipistrelle species, (brown) long-eared bat, serotine, noctule and barbastelle. This level of use, combined with less regular commuting through the development site by *Myotis* species and lesser horseshoe bat (and occasional use by greater horseshoe bat) indicates that the area is of some importance for bats. However, the development site does not support typically good bat habitat and there are no known important roosts in close proximity to the site. Much of the behaviour, particularly of the rarer species, indicates commuting rather then feeding (few feeding buzzes were recorded). The level and nature of use of the development site by bats is likely to be typical of Somerset and reflects the high level of survey effort available for the locality. Nonetheless, on the basis of all the available evidence, and in particular the number of species present including those identified above as being of medium value, it is assessed that the development site is of medium biodiversity value for its bat assemblage.
Otter	WCA Habitats and Species Regs 2010	UK BAP Priority Species Species of Principal Importance for Biodiversity Somerset Priority Species	Low	The survey results indicate that the watercourses connected into the wider freshwater systems (e.g. the Bum Brook) are likely to be used fairly regularly for commuting. However, the watercourses within the development site (which are poorly connected) do not support habitat likely to support otter for a sustained period.

Receptor	Applicable Legislation	Policy Implications	Value	Rationale
Invertebrate assemblage	N/A	UK BAP Priority Species Somerset Priority Species Species of Principal Importance for Biodiversity Nationally Scarce	Medium	The vast majority of the development site comprises habitats that are unlikely to support important invertebrate assemblages. However, a small number of Nationally Scarce species have been recorded from the more diverse habitats within the development site (e.g. Whitewall Brake and the coastal strip).
Somerset Notable plant species (on-site)	N/A	Somerset Notable	Low	Whilst all the notable species present within the development site are classified as 'uncommon' in Somerset (Ref. 20.71), these species have also been recorded in the wider area (as part of the survey work to support the proposed development) and most are widespread Nationally.
Designated Sites				
Bridgwater Bay SSSI	WCA	N/A	High	The SSSI has been designated at the National level on the basis of the valuable interest features.
Hinkley County Wildlife Site (CWS)	N/A	PPS 9 West Somerset Local Plan	Medium	CWSs are identified by local authorities as being of county importance for biodiversity conservation.

[1] Skylark is also listed on the West Somerset LBAP.

20.6.9 For each receptor, the impacts that are assessed arise as a result of a combination of the environmental changes (e.g. changes in noise, lighting etc.) that could contribute to a significant impact. In this sense, the impacts are already 'cumulative' and consequently, no further cumulative assessment is required in this section (recognising that wider cumulative impacts are assessed in **Volume 11** of this ES).

d) Other Constraints

20.6.10 In addition to the potential biodiversity receptors listed in **Table 20.14**, the development site also supports Himalayan balsam, which is listed on Schedule 9 of the WCA (Ref. 20.8). The Act makes it an offence to plant or otherwise cause to grow in the wild any plant listed on Schedule 9.

20.6.11 As a result, any works in areas to Bum Brook, which is the only part of the development site that supports Himalayan balsam, would need to include measures to prevent the spread of this species.

e) Assessment of Impacts

20.6.12 This section sets out the findings of the assessment of the impacts of the proposed development on the ecological receptors that are listed in Section 20.6 (b). For each receptor, the assessment addresses both the construction and the operational impacts of the development.

20.6.13 In summary, drawing on the findings that are set out in the remainder of this section, the environmental changes that are set out in Section 20.6 (b) would result in a combination of permanent and temporary adverse impacts on biodiversity. These have all been assessed as being minor or negligible adverse impacts, except in relation to the permanent loss of calcareous grassland within Hinkley CWS and the permanent loss of part of the same CWS (which are assessed as moderate and major adverse impacts respectively). Once the undeveloped part of the development site is restored, which would involve an extensive programme of habitat creation work, its biodiversity value would progressively increase as the created habitats mature. All the new habitats are likely to attract a wide range of species within about ten years of being established. However, particularly for woodlands, it would take many more years before the newly created habitats would support a flora and fauna that is characteristic of good examples of their type.

i. Off-Site Ditches and Associated Grazing Marsh

20.6.14 Off-site ditches and associated grazing marsh on Wick Moor, which forms part of Bridgwater Bay SSSI and the Severn Estuary SPA, could be affected by changes in:

- the quality and volume of flows into the ditches;
- groundwater levels; and
- air quality.

The likely ecological impacts of these changes are described below.

20.6.15 Holford Stream, which passes through the development site, discharges to ditches on Wick Moor, which forms part of Bridgwater Bay SSSI and the Severn Estuary SPA. Bum Brook, which runs along the southern boundary of the development site, also discharges into the SSSI (via West and East Brook). Water from these streams contributes to supporting water levels within the ditches on Wick Moor which, in addition to being important as habitat for invertebrates and flora that are cited as interest features of the SSSI, play a role in supporting the nature conservation interest of the grazing marsh.

20.6.16 Within the development site, Holford Stream would be culverted (on a different alignment to the existing stream), with the result that it would continue to drain into the SSSI/SPA. The culvert would remain in place throughout the construction and operational phases. Instead of being fed from the existing agricultural landscape, flows within the stream would be derived from drainage off the development site (e.g. from stock-piled materials' storage areas, construction platforms etc. during construction and from the surrounding landscape during operation), which would be channelled to Water Management Zones (WMZs) and/or ponds (the latter during operation), from which the water would be released into the culverted stream. There is not likely to be any change in the flows through the culvert during the construction and operational phases of the development.

20.6.17 Bum Brook would continue to receive surface water runoff from the development site, during both the construction and operational phases. During construction this would also be channelled via WMZs to remove sedimentation.

20.6.18 Implementation of the good practice design measures described in Section 20.6.1, and **Chapters 6** and **12** of this volume of the ES, would maintain the existing greenfield runoff rates in the culverted Holford Stream, and avoid or minimise increased sediment loading, nutrient enrichment and accidental pollution incidents during both the construction and operational phases. This would prevent adverse impacts on the cited freshwater invertebrate and plant features of the SSSI. Construction of the Holford Stream culvert ‘off-line’, so that grouting compounds can cure before the culvert becomes operational, would also avoid chemical pollution associated with the grouting materials (see **Chapter 6** and **Chapter 12** of this volume of the ES).

20.6.19 Based on the differences in geology underlying the development site and Wick Moor, there is unlikely to be groundwater permeability between the two areas (see **Chapter 15** of this volume of the ES). It is therefore unlikely that wetland areas on Wick Moor would be adversely affected by activities such as dewatering during the construction phase.

20.6.20 The various activities that make up the construction phase also have the potential to cause changes in air quality, notably through the generation of sulphurous and nitrous oxides, dust and PM_{10s} from exhaust emissions from on-site plant and machinery (see **Chapter 12** of this volume of the ES). These air quality changes could adversely affect the flora of the ditches and grazing marsh of Wick Moor (Bridgwater Bay SSSI) due to its proximity to the development site boundary and the likely sensitivity of the SSSI to NO_x and nitrogen deposition.

20.6.21 The air quality chapter of this ES (**Chapter 12** of this volume of the ES) concludes that, during the construction phase and without best practice control measures, conditions that could cause fugitive dust/PM_{10s} to travel towards Wick Moor would occur less than 28% of the time and that any impact resulting from this is likely to be limited to within 50m of the source (taken to be the development site boundary). With best practice control measures, the area affected would be even less, with the result that very little if any of the SSSI would be affected. Furthermore, it is unlikely that the activities that generate the most dust/PM_{10} would always coincide with the meteorological conditions most conducive to the transport of airborne dust.

20.6.22 In relation to potential adverse impacts arising from on-site exhaust emissions and air pollutant deposition, **Chapter 12** (of this volume of the ES) concludes that any changes in emissions and deposition during the construction phase would be negligible and therefore adverse impacts on Wick Moor are unlikely to occur. Increases in annual NO_x levels resulting from off-site exhaust emissions during construction have been identified as occurring along Wick Moor Drove, adjacent to Wick Moor. The highest increases in NO_x levels in this location occur on the western boundary of the SSSI at the start of the construction phase (2013) and extend approximately 10m east into the SSSI. Beyond this distance, significant changes in

NO_x levels are unlikely to occur (see **Chapter 12** of this volume of the ES). Therefore, the vast majority of the Wick Moor would remain unaffected by the increases in NO_x concentrations.

20.6.23 The various activities that make up the operational phase also have the potential to cause changes in air quality, notably through nitrogen deposition and the generation of sulphurous and nitrous oxides (see **Chapter 12** of this volume of the ES). These air quality changes could adversely affect the flora of the ditches and grazing marsh of Wick Moor due to its proximity to the development site boundary and the likely sensitivity of the SSSI to NO_x and nitrogen deposition.

20.6.24 In relation to nitrogen, the maximum deposition rates of 1.05kg N ha^{-1} yr^{-1} and 3.99kg N ha^{-1} yr^{-1} (see **Chapter 12**) that are predicted within the SSSI would occur during the start of operation and during routine testing from the EPR units respectively. When these values are added to the existing average local deposition rate, no exceedance of the critical load range for grazing marsh habitat is likely to occur as a result of these activities (based on data from APIS Ref. 20.72).

20.6.25 Changes in annual NO_x, SO_2 and NH3 concentrations would also occur as a result of the routine EPR unit testing during the operational phase (**Chapter 12** of this volume of the ES). However, these changes would be below the Air Quality Standard (AQS) critical concentration levels (as provided by APIS [Ref. 20.72]) for these pollutants by 56%, 90% and 39% respectively.

20.6.26 In conclusion, with the tried and tested measures that form part of the proposed development (as set out in Section 20.6.1 and **Chapters 12, 15 and 16** of this volume of the ES), it is likely that the impacts on the high value off-site ditches and associated grazing marsh on Wick Moor would be, at worst, of very low magnitude, resulting in a **minor adverse** impact.

ii. Other Off-Site Wetland Areas

20.6.27 Dewatering during the construction phase could affect wetlands not only on Wick Moor, but also within Hinkley CWS. .However, based on the differences in geology underlying the development site and Hinkley CWS, there is unlikely to be groundwater permeability between the HPC site and the CWS (see **Chapter 15** of this volume of the ES). It is not therefore likely that the wetland areas within Hinkley CWS would be adversely affected by activities such as dewatering during the construction phase. No impacts are predicted during the operational phase. Therefore, a very low magnitude, temporary impact is predicted, resulting in a **minor adverse** impact on the medium value wetland features of the Hinkley CWS.

iii. Lowland Calcareous Grassland

20.6.28 Approximately 1.2ha of calcareous grassland would be lost within Hinkley CWS and along the coastal strip during the construction phase. This equates to approximately 1% of the West Somerset calcareous grassland resource and less than 0.01% of the County resource (Ref. 20.73). This is assessed as a medium magnitude impact, due to the extent of the permanent loss of this habitat type, on a receptor of medium value (due its location within the Hinkley CWS – see **Table 20.14**), leading to a **moderate adverse** impact.

20.6.29 The only calcareous grassland outside of Hinkley CWS that would be lost as a result of the construction of the proposed development is within Bishop's Wood, an area of 2.3ha that was planted with trees in 1998/1999 but still supports species-rich grassland, although it is assessed as being of low biodiversity value. The loss of this grassland is also assessed as being of medium magnitude, resulting in a minor adverse impact.

20.6.30 The air quality chapter of this ES (**Chapter 12** of this volume of the ES) concludes that, during the construction phase and without best practice control measures, conditions that could cause fugitive dust/PM_{10s} to travel towards the calcareous grassland within the CWS outside of the site boundary would occur less than 28% of the time and that any impact resulting from this is likely to be limited to within 50m of the source (taken to be the development site boundary). With best practice control measures, the area affected would be even less, with the result that very little if any of the calcareous grassland within Hinkley CWS would be affected. Furthermore, it is unlikely that the activities that generate the most dust/PM_{10} would always coincide with the meteorological conditions most conducive to the transport of airborne dust.

20.6.31 In relation to potential adverse impacts arising from on-site exhaust emissions and air pollutant deposition, **Chapter 12** (of this volume of the ES) concludes that any changes in emissions and deposition during the construction phase would be negligible and therefore adverse impacts on off-site calcareous grassland are unlikely to occur. Increases in annual NO_x levels resulting from off-site exhaust emissions during construction have been identified as occurring along Wick Moor Drove, to the south-west of Hinkley CWS. The highest increases in NO_x levels in this location occur approximately 380m to the south-west of the CWS boundary at the start of the construction phase (2013). As the increase in NO_x concentration progressively reduces to a low level within a short distance of the source, it is unlikely that significant changes in NO_x levels would occur. Impacts on the calcareous grassland within the CWS are therefore unlikely to occur (**Chapter 12** of this volume of the ES).

20.6.32 Operation of the development would not have any direct impacts on the calcareous grassland habitats adjacent to the site or on those created during the latter stages of the construction phase. Indirect impacts could occur on these habitats through the generation of sulphurous and nitrous oxides, dust and PM_{10s} from exhaust emissions from on-site plant and machinery and the operation of HPC itself. However, as concluded in **Chapter 12** of Volume 2 of the ES, any changes in emissions during the operational phase would be negligible. In addition, the nitrogen deposition plume from the EPR units could result in degradation of created calcareous grassland. However, the plume is most likely to be focused to the east of the restored construction site (see **Chapter 12** of this volume of the ES) thereby minimising impacts on the restored site. In addition, the predicted maximum deposition rates for nitrogen that are predicted within the CWS during the start of operation and during routine testing from the EPR units (1.05kg N ha^{-1} yr^{-1} and 2.49kg N ha^{-1} yr^{-1} respectively – see **Chapter 19**), will not increase the existing average local deposition rate (as provided by APIS Ref. 20.72) beyond the critical load exceedance range for calcareous grassland.

20.6.33 Changes in annual NO_x, SO_2 and NH3 concentrations would also occur as a result of the routine EPR unit testing during the operational phase (see **Chapter 12** of this volume of the ES). However, these changes would be below the Air Quality

Standard (AQS) critical concentration levels (as provided by APIS Ref. 20.72) for these pollutants in relation to calcareous grassland by 6%, 89% and 45% respectively. As the potential impact due to changes in air quality is likely to be of very low magnitude on a medium value resource, this would result in a **negligible adverse** impact.

20.6.34 At the end of the construction phase, the restoration of the construction areas would commence. As part of this, 17.7ha of calcareous grassland (**Appendix 20R**) would be created on suitable soil using a combination of seed collected on the development site during 2009 and 2010 and an ‘off the shelf’ seed mix of British provenance. This would create an area of calcareous grassland almost 15 times the size of the area lost during the construction phase. The calcareous grassland would be created on the south-facing slopes south of Green Lane and would provide habitat connectivity for fauna between retained areas of calcareous grassland within Hinkley CWS and along the coastal grassland to the west of the development site (along the cliff edge).

20.6.35 The new areas of calcareous grassland would be managed for the benefit of biodiversity. The detailed objectives, prescriptions and programme of management and monitoring would be provided in an Integrated Land Management Plan (ILMP); this would be produced once the development site had been restored as it would need to respond to the specific site conditions at that time. In addition to specifying the grassland management regime, the ILMP is likely to include proposals for regular surveys to be used in monitoring the development of the grassland and informing management decisions.

20.6.36 With this management regime, it is likely that, after a period of about five to ten years, the newly created grassland would be a valuable biodiversity resource, supporting many of the species that are currently present on the calcareous grassland within the development site. At this stage, it is likely to be of low biodiversity value but, with the ongoing programme of high quality management, the objective would be for it to achieve medium biodiversity value by year 30 after the completion of the construction phase. As the area of habitat creation would be almost 15 times the size of that lost, the long term outcome would be of a medium magnitude, resulting in a **moderate beneficial** impact.

iv. Woodlands

20.6.37 With the exception of the small part of Branland Copse that is located within the development site (0.2ha), the construction of the proposed development would result in the clearance of all the woodland within the site. This totals 6.8ha (**Appendix 20R**), which is less than 0.01% of the West Somerset broad-leaved woodland resource (Ref. 20.73). The woodlands that would be lost are of low value and their total loss would be a medium magnitude impact, reflecting the permanent loss of a small area of habitat. On this basis, their loss would be a **minor adverse** impact.

20.6.38 To compensate for this loss, new areas of woodland would be created. These include 2.2ha of additional permanent woodland, using a species-rich mixture of native tree and shrub species (comprising whips and mature specimens), which was planted in the south-west corner of the development site (broadly along the western part of Bum Brook) at the beginning of 2011. Further permanent native, broad-leaved woodland (approximately 8.7ha) would be planted during the early stages of the construction phase on the land between the construction site boundary and the Bum Brook. In addition, approximately 1.4ha of temporary woodland/scrub would be planted on a bund along the north-western boundary of the development site at the beginning of the construction phase. It would be retained for the duration of the construction period. and would then be removed.

20.6.39 During the restoration of the construction areas, which would take place in the later stages of the construction phase, a further 28.8ha of broad-leaved woodland would be permanently planted in the southern and eastern areas of the development site. This would give a total of approximately 39.7ha of broad-leaved woodland on the restored areas, which is over five times the area of woodland that would be lost. This further woodland would be created using species that are typical of ancient semi-natural woodland in the surrounding area.

20.6.40 After an initial aftercare period of three years, the newly created woodlands within the development site would be subject to long-term management for the benefit of biodiversity, which would include creating a diverse age structure. Management activities would include the margins being fenced to prevent grazing by stock, localised gap creation, restocking/natural regeneration as appropriate and the creation of rides to maximise the amount of woodland edge habitat created. The management proposals, together with specific management objectives, and a programme of management and monitoring would be provided in the ILMP.

20.6.41 This management regime is initially likely to result in the newly planted woodland attracting a wide range of species that are associated with open woodland, scrub and grassland habitats. However, after about 10-15 years, it is likely that the canopy would become closed (other than where there are rides or where gaps are created), and the fauna and, to a lesser extent, the herbaceous flora, would include more woodland species. As the woodland continues to mature, and with the ongoing management programme, its flora and fauna would progressively become more characteristic of established woodland, as would its structural characteristics (e.g. uneven aged trees and the presence of dead wood habitats). After some 30-50 years, the woodlands are likely to be of low biodiversity value but, with the ongoing programme of high quality management, they are likely, in the longer term (e.g. after 100 years), to become of medium biodiversity value.

20.6.42 After 30-50 years, the magnitude of the biodiversity gain is assessed as medium on a low value resource, resulting in a **minor beneficial** impact. At this stage, the new woodland would not contain trees that are as old as many of those within the existing woodland and there would be likely to be less dead wood and associated fauna, and fewer woodland ground flora species. However, there would be a wider range of woodland habitats, reflecting the tailored management programme, within an area that is over five times the extent of the area that would be lost. Thus, although there would be a period of time when the newly created woodland does not fully compensate for the loss of woodland (i.e. the ten year construction phase plus up to some 30-50 years thereafter), it is assessed that the new woodland would, after this period, at least compensate for the loss of woodland, and, over subsequent years, would progressively more than compensate for the loss.

20.6.43 During construction and without best practice control measures, conditions that could cause fugitive dust/PM_{10} to travel towards the off-site woodland within the CWS would occur less than 28% of the time and, any impact resulting from this would be limited to within 50m of the source (taken to be the development site boundary). Furthermore, it is likely that the activities that generate the most dust/PM_{10s} would not always coincide with the meteorological conditions most conducive to the transport of airborne dust (see **Chapter 12** of this volume of the ES). With good practice control measures, the area affected is likely to be less, but given the proximity of the off-site woodland to the site, there remains the potential for an adverse impact to occur. No impacts are predicted in the construction phase in relation to on-site or off-site exhaust emissions and air pollutant deposition (see **Chapter 12** of this volume of the ES).

20.6.44 Operation of the development would not have any direct impacts on the woodland habitats adjacent to the site or on those created during the construction phase. Indirect impacts could occur on these habitats through the generation of nitrogen and sulphurous and nitrous oxides. However, as concluded in **Chapter 12 of Volume 2** of the ES, any changes in NO_x, SO_2 and NH3 during the operational phase would be below the critical levels for these pollutants in relation to woodlands.

20.6.45 Impacts on the woodlands could also result from the nitrogen deposition plume from the EPR units. As the plume is most likely to be focused to the east of the restored construction site (see **Chapter 12** of this volume of the ES), impacts on the created on-site woodlands are likely to very low magnitude. However, maximum deposition rates of 1.05kg N ha^{-1} yr^{-1} and 3.14kg N ha^{-1} yr^{-1} (see **Chapter 19**) are predicted within the off-site CWS woodlands during the start of operation and during routine testing from the EPR units respectively. The available information on the existing average local deposition rate (as provided by APIS [Ref. 20.72]) indicates that, for broad-leaved woodland, the baseline deposition rate is currently higher than the critical load range. Therefore, the additional nitrogen deposition rate resulting from the operational phase would increase the baseline exceedance in relation to off-site woodland within the CWS by a maximum of 13%, although this is considered to be a worst case scenario (as the weather conditions will not always result in the highest deposition rates). Impacts on off-site woodland during the construction and operation phases as a result of air quality changes are therefore assessed as a medium magnitude impact on a low value receptor, which results in a **minor adverse** impact.

v. Hedgerows

20.6.46 All the hedgerows within the development site would be lost during the construction phase, with the exception of the majority of the hedgerow that runs east-west across the centre of the site (largely along Green Lane), a hedgerow that connects Green Lane to the Common Land (located adjacent to the eastern boundary of the site) and the north-south hedgerow along the development site's western boundary (largely along Benhole Lane). The length of hedgerows that would be lost on the development site would total approximately 9.2km (approximately 83% of the total resource within the site), comprising 5.8km that is species-rich and 3.4km that is species-poor (**Appendix 20R**). A small amount of species-poor hedgerow would also be lost as a result of the highway improvement works.

20.6.47 Of the 58 hedgerows that would be lost, 30 meet the criteria for classification as being ecologically 'important' under the Hedgerows Regulations. All of the retained hedgerows have also been assessed as important and all are currently, and would remain, well connected to other hedgerows and woodland in the wider landscape.

20.6.48 The hedgerow losses would include a length along the eastern section of Green Lane, which needs to be removed in order to accommodate the access road and substation. However, habitat connectivity would be maintained via the retention of an existing hedgerow linking Green Lane to a hedgerow along the Common Land boundary. This hedgerow would be augmented by the creation of a second parallel hedgerow, which would be offset by approximately 5m. This would be planted during winter 2011/2012.

20.6.49 Green Lane would be fenced-off during the construction phase, with an approximately 40m wide strip of land to either side retained (and enhanced by planting with native grassland and wildflower species) to provide a buffer from disturbance during the construction phase. A similar strip of land would also be retained, planted and fenced-off to the east of Benhole Lane (within the site development boundary), thereby protecting this hedgerow.

20.6.50 Relative to the wider hedgerow resource in the local area, a limited area of this low value habitat type would be permanently lost. As such, the loss of hedgerows is assessed as being an impact of medium magnitude and, therefore, a **minor adverse** impact.

20.6.51 During the restoration of the construction area at the end of the construction phase, a hedgerow network, with the planting locations based on the hedgerow layout currently present, would be created using a woody species-mix that reflects the most species-rich hedgerows currently present within the development site. The hedgerow network would comprise wide, single hedgerows together with double hedgerows that are separated by footpaths or grassland. The creation of botanically diverse associated hedgerow flora would be achieved through the application of subsoil along hedge bases and the use of seed mixes of British provenance. This would result in 13.1km of hedgerow and edge habitat being created.

20.6.52 The restored (and retained) hedgerows within the development site would be managed for the benefit of biodiversity. The detailed objectives, prescriptions and programme of management and monitoring would be provided in the ILMP; this would be produced once the development site has been restored as it would need to respond to the specific site conditions at that time. The ILMP would include proposals for regular hedgerow management, which would be designed to ensure that the hedgerows remain species-rich and structurally diverse. Regular surveys of the hedgerows would be carried out to monitor their structure and condition, with the findings being used to determine whether there is any need to modify the management regime.

20.6.53 After about five years, the newly planted woody species are likely to have thickened-up sufficiently to form hedgerows that have few, if any, gaps. The hedgerows would then progressively mature and with their management targeted to deliver biodiversity benefits, would attract an increasing number of faunal species that are characteristic of this habitat type. After some 30 years, it is likely that the newly created hedgerows would be of low biodiversity value. As the habitat creation would be permanent, the outcome would be of a medium magnitude, resulting in a **minor beneficial** impact.

20.6.54 Thus, as with woodland and calcareous grassland, although there would be a period of time when the newly created hedgerows would not fully compensate for the loss of existing hedgerows (i.e. the ten year construction phase plus up to some 30 years thereafter), it is assessed that the new hedgerows would, after this period, at least compensate for the loss, and, over subsequent years, would progressively more than compensate for the loss. This conclusion reflects the new hedgerows and edge habitat not having the maturity of those that currently exist, but there being over twice the current length of these habitats.

vi. Watercourses

20.6.55 The construction phase would result in the loss of one watercourse, with a second watercourse being culverted, resulting in its natural characteristics being lost (approximately 2.0km of this habitat in total). However, during the construction phase, management of the vegetation along Bum Brook, involving willow pollarding, scrub removal and the reduction of the dominance of Himalayan balsam, is likely to increase the biodiversity value of this stretch of watercourse by allowing native species to re-colonise, resulting in increased species-richness. Also, wetland habitats (ponds and reedbeds) would be created within the southern part of the development site, adjacent to Bum Brook, at the beginning of the construction phase. Even allowing for this enhancement, the loss of watercourses on-site, which are of low biodiversity value, would be a medium magnitude impact, reflecting their permanent loss/modification. On this basis, the impacts would be **minor adverse**.

20.6.56 At the end of the construction phase, as part of the restoration of the development site, ditches would be created in the Holford Valley in the centre of the site. These are likely to be seasonally wet and would drain into a wetland area that would be established close to Benhole Lane on the western boundary of the development site (to provide water to Holford Stream). Given their ephemeral nature, the ditches are likely to be of very low biodiversity value and the impact is likely to be of very low magnitude. The impact is therefore assessed as being **negligible beneficial**.

vii. Habitat Networks

20.6.57 The network of habitat features within the development site (hedgerows, woodland and running watercourses), allows a range of species to pass through the area, particularly east-west, but also, to a limited extent (constrained by the coast), north-south. Most of the network would be lost (approximately 11.3km of hedgerows and watercourses) but the retention and enhancement of three larger habitat corridors within or adjacent to the development site would maintain north-south (Benhole Lane) and east-west (Green Lane and Bum Brook) habitat linkages across the site, thereby reducing the impact of severance on the local habitat network.

20.6.58 The impact on the network during the construction phase is assessed as being of medium magnitude on a low value resource, producing a **minor adverse** impact. However, the restoration of the construction site at the end of the construction phase would also create a new habitat network comprising hedgerows, woodland and flower-rich grassland, which would improve the habitat connectivity across the development site to areas such as Hinkley CWS and Wick Moor and also provide habitat linkages within the restored site. It is likely that the habitats would be sufficiently functional in ecological terms to operate effectively as habitat corridors within with a period of five to ten years after construction. The enhanced network representing a medium magnitude beneficial impact on a low value receptor, resulting in a **minor beneficial** impact.

viii. Birds using Terrestrial Areas

20.6.59 If undertaken during the breeding bird season, site clearance activities would have the potential to destroy active bird nests, which would be in contravention of the WCA (Ref. 20.8). To avoid this, vegetation clearance and/or management would, wherever possible, be completed outside of the breeding bird season (which is generally considered to be March to August inclusive). Should vegetation clearance be required during this period, a suitability qualified ecologist would survey the vegetation prior to its removal in order to check for the presence of active nests. If an active nest is found, it would be left undisturbed until the young have fledged.

20.6.60 With the adoption of these measures, there would be **no impact** on breeding birds in relation to legal protection.

20.6.61 Once the vegetation has been removed from the areas where construction activities would take place (i.e. excluding the retained habitats such as Green Lane), the cleared areas are likely to no longer support any of the bird species that currently breed on the development site. These include an estimated three pairs of the scarce lesser whitethroat. Also present are an estimated 23 pairs of skylark, seven of linnet, nine of yellow hammer and between one and 20 pairs of five other species that are listed as being of principal importance for biodiversity under the NERC Act. A small number of some of these species are likely to continue to breed in the areas of retained vegetation, whilst the cleared areas may attract other species.

20.6.62 With the exception of lesser whitethroat (which is assessed separately below), all of the farmland bird species that were recorded on the development site are widespread in lowland South-west England and should therefore be seen as forming part of large populations occurring over an extensive area. Although these species are declining across the UK they are responding to landscape-scale changes, such as the intensification of agriculture, rather than to the development of relatively small areas of suitable habitat. As such, the loss of those pairs that breed on the development site would not have an adverse impact on the conservation status of the species concerned.

20.6.63 The loss of vegetation and soil stripping that would occur during the construction phase would also reduce the amount of food and shelter that is available for the birds that currently occur on-site during the wintering and passage periods. Furthermore, the disturbance from construction activities within the boundary of the development site is likely to discourage the use of on-site habitats by wintering and passage birds (other than waterbirds). Although some birds would continue to use the development site during these periods, many others are likely to be displaced from the site. Notable species that are likely to be wholly or largely displaced are mobile flocks of passerines associated with coastal fields/lowland farmland such as linnet, skylark, redwing and meadow pipit.

20.6.64 The flocks of passerines that were recorded were largely outside of the development area, being most often observed feeding on Wick Moor. Numbers fluctuated markedly and in view of this and the frequency of occurrence during the surveys, it is likely that these mobile flocks were only present sporadically. As the fields within and adjacent to the proposed development area did not frequently support large numbers of birds and the larger flocks were only occasionally of county importance (i.e. in excess of 1% of the county population), the winter and passage bird community of the terrestrial habitats within the development site is of low biodiversity value. The displacement of these wide-ranging birds from the development site during the construction phase is unlikely to affect the conservation status of the species concerned.

20.6.65 On the basis of the assessment that is set out above relating to breeding and wintering birds, the magnitude of the impacts on these species is likely to be low, affecting a low value resource, and the scheme would, therefore, have a **minor adverse** impact in this respect. This impact would be partially compensated by the increased numbers of breeding and wintering birds that would be attracted to use the habitats that would be created as part of the restoration of the construction areas. This would include approximately 3.8ha of a crop grown specifically to benefit farmland birds (an annual cover crop). As the semi-natural habitats progressively mature, they would attract birds for foraging and nesting. Although the range of species that would colonise cannot be accurately predicted the range of habitats to be created is likely to attract many of the same species that are currently present within the environs of Hinkley Point (including declining farmland birds and lesser whitethroat). After about five years the hedgerows, species-rich grassland and other newly created habitats are likely to be sufficiently well established to support low value populations of breeding and wintering birds. This is likely to result in a low magnitude of impact on a low value receptor which would result in a **minor beneficial** impact.

20.6.66 There is also the potential for the construction phase to cause disturbance to birds that breed in close proximity to the development site, resulting in reduced breeding success and, potentially, a decline in their populations. The most likely response of the affected breeding bird community is a reduction in density and a change in composition. Numbers of those species that are well known for breeding in disturbed areas, such as the edges of industrial premises, along roadsides and adjacent to construction areas (including house sparrow, which is a species of principal importance for biodiversity), are unlikely to decline. For more disturbance-sensitive species, disturbance impacts are unlikely to occur over 250m from the development site (Ref. 20.64), within which area the breeding bird population (with the exception of Cetti's warbler, which is addressed separately below) is only of low importance.

20.6.67 Once HPC is operational, noise and human activity would continue to disturb birds that breed in close proximity to the nuclear plant. However, the level of disturbance would be reduced, in comparison to the construction phase, reflecting the fact that a substantial area of the construction site would have been restored to create wildlife habitats and agricultural land and that noise and visual disturbance would be a lower level.

20.6.68 Furthermore, the majority of birds that have been recorded within nearby terrestrial habitats (both during the breeding and wintering periods) have been associated with

Wick Moor. This is adjacent to the existing Hinkley Point Power Station Complex and the species that occur here are likely already to be habituated to the type of operational disturbance that is predicted to occur from the HPC station.

20.6.69 Consequently, as the bird community that is likely to be disturbed is of low biodiversity value and the area of disturbance is relatively small (in the context of the habitats supporting a similar community in the wider area) a very low magnitude of impact is predicted, which would have a **negligible adverse** impact.

ix. Lesser Whitethroat

20.6.70 The construction phase would result in the loss of three territories of lesser whitethroat that occur within the development site. Although there is potential for these birds to move into adjacent areas of retained habitat this cannot be presumed and therefore a medium magnitude of impact is predicted. Given the low biodiversity value of these three territories, their loss would have a **minor adverse** impact. The creation, as part of the restoration of the construction areas, of more edge habitats (e.g. hedgerows and scrub), together with appropriate long term management (tailored to the needs of lesser whitethroat) would be likely to attract at least as many breeding pairs of this species as would be lost. This would therefore be a **minor beneficial** impact, although it would not be achieved until some ten or more years after the hedges and woodland/scrub have been planted.

x. Cetti's Warbler

20.6.71 The population of Cetti's warbler that could be affected exists in areas outside the development site boundary. Cetti's warbler is a bird that is quite tolerant of disturbance, as evidenced by breeding pairs having been recorded close to the centres of human activity and industrial noise associated with the existing Hinkley Point Power Station Complex (and associated infrastructure) and to other busy areas within Somerset (e.g. Apex Leisure Park and Minehead Golf Course – Ref. 20.43). Given the distances from areas of works' activity and the ability of this species to exist in disturbed areas, it is likely that any impact of disturbance during the construction phase would not affect the species' survival. Hence the impact is likely to be of no more than low magnitude.

20.6.72 The types of disturbance that would be associated with the functioning of HPC would be broadly similar to those associated with HPB, which is closer to the population of Cetti's warbler than would be to the proposed HPC station. Therefore it is likely that any impact of disturbance would not affect the species' survival or productivity and would be of very low magnitude.

20.6.73 The combination of low magnitude disturbance during construction and very low magnitude disturbance during the operational phase, affecting a medium value species' population, is likely to result in an impact of **minor adverse** significance.

xi. Birds using Inter-tidal Areas

Construction

20.6.74 There is the potential for birds using the inter-tidal areas close to the development site to be adversely affected by disturbance caused by noise, human activity, lighting and vibration associated with the construction works. Any impacts would be likely to be confined to areas of intertidal habitats that are in close proximity to the construction area and could lead to displacement of waterbirds from the local area. However, the loss of the fields within the development site may also reduce the foraging, roosting and loafing area used by some species.

20.6.75 In assessing what are likely to be the impacts of disturbance, consideration has been given to:

- the numbers and distribution of waterbirds recorded during the intertidal bird surveys that are summarised in Section 20.5(b); and
- the extensive area of similar intertidal habitat in the vicinity of the development site (and further afield, but still within the Severn Estuary SPA and Ramsar Site) that could be used by any birds that are disturbed and is within the likely home-ranges of the species present.

20.6.76 The assessment draws upon the evidence presented below regarding the impacts of disturbance on birds using intertidal areas.

20.6.77 There is relatively limited information on the potential for construction work to act as a disturbing activity on waterfowl populations (through noise and visual disturbance). However, studies by the Institute of Estuarine and Coastal Studies (IECS) focusing on the effects of disturbance caused by construction works associated with flood defence and managed re-alignment on the Humber Estuary provide useful information (Ref. 20.74, Ref. 20.75). A comprehensive analysis of data recorded during a large-scale construction project within Cardiff Bay also provides useful information (Ref. 20.76).

20.6.78 Birds tend to be more affected by the presence of people than by noise from equipment; although the two causes of impacts are usually intimately related (i.e. noise is mainly created concurrently with human presence – Refs. 20.74 and 20.75). Disturbance events may result in a range of behavioural responses from birds within the area. At low levels, disturbance results in a detectable behavioural change with individual birds taking up alert postures; at greater levels of disturbance short-distance flights or movements on foot are undertaken within familiar habitats that are already regularly used (i.e. within a home-range); with large-scale disturbance events, displacement to areas outside of home-ranges may occur.

20.6.79 Disturbance can result in a reduction in energy intake and an increase in energy expenditure, which may ultimately result in a reduction in over-winter survival or subsequent breeding success. However, disturbance events that do not result in displacement are unlikely to result in the energy intake falling enough to result in a reduction in body condition. Disturbance that results in displacement into habitats that are already habitually used by a given individual (i.e. within their home-range) is unlikely to result in a detectable effect on body condition unless core foraging areas or secure roost sites are disturbed frequently. Disturbance that results in displacement into areas outside of a home-range is likely to have a greater impact on individual birds as the level of competition present may be high, the habitat patch quality may be low and the ability of an individual to exploit an unfamiliar habitat patch effectively may be compromised. The level of impact would be moderated by the frequency of disturbance events and their duration.

20.6.80 During works on the Humber Estuary, the responses of birds to visual and aural stimuli differed due to the type of construction activity, species, season, site topography, weather, tidal state and degree of habituation (Ref. 20.74 and Ref. 20.75). In general, however, detectable effects of disturbance were not recorded at distances greater than 250m, although many species continued to feed, loaf or roost within this distance. Reactions were more pronounced when construction activity was visible, with even loud activities (e.g. percussion piling) on the landward side of the seawall (where people were not visible to birds using the intertidal habitat) resulting in only minimal reactions from the birds present.

20.6.81 The Cardiff Bay study, which related to the construction of the Cardiff Barrage during 1991-1999, assessed the wider (i.e. population) influence of construction works on waterbirds. This work (Ref. 20.76) found that over the construction period, the densities of several species of waterfowl (teal, oystercatcher, dunlin, curlew and redshank) on mudflats adjacent to the works decreased in comparison to pre-construction levels. Construction work was also observed to reduce the feeding activity of oystercatcher, dunlin and redshank over these mudflat areas. Burton et al. (Ref. 20.76), on the basis of this work, suggest that disturbance from construction work may affect the ability of intertidal habitat to maintain waterfowl populations during the construction period. Further work on redshank that were completely displaced from Cardiff Bay (due to disturbance and habitat loss) showed that individual birds that moved to new areas had poorer body condition than birds that were already resident in those areas (Ref. 20.77)

20.6.82 When assessing impacts of the predicted disturbance associated with the proposed HPC development, the survey data that need to be used are those for Count Sectors 1-3. This is because Count Sectors 4 and 5 are over 500m east of the potential sources of disturbance and therefore are outside of the 250m zone which the Humber Estuary research indicates is the maximum area over which disturbance impacts are likely to occur (Ref. 20.74 Ref. 20.75). Accounting for both works on land and on the aggregates jetty, the 250m disturbance zone (see **Figure 20.5**) covers 19%, 97% and 26% of the intertidal habitats within Count Sectors 1, 2 and 3 respectively.

20.6.83 Data collected from Count Sectors 1 – 3 show that the cited species of the Severn Estuary SPA and Ramsar Site, and the Bridgwater Bay SSSI that regularly occur in these areas are wintering shelduck, wigeon, pintail and curlew, and passage whimbrel and ringed plover. Other species of note that make use of the inter-tidal areas located adjacent to the development site are herring gull and little egret. A roost of oystercatcher, a species which does not feature as part of the cited interest of any of the statutorily protected sites, is also a regular feature of the inter-tidal area to the west of the development site.

20.6.84 Dunlin, grey plover, lapwing, redshank, shoveler and teal all occurred within Count Sectors 1 – 3 on few occasions (between 0.5 and 6% of all survey dates) and in very small numbers (<1% of the Severn Estuary SPA population); some of the same species also occurred in small numbers on the neighbouring fields. These species can be discounted from the need for further assessment on the basis that they would not be prone to detectable population effects from the proposed construction works as the 250m disturbance zone (see **Figure 20.5**) does not contain areas that are used habitually by these birds. Therefore it is likely that any individuals of these species which are disturbed to such an extent that displacement occurs, would move short distances into areas that they habitually use at other times, which are likely to provide the required resources to support them.

20.6.85 Compared with these species, mallard and wigeon occurred in Count Sectors 1 – 3 more frequently (24% and 22% respectively of all survey dates) although in numbers that never exceeded 1% of the Severn Estuary SPA population. Occurrence was not, however, at a level that makes it likely that Count Sectors 1 – 3 were being used by these species as core foraging or roosting areas. The highest numbers of mallard were noted in Count Sector 1, with very small numbers recorded (four or fewer) in Count Sectors 2 and 3. Wigeon were noted in greatest numbers in Count Sectors 1 and 3 with only two counts of more than ten birds present in Count Sector 2 throughout the survey period. Larger numbers of both species were recorded at greater frequency within Count Sectors 4 and 5, which are therefore more likely to represent core foraging/loafing areas than the predicted disturbance zone within Count Sectors 1 – 3. Therefore it is likely that any individual mallard or wigeon that are disturbed to such an extent that displacement occurs would be able to move a short distance into areas that they habitually use and that are likely to provide the required resources to support them. As a result, detectable declines in the body condition of individuals would be unlikely to occur as the increased energy expenditure required to relocate a short distance would be negligible.

20.6.86 Mallard was noted in very low numbers within the terrestrial habitats within or adjacent to the development area; the peak count being of two individuals. Given this low level of usage it is therefore likely that no detectable effect on the Severn Estuary population of mallard would occur due to the loss of the fields within the development footprint. Wigeon were not recorded in the fields within the footprint of the proposed development or within 250m of the development site boundary.

20.6.87 Pintail was noted using Count Sectors 1 – 3 on six dates during the survey programme; the frequency of occurrence was considerably greater in Count Sectors 4 and 5. The number of pintail exceeded 1% of the Severn Estuary SPA population (with a range of 6 – 60 birds) on three of the six occasions; all these records were within Count Sector 3, where birds were recorded loafing. No foraging activity was recorded in Count Sectors 1 – 3 indicating that it is not a core foraging area; foraging by relatively large numbers of pintail was recorded in Count Sector 5. The data suggest that pintail do not habitually use Count Sectors 1 – 3 and, if disturbed in this area, could relocate to adjacent habitats that they already habitually use without a detectable impact on individual birds or the population as a whole.

20.6.88 Whimbrel occupied Count Sectors 1 – 3 on 12 of the 182 survey dates in numbers ranging from one to five individuals; the number and frequency of occurrence of whimbrel was greater in Count Sectors 4 and 5. Individuals spent time loafing and foraging in the months of April, May and August when these birds were migrating through the estuary. Given the small numbers and the sporadic occurrence, Count Sectors 1 – 3 are unlikely to form a core area where refuelling or resting takes place during the migratory periods. It is therefore likely that any whimbrel that is disturbed will occupy nearby habitats without detectably affecting their energy intake or energy expenditure. Thus their survival rate would not be adversely affected.

20.6.89 Curlew was recorded regularly in Count Sectors 1 – 3 throughout the year, with 141 occurrences over the course of 182 survey dates. Although usage was frequent, numbers were generally small, with a peak count of 25 individuals, representing 0.6% of the Severn Estuary SPA population. The fluctuating numbers in Count Sectors 1 – 3 suggest that individuals also use other areas for foraging, roosting and loafing (as would be expected given usual curlew behaviour of exploiting a variety of habitats, e.g. pasture fields, mudflats, saltmarsh etc.). This is likely to include Count Sectors 4 and 5, where much greater numbers of curlew were recorded foraging, loafing and roosting. Of these two sectors, Count Sector 5 (and the rest of Stert Flats) provides particularly good foraging opportunities for this species as the habitats present support greater densities of curlew's preferred invertebrate prey (e.g. large worms and bivalve molluscs). Given that the numbers of curlew in Count Sectors 1 – 3 are small, and displacement due to disturbance would be local and likely to be within existing home-ranges, it is concluded that no detectable decline in the local curlew population is likely to be realised through disturbance associated with the proposed development.

20.6.90 Curlew was recorded in small numbers (less than 1% of the SPA population) using the fields within and adjacent to the development area for foraging. The displacement of these birds from these fields has the potential to reduce the foraging resource available to this species. However, curlew are birds known to range widely during the winter period and are highly likely to feed across much of the farmland both to the east and west of the proposed development area (as well as on the inter-tidal habitats). It is therefore unlikely that the loss of a small number of fields within a landscape dominated by suitable habitat would be sufficient for a detectable effect on any individuals or the local population to be realised.

20.6.91 Ringed plover was noted 44 times (24% of survey dates) using Count Sectors 1 – 3; the majority were within Count Sector 1, where the potential for disturbance is lower than in the other count sectors (reflecting there being the smallest degree of overlap between the count sector and the disturbance zone). This species was recorded in all months of the year, usually in small numbers (less than five individuals); numbers exceeded 1% of the Severn Estuary SPA population (i.e. seven or more individuals) on only six occasions.

20.6.92 Although ringed plover was recorded throughout the year, its occurrence was sporadic. In view of this and the small numbers, it is likely that the potential disturbance zone does not provide core areas for any individuals. Indeed, due to ringed plovers' foraging preferences, the larger areas of mobile sands and muddy sands to the west of Count Sectors 1 provide better habitat for this species than the rock platforms that dominate the potential disturbance zone. It is therefore concluded that displacement of ringed plover from Count Sectors 1 – 3 would not be likely to result in abandonment (temporary or permanent) of home-ranges with the result that there would be no detectable effect of disturbance on the population.

20.6.93 The majority of shelduck recorded using Count Sectors 1 – 3 were loafing. All large aggregations that were recorded were of birds rafting on the water during the moulting period of July to August (**Figure 20.6**). Many of these birds were likely to be moulting and seeking to stay away from potential predators whilst they were flightless. Avoidance of any disturbance would therefore involve swimming or using the tidal current to move away from the source of disturbance into another nearby area of water (data collected in 2011 demonstrated the ability of shelduck to swim against the tide – see **Appendix 20Q**).

20.6.94 Surveys of shelduck that were undertaken during the moulting period in 2011, together with the surveys undertaken in 2007-2009 (see **Appendix 20Q** and **Figure 20.6** respectively), found that all but one flock of shelduck were outside the 250m disturbance zone around the jetty head. During the construction phase shelduck may also be disturbed by boats docking or leaving the temporary jetty. However, as shelduck are able to swim to avoid disturbance and the level of boat traffic would be low (as docking and disembarking can only take place at high tide), detectable levels of disturbance are not likely to occur.

20.6.95 Very few foraging shelduck were recorded in Count Sectors 1 – 3, which is likely to be due to the majority of the habitat in these areas being unsuitable for their foraging. By contrast, large numbers of foraging birds were regularly observed in Count Sector 5, where the extensive mudflats provide good foraging habitat. The much greater usage of Count Sector 5 together with the types of habitat present within Count Sectors 1 – 3 indicate that the latter count sectors are not likely to be core areas of the home-ranges of any foraging shelduck. Therefore any disturbance of shelduck in Count Sectors 1 – 3 is not likely to result in birds being displaced from their core foraging areas. Therefore no loss of body condition or impacts on survival are likely to occur.

20.6.96 Shelduck's usage of coastal fields within or adjacent to the development area was very limited both in terms of numbers and frequency of occurrence (see **Figures 3.5a-b** and **3.6a-b** in **Appendix 20B**). The loss of these fields is therefore unlikely to result in any detectable impacts on shelduck.

20.6.97 Little egret was regularly recorded in small numbers within the inter-tidal habitats and in the coastal fields. This species is known to move regularly to feed in different places throughout the day (Ref. 20.78) and therefore it is likely that the individuals present are using a variety of feeding opportunities (e.g. rock pools, field drains etc.) in order to forage efficiently. Given that this species is increasing across Somerset and elsewhere in the UK, it is apparent that the availability of foraging areas is not yet a limiting factor. Therefore given this species' ranging behaviour and the extent of suitable habitats in the area, it is unlikely that any displacement of birds from either a small area of intertidal habitat or agricultural fields would result in a detectable effect on the body condition or survival rate of any individual or the local population of this species.

20.6.98 Herring gull is a species that is well known for exploiting disturbed habitats (e.g. landfill sites, city centres etc.); it is also a highly mobile species and an opportunist feeder. Given these characteristics, it is likely that disturbance associated with the construction works would not result in a detectable effect on this species. The loss of a small number of fields to development is also unlikely to provide a significant reduction in the availability of food for this species.

20.6.99 Oystercatchers regularly use the disturbance zone (peak count of 100 foraging birds) for foraging and roosting. There were 554 records of oystercatcher from the 182 survey dates, with the majority (490) being of flocks of no more than 20 birds (there were 430 records of flocks between 1 – 10 birds). Only 13 of the records were of numbers in excess of 50 birds. Roosting usually occurred on the rock platforms adjacent to the inter-tidal habitats in the 2 hours either side of high tide. Most of the roosting birds were in Count Sectors 3 and 4 where disturbance from the proposed development would be minimal, as only about one quarter of Count Sector 3 would be disturbed. Foraging oystercatchers were generally widespread across Count Sectors 1 – 4.

20.6.100 As oystercatchers are widespread across the inter-tidal habitats in Count Sectors 1-5 and on Stert Flats, it is likely that individual birds using the areas within the disturbance zone are also habitually using other habitats in the area for foraging and roosting. Therefore it is likely that any disturbed individuals would only have to move a short distance to re-locate to areas with which they are already familiar. No detectable effects on body condition or the survival of individual oystercatchers are predicted due to the construction of HPC.

20.6.101 On the basis of the assessment that is set out above, the construction phase is likely to have a very low magnitude impact on birds using inter-tidal areas. This would result in a **minor adverse** impact on the high value populations associated with the Severn Estuary SPA and Ramsar Site, and the Bridgwater Bay SSSI.

Operation

20.6.102 During the operational period, there is the potential for birds using the inter-tidal areas to be adversely affected by disturbance caused by noise, human activity and lighting associated with the functioning of the power station and by changes in inter-tidal plant/animal communities caused by the discharge of warm water and/or chemical pollutants from the sub-tidal outfall structure.

20.6.103 The level of disturbance on the foreshore would be reduced significantly during the operation of the plant as the temporary jetty that would have been used to import aggregates and other construction materials would have been removed, thereby eliminating much of the human and boat activity that is visible to waterbirds along the foreshore. Disturbance is therefore likely to be similar to that caused by the operational use of the existing Hinkley Point Power Station Complex.

20.6.104 Bird data for Count Sectors 4 and 5 show large numbers of birds using intertidal areas adjacent to the existing Hinkley Point Power Station Complex. This suggests that the activity associated with these industrial areas is compatible with waterbirds making extensive use of nearby intertidal habitats. On this basis, it is likely that any disturbance impacts on birds using the intertidal areas adjacent to HPC would be of very low magnitude.

20.6.105 The overall magnitude of the operational impact on inter-tidal birds would, however, also be influenced by the discharge from the HPC plant of warm water, chlorine and hydrazine, which has the potential to reduce the number and/or biomass of invertebrates present within Bridgwater Bay. Information from BEEMS Report TR184 (see **Chapter 19** in Volume 2 of this ES) shows that the modelled dispersal of the thermal plume from the sub-tidal outfall structure of HPC is largely in areas that are offshore. However there is an overlap with a proportion of the intertidal habitats of Stert Flats; a very small overlap with Berrow Flats is also predicted (**Chapter 19** in Volume 2 of this ES). Modelling shows that the thermal plume is likely to result in an increase in temperature of between 0-3°C across these areas. This is likely to affect populations of the Baltic tellin (*Macoma balthica*) and the brown shrimp (*Crangon crangon*).

20.6.106 Conservative modelling predictions suggest that the numbers of *M. balthica* within the mudflats would not fall; rather the individuals present would suffer a reduction in growing season (this species does not grow in warmer temperatures e.g. as typically occur in the summer months). The population of *M. balthica* present within the inter-tidal habitats of Bridgwater Bay comprises small and young individuals with large and old specimens being largely absent. Therefore a reduction in growing season is unlikely to disrupt the recruitment rate to the population (as the data suggest that *M. balthica* on Stert Flats is derived from reproduction elsewhere); rather a similar number of smaller individuals would persist. It should be noted that the density and size of *M. balthica* currently resident within the thermal plume of the operational HPB station is no different to that across Stert Flats suggesting that the modelled impacts are highly precautionary.

20.6.107 Across Stert Flats (to the east of Hinkley Point) the predicted reduction in biomass of *M. balthica* is 11% with a further 2% reduction across Berrow Flats (to the north of the River Parrett). This prediction is based on HPC operating at 100% of capacity alongside HPB operating at 70% (its current output). It should be noted that HPB would eventually be decommissioned which would reduce the predicted effect to a 6.7% reduction in biomass across Stert Flats and less than 2% across Berrow Flats.

20.6.108 *M. balthica* is a species that is preyed upon by a number of birds that feed in Bridgwater Bay. The species that occur frequently in this area that are known to include *M. balthica* in their diet are shelduck, mallard, pintail, grey plover, dunlin, black-tailed godwit, whimbrel, curlew and redshank. None of these species however, specialise on *M. balthica*.

20.6.109 The distribution of *M. balthica* is not uniform, with greater levels of biomass being present on the lower shore. On the mid and upper shores of Stert Flats species such as *Hediste diversicolor*, *Hydrobia ulvae* and *Nephtys hombergii* provide a significant amount of the prey biomass present (**Chapter 19** in Volume 2 of this ES). Despite these distributional differences in prey composition the distribution of waterbirds does not mirror this pattern (Appendix 20C); this suggests that individual birds are more generalist feeders. As *M. balthica* represents between 30% – 90% of the biomass in various areas of Stert Flats the reduction of up to 11% of this resource (i.e. 3.3% to 9.9% of biomass) is relatively small and is likely not to reduce significantly the prey resource available to the birds present. However, given that there is no current detectable effect on the size or abundance of *M. balthica* due to the HPB plume (**Chapter 19** in Volume 2 of this ES), it is likely that the impact on this species would be lower than is predicted by the model.

20.6.110 As the predicted reduction in *M. balthica* biomass is relatively low and is within the usual range of between year fluctuations, the conservative nature of the modelling output and the amount of alternative prey available for the birds using Stert and Berrow Flats, it is unlikely that the number of birds that could be supported in the area would be reduced.

20.6.111 It is also of note that brown shrimp numbers could increase due to the warm water outfall as the higher temperatures are likely to increase growth and metabolic rates. This increase in a different prey item could benefit a number of species that feed on crustaceans.

20.6.112 An individual-based model of the bird/invertebrate system (i.e. a model that addresses the impacts on individual birds) for the area affected by the thermal plume has also been constructed (**Chapter 19** in Volume 2 of this ES). This model (known as the MORPH model) supports the conclusions drawn from the evidence described above as its initial outputs suggest that the birds present within the affected area would not suffer a reduction in body condition or survival due to the predicted effects of the thermal plume.

20.6.113 A further factor that influences the assessment of birds during the operational phase relates to the use of chlorine or hydrazine in the reactor cooling system (as is likely to be necessary from time to time). This would result in, breakdown products from these chemicals being released from the sub-tidal outfall structure. Modelling of these chemicals (**Chapter 19** in Volume 2 of this ES) shows that concentrations of hydrazine are not likely to be at a level that would result in any effects on the invertebrates that inhabit the mudflats to the east of Hinkley Point. The by-products of chlorination are likely to result in effects on the in-fauna around the HPB outfall if both HPB and HPC are operational at the same time. As the extent of the area affected is very limited and the predicted levels of chlorination are very low, no detectable impact on birds using the Severn Estuary is likely to be realised.

20.6.114 On the basis of the assessment that is set out above, the warm water outfall and chemical output is likely to have a very low magnitude impact on birds using inter-tidal areas, as is disturbance. The combination of these changes is likely not to result in a reduction in birds' body condition or survival, with the result that the overall magnitude of the impact would be very low, resulting in a **minor adverse** impact on the high value populations associated with the Severn Estuary SPA and Ramsar Site, and the Bridgwater Bay SSSI.

xii. Badgers

20.6.115 The clearance of the development site during the construction phase would result in the loss or reduction in size of the territories of up to nine badger social groups and the destruction of approximately 25 setts. To ensure that this sett destruction work does not contravene the Protection of Badgers Act 1992 (Ref. 20.14), it would be undertaken in accordance with measures that have been developed in association with a specialist badger consultant, and in consultation with NE and Somerset County Council's ecologists. These measures are set out in a confidential report that has been submitted to NE, and provided the basis upon which a mitigation licence was granted in July 2010 (**Appendix 20D**). The measures include the creation of six permanent and two temporary artificial setts, and supplementary feeding of badgers.

20.6.116 In the unlikely event of blasting being required to extract rock for use in the construction phase, information would be gathered about any nearby badger setts and a strategy would be devised to avoid disturbance that would result in the Protection of Badgers Act being contravened. Similarly, during operation, information about the location of setts would be used to ensure that the management of the restored part of the site is undertaken in such a way that the Protection of Badgers Act is not contravened.

20.6.117 With the adoption of these measures, there would be **no impact** on badgers in relation to legal protection.

20.6.118 Once restoration of the construction area is complete, the created habitats would be available for foraging and sett building by the badgers that were relocated to artificial setts outside of the development site at the start of the development. Therefore, it is expected that the territories of the adjacent badger social groups would alter to incorporate the new resources. However, impacts relating to biodiversity conservation value are not likely to be significant for the reasons set out in **Appendix 20N**.

xiii. Barbastelle

20.6.119 No barbastelle roosts would be directly affected by the proposed development, but site clearance during the construction phase would result in the permanent loss of habitat that is used by barbastelle for commuting and foraging. The habitat that would be lost is primarily arable land (97.6ha) and agriculturally improved grassland (46.7ha), which are habitats of low value for foraging barbastelle (e.g. Ref. 20.79), but also includes approximately 2.4ha of hedgerow and 7.9ha of woodland/scrub, habitats that are more valuable to barbastelle (**Appendix 20R**).

20.6.120 Other existing areas of habitats of value to commuting and foraging barbastelle would be retained within the development site, namely Green Lane and the associated hedgerow connecting to the Common Land, and Benhole Lane. These habitat corridors, combined with structures and tree planting to bridge the gaps created in Green Lane as a result of the haul roads, would ensure habitat connectivity and opportunistic foraging for barbastelle are maintained throughout the construction phase.

20.6.121 The on-site habitat creation proposals during the early stages of the construction phase would provide some compensation for the habitats that are loss. This would include 18.6ha of wildflower grassland, 12.3ha of woodland/scrub and 0.6ha of hedgerow. In addition, a further 1ha of woodland has been created off-site, together with 0.3ha of species-rich hedgerows. These permanent off-site areas will also provide valuable habitat for barbastelle.

20.6.122 However, in order to avoid a potential decrease in the availability of foraging habitat for barbastelle during the construction phase, a further 25ha (approximately) of off-site arable or agriculturally improved grassland would be converted temporarily (for the duration of the construction phase) to species-rich wildflower grassland. This would be done prior to the commencement of construction (further information is provided in the **Habitats Regulations Assessment** report).

20.6.123 During the final stages of the construction phase, the construction area would be restored to a mosaic of semi-natural habitats, which would include species-rich grassland, woodlands and double hedgerows (which with the retained semi-natural habitats would total approximately 94ha – **Appendix 20R**). This mosaic would be designed to provide good foraging habitat for barbastelle, with micro-climatic conditions that would support a wide range of invertebrates. The habitats would also provide a network of commuting routes, linking to off-site habitats. The benefits of the new grasslands would accrue in the short term, whilst woodland and hedgerows would take longer to be of value to barbastelle.

20.6.124 In addition, the **Lighting Strategy** has been designed to minimise any adverse impacts on retained and created habitats during the construction phase. It is also designed to limit light spill during operation, when lighting would be confined to the access road, the built development and the security zone immediately adjacent to the security fence.

20.6.125 The overall magnitude of impact on barbastelle during construction, taking account of the habitat retention and creation during the early stages of the construction phase and the lighting strategy that would be adopted is assessed as very low, resulting in a temporary **minor adverse** impact on this high value receptor. In the longer term (likely to be from about ten years after restoration onwards), the habitats that are created during the restoration phase are likely to result in there being better habitat for barbastelle than currently exists on the site, representing at least a low magnitude benefit on a receptor of medium value, resulting in a **minor beneficial** impact.

xiv. Bat assemblage (including lesser horseshoe and greater horseshoe bats)

Impacts on Roosting

20.6.126 The construction phase would result in the loss of three confirmed ephemeral common pipistrelle roosts, all of which are in disused, derelict barns (a fourth barn and associated bat roost is being retained). A single confirmed but ephemeral bat roost within a tree would also be lost. Given the small number of bats using the roosts and the common species recorded, it is likely that their loss would not affect the conservation status of the local bat population[10]. Measures would be implemented during the demolition of the barns in order to minimise the potential to disturb roosting bats. These measures would include a requirement for additional bat surveys, using lights to discourage bats from returning to roost in the barns and phased demolition/soft-felling under ecological supervision. These works would also occur during the summer months in order to ensure that disturbance to potential hibernating bats is minimised.

20.6.127 In order to provide a replacement roost for the bats that would be displaced from the demolished barns, a purpose built, permanent ‘bat barn’ was constructed during August and September 2011. The bat barn has been designed to provide improved conditions for roosting pipistrelle, compared to the roost structures that are to be lost, and also incorporates features that could be used by a wider range of species (such

[10] To ensure compliance with the legal protection afforded to bats, no destruction of the barns with bat roosts or removal of trees with significant potential to support roosts would be undertaken until a method statement has been submitted to NE and a European Protected Species (EPS) licence for the works has been issued.

as *Myotis* species, long-eared and horseshoe bats). The building is located in a sheltered position that will remain unlit, along the development site's south-western boundary, adjacent to Benhole Lane, as this is close to the barns that would be demolished and is also located along a route that is used by commuting bats. The supplementary planting of scrub around the building would darken the local area, making it more attractive to bats. The detailed design of the new building has been worked up in consultation NE, and draws on best practice and examples of recent successful projects.

20.6.128 With respect to the loss of trees, each medium and high potential roost feature on trees that are to be lost, as well as the confirmed roost, have been replaced by three bat boxes, resulting in 60 boxes being erected (a mix of Schwegler 2F and 1FF boxes). These have been installed in Branland Copse North and South and Hankley Brake. Two boxes have been attached to each suitable tree to provide different micro-climatic conditions.

20.6.129 With the adoption of the measures described above, there would be **no impact** on bats in relation to legal protection.

Impacts on Foraging and/or Commuting

20.6.130 The loss of most of the hedgerows and all of the woodlands on the development site would reduce the habitat that is available for use by foraging and commuting bats. Retention of the hedgerows along most of Green Lane (with the addition of the structures and tree planting to bridge the gaps created by the haul roads) and on Benhole Lane, combined with Bum Brook, would ensure that habitat connectivity and commuting routes are maintained around and across the construction site. Whilst these retained areas would also provide some foraging habitat, the additional woodland planting and wildflower seeding along the western and southern boundaries of the development site (on land that is currently in arable use and which provides limited foraging opportunities for bats), and the woodland, hedgerows and wildflower grassland off-site, is likely to increase the invertebrate biomass available to foraging bats than would otherwise be available during this phase of development.

20.6.131 Furthermore, the **Lighting Strategy** would ensure that these retained habitats are not adversely affected by light spill during construction, so that they continue to be of value to, and used by, light-sensitive species such as long-eared and horseshoe bats.

20.6.132 Towards the end of the construction phase, a total of approximately 94ha of semi-natural habitats would be available to the bat assemblage, as described above for barbastelle. As the created habitats mature, they would progressively provide better habitats for foraging and commuting bats. Through adherence to the **Lighting Strategy**, light spill into these habitats from the operational lighting (which would be confined to the access road, the built development and the security zone immediately adjacent to the security fence) would be limited.

20.6.133 Overall, the magnitude of the construction phase impact is assessed as low on a medium value receptor. Construction would therefore have a **minor adverse** impact, on the bat assemblage. In the longer term (likely to be from about ten years after restoration onwards), the habitats that are created during the restoration phase are likely to result in there being better habitat for the bat assemblage than currently exists on the site. This would represent at least a low magnitude impact on a receptor of medium value, resulting in a **minor beneficial** impact.

xv. Otters

20.6.134 Otter is known to occur on watercourses adjacent to the development site and in the wider area, but frequent use of the watercourses on the site is unlikely due to their size, lack of connectivity and seasonal nature, which provide very limited foraging and breeding opportunities as found during the surveys to support this ES. Therefore, the permanent loss of watercourses on the development site is not likely to affect the conservation status of the local otter population. The woodland and scrub that is created close to the Bum Brook, as part of the restoration scheme, could provide temporary day-resting places for otter, but this enhancement is also unlikely to affect the species' conservation status. Overall, impacts would therefore be of very low magnitude on a low value resource, resulting in a **negligible adverse** impact. There would be **no impact** on otter in relation to legal protection.

xvi. Reptiles

20.6.135 A small population of slow-worm is present on part of the Green Lane. This part of Green Lane would be retained (with an adjacent strip of species-rich grassland planted) and fenced off during the construction phase to avoid damaging the reptile habitat and the reptiles present. This would avoid harming the slow-worms along the Green Lane and prevent the associated contravention of the WCA (Ref. 20.8).

20.6.136 It is likely that small numbers of reptiles (e.g. grass snake) occur where there is suitable habitat both at other locations within the development site and at some of the highway improvement sites. To avoid contravention of the WCA in these circumstances, a strategy would be implemented such that suitable areas of reptile habitat away from Green Lane and on the highway improvement sites (e.g. areas of rough grassland or ruderal habitat) would be identified by a suitably qualified ecologist and visually checked (which would including checking under potential refugia if present) to ensure that reptiles are not present prior to works at the start of each day. If present, reptiles would be re-located to suitable habitat outside of the construction works' area.

20.6.137 Management of the restored site would be undertaken so as to ensure that harm to reptiles is avoided. This would be achieved, for example, by managing habitats suitable for reptiles during the winter months or using a phased approach (that allows reptiles to passively move away from a managed area).

20.6.138 With the adoption of the measures outlined above, there would be **no impact** on reptiles in relation to legal protection.

20.6.139 The restoration would include extensive areas of habitat, such as south-facing calcareous grasslands, scrub, hedgerows and woodland edges, which would provide a much larger extent of suitable reptile habitat than is currently present on-site. It is likely that much of the newly created habitat would provide suitable habitat for reptiles within about five years after restoration takes place. Reptiles are likely to colonise these habitats (e.g. from the mosaic of habitats south of the existing Hinkley

Point Power Station Complex) and increase the current population, resulting in a beneficial impact. However, impacts relating to biodiversity conservation value are not likely to be significant for the reasons set out in **Appendix 20N**.

xvii. Great crested newts

20.6.140 The proposed works at those highway improvement sites where there is the potential for great crested newts to occur would result in vegetation removal or management of very small areas of rough grassland and scrub. These areas could provide suitable terrestrial habitat for small numbers of great crested newt, although they do not provide habitat for hibernation. To avoid these works harming individual great crested newts, which would be in contravention of the WCA (Ref. 20.8) and the Habitats and Species Regulations 2010 (Ref. 20.9), a strategy would be implemented with the objective of ensuring that the works are completed in a manner that minimises the risk of encountering and harming great crested newts. The strategy is likely to include measures such as completing the works during the winter when great crested newts are hibernating, using habitat manipulation to make the small works' areas unsuitable for great crested newts and/or supervised phased clearance of vegetation. These works would be completed under a Method Statement.

20.6.141 With the adoption of the measures outlined above, there would be **no impact** on great crested newts in relation to legal protection at the highway improvement sites. Impacts relating to biodiversity conservation value are not likely to be significant for the reasons set out in **Appendix 20N**.

xviii. Invertebrate assemblage

20.6.142 Most of the invertebrates recorded within the development site are common, typical of the habitats present and of low biodiversity value, although the assemblage as a whole is assessed as being of medium value. The loss, during the construction phase, of areas of semi-natural habitat within the development site (e.g. some areas of woodland, calcareous grassland and cliff vegetation) would result in a reduction in the population size of the species present, but this is unlikely to alter their conservation status within the context of the wider populations of which they are likely to form a part. Light spill onto the retained habitats would be minimised to minimise potential impacts on nocturnal invertebrates. The construction phase would therefore result in a low magnitude and **minor adverse** impact.

20.6.143 Operation of the development would not have any further direct or indirect impacts on the invertebrate assemblage. However, the restored site would provide a diverse range of species-rich, semi-natural habitats that are likely to attract a wide range of invertebrates, including those notable species that are currently found within the woodland and calcareous grassland habitats within the development site. After about five to ten years following the completion of the construction stage, the newly created habitats on the development site are likely to have matured sufficiently to support an invertebrate assemblage that is of at least low value. The magnitude of the impact on invertebrates is assessed as low, resulting in a **minor beneficial** impact.

xix. Somerset Notable Plant Species (on-site)

20.6.144 All the Somerset notable plant species recorded on-site are located within areas of calcareous grassland that will be permanently lost during the construction phase of the development. As a result, these species will also be permanently lost from the development site during this phase and no direct or indirect impacts on them are likely during the operational phase. This is assessed as a medium magnitude impact on a low value receptor, which results in a **minor adverse** impact.

20.6.145 The seeds that were collected from the on-site calcareous grassland during 2009 and 2010 were from species that included the Somerset notable species present within the development site. This seed would be used in creating new areas of calcareous grassland as part of the construction area restoration. Furthermore, all the Somerset notable plant species that would be lost from the development site are also present within the calcareous grassland located within the adjacent retained area of the Hinkley CWS, from which at least some of these species are likely to spread naturally into the newly created grassland. The notable species are therefore likely to be able to re-colonise the development site.

20.6.146 Consequently, it is likely that the newly created calcareous grassland on the restored construction area would support the Somerset notable plant species that would have been lost from the development site during the construction phase. This would represent a low magnitude impact on a low value resource, resulting in a **minor beneficial** impact.

xx. Bridgwater Bay SSSI

20.6.147 As set out in the sections above, potential impacts on two of the designated features of the Bridgwater Bay SSSI have been identified. These are the bird community, and the ditch and grazing marsh habitats.

20.6.148 During the construction and operational phases, there is the potential for low level disturbance of waders and wildfowl and for a potential reduction in the prey resource caused by thermal and chemical discharges. These impacts have been assessed as minor adverse.

20.6.149 Three potential impacts have been identified in relation to the ditches and grazing marsh that form part of the SSSI (in relation to changes in water quality and volume, changes in groundwater and changes in air quality). These have been assessed collectively as minor adverse.

20.6.150 Based on the assessments described above in relation to the bird community and the ditches and grazing marsh within the SSSI, and the measures that have been included within the scheme design to reduce potentially significant adverse impacts, no adverse impact on the integrity of the Bridgwater Bay SSSI is likely. Therefore, the magnitude of impact is assessed as very low, resulting in a **minor adverse** impact on the high value Bridgwater Bay SSSI.

xxi. Hinkley County Wildlife Site

20.6.151 Those parts of the Hinkley CWS that would be lost as a result of the construction phase (approximately 24ha in total, which is approximately 58% of the total CWS area) largely comprise improved grassland, tall ruderal vegetation and secondary woodland, all of which are of low nature conservation value; the majority of the habitats within the CWS that are of higher biodiversity value would not be affected. Nonetheless, the losses during construction would reduce the extent of the CWS's mosaic of habitats, and its woodland and calcareous grassland cover, which supports several Somerset County Notable species (the primary reason for the CWS designation) that are found throughout the extent of the CWS.

20.6.152 As described above, impacts on the calcareous grassland within the CWS during construction and operation resulting from changes in air quality are assessed as negligible adverse. However, impacts on the woodland within the CWS have been assessed as medium magnitude with an overall minor adverse impact predicted in relation to air quality changes. As it is the calcareous grassland habitat that supports the majority of the Somerset notable vascular plant species (for which the CWS has been designated), it is unlikely that changes in air quality would significantly impact Hinkley CWS

20.6.153 However, it is assessed that overall the development would have an adverse effect on the integrity of the CWS, primarily as a result of habitat loss during the construction phase. This is assessed as a high magnitude impact on a medium value receptor, leading to a **major adverse** impact.

20.7 Additional Good Practice Measures

20.7.1 In addition to the good practice measures that are set out in Section 20.6.1, a range of other standard good practice measures, which are not receptor-specific, would be implemented including:

- provision of an Ecological Clerk of Works (ECoW) during all site clearance activities;
- ecological supervision by the ECoW of activities that have been incorporated into the proposed development in order to avoid or reduce adverse impacts on wildlife; and
- provision of an escape route for animals in deep trenches.

20.7.2 Additionally, the following good practice measures would be implemented to minimise disturbance to wintering and passage intertidal birds during the construction phase.

- Erection of construction fencing along the northern boundary of the development site to restrict access by construction workers to the inter-tidal area to the north.
- The jetty and approach road (through the inter-tidal) would be constantly rather than intermittently lit each night during the construction phase. This would be through the use of directional lighting (with cowling), so that only the jetty and immediate works area is lit and light spill into the inter-tidal is limited. This would

allow bird species using the inter-tidal and inshore waters to habituate to the development area rather than being regularly displaced from roosting areas by changes in lighting.

- Movement of personnel outside of the footprint of the works (e.g. on to the inter-tidal rock platforms and open mud in Count Sectors 4 and 5, to the low water mark and west into Count Sector 1) would be restricted.
- Construction of the jetty would be undertaken and, as appropriate, scheduled to avoid or reduce impacts on birds using the inter-tidal areas (e.g. as far as possible piling on the foreshore would be scheduled to take place over the summer period July – September).

20.7.3 Regular monitoring surveys of fauna present within the retained and created habitats during the construction phase would be undertaken as part of the ILMP to ensure that, if legally protected species colonised these habitats, the development would continue to avoid contravention of the legislation relating to protected species. This may require additional, appropriate mitigation measures, which would be devised and employed, in consultation with NE where appropriate.

20.7.4 Environmental impacts and disturbance arising from development site activities would be managed through a range of control measures and monitoring procedures which are outlined in an Environmental Management and Monitoring Plan (EMMP) and detailed in associated Subject-Specific Management Plans (SSMPs).

20.8 Summary of Impacts

20.8.1 **Table 20.15** provides summary information about the impacts that have been assessed.

Table 20.15: Summary of Environmental Measures incorporated into the Scheme and Likely Significance of Residual Impacts

Receptor	Potential Impact	Magnitude	Description	Value/Sensitivity	Significance	Proposed Mitigation/ Best Practices	Residual Impact
Off-site ditches and grazing marsh	Changes in quality of the receptor as a result of the combined impacts of changes in water flows, groundwater and air quality	Very low	Adverse	High	Minor adverse	None required (measures in scheme design)	Minor adverse
Off site wetland areas	Changes in groundwater altering the water level	Very low	Temporary Adverse	Medium	Minor adverse	None required (measures in scheme design)	Minor adverse
Lowland calcareous grassland	Loss of habitat within Hinkley CWS	Medium	Adverse, permanent	Medium	Moderate adverse	None required (measures in scheme design)	Moderate adverse
	Loss of habitat outside of CWS	Medium	Adverse, permanent	Medium	Minor adverse	None required (measures in scheme design)	Minor adverse
	Creation of calcareous grassland	Medium	Permanent Beneficial	Medium	Moderate beneficial	None required (measures in scheme design)	Moderate beneficial
Woodland	Loss of woodland habitat	Medium	Adverse, permanent	Low	Minor adverse	None required (measures in scheme design)	Minor adverse
	Creation of woodland habitat	Medium	Permanent Beneficial	Low	Minor beneficial	None required (measures in scheme design)	Minor beneficial
	Reduction in quality of off-site woodland as a result of changes in air quality	Medium	Adverse	Low	Minor adverse	None required (measures in scheme design)	Minor adverse

Receptor	Potential Impact	Magnitude	Description	Value/Sensitivity	Significance	Proposed Mitigation/ Best Practices	Residual Impact
Hedgerows	Loss of hedgerow habitat	Medium	Adverse, permanent	Low	Minor adverse	None required (measures in scheme design)	Minor adverse
	Creation of hedgerow and edge habitats	Medium	Permanent Beneficial	Low	Minor beneficial	None required (measures in scheme design)	Minor beneficial
Watercourses	Loss of habitat	Medium	Adverse, permanent	Low	Minor adverse	None required (measures in scheme design)	Minor adverse
	Creation of ditch habitat	Very low	Beneficial Permanent	Very Low	Negligible beneficial	None required (measures in scheme design)	Negligible beneficial
Habitat networks	Loss of habitat connectivity	Medium	Temporary Adverse	Low	Minor adverse	None required (measures in scheme design)	Minor adverse
	Creation of habitat corridors	Medium	Permanent Beneficial	Low	Minor beneficial	None required (measures in scheme design)	Minor beneficial
Birds using terrestrial areas	Damage to active nests (contravention of WCA)	No impact	No impact	LP	No impact	None required (measures in scheme design)	No impact
	Reduction in breeding and wintering bird populations as a result of habitat loss	Low	Adverse	Low	Minor adverse	None required (measures in scheme design)	Minor adverse
	Increase in populations caused by increase in habitat area	Low	Beneficial, permanent	Low	Minor beneficial	None required (measures in scheme design)	Minor beneficial

Receptor	Potential Impact	Magnitude	Description	Value/Sensitivity	Significance	Proposed Mitigation/ Best Practices	Residual Impact
	Decline in population caused by disturbance	Very low	Adverse permanent	Low	Negligible adverse	None	Negligible adverse
Lesser whitethroat	Loss of three breeding pairs due to habitat loss	Medium	Adverse	Low	Minor adverse	None	Minor adverse
	Increase in habitat availability due to habitat creation	Low	Permanent Beneficial	Low	Minor beneficial	None required (measures in scheme design)	Minor beneficial
Cetti's warbler	Decline in population caused by disturbance	Low	Adverse	Medium	Minor adverse	None	Minor adverse
Birds using inter-tidal areas	Changes in the survival of waterbirds affecting their conservation status	Very low	Adverse	High	Minor adverse	None required (measures in scheme design)	Minor adverse
Badgers	Harm to badgers and disturbance of active setts	No impact	No impact	LP	No impact	None required (measures in scheme design)	No impact
Barbastelle	Decline in population resulting from loss of commuting and foraging habitats	Very low	Adverse	High	Minor adverse	None required (measures in scheme design)	Minor adverse

Receptor	Potential Impact	Magnitude	Description	Value/Sensitivity	Significance	Proposed Mitigation/ Best Practices	Residual Impact
	Increase in suitable habitat availability	Low	Permanent Beneficial	Medium	Minor beneficial	None required (measures in scheme design)	Minor beneficial
Bat assemblage	Harm to individual bats during roost destruction, thereby contravening legislation in respect to bats	No impact	No impact	LP	No impact	None required (measures in scheme design)	No impact
	Decline in population resulting from loss of roosts, foraging and commuting habitat	Low	Adverse	Medium	Minor adverse	None required (measures in scheme design)	Minor adverse
	Increase in population due to increased habitat availability	Low	Beneficial, permanent	Medium	Minor beneficial	None required (measures in scheme design)	Minor beneficial
Otter	Decline in population due to disturbance and loss of habitat	Very low	Adverse	Low	Negligible adverse	None required (measures in scheme design)	Negligible adverse
	Harm or disturbance to otters, thereby contravening the legislation in relation to otters	No impact	No impact	LP	No impact	None required (measures in scheme design)	No impact
Reptiles	Harm to reptiles	No impact	No impact	LP	No impact	None required (measures in scheme design)	No impact

Receptor	Potential Impact	Magnitude	Description	Value/Sensitivity	Significance	Proposed Mitigation/ Best Practices	Residual Impact
Great crested newts	Harm to individual great crested newts	No impact	No impact	LP	No impact	None required (measures in scheme design)	No impact
Invertebrate assemblage	Decline in populations resulting from loss of habitat	Low	Adverse	Medium	Minor adverse	None required (measures in scheme design)	Minor adverse
	Increase in populations due to increased habitat availability	Low	Beneficial, permanent	Low	Minor beneficial	None required (measures in scheme design)	Minor beneficial
Somerset Notable plant species (on-site)	Loss of individual plants	Medium	Adverse	Low	Minor adverse	None required (measures in scheme design)	Minor adverse
	Increase in local distribution	Low	Beneficial, permanent	Low	Minor beneficial	None required (measures in scheme design)	Minor beneficial
Bridgwater Bay SSSI	Impact on site integrity	Very low	Adverse	High	Minor adverse	None required (measures in scheme design)	Minor adverse
Hinkley CWS	Loss of habitat and impact on site integrity	High	Adverse, permanent	Medium	Major adverse	None required (measures in scheme design)	Major adverse

APPENDICES

21. RADIOLOGICAL

21.1 Introduction

21.1.1 This chapter provides an assessment of the potential radiological impacts during the construction and operation of the proposed development of two UK EPR reactor units and associated facilities (including the Interim Spent Fuel Store (ISFS)) at Hinkley Point C (HPC). Where reasonably practicable, mitigation measures are identified to prevent or reduce any potential adverse impacts that are assessed to be of significance.

21.1.2 The HPC site is adjacent to the existing Hinkley Point A (HPA) and Hinkley Point B (HPB) nuclear licensed sites and lies on the south side of Bridgwater Bay which forms part of the Bristol Channel. The Hinkley Point A and B sites are authorised to discharge strictly limited quantities of liquid and gaseous radioactive effluent into the environment under environmental permits issued by the Environment Agency. The combined impact of HPA, HPB and HPC (collectively referred to as the 'Hinkley Point Sites') is assessed.

21.1.3 This assessment of the potential radiological impact of the development considers the extent to which any radiological contamination, if already present in the soil or groundwater on the HPC site, could result in the radiation exposure of members of the public or workers if mobilised during the construction phase of the proposed development.

21.1.4 This assessment considers the impacts of permitted discharges of radioactive liquid and gaseous effluents and disposal of solid radioactive wastes from routine activities during the operation of the UK EPR reactor units. During operation, the generation of radioactive effluents and wastes will be minimised as far as is reasonably practicable. Some radioactive waste is unavoidably produced by activities associated with operating and maintaining the HPC reactors and associated facilities and, ultimately, from decommissioning the plant. As a result of start-up, operation at power and shutdown for refuelling of each reactor, HPC will produce:

- liquid radioactive discharges;
- gaseous radioactive discharges; and
- solid radioactive waste.

21.1.5 Systems for collecting and treating primary circuit water, fuel pool purification systems, operation of a radioactive laundry facility on-site and washings from plant decontamination result in the generation of liquid radioactive effluents. Techniques are applied to minimise the amount of radioactivity produced. After treatment to reduce as far as is reasonably practicable the radioactive content of the effluent, it is sampled and monitored prior to final discharge via the cooling water outfall. Before entering the sea, the effluent it is subject to considerable dilution with cooling water before entering the sea.

21.1.6 Gaseous radioactive effluents are a by-product of degassing the water in the primary circuit of each reactor. Techniques are used to minimise the amount of radioactive gaseous effluents generated at source. Radioactive gaseous effluents are treated by processing systems to reduce the radioactive content. Radioactive gaseous effluents are also produced from maintenance and operations in building areas containing radioactivity. Ventilation systems filter and reduce the radioactive content of the effluent before discharge to atmosphere through dedicated stacks. The height of the stacks is optimised to ensure the impacts are minimised. Discharges from the stacks are continuously sampled and monitored.

21.1.7 The treatment of gaseous and liquid radioactive effluents and maintenance of radioactive plant and equipment produces solid radioactive waste. This includes spent ion exchange resins and spent filter media. In addition, wastes arise from worn-out components, contaminated protective clothing and tools, rags and waste oil.

21.1.8 Solid radioactive wastes that can be disposed of will be treated, packaged and transported to appropriately permitted facilities. Solid radioactive wastes requiring interim storage prior to disposal will be stored in secure facilities on the HPC site. These facilities have the potential to contribute to the radiation exposure of workers and members of the public in the immediate vicinity of the site. The management of spent fuel and radioactive waste are detailed **Chapter 7** of this volume. This approach is consistent with the Government's policy of "*concentrate and contain*" radioactive wastes in a solid form where practicable (Ref. 21.1).

21.1.9 The assessment of radiological impacts from HPC takes into account:

- the current radiological baseline of the site;
- the maximum proposed permitted radioactive discharges during operation;
- the estimated direct radiation exposure from the storage of spent fuel and radioactive waste, and the transport of radioactive materials to and from the site;
- appropriate risk assessment methodology and criteria;
- mitigation measures in place in the design of the UK EPR; and
- cumulative impacts with HPA and HPB.

21.2 Scope and Objectives of Assessment

21.2.1 The scope of this assessment has been developed through the consideration and application of radiological protection principles to humans and non-human species. It has also been informed by the on-going Generic Design Assessment (GDA) process and the pre-application consultation. The assessment of radiological impacts on human and non-human species arising from the proposed development have been undertaken by adopting the methodologies described in Section 21.4. The existing baseline conditions, against which the likely environmental effects of the development are assessed have been determined through a combination of literature reviews and site surveys, are described in Section 21.5; this section also identifies existing and future receptors.

21.2.2 This chapter summarises the current radiological baseline of the HPC development site, for seawater, groundwater, surface water and soil. Results of the site investigations for Hinkley Point C provide no evidence of elevated levels of anthropogenic (man-made) radioactive contamination on the proposed HPC development site at levels at which they could be considered radioactive as defined by the relevant legislation (see **Chapter 14** of this volume). The radiological risk to workers and members of the public during the construction phase is therefore considered to be negligible. In accordance with the definitions of contaminated land (Ref. 21.2), as the land is not contaminated with radioactivity and harm is not being caused, nor is there significant possibility of such harm being caused, a radiological assessment has not been undertaken for the construction phase.

21.2.3 Potential radiological impacts on humans and non-human species as a result of liquid discharges to the Bristol Channel and gaseous discharges to the atmosphere during operation of HPC are described and assessed in Section 21.6. This chapter also contains an assessment of the annual dose to the most exposed members of the public from direct radiation exposure and an assessment of the radiological impact due to the transport of radioactive waste and fuel from the site.

21.2.4 The cumulative future impacts from the HPA, HPB and HPC sites are assessed. The assessment:

- is based on discharges at current authorised limits for HPA and HPB and uses the limits proposed by EDF Energy for HPC;
- assumes that discharges from HPA and HPB continue for the next 50 years and in parallel with those from the proposed HPC site. This is a conservative assumption, as HPA is planned to be decommissioned in the next 50 years. HPA will be decommissioned into a quiescent state known as 'care and maintenance' and HPB is planned to be shut down, defuelled and, after a period of care and maintenance, decommissioned;
- assumes that the discharges from HPB during decommissioning will not increase above their current permitted limits. Any increases that could arise are likely to be limited in time to address specific activities during the decommissioning programme to reduce the hazard on site to assist in achieving the site's restoration. Any changes to the proposed limits at HPB would be subject to regulatory review and approval;
- is based on the fact that after initial decommissioning activities on site, HPB will enter a period of care and maintenance where there will be only low levels of radioactive discharges. The main period of decommissioning activity on the HPB site will take place after this period of care and maintenance, and this is currently scheduled to take place after HPC has ceased operation; and
- takes account of HPC's proposed plan for decommissioning and site restoration which means that most of the activities on the HPC site (except for the ongoing operation of the ISFS) are expected to be completed before HPB final site clearance work begins. This assumption is in full accord with the UK Strategy for Radioactive Discharges published by DECC in 2009 (Ref. 21.3), which describes the anticipated discharges from the nuclear power sector over time. The UK strategy anticipates a continued and progressive reduction in discharges over time from the existing fleet of power stations as they enter decommissioning. In this light, the assumption of current discharge limits is considered a reasonable and conservative basis for predicting the combined impacts of the stations, particularly so given that the actual discharge levels from HPB are typically less than half of the current limits and often far lower than this for specific groups of radionuclides that are limited in Hinkley Point B's permit.

21.2.5 Discharges from commissioning of HPC will be no greater than those during operation, therefore for the purposes of this assessment it is assumed that the impacts from commissioning will be bounded by those for the operation of HPC.

21.2.6 This assessment does not address radiological impacts during decommissioning of HPC. These impacts will be addressed under a separate Environmental Impact Assessment (EIA) carried out under the specific legislative framework of the Nuclear Reactors (Environmental Impact Assessment for Decommissioning) Regulations 1999 (Ref. 21.4). The radiological impacts to members of the public from decommissioning are expected to be less than those arising during the operational period.

21.2.7 Appropriate mitigation measures aimed at reducing the impact of HPC on humans and non-human species is presented in Section 21.7. The assessment of residual impacts following the implementation of the mitigation measures are identified in Section 21.8.

21.2.8 Separate to the ES, an assessment of the impact on human health from the operation of HPC including radiological impacts is presented in the **Health Impact Assessment** (**HIA**), this also includes details on radioactive environmental monitoring (Ref. 21.63).

21.3 Legislation, Policy and Guidance

21.3.1 This section provides an overview of the principle sources of legislation that apply to radiological protection, starting with international agreements and protocols and then describing how these cascade down through European legislation and are implemented in the United Kingdom. A central requirement of much legislation centres on maintaining doses to members of the public and workers to ensure they are As Low As Reasonably Achievable (ALARA) or As Low As Reasonably Practicable (ALARP). The latter is specifically applied in the UK and requires the employer (or operator of a nuclear facility) to provide systems (engineered means, operational means and protective equipment) to reduce the radiation dose until the cost of implementing those measures (in time, trouble or money) is considered to be grossly disproportionate to the radiation risk averted. Both terms are, however, used in published UK regulatory guidance, ALARP generally by the Office of Nuclear Regulation (ONR) and ALARA by the Environment Agency.

a) International

i. Human Radiological Protection Principles

21.3.2 The framework for radiation protection worldwide is based on the International Atomic Energy Agency (IAEA) Basic Safety Standard (BSS) (Ref. 21.5). Although the IAEA BSS has no legal standing per se, it is used by Member States as a basis for their legal radiological protection systems.

21.3.3 The scientific basis of the BSS (Ref. 21.5) is based on the recommendations of the International Commission on Radiation Protection (ICRP). Its latest published recommendations are ICRP 103 (Ref. 21.6). However, the recommendations in current use within the BSS (Ref. 21.5) are ICRP 60 (Ref. 21.7) owing to the time taken for the recommendations to become legally adopted in those States where they are applied. It is likely that the 2007 recommendations will be in place in the UK once HPC is operational.

21.3.4 Other organisations provide input into the IAEA BSS (Ref. 21.5), including the Food and Agriculture Organisation of the United Nations; the International Labour Organisation; the Nuclear Energy Agency of the Organisation for Economic Co-operation and Development; the Pan American Health Organisation and the World Health Organization.

21.3.5 The principles for radiation protection described in the ICRP 60 (Ref. 21.7) recommendations and developed in the ICRP 103 (Ref. 21.6) recommendations are those of:

- Justification: Any decision that alters the radiation exposure situation should do more good than harm;
- Optimisation of protection: The likelihood of incurring exposures, the number of people involved and the magnitude of their individual doses should all be kept as low as reasonably achievable, taking into account economic and societal factors; and
- Dose limitation: The total dose to any individual from regulated sources in planned exposure situations, other than medical exposure of patients, should not exceed the appropriate limits recommended by the ICRP.

ii. Non-human Radiological Protection

21.3.6 In the past, non-human species have been considered to be adequately protected by the radiation protection systems developed for the protection of humans. For example, ICRP 60 (Ref. 21.7) states that:

> *"The Commission believes that the standard of environmental control needed to protect man to the degree currently thought desirable will ensure that other species are not put at risk. Occasionally individual members of non-human species might be harmed but not to the extent of endangering whole species or creating imbalance between species."*

21.3.7 More lately, ICRP Publication 91 describes a framework for assessing the impact of ionising radiation on non-human species (Ref. 21.8). This was designed to harmonise with the existing ICRP approach to the protection of human beings, but not to set regulatory standards. It sets out a systematic, risk-based approach to assessing radiological impacts on non-human species. This approach has been reiterated in the ICRP 103 (Ref. 21.6) recommendations. Other organisations have developed assessment tools to determine the risk of radiation exposure to non-human species. These are described in later sections of this chapter.

21.3.8 The IAEA (Ref. 21.5) and ICRP (Ref. 21.6 and Ref. 21.7) documents have no legal standing in their own right. However, they do influence the development of the legal system for radiation protection internationally.

iii. Transport

21.3.9 The IAEA formulates regulations for the Safe Transport of Radioactive Materials that give standards of safety for radiation, criticality and thermal hazards to persons, property and the environment due to the transport of radioactive materials. The regulations were first published in 1961 and have been subject to periodic reviews, the latest of which were published in 2009 (Ref. 21.9). The IAEA also publish supporting advisory material and guidance.

21.3.10 In addition, the United Nations publish Recommendations on the Safe Transport of Dangerous Goods known as the "Orange Book" (Ref. 21.10) where goods are divided in to nine classes, Class 7 being radioactive materials. An expert group of the Economic and Social Council of the United Nations issued a resolution that entrusted the task of establishing recommendations for the safe transport of radioactive materials to the IAEA thus ensuring compatibility between IAEA regulations (Ref. 21.9) and the "Orange Book" (Ref. 21.10).

b) European

i. Human Radiological Protection

21.3.11 The Euratom Treaty (Ref. 21.11) came into force on 1st January 1958 and established a European Atomic Energy Community, widely known as Euratom. Under Articles 31 and 32 of the Treaty, the Commission of the European Communities is required to develop radiological protection standards for application in Member States in three formats:

- Regulations - Apply directly to Member States;
- Directives and Decisions of Council - Set goals and standards that must be translated into Member States legislation; and
- Recommendations and communications – These are not mandatory.

21.3.12 Central to these and implementing the IAEA BSS (Ref. 21.5) is Council Directive 96/29/Euratom BSS dated 13th May 1996, which lays down basic safety standards (BSS) for the protection of the health of workers and the general public against the dangers from ionising radiations. This Euratom BSS (Ref. 21.12) also provides the dose coefficients required to calculate doses to members of the public from intakes of radionuclides.

ii. Non-human Radiological Protection

21.3.13 In Europe, there are no regulations for the protection of non-human species from radiation hazards. However, the Habitats and Birds Directives (Ref. 21.13) covers general requirements for the protection of non-human species (plants, animals) and their habitats. The regulators in the UK (the Environment Agency, Scottish Environment Protection Agency and Northern Ireland Environment Agency, 'the Environment Agencies') have a duty to comply with the implementation of these, in particular covering:

- Existing authorisations, consents, licences and permissions or variations for discharges of chemicals; and
- Ensuring that no Agency-authorised activity or permission results in an adverse effect, either directly or indirectly on the integrity of identified European sites (Natura 2000 sites).

iii. Transport

21.3.14 In Europe, the IAEA Regulations for the Safe Transport of Radioactive Materials have been implemented into separate regulations and agreements depending on the mode of transport. These are the “International Regulations Concerning the Carriage of Dangerous Goods by Rail” (RID) (Ref. 21.14); the European agreement for the “International Carriage of Dangerous Goods by Road” (ADR), (Ref. 21.15) and the European agreement for the “International Carriage of Dangerous Goods by Inland Waterways” (ADN) (Ref. 21.16).

c) National

i. Human Radiological Protection

21.3.15 A number of Acts and Regulations govern the exposure or potential exposure of workers and the general public to ionising radiations. The principle ones (that are supported by a wide range of Codes of Practice and guidance) are outlined below, together with their principal requirements.

The Nuclear Installations Act 1965

21.3.16 The Nuclear Installations Act 1965 (amended 1969) (Ref. 21.17) governs nuclear installations in the UK by the issue of site licences by the ONR. The licenses cover a standard set of 36 detailed requirements to be addressed by a site licensee covering, for example, management systems; safety cases, plant safety; construction; plant modifications; operations, accumulation/disposal of radioactive waste and decommissioning.

Ionising Radiations Regulations 1999;

21.3.17 Radiation exposure of the worker and the general public is regulated by the Ionising Radiations Regulations 1999 (IRR99) (Ref. 21.18). These regulations were made under the Health and Safety at Work, etc. Act 1974 and implement the Euratom Basic Safety Directive 96/29/Euratom (Ref. 21.12). The regulations define the dose limits that meet the requirements of the ICRP and also specify that radiation exposures are required to be as low as reasonably practicable (ALARP). The duty is on the employer or operator to ensure that these requirements, amongst others, are complied with. In the case of the general public, the effective dose limit is 1 milli-sievert (mSv) per year from man-made sources.

Environmental Permitting (England and Wales) Regulations 2010

21.3.18 The use, accumulation, storage, disposal and discharge of radioactive materials in the UK was regulated via authorisations issued under the Radioactive Substances Act 1993 (RSA 93) (Ref. 21.19) was recently updated under the Environmental Permitting Regulations 2010 (Ref. 21.20). These require that a person must not operate a regulated facility except under the authorisation of an Environmental Permit issued by the relevant regulatory body. This includes undertaking activities with radioactive substances, where a person uses premises for the purposes of an undertaking and that person disposes of radioactive waste from those premises.

21.3.19 The Environmental Permitting Regulations are regulated by the Environment Agency in England and Wales. It contains the regulatory framework under which permits to make radioactive discharges (gas, solid or liquid) to the environment are issued to operators of premises, including licensed nuclear sites. On a Nuclear Licensed Site, the accumulation of radioactive waste is regulated by ONR under a section of the Nuclear Installations Act (Ref. 21.17), specifically site License Condition 32. A Memorandum of Understanding between the Environment Agency and the ONR ensures a consistent and seamless approach between the control of the radioactive wastes on the sites and any subsequent discharge or disposal.

21.3.20 Permits to discharge radioactive waste are only granted after a rigorous assessment process which includes the requirement for a prospective assessment of the potential radiological impacts on the public. More recently this requirement has been extended to impacts on non-human species. The prospective dose assessments are determined using modelling. This is because it is not practicable to measure exposure directly (or in advance of the operations of the plant) and it is essential to show that any doses received would be below regulatory guidelines and also in accordance with the principles of ALARA (outlined above). Once these and other assessments are completed, there is a period of consultation on the Environment Agency's proposed decision as to whether to grant a permit. The permit will also impose a wide range of requirements to protect the public and environment by the permit holder. After issue, the permits will also be subject to periodic reviews.

21.3.21 Schedule 23, Part 3 of the Environmental Permitting Regulations 2010 (Ref. 21.20) implements the relevant requirements of the Basic Safety Standards (BSS) Directive (Ref. 21.12) which are:

- all public ionising radiation exposures from radioactive waste disposal are kept ALARA;
- the sum of doses arising from such exposures does not exceed the individual public dose limit of 1 mSv per year;
- the individual dose from any single site (referred to as the site constraint) does not exceed 0.5 mSv per year and;
- the individual dose received from any new discharge source (referred to as the source constraint) since the 13 May 2000 does not exceed 0.3 mSv per year.

ii. Radiological Protection Due to Radioactive Transport in the UK

21.3.22 In the UK, the ADR (Ref. 21.15) and RID (Ref. 21.14) have been adopted in the Carriage of Dangerous Goods and the Use of Transportable Pressure Equipment Regulations 2009 (Ref. 21.21). These regulations apply to the transport of radioactive materials by road and rail and detail any UK specific derogations. Dose limitation is enforced through the IRR99 (Ref. 21.18) for both members of the public and workers.

iii. Radiological Protection of Non-human Species in the UK

21.3.23 As for European legislation, in the UK there are no specific regulations for the protection of non-human species from radiation sources. However, UK regulations are in place to enforce the European Directives in the UK, the main one being the Conservation (Natural Habitats) Regulations (Ref. 21.22). These implement the Habitats Directive (1992) (Ref. 21.13) in the UK and require steps to maintain and restore to favourable conservation status the habitats and species of EU Community level interest.

21.4 Methodology

21.4.1 This section describes the methodology that has been adopted for the production of the assessment presented in this chapter.

a) Study Area

21.4.2 The geographical extent of the study area for this assessment includes:

- the HPC development site;
- four habitats of interest in the vicinity of the HPC site; and
- communities within a radius of approximately 20km of the HPC site.

b) Baseline Assessment

21.4.3 The area surrounding HPC has been the subject of monitoring and assessment for many years. This is primarily due to the presence of the adjacent HPA and HPB sites. The methodology for the baseline assessment has been to use these existing data and to complement them with additional surveys. Primary sources of information to develop the baseline are:

- Radioactivity in Food and Environment Reports - these are prepared annually by the Environment Agencies of England, Wales, Scotland and Northern Ireland and the Food Standards Agency. They present the results of a comprehensive programme of monitoring and sampling of foodstuff and the environment. They provide a retrospective assessment of the dose to members of the public based on measurements of external radiation levels local to a site and the concentration of radionuclides measured in various foodstuffs farmed or caught near nuclear sites.
- HIA. This provides a summary of the discharges made from the existing HPA and HPB sites and the measured concentration of radioactivity in the environment around Hinkley Point for the calendar year of 2008.
- A number of surveys undertaken to determine the radiological characteristics of the proposed development site at HPC and the surrounding area.
- Sampling and analysis of sea water, groundwater and surface water.
- Walkover radiation surveys to detect man-made (anthropogenic) radionuclides.
- Surveys and sampling to determine the concentration of radionuclides in the soil and marine sediment.

c) Assessment Methodology

i. Summary of Approach for the Assessment

21.4.4 The following sections describe the methodology adopted for assessing the actual and potential radiological impacts from the proposed HPC development. The Environment Agency has published, along with other relevant parties, guidance on undertaking prospective dose assessments (Ref. 21.46). This document describes a series of principles that should be considered when undertaking dose assessments of future discharges. The approach used in this assessment is consistent with the relevant principles of this guidance. The graded approach adopted is also entirely consistent with the guidance.

21.4.5 There is currently no statutory defined method for carrying out an assessment of radiological impacts for EIA. General guidelines are available in, for example, the Department of the Communities and Local Government (Ref. 21.23), IEMA (2006) (Ref. 21.24) and the Environment Agency (Ref. 21.25). Using these guidelines, the approach adopted in this chapter of the ES is based on the following steps:

- Definition of the current baseline within and around the site.
- Undertake the impact assessment - this covers the radiological impacts from HPC and assessment of these against recognised radiological protection standards for a specified range of human and non-human receptors. The method estimated discharges from two UK EPR reactors and associated facilities on the HPC site based on operating feedback from existing pressurised water reactors (PWR) of similar design and information provided in the Generic Design Assessment (GDA) PCER, the subsequent movement of which through the environment (air, water, soil) and into the food chain is predicted using a range of industry-standard computer models. Non-human species cover a generic range plus some site-specific species selected on the basis of ecological surveys of the site.
- Identify mitigation measures - this includes design and management controls which reduce the potential impact, and are consistent with the legal requirement to use 'Best Available Techniques' (BAT) to ensure the radiological impact of radioactive effluent discharges and waste disposals are minimised and to reduce radiation doses to members of the public and workers to As Low As Reasonably Achievable (ALARA).
- Assess any residual impacts - undertaken following the implementation of any proposed mitigation measures.

ii. Basis for the Assessment

21.4.6 EDF Energy uses risk factors published by the International Commission of Radiological Protection (ICRP), which are the basis of those used by the UN International Atomic Energy Agency, the European Commission and regulatory bodies across the world, including those in the UK. These factors are supported by a wide range of sources covering a range of epidemiological data including Japanese atomic bomb survivors, post-Chernobyl studies, exposures following atmospheric testing of nuclear weapons, nuclear industry workers and their children, those exposed to X-rays for therapeutic or diagnostic reasons, patients and workers exposed to radioisotopes of radium, patients exposed to thorium in the contrast medium Thorotrast, and workers and members of the public exposed to radon and its decay products, among other studies.

21.4.7 The Committee Examining Radiation Risks of Internal Emitters (CERRIE) was an independent committee established by the UK Government because of concern that public perception of the risks from exposure to radiation from radionuclides deposited within the body may be at variance with official scientific advice. The Committee operated between 2001 and 2004. CERRIE's remit was to *"consider present risk models for radiation and health that apply to exposure to radiation from internal radionuclides in the light of recent studies and to identify any further research that may be needed"*. It comprised a broad spectrum of the scientific community and included those critical of ICRP. In its final report (Ref. 21.26) CERRIE concluded that *"it was important that doses and risks from internal emitters should be calculated on the basis of best current information, using central values, and with no bias towards 'conservatism' or 'pessimism' (as is sometimes implied). Introduction of such subjective considerations had no place in an objective assessment.*"

21.4.8 The Committee on Medical Aspects of Radiation in the Environment (COMARE) was established in November 1985 to advise Government and the devolved authorities on the health effects of natural and man-made radiation and to assess the adequacy of the available data and the need for further research. It is an independent group of experts from a variety of relevant disciplines. COMARE endorsed the approach advocated by CERRIE in their 9th report (Ref. 21.27).

21.4.9 CERRIE recognised that, *"amongst the very broad array of natural and man-made radionuclides, some were more hazardous than others*" and that the "degree of hazard did not depend on their origin, but on their individual physical, chemical and radiological properties". Furthermore the Committee "unanimously agreed that radionuclides did not differ intrinsically in their effectiveness depending on whether they were man-made or naturally occurring."

21.4.10 CERRIE investigated a number of biological mechanisms that could affect the current understanding. CERRIE concluded that there was general agreement that induced genomic instability, bystander effects, minisatellite mutation induction and specific issues of microdosimetry were *"real and some may well be an integral part of cellular and tissue response"*. There was, however, substantial disagreement as to whether the available data were sufficient to draw firm conclusions on the implications for radiation-induced health effects. CERRIE members were "*less persuaded*" on the scientific argument that these phenomena challenged the current estimates of low dose effects that were held by a minority of the Committee.

21.4.11 Most members were not persuaded of the existence of the biphasic response or of its generality. Serious shortcomings in the data and the presentation were noted. The majority view of CERRIE was that the evidence available substantially contradicted the second event theory. With respect to hot particles, *"most of the Committee agreed that little information existed which supported enhanced risks from exposures to 'hot' particles, although most studies used relatively high doses."* The majority of the Committee remained unconvinced on the possibility that 'warm' particles presented a high risk, though this could not be ruled out mainly because of the paucity of evidence presented.

21.4.12 Based on the work undertaken by CERRIE and the subsequent review by COMARE, EDF Energy believes it is using the best available information in determining the impacts of its radiological releases.

21.4.13 Furthermore, in response to concerns raised during earlier consultations relating to health risks (especially in light of local studies carried out in the areas purporting to establish a link between radiation exposure resulting from operations at the existing power stations and cancer and other adverse health effects), EDF Energy refers to the information presented by the Health Protection Agency, the South West Public Health Observatory, and the COMARE. The Health Protection Agency provides expert information on the effects of exposure to radiation and has a significant advisory role in the UK – that part of the Health Protection Agency dealing with radiation, the Radiation Protection Division (RPD), was formerly the National Radiological Protection Board (NRPB). The Health Protection Agency is supported by the Advisory Group on Ionising Radiation (AGIR) and its sub-groups, composed of independent experts. The South West Public Health Observatory investigates those factors affecting public health in South West England.

21.4.14 The Health Protection Agency has published information on how the risks to health resulting from exposure to radiation are identified and quantified. Reports reviewing radiation risks are available on their web-site (www.hpa.org.uk) and include HPA-RPD-055 (Ref. 21.28) and HPA-RPD-066 (Ref. 21.29). The extensive scientific evidence on the effects of radiation is assessed by international expert bodies such as the United Nations Scientific Committee on the Effects of Atomic Radiation (UNSCEAR) and the International Agency for Research on Cancer (IARC) of the World Health Organisation (WHO), and various national bodies such as the US National Academies and the Health Protection Agency. These scientific reviews are regularly evaluated by the International Commission on Radiological Protection (ICRP), which makes recommendations in an international context on radiological protection measures, and these recommendations are in turn assessed by national bodies like the HPA for incorporation into national radiological protection legislation.

21.4.15 The Health Protection Agency, among other bodies, has considered in some detail the arguments raised by groups such as Green Audit that radiation risk estimates have been seriously underestimated. Although there are inevitably some uncertainties in radiation risk estimates the Health Protection Agency has concluded that claims that risks have been grossly underestimated are "*unsubstantiated*", and that "*Current estimates are as likely to overestimate as to underestimate the very low risks at very low doses*." On the opposite wing of opinion to groups such as Green Audit are those who believe that low levels of exposure to radiation pose no risk, or are even beneficial. Indeed, a report of the French Academy of Sciences and National Academy of Medicine concluded that the risk models currently underlying radiological protection produce "*a probably marked over-estimation of the risk of doses lower than a few dozen mSv*". The Health Protection Agency in its report HPA-RPD-066 (Ref. 30.29) concludes, "*The system of protection recommended by the ICRP is based on sound scientific analyses published by international bodies*."

21.4.16 In its Tenth Report published in 2005 (Ref. 21.30), COMARE considered the incidence of childhood leukaemia and other childhood cancers in the vicinity of nuclear installations in Great Britain between 1969 and 1993. Based on an assessment of 32,000 cases, it concluded that "*there is no evidence from this very large study that living within 25 km of a nuclear generating site in Britain is associated with an increased risk of childhood cancer*" (Ref. 21.30). COMARE found that the incidence of childhood leukaemia and of other childhood cancers around Hinkley Point was at expected levels.

21.4.17 COMARE has recently published its fourteenth report (Ref. 21.31) which considers information from other international studies, notably the Kinderkrebs in der Umgebung von Kernkraftwerken (KiKK) study (Ref. 21.32 and 21.33) but also including studies from France, Spain, Sweden, Finland, USA, Canada and Japan. In addition, this report reviews the evidence from Great Britain including the extension of the original dataset used in the COMARE Tenth Report to cover the period 1969 to 2004, as well as presenting a new geographical data analysis for British nuclear power plants. COMARE reviewed the evidence from all these studies, often using different methodologies, to determine whether there is an increased risk of childhood leukaemia in the vicinity of nuclear power plants. It has also considered additional factors that may have influenced the results of each study, including the status of cancer registries, the types of reactors used in the various countries, and the associated radionuclide discharges and doses to the general public from these discharges and other sources of exposure. COMARE also investigated the proposal that there is a substantial underestimation of the risk of childhood cancers from the intake of radionuclides and that discharges of tritium and carbon-14 may be responsible, in part, through in-utero exposure of embryos and foetuses; COMARE found that evidence presented to date "*does not support this suggestion*". Based on this exhaustive and systematic review, COMARE reaffirms the advice in its 2005 review (Ref. 21.30) that there is "*no evidence to support the view that there is an increased risk of childhood leukaemia and other cancers in the vicinity of NPPs (nuclear power plants) in Great Britain*".

21.4.18 COMARE has been asked to review various studies conducted by Green Audit and has made a number of critical observations on the methods used in these studies (see www.comare.org.uk/comare_docs.htm#statements), which are self-reported by Green Audit rather than being published in the usual way in mainstream scientific journals that check studies meet the required scientific standards prior to publication. Specifically, COMARE was asked by the Department of Health to undertake a detailed consideration of the Green Audit report entitled 'Cancer in Burnham-on-Sea North – Results of the PCAH [Parents Concerned About Hinkley] Questionnaire' and advise on the implications it may have for the health of people living in Burnham-on-Sea. Green Audit reported the results of a household survey of the Burnham North ward, which claimed that there were excess cancers associated with exposure to man-made radioactivity via the local estuarine sands.

21.4.19 Further work carried out by the South West Cancer Intelligence Service (SWCIS, now part of the South West Public Health Observatory) at the request of Somerset Coast Primary Care Trust showed that the Green Audit study only covered a small sample of the cases arising in the ward. When the complete cancer registration data set for the ward was used, SWICS showed there was no cancer excess other than for leukaemia. When this excess of leukaemia cases was investigated, the majority of the extra cases proved to be chronic lymphocytic leukaemia (CLL), a cancer not considered by previous investigators and reviewers to be associated with exposure to radiation. The report concluded, "*SWCIS has found no evidence of increased risk of cancer linked to radiation in these wards*".

21.4.20 The Green Audit report was intended to address the concerns of the local community, and did indeed involve them; however, COMARE concluded that "*it is so deeply flawed that it cannot provide any reliable information or conclusions about rates of cancer in Burnham*". COMARE also requested that Green Audit withdrew its report "*so as not to cause further unjustified local concern*", stating that:

> *"The community's interest in establishing the facts are not well served by studies with such deficiencies and it is essential that future studies should have the highest possible standards of design".*

21.4.21 COMARE further requested that in future Green Audit should follow normal scientific practice and submit their reports for peer review rather than releasing their reports without such review. COMARE concluded that "*the Green Audit study and report* *provide no reliable information whatsoever about cancer in Burnham-on-Sea*" and "*the SWCIS study conclusively demonstrates that there is no association between cancer incidence in Burnham-on-Sea and its local estuary and Hinkley Point Nuclear Power Station*".

21.4.22 The South West Public Health Observatory has investigated claims by Green Audit of increased levels of infant mortality around Hinkley Point. The Observatory found no evidence of increased infant mortality in the area, and notes that the statistical analysis undertaken by Green Audit "*is misleading and might easily cause unnecessary anxiety to local people*".

21.4.23 The methodology used in this assessment of radiological consequences is based on the internationally recognised and scientifically rigorous approaches currently available, consistent with regulatory guidance and expectation. As with all scientific work the data used is subject to some uncertainty and knowledge continues to grow, primarily focussed on further reducing these uncertainties. EDF Energy supports this work to improve our understanding based on rigorous and diligent scientific endeavour. Work to date, including that undertaken by independent bodies such as COMARE, continues to support the scientific basis for the data used in the assessments presented in support of the DCO application.

iii. Initial Radiological Assessment (IRA) - Impact on Humans

21.4.24 The Environment Agency has provided a methodology for carrying out an Initial Radiological Assessment (IRA). This methodology document consists of two parts: (i) a user report containing an overview of the methodology and tables of "*dose per unit release*" (DPUR[1]) for a large number of radionuclides; and (ii) a methods and input data report.

21.4.25 The purpose and scope of the initial assessment methodology is to provide a system for undertaking an initial cautious prospective assessment of the dose arising from sources of radioactive discharges to the environment and to identify those sources of discharges for which a more detailed assessment should be undertaken. The assessment consists of up to three stages:

- **Stage 1**: the Initial Radiological Assessment (IRA) is carried out using default data as defined in the IRA methodology. If the assessed dose is greater than 20 micro-sieverts per year (µSv y^{-1}) then a Stage 2 Assessment must be completed.
- **Stage 2**: the assessment uses refined data, as defined in the IRA methodology, which is more suited to the site in question. If assessed doses are greater than 20 µSv y^{-1} then a Stage 3 Assessment must also be completed.
- **Stage 3**: this assessment is a separate site-specific assessment.

21.4.26 In the IRA the Environment Agency states that if direct radiation exposure of the public from sources on a site is known to occur, an assessment of direct radiation dose should be made. This is provided in **Appendix 21A,** the HIA and is

[1] In Calculating the DPURs, discharges are assumed to be continuous, uniform routine releases that continue for 50 years. Dose assessment calculations are carried out at the 50th year. It is a modelling assumption that most radionuclides will reach equilibrium in the environment within 50 years.

summarised in this chapter. An assessment of the potential radiation exposure from the transport of radioactive material is also included, although it should be noted that this is not considered as part of the assessment of direct radiation 'shine' from the site.

21.4.27 In order to complete an assessment of dose to members of the public, it is necessary to determine which individuals would be subject to the highest exposure to each of the sources of radioactivity. This is done by modelling potential discharges and environmental concentrations and making assumptions regarding the habits of individuals who may receive a radiation dose as a result of discharges to the environment. For prospective assessments, i.e. those assessments looking at the impact of discharges made in the future, it is usual practice to define a set of characteristics for a hypothetical group of people whose habits would result in them being subject to the highest exposure to any radioactive discharges from the site. The hypothetical group of people following these habits has been termed the 'Critical Group'. Although this term is being replaced with the term 'representative person' the concept is the same. Within this assessment, the phrase 'Critical Group' is used throughout to avoid confusion and ensure consistency with many of the regulatory guidance documents that have been published.

21.4.28 In order to undertake a rigorous and robust assessment a range of 'Candidate Critical Groups' have been identified, that cover different groups of individuals with habits (including food consumption patterns) that might potentially result in them receiving the highest dose due to discharges and direct radiation (excluding transport). The subsequent assessments then allow those who are predicted to receive the highest dose (the Critical Group) to be identified.

21.4.29 Habit data and food intake patterns for the Hinkley Point area that enable the calculation of ingestion dose are taken from reports produced by the Centre for Environment, Fisheries and Aquaculture Science (CEFAS). The survey used in this assessment was conducted around Hinkley Point in 2006 (Ref. 21.34).

21.4.30 The IRA for HPC identifies two local candidate Critical Groups for assessment. These are:

- releases to air - local resident farming family; and
- releases to coastal water - fisherman family.

21.4.31 The criteria for assessment of the impact on humans are individual radiation dose exposures and collective radiation exposure (referred to as collective dose) over a defined population.

Individual Dose Assessment Criteria

21.4.32 The criteria used for determining the magnitude of radiological impacts on individual members of the public are based upon the constraints summarised in **Table 21.1**. In the assessment section the estimated doses from the operation of HPC are also compared against baseline doses resulting from natural background sources.

Table 21.1: UK Dose Limits, Constraints and Guidelines derived from International and European Regulations and Guidance

Dose	Source of the Dose Criterion used in the Assessment
1.0 mSv y^{-1}	1.0 mSv y^{-1} is the UK public dose limit as defined in the Ionising Radiations Regulations 1999 (Ref. 21.18). It includes all contributions from man-made sources but excludes medical or occupational exposure.
0.5 mSv y^{-1}	0.5 mSv y^{-1} is the site dose constraint to a member of the public from discharges from Hinkley Point A, Hinkley Point B and the proposed impacts from HPC. The site constraint is defined in the Environmental Permitting Regulations (England and Wales) 2010 (Ref. 21.20).
0.3 mSv y^{-1}	0.3 mSv y^{-1} is the source dose constraint for members of the public for a single power station and includes the contribution from discharges and direct radiation. The site constraint is defined in the Environmental Permitting Regulations (England and Wales) 2010 (Ref. 21.20).
0.02 mSv y^{-1}	0.02 mSv y^{-1} is the screening value defined by the Environment Agency used in radiological assessments below which further detailed studies are not warranted (Ref. 21.20).
0.01 mSv y^{-1}	0.01 mSv y^{-1} follows statutory guidance issued to the Environment Agency for England & Wales, below which regulators should not seek further reductions in public dose, provided the operator is using best available techniques to limit discharges (Ref. 21.35).

21.4.33 Advice regarding the use of the 10 µSv per year (0.01 mSv per year) criterion is relatively recent. Older documents, and this assessment necessarily makes a comparison to a 20 µSv per year criterion. In either case the risk is broadly comparable (approximately 10^{-6} per year) and BAT continue to apply to the reduction of radioactive discharges and hence radiological impacts.

Collective Dose Assessment Criteria

21.4.34 Collective dose is the sum of doses received by members of a population from all the significant exposure pathways from a given source. It is a means by which the radiological impact on society rather than the individual is assessed. The concept of collective dose can be a useful tool in optimising the level of radiological protection. For instance, it can help to ensure a proper balance between individual and societal protection. Wherever practicable, doses should be distributed in a way which is equitable and a reduction in doses to members of the public may not be justified if it results in a very high individual dose to a worker, or group of workers. ICRP state that collective effective dose is not intended as a tool for epidemiological risk assessment, and it is inappropriate to use it in risk projections. Furthermore, "*the aggregation of very low individual doses over extended time periods is inappropriate, and in particular, the calculation of the number of cancer deaths based on collective effective doses from trivial individual doses should be avoided*." (Ref. 21.6).

21.4.35 There is no legal dose limit on collective doses. However, the International Atomic Energy Agency (IAEA) has presented dose criteria which are considered sufficiently low that doses arising from sources or practices that meet these criteria may be exempted from regulatory control. This criterion, included in UK regulatory guidance, is that the collective dose should be less than about 1 man Sv per year of operation (Ref. 21.46).

21.4.36 The average individual dose within a population can be determined by dividing the collective dose by the number of people exposed. This value, known as a per caput dose, gives an indication of the individual risk across a population. In combination with the estimated Critical Group dose it gives an indication of the potential health risks associated with the operation of a particular facility.

21.4.37 The Environment Agency interim guidance document for the assessment of prospective public doses principles (Ref. 21.46) stated that discharges giving rise to per caput doses of less than a few nano-sieverts (nSv) per year of discharge can be regarded as "*minuscule and the contribution to total doses to individuals will be insignificant*.".

iv. Radiological Impact Assessment - Impact on Non-human Species

21.4.38 Radiological impacts on non-human species, unlike those on humans, have no absolute regulatory or universal 'value'. This is because different non-human species or their habitats have different perceived values depending on, for example, their rarity, sensitivity or location. After estimating the level of significance from the doses there is therefore a need to consider these aspects of the species or habitat affected and draw a final conclusion on the magnitude of the radiological impact and its significance. The methodology for undertaking this evaluation follows the generic methodology set out in **Volume 1**, **Chapter 7** of the ES.

21.4.39 The International Commission for Radiological Protection (ICRP) Publication 91 describes a framework for assessing the impact of ionising radiation on non-human species (Ref. 21.8). It sets out a systematic, risk-based approach, reiterated in the ICRP 103 recommendations (Ref. 21.6).

21.4.40 There are no specific UK regulations for the protection of non-human species from radiation sources. However, UK regulations are in place to enforce the European Directives in the UK, the main one being The Conservation of Habitats and Species Regulations 2010 (formerly the Conservation (Natural Habitats &c. Regulations 1994 (Ref. 21.36). These implement the European Union (EU) Habitats Directive (1992) (Ref. 21.13) in the UK and require steps to maintain and restore to favourable conservation status the habitats and species of EU Community level interest.

21.4.41 In the GDA Process and Information Document (Ref. 21.37) the Environment Agency requires that an assessment of the likely impact of the radioactive discharges on non-human species is carried out. They refer to Environment Agency Research and Development Publication 128 (Ref. 21.38) and make recommendations for carrying out generic radiation dose assessments.

21.4.42 The Environment Agency concluded that it is unlikely there will be any significant effects in populations from ionising radiation at the chronic dose rates listed below:

- 40 µGy h^{-1} for terrestrial animal populations;
- 400 µGy h^{-1} for terrestrial plant populations;
- 400 µGy h^{-1} for populations of freshwater and coastal organisms; and
- 1,000 µGy h^{-1} for populations of organisms in the deep ocean.

21.4.43 The computer modelling code ERICA (Ref. 21.39) and associated radiological effects database FREDERICA (Ref. 21.40) are assessment tools for predicting the dose and effects on non-human species from radioactivity in the environment. The ERICA default screening dose rate is 10 µGy h^{-1}. Therefore assessments falling below this screening level would cause no measurable harm to non-human species and so 10 µGy h^{-1} can be regarded as the bounding dose assessment criteria.

21.4.44 EDF Energy recognises the regulatory screening level of 40 µGy h^{-1} for all non-human species (Ref. 21.41). In undertaking our assessment we have applied the more stringent screening level used in the ERICA tool of 10 µGy h^{-1}.

d) Limitations, Constraints and Assumptions

21.4.45 The UK EPR is a pressurised water reactor drawing on aspects of previous designs but including additional evolutionary features that, among other things, reduce the amount of waste per unit electrical generation. Generation of electricity by all forms of pressurised water reactors unavoidably results in the generation of some liquid and gaseous radioactive effluents and solid radioactive waste. Techniques are applied to minimise the amount of radioactive effluents and waste generated in the first place and then abatement measures are used to further reduce the amount of liquid and gaseous radioactive effluents discharged. Storage buildings on the site are designed and built to minimise direct "shine" of radiation but nevertheless may result in some very small addition to background radiation from natural sources (such as soil or materials used in houses).

21.4.46 More details on the operation of HPC can be found in **Chapter 4** of this volume and more details on the management of solid radioactive waste and spent fuel can be found in **Chapter 7** of this volume. Details on limitations, constraints and assumptions are provided below.

i. Radioactive Liquid Discharges

21.4.47 As noted in Section 21.1, systems collecting and treating primary circuit water, fuel pool purification systems, operation of radioactive laundry facilities and washings from plant decontamination will result in the production of radioactive liquid effluents. There will be a small contribution to the liquid effluent arisings from the ISFS. These liquid effluent arisings from the ISFS are included in the assessment of radiological impacts.

21.4.48 Radioactive liquid effluents associated with HPC will be collected in engineered systems, preventing leakage. These systems segregate the different liquid effluent streams to facilitate their effective management and treatment. Particular types of liquid effluent will, where practicable, be recycled whilst other effluent streams will be processed in an Effluent Treatment Building (ETB). Liquid radioactive effluents will be treated using a variety of techniques including, evaporation, ion exchange and filtration to reduce the radioactive content of the effluents prior to storage in the holding and monitoring tanks.

21.4.49 Liquid radioactive effluents in the holding and monitoring tanks will be discharged into the cooling water discharge system after sampling and monitoring. Each discharge will thus be subject to a considerable dilution with cooling water before entering the sea. **Table 21.2** below shows the estimated maximum annual radioactive content of liquid discharges and the proposed limits from the operation of HPC (Ref. 21.42).

21.4.50 In light of information presented in the GDA draft decision document (Ref. 21.43) prepared by the Environment Agency and further detailed assessment of site and operator specific aspects, the proposed discharge limits have been amended. This has been done in order to envelope the levels foreseeably required at all stages over the operating life of the facility. The assessment is based on the revised levels. Notwithstanding this, the changes have not resulted in a material change in the impacts to the public and non-human species as presented in earlier consultations.

21.4.51 Notably, the following changes have been made:

- EDF Energy has responded to the Environment Agency GDA Public Consultation Document noting that a prospective operator may choose to have a different operating regime that could result in peaked rather than uniform discharges of tritium in liquid discharges. Although this does not affect the total quantity of tritium discharged in a fuel cycle, typically in the order of 18 to 22 months, the 12-month rolling limit required in the RSR environmental permit could be affected. To address this, and consistent with EDF Energy's response to the Environment Agency, this application proposes a limit of 200 TBq for a 12-month rolling period. The increase in the proposed limit of tritium from 150 to 200 TBq does result in a corresponding increase in doses from tritium. In real terms the increase in liquid tritium discharges adds less than 0.001 μSv y^{-1} to the dose to the most exposed age group in the critical group and represents an increase of 0.001% to the most exposed age group for liquid and gaseous discharges. Given the doses are reported to two significant figures, the increases in the doses from the additional tritium discharge are not observed in the final reported results.
- A separate limit for caesium-137 in liquid discharges is proposed for HPC. The proposed limit for caesium-137 is consistent with the data presented in the PCER (Ref. 21.44). The limit has been rounded to two significant figures from 1.89 GBq y^{-1} to 1.9 GBq y^{-1}. This has the affect of increasing the discharge by 0.5%. This has a corresponding increase in doses from caesium-137 through relevant pathways.
- A limit for the aqueous discharge of Iodine-131 is not proposed due to the very low levels of discharge resulting in a corresponding small impact. The limitation of other radionuclides provides a better mechanism for ensuring regulatory compliance. This is consistent with the approach outlined in the Environment Agency GDA Draft Decision Document (Ref. 21.43). The impact of discharges of liquid effluent containing iodine-131 has been included in the dose assessment presented in this chapter.

Table 21.2: Maximum Estimated Activities expected in Liquid Discharges from HPC

Radionuclide	Annual liquid discharge rates GBq y^{-1}	Proposed Limits GBq y^{-1}
H-3	200,000	200,000
C-14	190	190
Ag-110m	1.14	18.1
Mn-54	0.54	
Sb-124	0.98	
Sb-125	1.630	

Radionuclide	Annual liquid discharge rates GBq y^{-1}	Proposed Limits GBq y^{-1}
Te-123m	0.52

Co-58	4.14	
Co-60	6	
Ni-63	1.92	
Cs-134	1.12	
Cs137	1.9	1.9
I-131	0.1	–

21.4.52 Details of the production mechanisms for each of the specific nuclides (such as tritium and carbon-14) and groups of nuclides (such as Co-60 and Co-58, which are activation products, or Cs-137 and I-131, which are fission products) are given in the Chapter 2 of the Radioactive Substances Regulations Environmental Permit Submission for HPC (Ref. 21.45).

21.4.53 The discharge of radioactivity into the marine environment has the potential to cause a number of impacts, and these are assessed in this chapter:

- internal radiation exposure to members of the public from the consumption of local foodstuffs containing radioactivity;
- internal radiation exposure to members of the public from the inhalation of sea spray containing radioactivity from discharges; and
- external radiation exposure to members of the public from radioactivity present in shoreline or estuary sediment.

21.4.54 This approach is consistent with assessing the impact of relevant future exposure pathways as described in the environment agencies Joint Guidance (Ref. 21.46). An assessment on the impact of radiation exposure on non-human species has also been included.

ii. Radioactive Gaseous Discharges

21.4.55 As noted in Section 21.1 of this chapter, gaseous radioactive effluents are primarily a by-product of degassing the water from the primary circuit of each reactor. Gaseous effluent processing systems reduce the radioactive content of this ‘reactor off-gas’ using a combination of radioactive decay and adsorption ‘beds’, high efficiency filters and recombination units.

21.4.56 Gaseous radioactive effluent is also a by-product of maintenance and operations in buildings. These areas are serviced by ventilation systems which filter and reduce the radioactive content of the effluent before discharge to atmosphere through dedicated stacks. The particulate content of the effluent is filtered using high efficiency filters to retain particulate material, and charcoal adsorption filters can also be used to reduce the concentration of radioactive iodine in the discharge.

21.4.57 All gaseous discharges to atmosphere from each main discharge stack will be continuously sampled and monitored. The height of the stack for each UK EPR unit has been optimised for the Hinkley Point site to ensure dispersal under all prevailing local weather conditions.

21.4.58 Discharges of radioactive gaseous effluent may be carried out from ‘minor routes’, such as the stack associated with an ISFS. The radioactive content of these discharges will be significantly lower than discharges from the main stacks. The contribution from these minor routes will be assessed and reported but is considered to be a very small component of the overall discharges and so ‘minor route’ discharges are not considered separately in this assessment but are included in the proposed site limits and therefore the radiological impact assessment.

21.4.59 In light of increased understanding of UK custom and practice and reflecting the position proposed in the Environment Agency GDA Public Consultation Document (Ref. 21.43) a separate limit for the gaseous discharges of iodine-131 is proposed rather than a combined limit for isotopes of iodine. The proposed limit is based on a rounded value of 0.4 GBq y^{-1}. This change represents a slight uplift in the values used in the dose assessment, however, the impact of this increase in dose on the most exposed age group in the critical group is 0.027 μSv y^{-1} and represents less than 0.6% of the critical group dose. Given the doses are reported to 2 significant figures, the increase in the doses from the rounding of the gaseous iodine-131 limit is not observed in the final reported results. A separate limit on iodine-131 is proposed which is consistent with the input data used in the dose assessment presented in this chapter. The dose assessment includes iodine-131 and iodine-133, although the latter is not included in the proposed limit.

21.4.60 **Table 21.3** below shows the estimated maximum annual radioactive content of gaseous discharges from the operation of HPC (Ref. 21.47) and these have been used in this assessment.

Table 21.3: Maximum Estimated Activities expected in Gaseous Discharges from HPC

Radionuclide	Annual gaseous discharge rates GBq y^{-1}	Proposed Limits GBq y^{-1}
H-3	6,000	6,000
C-14	1,400	1,400
Kr-85	6,260	45,000
Xe-133	28,400	
Xe-135	8,920	
Ar-41	1,306	
Xe-131m	135	
I-131	0.364	0.4
I-133	0.436	–
Co-58	0.0612	0.24
Co-60	0.0722	
Cs-134	0.0562	
Cs-137	0.0504	

21.4.61 Details of the production mechanisms for each of the specific nuclides (such as tritium and carbon-14) and groups of nuclides are given in the Chapter 2 of the HPC Radioactive Substances Regulations Environmental Permit Submission (Ref. 21.45).

21.4.62 The discharge of radioactivity into the atmosphere has the potential to cause a number of impacts, and these are assessed in this chapter:

- internal radiation exposure to members of the public from the consumption of local foodstuffs containing radioactivity;
- internal radiation exposure to members of the public from the inhalation of radioactivity in a gaseous discharge plume; and
- external radiation exposure to members of the public from radioactivity present in the terrestrial environment.

21.4.63 This approach is consistent with assessing the impact of relevant future exposure pathways as described in the environment agencies Joint Guidance (Ref. 21.46). An assessment on the impact of radiation exposure on non-human species has also been included.

iii. Sources of Direct Radiation Exposure

21.4.64 Direct exposure to radiation from the reactor buildings for members of the public will be negligible as the concrete shielding present will ensure contact radiation dose rates for the buildings are very low. Thus, direct radiation from the reactor buildings will not be measurable at the site boundary. The waste stores will be designed to limit escape of radiation shine but that, nevertheless, small amounts of shine will contribute a small additional component to the normal radiation background around the site. In the UK, assessments of direct radiation are usually carried out by monitoring radiation levels at the site boundary and at the nearest habitation.

21.4.65 It will also be necessary to transport radioactive materials to and from the HPC site. These materials may include radioactive sources for non-destructive testing and examinations, fresh nuclear fuel, radioactive equipment or plant components requiring off-site examination or maintenance, and radioactive waste. HPC will have an ISFS but the transport of spent nuclear fuel is conservatively included in the assessment. Members of the public may be exposed to direct radiation whilst the material is being transported. Although not included as part of the 'direct radiation' component for the purposes of assessing the impact on the most exposed person in the vicinity of Hinkley Point, this radiological impact is assessed against the relevant criteria.

21.5 Baseline Environmental Characteristics

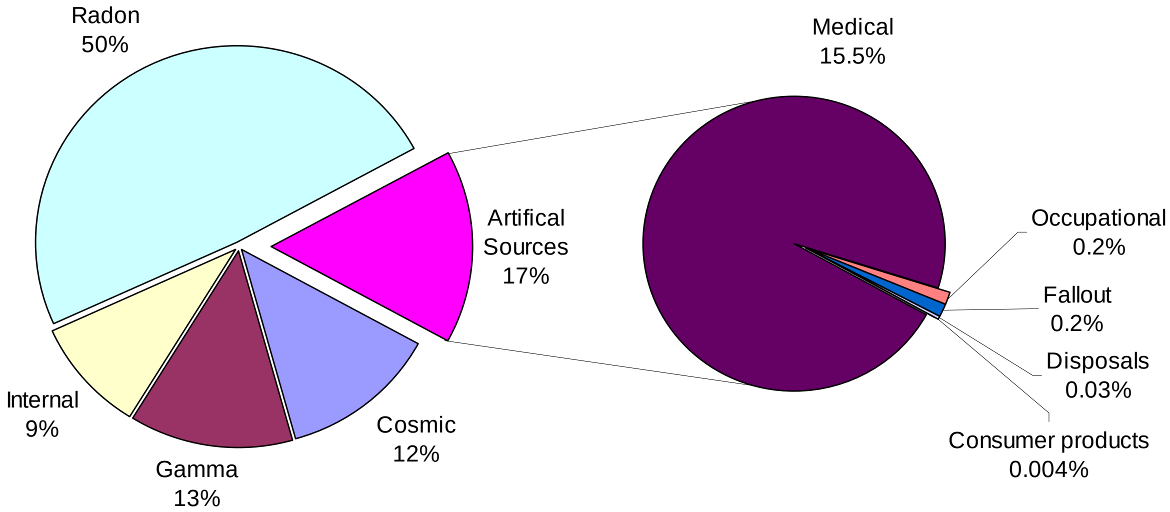
a) Sources of Ionising Radiation Exposure in the United Kingdom

21.5.1 Radiation describes any process in which energy travels through a medium (other than by conduction) or through space. There are two broad classes of radiation: ionising radiation from sources such as radioactive materials or x-ray machines and which causes ionisation in material it interacts with and non-ionising radiation (such as radio waves or infrared and visible light) originating from other sources. For the purposes of this assessment, only ionising radiation is considered.

21.5.2 All individuals in the UK are exposed to ionising radiation to a varying degree from natural and anthropogenic sources. Natural sources include cosmic radiation from the sun and stars, gamma radiation from soil and rocks, internal exposure from naturally occurring radioactive material (such as potassium-40) in food and within the body, and exposure to the radioactive gas radon. Anthropogenic sources include medical exposure to radiation (such as X-rays), occupational exposure for persons working with ionising radiation, fallout from the testing of nuclear weapons, exposure to products containing radioactivity (such as smoke detectors) and discharges from the nuclear industry.

21.5.3 The 2005 review of ionising radiation in the UK by the Health Protection Agency (Ref. 21.48) evaluated the magnitude of exposure of individuals in the UK to ionising radiation. The average radiation exposure for individuals in the UK has been stated to be 2,700 µSv y^{-1}, most of which is from natural sources with the majority of the man-made component being due to medical sources. The contribution from radioactive discharges from the nuclear industry is stated to be 0.9 µSv y^{-1}, i.e. less than 0.1% of total radiation exposure (Ref. 21.48). The breakdown of the UK annual average dose from Reference 21.48 is illustrated in Plate 21.1.

Plate 21.1: Annual Average Exposure of the UK Population from all Sources of Ionising Radiation



Taken from Health Protection Agency (2005) Ionising Radiation Exposure of UK Population: 2005 review (HPA-RPD-001).

21.5.4 The dose limit for members of the public in the UK is 1 mSv per year (or 1,000 µSv y^{-1}) (Ref. 21.18), this is consistent with international guidance and legislation. With the exception of medical exposures, no activity is permitted to give rise to discharges which would cause this limit to be exceeded. The dose limit applies to the sum of current and past licensed activities.

21.5.5 In addition to dose limits, the environmental legislation (Ref. 21.20) also applies dose constraints, these are levels at which doses from routine operations should not exceed. A source dose constraint ensures that an individual does not receive a dose from any new discharge source that exceeds 300 µSv y^{-1}. A site constraint ensures that an individual does not receive a dose from a single site that exceeds 500 µSv y^{-1}.

21.5.6 For the purposes of this assessment HPC is considered to be a single source and the contribution from HPA, plus HPB and HPC, is considered to be a single site (the Hinkley Point Sites) for the purposes of assessment against the site constraint.

b) Existing Monitoring Data from Around Hinkley Point

21.5.7 Since 1995 the environment agencies of the United Kingdom and Northern Ireland and the Foods Standards Agency have undertaken independent radiological monitoring of food and environmental samples in the UK, especially near nuclear sites. The results are produced in an annual Radioactivity in Food and the Environment (RIFE) report (Ref. 21.49/50/51/52/53/54/55/56/57/58/59/60/61/62) and are available to the public. The RIFE reports also present retrospective dose assessments based on the measured activity concentrations in various foodstuffs farmed or caught locally to nuclear sites. In addition, dose rates recorded from the environment and local occupancy and habit data (such as the consumption of local foodstuffs) are used to determine the level of exposure.

21.5.8 This monitoring undertaken by the environment agencies and Foods Standards Agency is separate and in addition to the monitoring carried out by the site operators as part of their obligations under their discharge permits.

21.5.9 Summaries of radioactive liquid and gaseous discharges made from existing sites in the Hinkley Point region and of measured concentrations of radioactivity in the environment around Hinkley Point for the calendar year 2008 are provided in the HIA (Ref. 21.63). The annual radiation dose to the most exposed person (also referred to as the Critical Group, or representative person) is reported in the RIFE report for 2008 (Ref. 21.62) to be 37 µSv y^{-1} for seafood consumers and 6 µSv y^{-1} for terrestrial foodstuff consumers. An assessed hypothetical total annual dose integrating across all pathways and including the contribution from direct radiation from proximity to the existing HPA and HPB sites is reported to be 45 µSv y^{-1}.

21.5.10 Recent RIFE reports (RIFE-8 to RIFE-14 inclusive (Ref. 21.49 to 21.62) include an extensive list of nuclides and measurement types. The reports show that:

- the only nuclide consistently detected in drinking water and surface water is naturally occurring potassium-40;
- a consistent positive result for gross beta, considered to be the presence of the naturally occurring radionuclide potassium-40, is measured in sea water;
- mud and sediment taken from 1.6km from the discharge pipeline, from Watchet and from Stolford shows consistent positive results for caesium-134 and caesium-137. The RIFE reports suggest that this represents the combined effect of releases from HPA and HPB, plus other nuclear establishments, along with historic contributions from Sellafield and fallout from historical weapons testing and Chernobyl. This is consistent with the results of site investigation carried out at the HPC proposed development site (see Section d), below); and
- external gamma radiation dose rate measurements were barely above the limits of detection (for the survey equipment used).

21.5.11 From the review of the RIFE reports, monitoring of food and the environment in the vicinity of Hinkley Point indicates that current radiation doses to the most exposed members of the public from radioactive discharges and direct radiation shine are a small fraction (less than 5%) of the 1 mSv y^{-1} public dose limit.

c) Surveys of the HPC Proposed Development Site

21.5.12 Radiation and radioactive contamination surveys of the proposed development site at Hinkley Point have been carried out as detailed in **Chapter 4** of this volume and are summarised in **Appendix 21A**.

21.5.13 Soil monitoring surveys for radioactive contamination were carried out for the Built Development Area West (BDAW) in July and October 2008 and for the Built Development Area East (BDAE) and Southern Construction Phase Area (SCPA) commencing October 2009.

21.5.14 The results from the BDAW show that there is no evidence of significant contamination with anthropogenic radionuclides. The concentration of radioactivity in soils was similar to background levels found throughout the UK, with caesium-137 radioactivity consistent with atmospheric fallout from the Chernobyl accident in 1986. Other radionuclides, such as tritium and carbon-14 which can be present both naturally and from man-made sources were detected in some samples at levels consistent with anticipated background levels. Some naturally occurring radionuclides, such as protactinium-234m and radium-226, were detected in the samples. However, no samples were found to be “radioactive” as defined by the Environmental Permitting (England and Wales) Regulations 2010 (Ref. 21.20).

21.5.15 A walkover survey on the BDAE and the SCPA was completed in October 2009. In general, the walkover survey recorded measurements that were low and at levels either at or below anticipated background levels for the area. Enhanced readings above general background were found in the north-east corner of the BDAE. These elevated readings are thought to be due to external radiation originating from a building on the HPA site used to store radioactive waste rather than any radioactivity in the ground.

21.5.16 During the course of these surveys two locations were identified with elevated readings. Further samples were collected from these locations and submitted for additional testing. The results for these samples provided no evidence of contamination by anthropogenic radionuclides. A small area of the BDAE, which was the site of a former sewage works, was found to contain elevated levels of natural uranium, which was associated with granitic material observed in this area. The levels found were below the limit specified in The Radioactive Substances (Phosphatic Substances, Rare Earths etc.) Exemption Order (Statutory Instrument, 1962, No.2648) and would not be of regulatory concern. The remaining results for the BDAE and the SCPA were entirely consistent with those found and reported for the BDAW.

21.5.17 Direct radiation measurements performed and presented in **Appendix 21A** show the contribution from the background levels of radioactivity as well as any contribution from the neighbouring facilities. These levels are comparable with UK national average values.

21.5.18 The radiological risk to workers and members of the public during the construction phase can be regarded as very low and further assessment is not warranted.

21.5.19 In addition, analysis for anthropogenic radionuclides in sea water, groundwater and surface water samples was undertaken, the results of which were as follows:

- the sea water samples monitoring showed levels to be at, or very close to, the limit of detection;
- the groundwater samples monitoring showed the presence of tritium in some samples but at levels considerably lower than the Drinking Water Inspectorate's (DWI) screening value (100 Bq l^{-1}). No other artificial radionuclides were measurable in the samples; and
- the surface water analysis showed some very low levels of radioactivity in some samples (all tritium and gross beta analyses were below the DWI screening levels; one result for gross alpha results (0.15 Bq l^{-1}) was recorded above the DWI screening level but this was well below World Health Organisation screening level (0.5 Bq l^{-1}). This result was not repeated in subsequent sampling campaigns.

Therefore all of the results would not present a hazard to human and non-human health or be of regulatory concern.

21.5.20 Surveys of soil and groundwater on the proposed development site at HPC show that there is no evidence of elevated anthropogenic radioactive contamination being present. Harm as defined in the relevant statutory guidance (Ref. 21.2) is not being caused, nor is there a significant possibility of such harm being caused. The radiological risk to workers and members of the public during the construction phase can be regarded as very low and further assessment is not warranted.

21.6 Assessment of Impacts

a) Operational Impacts

21.6.1 For the reasons stated in Section 12.2 separate radiological assessments have not been undertaken for the construction or commissioning phases of HPC.

i. Generic Design Assessment (GDA)

21.6.2 A Stage 1 assessment was undertaken as part of the Pre-Construction Environmental Assessment (Ref. 21.44), submitted for the Generic Design Assessment (GDA) carried out by the Health and Safety Executive (HSE) and the Environment Agency to assist the licensing process. The PCSR report is based on a single unit UK EPR. As described in **Appendix 21A**:

- A Stage 1 assessment is intentionally highly conservative.
- Estimated doses to the Critical Group exceeded 20 µSv y^{-1} and therefore a Stage 2 assessment was appropriate.

21.6.3 A Stage 2 assessment was completed for a single UK EPR unit as part of the PCER (Ref. 21.44). As noted in **Appendix 21A**:

- Conservative assumptions were made regarding an effective stack height and a local marine compartment volumetric exchange rate.
- All other assumptions and parameters remained unchanged from the Stage 1 assessment.

- It is appropriate for a Stage 2 assessment to sum the doses from all release routes to estimate a potential Critical Group dose.
- Estimated doses to the Critical Group exceeded 20 µSv y^{-1} and therefore a Stage 3 assessment was appropriate.

21.6.4 A Stage 3 assessment was completed for a single UK EPR as part of the PCER (Ref. 21.44). As described in **Appendix 21A**:

- The 'site' was derived from conservative characteristics of the environment around existing UK nuclear sites, with respect to dispersion of liquid and gaseous discharges, habitation distances from sites and weather conditions.
- A standard assessment tool (PC-CREAM 98) (Ref. 21.64) was used to calculate individual doses from routine releases.
- Three scenarios (a 'farming family', a 'fishing family' and a 'local resident') were assessed in order to determine those representative members of the public subject to the highest exposures (i.e. the Critical Group).
- Direct radiation doses were assessed to be very low (less than 5 µSv y^{-1}).
- Estimated total doses to the Critical Group were 25.8 µSv y^{-1}, exceeding 20 µSv y^{-1}, and therefore a site-specific radiological impact assessment was appropriate.

ii. Hinkley Point Site-specific Assessment for Impacts on Humans

Introduction to the Site-specific Assessment

21.6.5 **Appendix 21A** outlines a methodology for the assessment of the impact on the human population around HPC. These methods were used to assess doses from HPA and HPB in order to determine the cumulative dose from the Hinkley Point Sites, and the methods were consistent with the general methods developed for the GDA and the relevant Environment Agency guidance (Ref. 21.46). The methods were confirmed in the **HIA** (Ref. 21.63) that they represented reasonable approaches and are based on widespread methods adopted within the UK. HPA and HPB and the proposed HPC (the Hinkley Point Sites) are assumed to discharge into the same local marine environment and the local terrestrial environment and give rise to exposures via the same exposure pathways.

21.6.6 Assessment methodologies were developed (see **Appendix 21A**) to assess the impacts from a number of scenarios. These are for:

- the assessment of individual doses as a result of continuous releases of gaseous and liquid discharges to the environment;
- the assessment of direct radiation dose exposures;
- the assessment of radiation exposure from transport;
- the assessment of collective doses;
- the assessment of individual doses as a result of short-term releases to atmosphere;
- the assessment of individual doses as a result of build-up of radioactive materials in the environment; and

- annual dose assessment of the Critical Group.

21.6.7 The assessments were based upon the proposed limits of discharges to the environment, as summarised in Section 21.3 of this chapter and site specific characteristics relating to the two UK EPR units and associated facilities (discharge, dispersion and dose uptake pathways). The proposed limits for discharge values used in the assessment are derived from operational feedback from current PWRs (of similar design to the UK EPR) and are appropriate for carrying out a site specific radiological assessment for HPC. Site characteristics detailed in **Appendix 21A** are based on best available information.

The Assessment of Individual Doses from Continuous Releases

21.6.8 Two Candidate Critical Groups (the 'farming family' and the 'fishing family') were used as the basis for determining the Critical Group from all HPC discharges. The group subject to the highest exposure would then be considered the Critical Group.

21.6.9 It was conservatively assumed that a farming family living near the coast could be exposed to gaseous discharges through the terrestrial pathways of:

- ingestion of contaminated foodstuffs (green vegetables, root vegetables, domestic fruit and wild/free fruits, dairy products and meat) grown or raised on the farm; and
- inhalation of, and external exposure to, the plume and deposited radionuclides.

21.6.10 The two foodstuffs contributing the highest fraction of dose were assumed to be consumed at the 'critical' (maximum) rates in the appropriate CEFAS reports and all other foodstuffs were assumed to be consumed at average rates. This is known as the "Top Two" method. It ensures a realistically conservative estimate of ingestion dose for prospective assessments and is consistent with the GDA study method but applies local habit data (Ref. 21.34) rather than generic national data for a more realistic assessment.

21.6.11 It was also conservatively assumed the farming family could be exposed to marine discharges through the marine pathways of ingestion of locally sourced seafoods, external exposure to beach sediments and inhalation of sea spray when spending recreational time on a local beach. Average consumption rates of fish and shell fish and recreational activity times were taken from the CEFAS (Ref. 21.34) study to determine exposures. This Candidate Critical Group is therefore referred to as the 'farming family with marine and gaseous exposure'.

21.6.12 As detailed in **Appendix 21A** it is assumed that a fishing family could be exposed to liquid discharges through:

- contact with contaminated fishing gear and beach sediments;
- from ingestion of seafoods; and
- inhalation of seaspray.

21.6.13 This fishing family could live locally and would therefore be exposed to the same terrestrial pathways as the 'farming family'. It was conservatively assumed that this family might live at the same location as the 'farming family with marine and gaseous exposures' and thus would also be exposed to the highest airborne and deposited activity concentrations from gaseous discharges from HPC. It was also assumed that they would consume locally grown produce at average rates. They are therefore referred to as the 'fishing family with marine and gaseous exposure'.

21.6.14 In each case, individual doses were calculated for three age groups: adult, 10 year old child and one year old infant. The calculated doses are presented in **Table 21.4** below.

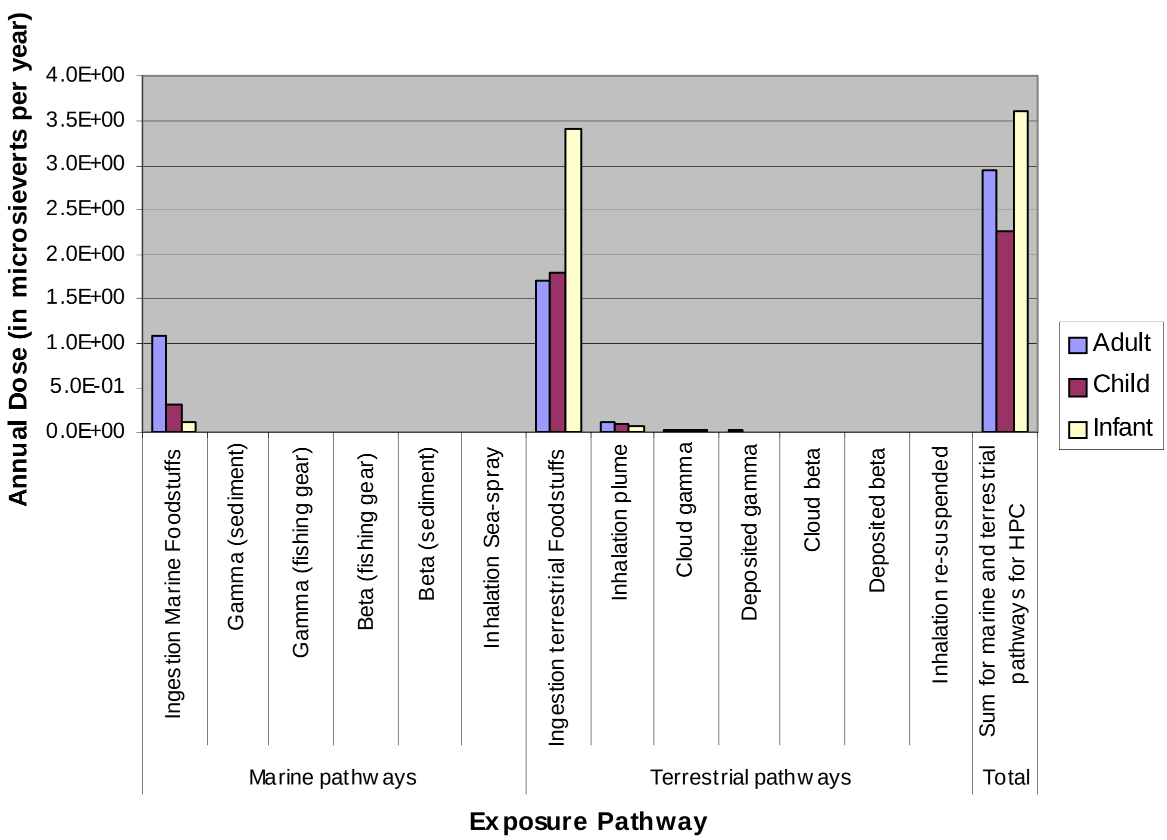
Table 21.4: Candidate Critical Group Doses from HPC Discharges

Doses in Microsieverts per Year (µSv y^{-1})			
	Adult	**Child**	**Infant**
Farming Family			
Terrestrial pathways	2.4	2.2	4.4
Marine pathways	0.3	0.3	0.1
Total	**2.7**	**2.5**	**4.5**
Fishing Family			
Terrestrial pathways	1.9	2.0	3.5
Marine pathways	1.1	0.3	0.1
Total	**3.0**	**2.3**	**3.6**

21.6.15 The 'farming family with marine and gaseous exposure' represents the Candidate Critical Group who may be exposed to gaseous discharges from the proposed HPC reactors and via marine pathways. As noted above detailed in **Appendix 21A**, ingestion rates, inhalation rates and occupancy factors were assigned for members of the family. It was assumed that these individuals do not participate in fishing and therefore are not exposed through the handling of fishing gear exposure pathway.

21.6.16 The predicted doses to the 'farming family with marine and gaseous exposure' Candidate Critical Group were calculated to be 2.7, 2.5 and 4.5 µSv y^{-1} for adults, children and infants respectively. **Plate 21.2** presents the breakdown of the doses by exposure pathway for each age group of the Candidate Critical Group. The dose of 4.5 µSv y^{-1} is the highest dose estimated due to radioactive liquid and gaseous discharges from the HPC site. The estimated doses are dominated by contributions from discharges of C-14, tritium and, for the infants, iodine-131. Carbon-14 and tritium account for about 90% and 3% respectively of the total dose received by the Candidate Critical Group.

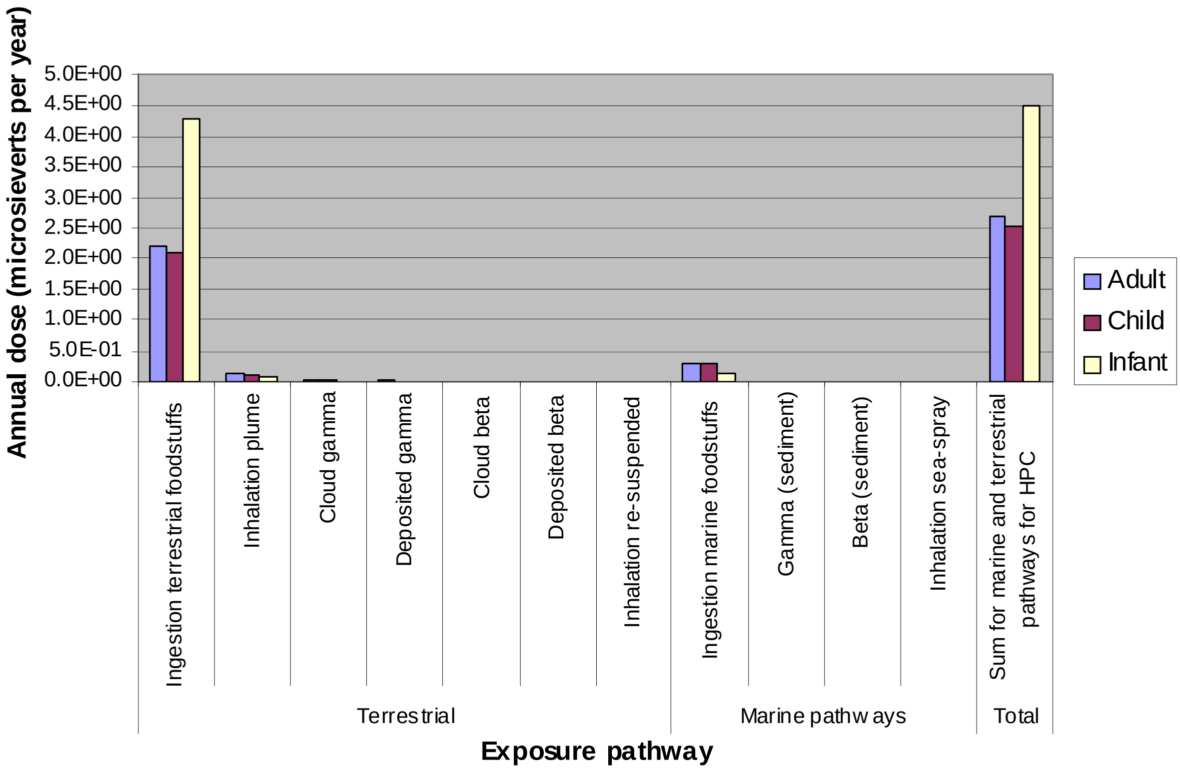
Plate 21.2: Breakdown of Dose by Pathway to the Fishing Family with Marine and Gaseous Exposure



21.6.17 The 'fishing family with marine and gaseous exposure' represents the Candidate Critical Group who may be exposed to radiation and radioactivity from discharges into the marine environment and via terrestrial pathways. The radiation exposure to the same three age groups as the 'farming family with marine and gaseous exposure' was determined, using assigned ingestion rates, inhalation rates and occupancy factors. There are some foodstuffs (marine plants and algae) consumed by members of the public in the CEFAS survey (Ref. 21.34) that have not been included in the current assessment, because they are only consumed in small quantities by very few individuals.

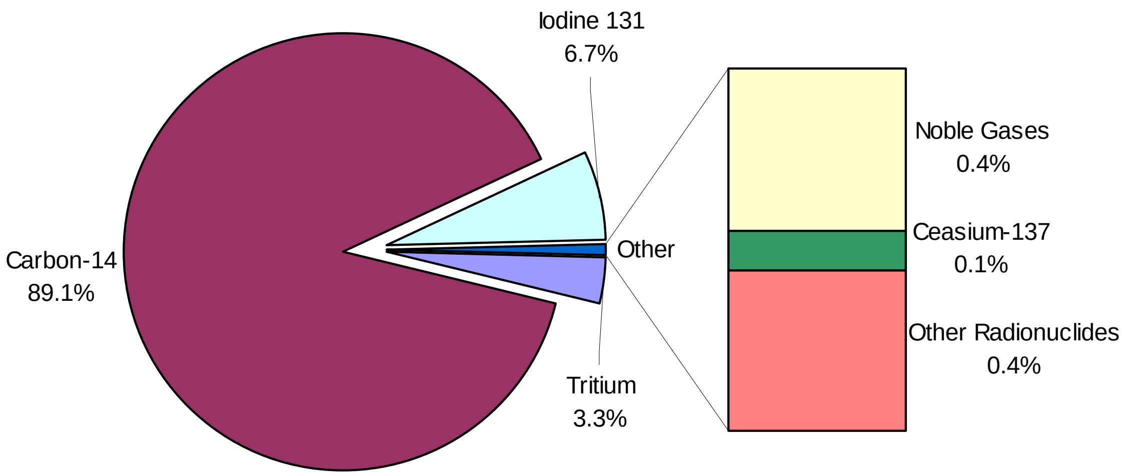
21.6.18 The predicted doses to the 'fishing family with marine and gaseous exposure' Candidate Critical Group were calculated to be 3.0, 2.3 and 3.6 µSv y^{-1} for the adult, child and infant members respectively. **Plate 21.3** presents the breakdown of the doses by exposure pathway for each age group of the Candidate Critical Group. The estimated doses are dominated by contributions from discharges of C-14, tritium and, for the infants, iodine-131. Carbon-14 and tritium account for about 90% and 3% respectively of the total dose received by the Candidate Critical Group.

Plate 21.3: Breakdown of Dose by Pathway to the Farming Family with Marine and Gaseous Exposure



21.6.19 The highest doses due to discharges from HPC are those to infants in the ‘farming family with marine and gaseous exposure’. This is therefore the Critical Group for all radioactive discharges to the environment from HPC. **Plate 21.4** illustrates the breakdown of the critical group dose by radionuclide. The assessed dose of 4.5 µSv y^{-1} can be regarded as low.

Plate 21.4: Breakdown of Dose by Radionuclide to Infant Age Group for the Farming Family with Marine and Gaseous Exposure Critical Group for HPC



The Assessment of Direct Radiation Exposure from HPC

21.6.20 As described in Section 12.3 of this chapter direct exposure to radiation (also referred to as radiation ‘shine’) from the reactor buildings for members of the public will be negligible, as the thickness of concrete shielding present in the building structures will ensure external contact dose rates are low and would be difficult to measure at the site boundary.

21.6.21 Direct radiation emanating from the Interim Storage Facility for Intermediate Level Waste (ILW) store and the ISFS will contribute to radiation exposure for a member of the public. In the UK, assessments of direct radiation are usually carried out by monitoring radiation levels at the site boundary and at the nearest habitation. Estimates of direct radiation exposure from HPA and HPB to local residents living within 1km of the existing Hinkley Point Site, including contributions from discharges, were 4 µSv y^{-1} in 2007 (Ref. 21.61).

21.6.22 **Appendix 21A** outlines the conservative assumptions made during the assessment of potential direct radiation dose from HPC. A radiation dose rate appropriate for an 'undesignated' building was assumed to be at a distance of 1 metre from the outer wall of the building. For the purposes of this assessment, an ILW and a Spent Fuel building were assumed to be located at a distance of approximately 40m from the coastal footpath that runs parallel to the northern boundary of the Hinkley Point Site. The dose rate at this location was calculated for several exposure scenarios:

- A reasonably conservative scenario where a person walks along the nearby coastal path over a distance of about 800m daily, spending about 20 minutes walking past the site and would receive an additional dose of 1.5 µSv y^{-1}.
- A local resident spending the whole year in close proximity to the HPC site, at a distance of ~1.3km, but also taking into account the reduced dose rate while indoors (due to shielding effects of the walls of the dwelling), was calculated to receive an additional annual dose of 0.0014 µSv y^{-1}.

21.6.23 A summary of the doses from direct radiation from the proposed HPC site is shown in **Table 21.5** below:

Table 21.5: A summary of the doses to the public due to direct radiation from an Interim Facility for Spent Fuel and ILW on the HPC site.

Scenario	Estimated Dose µSv y^{-1}
Coastal path	1.5
Closest dwelling	0.0014

21.6.24 The data in **Table 21.5** shows that the impacts on these receptors are 'very low', especially considering that the assumptions used in the assessment are conservative and actual doses are expected to be less than those estimated.

21.6.25 The dose rate due to direct radiation from these facilities on the HPC site at the more distant location assumed for the 'farming' or 'fishing' families with exposure from HPC liquid and gaseous discharges is estimated to be smaller than for the dwelling above and so need not be considered in assessing the dose from the HPC site to these two Candidate Critical Groups.

The Assessment of Direct Radiation Exposure from Transport

21.6.26 An assessment of the radiological consequences of the transport of radioactive materials to and from HPC was carried out and considered the transport of the following radioactive materials:

- radiography sources (used for non-destructive testing (NDT) of plant and equipment);
- spent fuel assemblies;
- new uranium fuel assemblies; and
- low-level radioactive waste (LLW).

21.6.27 An assessment of radiation doses arising from spent fuel transport from the HPC site was included in the assessment however this is a conservative assumption, since the ISFS is expected to be on HPC pending disposal at the UK Geological Disposal Facility. The transport of ILW was excluded from the assessment, since interim storage is assumed to be on site.

21.6.28 The assumptions of the number of radioactive material consignments, the surface radiation dose rates, the proximity to dwellings in the Hinkley Point area during transport are all described in **Appendix 21A** The highest annual dose received by a member of the public living adjacent to the Bridgwater railhead and exposed to spent fuel flasks was estimated to be 2 μSv y^{-1}. Members of the public standing at a bus stop could receive doses of up to 1.8 μSv y^{-1} should they be exposed to all four material scenarios (NDT sources, spent fuel, new fuel, LLW). Members of the public living in a house close to a road have been conservatively estimated to receive doses of up to 1.67 μSv y^{-1} from transports of new fuel.

21.6.29 Assuming that spent fuel will be stored on the HPC site, annual assessed doses would be reduced to a maximum of 1.67 μSv y^{-1}. These assessed doses are well below the relevant dose limit for members of the public of 1 mSv y^{-1} from man made sources (specified in the Ionising Radiations Regulations (Ref. 21.18)) and which is applicable to exposure due to transport operations. Furthermore, the scenarios considered are conservative and the assessed doses are unlikely to be realised in practice.

The Assessment of Radiation Dose exposure from Gaseous and Liquid Discharges and Direct Radiation

21.6.30 **Table 21.6** summarises the prospective doses to members of the two Candidate Critical Groups due to discharges and direct radiation from HPC. It is noted that the small dose from direct radiation would not add measurably to the doses assessed from discharges only.

Table 21.6: Summary of Prospective Doses to Candidate Critical Groups from Liquid and Gaseous Radioactive Discharges and Direct Radiation from HPC

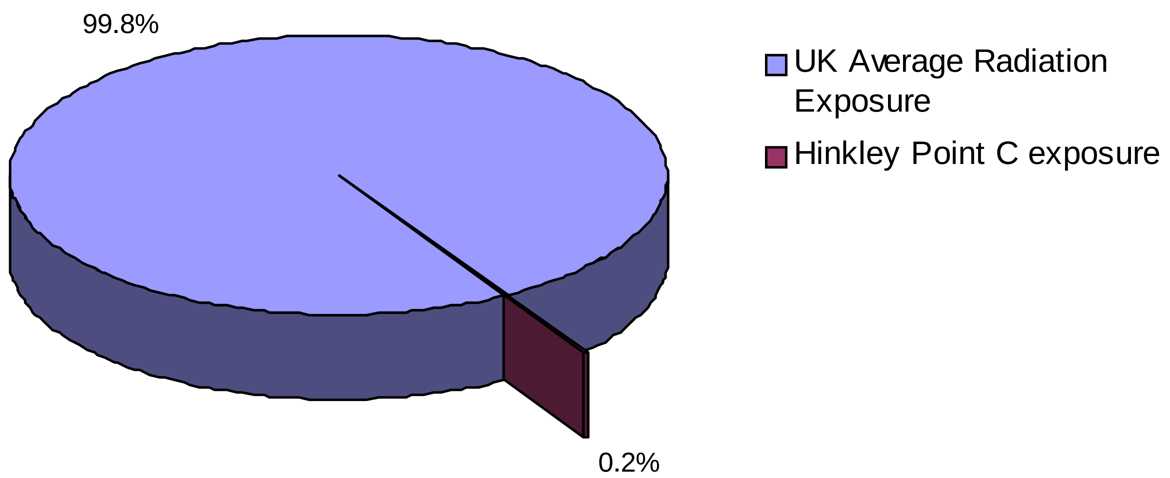
Summary of Prospective Doses in Microsieverts per Year (µSv y^{-1})		
Age Group	**Farming Family with Marine and Gaseous Exposures**	**Fishing Family with Marine and Gaseous Exposures**
Adult	2.7	3.0
Child	2.5	2.3
Infant	4.5	3.6

21.6.31 The highest doses due to discharges and direct radiation from HPC are those to infants in the 'farming family with marine and gaseous exposure'. This is therefore the Critical Group for all radioactive discharges to the environment and direct radiation from HPC.

21.6.32 As previously indicated the source dose constraint of 300 µSv y^{-1} is the maximum dose to people that may result from discharges from a single new source. The critical group doses to adults, children and infants are respectively 2.7, 2.5 and 4.5 µSv y^{-1} for HPC. The doses to this group are much lower (approximately 1.5%) than the source dose constraint of 300 µSv y^{-1}.

21.6.33 The estimated dose for discharges at proposed limits is below 10 µSv y^{-1}. This is the level at which the UK Government in its statutory guidance to the Environment Agency (Ref. 21.35) has indicated that it would not seek further progressive reductions in discharge limits as long as the application of best available techniques continues to be implemented. **Plate 21.5** illustrates the relative proportion of the critical group dose compared to the national average annual exposure from all sources of ionising radiation. It equates to approximately 0.2% of the total annual average exposure. The assessed dose of 4.5 µSv y^{-1} can be regarded as low.

Plate 21.5: Comparison of National Annual Average Exposure in the UK to the Dose to the HPC Critical Group



The Assessment of Collective Radiation Dose Exposure

21.6.34 Collective doses from gaseous and liquid discharges were calculated using the PC-CREAM (Ref. 21.64) modelling tool. The HPA and HPB sites which are already built in to the model, were used to define the population and agricultural product distribution within the European Community and the regional marine compartment into which the discharge is released. An effective stack height of 23.3m was used to represent the physical stack height of 70m to account for the impact of plume rise and buildings on the site. Collective doses were truncated at 500 years consistent with the Environment Agency guidance (Ref. 21.46).

21.6.35 The population groups to be considered are the UK, Europe and the world. The population data for the UK, Europe and the world was assumed to be 55 million, 700 million and 10 billion respectively as these are the values used by PC-CREAM 98 (Ref. 21.64) to estimate collective doses.

21.6.36 Average individual doses ('per caput') for populations in the collective dose assessment were also calculated, allowing per caput doses to be compared with dose constraints. The collective and per caput doses to the UK, European and world populations from HPC gaseous and marine discharges are presented in **Table 21.7** below.

Table 21.7: Collective Dose to the UK, European and World Populations from HPC Discharges

Collective Dose Results			
	UK	**Europe**	**World**
Collective Dose (Man Sv)			
Atmospheric	0.36	3.0	24.6
Liquid	0.02	0.2	2.2
Total Collective dose	0.4	3.2	26.8
Average per Caput Dose (nSv)			
Atmospheric	6.6	4.3	2.5
Marine	0.4	0.3	0.2
Total per caput dose	6.9	4.6	2.7

21.6.37 Total HPC discharges will result in *per caput* doses of less than 7 nSv to the UK population. The Health Protection Agency has stated that discharges giving rise to per caput doses of less than a few nano-sieverts per year of discharge can be regarded as "*minuscule and the contribution to total doses to individuals will be insignificant*" (Ref. 21.46).

21.6.38 The estimated collective dose in the UK is 0.4 manSv which is very low by comparison with the national collective doses from medical exposures of 24,000 manSv (Ref. 21.65). In addition it is less then the IAEA criterion used in the UK regulatory guidance of 1 man Sv per year of practice below which the IAEA would consider that such a practice be exempt from regulatory control (Ref. 21.46).

The Assessment of Individual Doses Resulting from Short-term Discharges

21.6.39 Doses have been calculated arising from potential short-term gaseous discharges from a single UK EPR stack with separate calculations undertaken for the UK EPR Unit 1 and Unit 2 stacks for the same receptor location and assumed total discharge amounts and discharge rates. Potential short-term doses, including via the food chain, were calculated for a local Critical Group based on the methods described in NRPB-W54 (Ref. 21.66). The doses were then compared with the assessment criteria.

21.6.40 The pathways of exposure and the exposure times which have been considered to assess the short-term impact are the following:

- ingestion of foodstuffs (the associated dose is calculated in the year following the short-term release);
- inhalation and external irradiation from the plume (the associated doses are calculated for the period of the passage of the plume);
- ingestion doses were calculated using the 'Top Two' method described above; and
- external irradiation from deposited radionuclides (the associated dose is calculated for the year following the release).

21.6.41 The results for the assumed intake rate (Ref. 21.34) were 0.26, 0.23 and 0.45 µSv per discharge for adult, child and infant age groups respectively. For infants (the most exposed individual) the most significant exposure route is ingestion (97% of the dose received) followed by inhalation (2%). The most significant radionuclide is C-14 (95% of the dose received) followed by tritium (2%).

21.6.42 The predicted short-term dose is significantly less than the predicted dose due to the continuous release and therefore the calculations of doses to the Critical Group bound the radiological assessment for HPC. The prospective doses estimated due to the short-term gaseous discharges from HPC are significantly less than the relevant dose criteria, that is the source constraint of 300 µSv y^{-1} or the public dose limit of 1,000 µSv y^{-1}.

The Assessment of Individual Doses from the Build-up of Radionuclides

21.6.43 EDF Energy has designed the facilities and will operate them in such a manner to minimise the discharges of gaseous and aqueous effluents through the application of Best Available Techniques. The proposed techniques will need to satisfy regulatory scrutiny through the determination of the relevant environmental permit applications. EDF Energy has included an assessment of the potential build-up of the radioactivity in the marine and terrestrial environment to show that the operations of HPC would not prejudice the future use of the land and sea.

21.6.44 The Environment Agency has highlighted that at the end of the life of a power station, land may not be able to return to free and unrestricted use due to potential build-up of radionuclides. Build-up refers to the accumulation of radionuclides in environmental media due to discharges and accounts for the effects of gradual accumulation of radionuclides over the operating life of the plant. A range of potential groups can then be exposed to this source of radioactivity.

21.6.45 Potential activity concentrations in soil were assessed using calculated activity concentrations in air. Activity concentrations in sea water and on the local beach were also calculated (see **Appendix 21A)**. The significance of the impact of the build-up of radioactivity will depend on the future use of the land and activities in the sea.

21.6.46 A methodology for estimating doses to members of the public from future use of land previously contaminated with radioactivity was used (Ref. 21.67). A review of potential uses of the sea was carried out based on uses discussed in the CEFAS study (Ref. 21.34). Scenarios where occupancies are high and/or intakes of radionuclides occur will give the highest doses. Potential uses included:

- water sports;
- beach combing/walking;
- hobby fishing (including consumption of catches);
- commercial fishing, and
- houseboat dwelling.

21.6.47 The results for the airborne concentrations and consequent concentration in soil at the off-site location with the highest concentration are described in **Appendix 21A**.

21.6.48 The most restrictive scenario for which the build-up of discharges to the atmosphere has been assessed would be construction on potentially contaminated land (**Appendix 21A)**. It has been assumed that the most contaminated land off-site would be used for a future development and the total dose to a construction worker as a consequence of the future build-up of nuclides due to the emissions from the HPC reactors has been calculated to be 0.0044 µSv y^{-1}. It should be noted that the predicted annual exposure to a future-use construction worker is based on the build-up of activity at the location of maximum predicted concentration outside the site boundary. The extent of this area of maximum concentration is relatively small and will reduce with distance from the site.

21.6.49 The dose to members of the public from future use of the sea has been assessed for the 'fishing family' group, but excluding the atmospheric contribution. The total dose to the 'fishing family' from marine discharges was calculated to be 1.08, 0.3 and 0.12 µSv y^{-1} to adults, children and infants respectively.

21.6.50 Based upon the calculated doses, the radiological impact of the potential build-up of radionuclides from discharges from the proposed HPC can be regarded as very low.

iii. HPC Assessment for Impacts on Non-human Species

21.6.51 To enable the assessment of the radiological impact on non-human species resulting from continuous discharges from HPC, four representative habitats were selected for the species they are likely to support in the vicinity of the proposed power station site:

- Habitat 1: lies adjacent to the HPC boundary, whilst it is not within a Site of Special Scientific Interest (SSSI) it is directly adjacent to Bridgwater Bay SSSI and is part of the Hinkley Point Wildlife Site.

- Habitat 2: comprises the coastal mudflats and marine habitat of the adjacent estuary and is within the boundaries of the nationally recognised Bridgwater Bay SSSI, the Severn Estuary Special Area of Conservation (SAC) and Special Protection Area (SPA) and the internationally designated Severn Estuary Ramsar site.
- Habitat 3: lies within the Bridgwater Bay National Nature Reserve and includes both shoreline and a fringing terrestrial area.
- Habitat 4: comprises a small freshwater pond and lies within Habitat 1 and hence is immediately adjacent to Bridgwater Bay SSSI.

A map describing the location of the assessed habitats is presented in **Plate 21.6**.

21.6.52 For the assessment of impacts upon marine biota from liquid radioactive discharges, by assessing the average activity concentration in a small area of sea around the discharge point the radiation exposure over a period of time for any biota present is more likely to be determined (see **Appendix 21A**). The local compartment defined for modelling HPC was used to determine concentrations in seawater and seabed sediments.

21.6.53 For the assessment of impacts from gaseous radioactive discharges, using meteorological data it was possible to calculate at specific bearings and distances from the HPC stacks the concentration in soil and air of gaseous discharged radionuclides.

21.6.54 A summary of the results of the assessment on non-human species is presented in **Plate 21.7** to **Plate 21.10**.

21.6.55 The following conclusions can be drawn from the assessments:

- Habitat 1 is adjacent to a Special Site of Scientific Interest (SSSI) and it is a habitat for bats and therefore special protection of the bats and their roosts must be considered. All of the estimated doses from HPC discharges are below the most stringent assessment level (10 µGy h^{-1}) described in Section 12.4.
- Habitat 2, as part of Bridgwater Bay, is a designated site and therefore of interest for regulatory purposes. All of the estimated doses from HPC discharges are below the most stringent assessment level (10 µGy h^{-1}) described in Section 12.4.
- Habitat 3 has some sites and habitats within it that have specific designated status and therefore are of high importance to stakeholders. However, all estimated doses from HPC discharges are below the most stringent assessment level (10 µGy h^{-1}) meaning that there would be no measurable effects on these organisms as a result of radioactivity present from radioactive discharges.
- Habitat 4 is adjacent to a SSSI or other designated site and all the estimated doses from the HPC discharges are below the most stringent assessment level (10 µGy h^{-1}).

21.6.56 Overall, the radiological impact on non-human species for discharges from the proposed development at HPC has been assessed as very low.

b) Cumulative Operational Impacts

i. Assessment of Cumulative Radiological Impact on Humans

21.6.57 The methodology used to determine the radiological impact resulting from discharges from HPA and HPB is described in Section 21.4. For HPA and HPB the assessment is based on discharges at current authorised limits rather than actual discharge values, which is a conservative assumption. In addition, the estimates of cumulative impacts assume that discharges from these facilities continue for the next 50 years and in parallel with those from the proposed HPC site, which is also a conservative assumption, since within the next 50 years HPA is planned to be decommissioned into a quiescent state known as 'care and maintenance' and HPB is planned to be shut down, defuelled and decommissioned.

21.6.58 For the purposes of assessing the cumulative impact from radiological discharges it has been assumed that the discharges from HPB during decommissioning will not increase above their current permitted limits. Any increases that could arise are likely to be limited in time to address specific activities during the decommissioning programme to reduce the hazard on site to assist in achieving the site's restoration and would need to be agreed in advance with the regulator and approved. It is expected that after initial decommissioning activities on site, HPB will enter a period of care and maintenance where there will be only low levels of radioactive effluent discharges. The main period of decommissioning activity on the HPB site will take place after this period of care and maintenance, and this is currently scheduled to take place after HPC has ceased operation. The proposals for the decommissioning of HPC means that most of the decommissioning on the HPC site are expected to be completed (with only the ISFS remaining) before HPB final site clearance work begins.

21.6.59 The discharges from HPA and HPB used for these assessments are presented in **Table 21.8** and **Table 21.9** below.

Table 21.8: Annual Gaseous Discharge Limits for HPA and HPB

Radionuclide	Annual Gaseous Discharge Limits (GBq y^{-1})	
	HPA	HPB
H-3	1,500	12,000
C-14	600	3,700
Ar-41	-	100,000
I-131	-	1.5
Co-60	-	0.1
S-35	-	350
Beta[1]	0.15	1

[1] Assumed to be Co-60 for HPA and HPB discharges

Table 21.9: Annual Liquid Discharge Limits for HPA and HPB

Radionuclide	Annual Liquid Discharge Limits (GBq y^{-1})	
	HPA	HPB
H-3	1,800	650,000[1]
Co-60	-	10
Cs-137	1,000	100
S-35	-	2,000
Other radionuclides[2]	700	80

[1] 0.025% of H-3 assumed to be discharged as Organically Bound Tritium (OBT)

[2] Assumed to be Cs-134 for HPA and HPB

ii. Cumulative Effects on the Candidate Critical Groups from the Hinkley Point Sites Discharges

21.6.60 The doses to the two Candidate Critical Groups of the farming and fishing families assumed to reside at the same locality and where maximum exposure to airborne and deposited activity from HPC gaseous discharges occurs, but due specifically to discharges from HPA and HPB, were estimated. The methodology was the same as that used to estimate doses to these two Candidate Critical Groups due to discharges from HPC.

Doses to the Farming Family Candidate Critical Group

21.6.61 The cumulative doses to the 'farming family with marine and gaseous exposure considered in the current assessments from liquid and gaseous discharges from the collective Hinkley Point Sites are given in **Table 21.10**. These cumulative doses conservatively assume all three reactor sites discharge at the authorised limits simultaneously. A breakdown of how these total cumulative doses are built up from those due to the discharges from the Hinkley Point Sites is provided in **Appendix 21A**.

Table 21.10: Cumulative Dose to the 'Farming Family with Marine and Gaseous Exposure' exposed to liquid and gaseous discharges from Hinkley Points A, B and C

Age Group	Total Predicted – Cumulative Dose μSv y^{-1}
Infant	17.2
Child	7.3
Adult	6.8

21.6.62 Overall, the infant members of the 'farming family with marine and gaseous exposure' receive the greatest dose from cumulative discharges. The dose to all age groups is dominated by contributions from the terrestrial pathways which, in the case of the infant make up 98% of the cumulative dose received. C-14 and S-35 again dominate these cumulative doses to all age groups and make up 40% and 53% respectively of that to the infant age group, through the consumption of milk and milk products.

21.6.63 The cumulative dose from all three reactor sites to all ages in the fishing family Critical Group are a fraction (less than 3%) of the site dose constraint of 500 μSv y^{-1}.

Doses to the Fishing Family Candidate Critical Group

21.6.64 The cumulative doses to the 'fishing family with marine and gaseous exposure' Candidate Critical Group considered in the assessments from liquid and gaseous discharges from the Hinkley Point Sites are given in **Table 21.11**. These cumulative doses conservatively assume all three reactor sites discharge at the authorised limits simultaneously. A breakdown of how these total cumulative doses are built up from those due to the discharges from the Hinkley Point Sites is provided in **Appendix 21A**.

Table 21.11: Cumulative Dose to the 'Fishing Family with Marine and Gaseous Exposure' exposed to Liquid and Gaseous Discharges from Hinkley Point A, B and C (the Hinkley Point Sites)

Age Group	Total predicted Cumulative Dose μSv y^{-1}
Infant	13.2
Child	6.5
Adult	7.8

21.6.65 Overall, the infant members of the 'fishing family with marine and gaseous exposure' receive the greatest dose from cumulative discharges. Although this is classed as a fishing family, the dose to all age groups is dominated by contributions from the terrestrial pathways which, in the case of the infant make up 98% of the cumulative dose received. C-14 and S-35 again dominate these cumulative doses to all age groups and make up 41% and 55% respectively of that to the infant age group, through the consumption of milk and milk products. Therefore although it is a fishing family candidate critical group, the bulk of the exposure is due to terrestrial routes.

21.6.66 The cumulative dose from the Hinkley Point Sites to all ages in the 'fishing family with marine and gaseous exposure' Critical Group are a fraction (less than 3%) of the site dose constraint of 500 μSv y^{-1}.

Critical Group for the Hinkley Point Sites from all Gaseous and Liquid Discharges

21.6.67 For both these Candidate Critical Groups, approximately half of the cumulative dose to adults and three-quarters of the cumulative dose to infants is due to the discharges from the HPB site, which is currently operating. These would therefore decrease significantly when the HPB site ceases operation, current scheduled to close in 2016 if no life extension occurs. A much smaller fraction of the cumulative dose is due to discharges from the HPA decommissioning site.

21.6.68 The highest doses due to all gaseous and liquid radioactive discharges from the Hinkley Point Sites are those to the infants in the 'farming family with marine and gaseous exposure'. This is therefore considered to be the Critical Group.

21.6.69 **Plate 21.11** shows a breakdown of the prospective cumulative doses due to liquid and gaseous discharges from the Hinkley Point Sites to each of the age groups in the Critical Group of the 'Farming Family with marine and gaseous exposure' (as a percentage of the cumulative dose for each age group). Discharges from HPA account for between about 3% to 15% of the cumulative prospective dose to the three age groups. Discharges from HPB account for between about 47 and 70% and those from HPC account for between about 26 and 40% of the cumulative prospective dose.

21.6.70 **Plate 21.12** shows that the cumulative prospective doses to the in farming family with marine and gaseous exposure Critical Group are dominated by contributions from S-35 and from C-14. S-35 makes up the bulk of the dose to the infant, whilst C-14 dominates that to the child and adult. All of the dose from S-35 is attributable to the HPB reactor site. Cumulative doses from C-14 are due mainly to HPC. Information presented earlier shows that methods to mitigate the discharges of this from the UK EPR are consistent with best international practice and subject to on-going assessments to ensure compliance with the requirements of BAT.

21.6.71 In summary, the data shows that the HPA and HPB sites make the largest contribution to the cumulative doses to all age groups for both Candidate Critical Groups. The Critical Group dose of 17.2 µSv y^{-1} from the cumulative liquid and gaseous discharges from the Hinkley Point Sites is significantly below the site constraint of 500 µSv y^{-1}.

iii. Total Dose from the Hinkley Point Sites

21.6.72 To allow comparison of the Hinkley Point Sites discharge doses with the with the Public Dose Limit from man-made sources (excluding medical sources) of 1,000 µSv y^{-1}, it is necessary to take into account historical and future discharges from HPA, HPB and HPC and future direct radiation from other facilities on the Hinkley Point Sites.

21.6.73 Retrospective Critical Group doses as a result of discharges from the existing Hinkley Point Sites are assessed annually in the RIFE reports. The highest retrospective dose in recent years was 40 µSv to seafood consumers. This dose also includes a contribution from discharges from the GE Healthcare Cardiff site, which produces H-3 and C-14 for medical research.

21.6.74 Direct radiation dose from the existing HPA and HPB stations was measured to be 4 µSv y^{-1} in 2007 in Table A4.1 of RIFE-13 (Ref. 21.61). This value is appropriate to use as the future direct radiation dose for the Hinkley Point Sites as it was determined that the direct radiation dose at the closest dwelling to HPC would be 0.0014 µSv y^{-1} and as HPA and HPB are decommissioned direct radiation doses from these facilities should reduce.

21.6.75 Summing the retrospective Critical Group dose (40 µSv to seafood consumers) with the direct radiation dose and the future exposures Critical Group dose (from 50 years of combined discharges from the Hinkley Point Sites) results in the summated dose for the site of 61 µSv. This is highly conservative and includes discharges not originating from each of the Hinkley Point Sites.

21.6.76 The total dose, including the contribution from historic discharges to the environment should be compared against the public dose limit of 1 mSv per year (Ref. 21.46). The assessed total dose of 61 µSv y^{-1} represents 6% of the public dose limit.

iv. Cumulative Collective Dose from Hinkley Point Sites Discharges

21.6.77 The collective doses to the UK, European and world populations due to gaseous and liquid discharges from the Hinkley Point Sites are presented in **Table 21.12** below.

Table 21.12: Collective Dose to the UK, European and World Populations from Hinkley Point Site Discharges

Collective Population			
	UK	Europe	World
Collective Dose (Man Sv)			
Gaseous discharges	1.9	13.5	100.3
Liquid discharges	0.025	0.2	2.2
Total Collective dose	1.9	13.7	102.5
Average per Caput Dose (nSv)			
Gaseous discharges	34.5	19.3	10
Liquid discharges	0.45	0.3	0.2
Total per caput dose	35	19.6	10.3

21.6.78 The collective dose due to liquid and gaseous discharges from the Hinkley Point Sites is dominated by carbon-14, which accounts for 74, 92 and 100% of the dose to populations of the UK, Europe and the world respectively.

21.6.79 Per caput doses from all Hinkley Point Site discharges are in the nSv y^{-1} range and thus in accordance with Environment Agency guidance (Ref. 21.46) the contribution to total doses to individuals will be insignificant. The per caput doses to the UK and European populations that are above this ‘few nSv’ range are still well below those of a ‘few µSv’ and can be considered as ‘trivial’ and well below those in the higher end of the µSv range that the Environment Agency state might require some additional consideration. Therefore, collective and per caput doses from the Hinkley Point site have been assessed as low.

v. Build-up Due to Cumulative Discharges from the Hinkley Point Sites

21.6.80 Calculated results for the soil concentration at the area off-site with the highest concentration at year 60 due to all Hinkley Point gaseous discharges to the atmosphere and the activity concentration in the sea water and seabed sediment off the coast of Hinkley Point at year 60 from all Hinkley Point Site marine discharges are presented in **Appendix 21A**.

21.6.81 Following the methodology previously outlined in this chapter, the total dose to a construction worker as a consequence of the build-up of nuclides as a result of emissions from the Hinkley Point Sites has been calculated to be 0.018 µSv y^{-1}.

21.6.82 The annual exposure due to the future use of the marine environment resulting from the cumulative discharges from the Hinkley Point Sites is likely to be associated with commercial fishing and leisure activities. Therefore the dose to members of the public from future use of the sea has been assessed as the ‘fishing family’ group. The dose due to build-up to the ‘fishing family with marine and gaseous exposure’ from all marine discharges from the Hinkley Point Sites was calculated to be 2.8, 0.67 and 0.24 µSv y^{-1} for adults, children and infants respectively. When compared against the site constraint of 500 µSv y^{-1} and the annual average UK dose exposure from all sources of 2,700 µSv y^{-1}, this has been assessed as having very low impact.

vi. Assessment of Cumulative Radiological Impact on Non-human Species

21.6.83 The biota in the freshwater habitat most affected by cumulative liquid and gaseous discharges from the Hinkley Point Sites was calculated to be insect larvae, which would experience a dose of 2.97 µGy h^{-1}. This is below the ERICA screening value of 10 µGy h^{-1} and well below the Environment Agency regulatory screening level of 40 µGy h^{-1}. All other biota and habitats are even further below the ERICA screening level.

c) Post-operational Impacts

21.6.84 As stated in Section 21.2, discharges of radioactive effluent during decommissioning of HPC are expected to be lower than those that will occur during operations. Decommissioning impacts are, therefore, bounded by the assessment undertaken for operational activities.

21.6.85 Similarly, the assessment of the cumulative future impacts from the Hinkley Point Sites includes discharges from decommissioning of each of the sites. Cumulative post-operational impacts are, therefore, bounded by the assessment undertaken for operational activities.

21.7 Mitigation of Impacts

a) Management of Radioactive Waste Using Best Available Techniques

21.7.1 The Environmental Permitting (England and Wales) Regulations 2010 (Ref. 21.20) translate the European Commission Basic Safety Standards (1996) (Ref. 21.12) into UK law and require the Environment Agency to ensure that:

> *"all exposures to ionising radiation of any member of the public and of the population as a whole resulting from the disposal of radioactive waste are kept as low as reasonably achievable, taking into account economic and social factors."*

21.7.2 BAT is a term defined in the OSPAR Convention (Ref. 21.68) and Directive 2008/1/EC on Integrated Pollution Prevention and Control (IPPC) (Ref.21.69). These definitions are essentially the same. They state that:

> *"Best available techniques shall mean the most effective and advanced stage in the development of activities and their methods of operation which indicate the practical suitability of particular techniques for providing in principle the basis for emission limit values designed to prevent and, where that is not practicable, generally to reduce emissions and the impact on the environment as a whole, special consideration shall be given to:*
>
> *a) comparable processes, facilities or methods of operation which have recently been successfully tried out;*
>
> *b) technological advances and changes in scientific knowledge and understanding;*
>
> *c) the economic feasibility of such techniques;*
>
> *d) time limits for installation in both new and existing plants;*

e) the nature and volume of the discharges and emissions concerned.

'techniques' shall include both the technology used and the way in which the installation is designed, built, maintained, managed, operated and decommissioned,

'available' techniques shall mean those developed on a scale which allows implementation in the relevant industrial sector, under economically and technically viable conditions, taking into consideration the costs and advantages, whether or not the techniques are used or produced inside the Member State in question, as long as they are reasonably accessible to the operator,

'best' shall mean most effective in achieving a high general level of protection of the environment as a whole."

21.7.3 BAT is the means by which an operator optimises the operation of a practice in order to reduce and keep exposures from the disposal of radioactive waste into the environment as low as reasonably achievable (ALARA), economic and social factors being taken into consideration. Those techniques which represent BAT are also taken to have met the requirements of optimisation and ALARA. This means that if further reductions in exposure are reasonably practicable then they should be implemented.

21.7.4 This approach is reinforced by the relevant regulatory requirements, and it means that sites will operate at levels considerably below the prescribed dose limits.

21.7.5 The environmental permit granted under the Environmental Permitting (England and Wales) Regulations 2010 (Ref. 21.20) would include specific conditions to address this legal requirement. BAT is required to optimise performance, taking into account the broad range of factors indicated above to prevent, or where this is not possible, minimise the:

- activity in the radioactive waste produced;
- activity discharged in gaseous and aqueous effluents;
- volume of solid waste produced; and
- risks and environmental impacts of discharges and disposals.

21.7.6 As part of the Generic Design Assessment (GDA) of candidate nuclear power plant designs in the UK, the Environment Agency has published a Process and Information Document (PID) (Ref. 21.37) for requesting parties to provide an evaluation of options considered in the design of their nuclear power plants. The analysis should include an evaluation of abatement options and show that the Best Available Techniques (BAT) will be used to minimise the production and discharge or disposal of waste.

21.7.7 As part of the GDA for the UK EPR, the use of BAT for abatement of discharges has already been discussed and further developed in relevant sections of the Pre-Construction Environmental Report (Ref. 21.70). Demonstrating the application of BAT remains an on-going consideration throughout the rest of the design, operational and eventually the decommissioning phases of the UK EPR. The demonstration of environmental optimisation is a key element of the environmental permit submission (Ref. 21.71).

21.7.8 Permits are only granted after a rigorous assessment process which includes the prospective assessment of the impacts on the public and non-human species. The prospective assessments are determined using modelling because it is not practicable to measure the exposure directly and it is essential that it can be shown that any doses received would be below regulatory guidelines and ALARA.

21.7.9 The fundamental aim in the application of BAT is to prevent and, where that is not practicable, minimise waste generation and discharges to the environment. There is no lower limit on doses below which the general requirement for optimisation does not apply. DECC and the Welsh Assembly Government (Ref. 21.35) have issued Statutory Guidance to the Environment Agency for England and Wales which includes the provision that, *"where the prospective dose to the most exposed group of members of the public is below 10 µSv y^{-1} from overall discharges… the Environment Agency should not seek to reduce further the discharge limits in place, provided that the holder of the authorisation applies and continues to apply BAT"*.

21.7.10 A permit for the disposal of radioactive effluents and waste from the proposed new development at HPC has been applied for separately from the DCO application. The information that supports the permit application demonstrates the application of environmental optimisation in the design and management of the plant through the application of BAT. The permit requires the 'environment case' that supports the application of BAT to be maintained, reviewed and updated (Ref. 21.71).

21.7.11 BAT is not merely concerned with abatement and other end-of-pipe controls. It applies across the whole lifecycle of the plant from design, through procurement, construction, commissioning, operation and decommissioning.

21.7.12 BAT also applies to the operation, maintenance, testing, calibration, sampling, measuring and analysis of relevant plant, systems and equipment. It also relates to the procedures and management systems that may impact on environmental performance.

21.7.13 The fundamental design of the reactor circuit, the material composition of components in the reactor circuit that could produce radioactivity by neutron activation and the management arrangements for the control of reactor circuit chemistry will all minimise the production of radioactivity at source. BAT applies not only to the design but also how it is constructed, commissioned, operated and, ultimately decommissioned. BAT applies to the technology and the way they technology is managed and implemented.

b) Overall Minimisation of Liquid Radioactive Discharges

21.7.14 The minimisation of radioactive isotopes in liquid discharges from the UK EPR and the reduction in overall radiological impact from the site centres on the design and management features, details of which are built on the information presented in the PCER (Ref. 21.70) and are further detailed in the RSR Environmental Permit Submission (Ref. 21.71) but are also summarised below:

- Minimisation at source. This includes ensuring the leak-tightness of the fuel pins to minimise release of tritium and other fission products such as iodine into the reactor coolant, and controlling the pH of the coolant to minimise corrosion effects that could give rise to activation products such as Co-60.

- Recycling and re-use of liquids (where practicable) in the reactor systems, to reduce the overall volume and activity of liquid requiring treatment and disposal.
- Partitioning of radionuclides (where practicable) for disposal in the manner which causes the least environmental impact.
- Optimisation of the dispersion of the cooling water by the design of the cooling water outfall, which will minimise the impacts associated with liquid radioactive discharges.
- Treatment of discharges using combinations of filters, ion exchange resins and evaporators that remove activity from the effluents, concentrating and containing them into more compact and easily managed solid waste forms and allow, as far as reasonably possible, recycling of the treated liquid effluents.

c) Overall Minimisation of Gaseous Radioactive Discharges

21.7.15 The minimisation of radioactivity in gaseous discharges from each UK EPR unit centres on the following design and management features. Further details which are built on the information in the PCER (Ref. 21.70) and which are presented in the RSR Environmental Permit Submission (Ref. 21.71) but are also summarised below include:

- Minimisation at source. The minimisation of gaseous activity at source relies on the same basic principles as for the liquids, especially maintaining the leak-tightness of the fuel pins since this is the main source of gaseous and volatile fission products in gaseous effluent streams. Safety considerations are also taken into account in the application of BAT - for example, the nitrogen blanket is used in the chemical and volume control system increases the production and discharge of carbon-14 discharge from the site, but it is a much safer blanketing gas than hydrogen which has been used in other pressurised water reactor designs.
- Recirculation and recycling of gases (where practicable).
- Partitioning of radionuclides (where practicable) for disposal in the manner which causes the least environmental impact.
- Optimisation of the dispersion of the gaseous effluent by the design of the discharge stacks to minimise the impact of radioactive gaseous discharges.
- Treatment of gaseous effluents using charcoal adsorption plant that permits radioactive decay of short half-life isotopes, and filters and catalytic recombination units that remove radioactivity from the effluents, concentrating and containing it into more compact and easily managed solid waste forms.

21.7.16 In the UK EPR, the design and operation of the heating, ventilation and air conditioning systems that extract air from potentially active areas throughout the plant follows a common approach based on currently accepted international methods used in all nuclear facilities. This minimises the risk of elevated radioactive gaseous discharges by ensuring all contaminated air is processed using the techniques noted above.

d) Mitigation for Specific Radioactive Isotopes

21.7.17 From the site-specific assessments described in this chapter, it has been shown that doses to the most exposed members of the local population from the operation of HPC from radioactive discharges are below the 10 µSv y^{-1} criterion below which the Environment Agency will not pursue further reductions in discharge limits as long as BAT continues to be applied (Ref. 21.35). The majority of the doses (approximately 90%) arise from discharges of the radioactive isotopes carbon-14 (C-14) and tritium (approximately 3%). For infants, and to a lesser extent children, iodine contributes between 7 and 3% of their does. Consequently the mitigation measures for these radionuclides are discussed in more detail below.

i. Carbon-14

21.7.18 C-14 in discharges from a PWR occurs in liquids and gases. It is assumed that 80 % of the discharges are as methane ($^{14}CH_4$), and 20 % as carbon dioxide ($^{14}CO_2$) (except for the purposes of dose calculations where a more conservative assumption is assessed). In the UK EPR, C-14 is minimised at source as far as possible by improved utilisation of the reactor fuel, which reduces the amounts of C-14 produced per unit of electrical energy produced. Some increased C-14 production in the UK EPR arises from the use of a nitrogen cover gas in one of the coolant processing tanks attached to the reactor circuit, the Volume Control Tank (VCT), but as noted above this has been implemented to avoid the more routine use of hydrogen that would otherwise present a flammability hazard in this part of the plant.

21.7.19 Within the various primary coolant and liquid effluent processing systems, degasification of liquids assists in the partitioning of C-14 into the gaseous effluent route and the majority of the C-14 is discharged in gases, with only a small proportion being in liquid or solid waste forms. Discharges of carbon-14 in gaseous form generally have a lower radiological impact than those discharged in liquid form.

21.7.20 As part of the overall design philosophy for the UK EPR, an extensive assessment of potential methods for the abatement of C-14 in liquids and gases has been carried out, including reference to IAEA Technical Report 421 (Ref. 21.72). None of these methods are currently used on operational power reactors and some are not technically feasible on a PWR. This is consistent with the conclusion drawn in the Environment Agency Draft Decision Document on the GDA (Ref. 21.43).

21.7.21 Overall, the design of the EPR represents the application of BAT with respect to discharges of C-14, and thus the potential radiological impact from discharges of C-14, provided levels of dissolved nitrogen in the primary coolant (the main avoidable source of this nuclide) are optimised.

ii. Tritium

21.7.22 Tritium makes up the bulk of the total radioactivity discharged in liquids and is about 10% of the total activity discharged in gases from HPC. However, it only makes a small contribution to the overall radiological impact due to discharges from HPC. In liquid discharges from the UK EPR, the majority of the tritium is present as tritiated water and in gases it is present as tritiated water vapour.

21.7.23 In the UK EPR, the generation and release of tritium is minimised at source by a number of measures including the use of Zircalloy M5 fuel cladding which retains the bulk of the tritium formed by fission in the fuel, and the optimisation of boron and lithium concentrations. This includes the use of enriched boron and depleted lithium, combined with the use of burnable poisons in some fuel rods (including avoidance of boron and use of gadolinium) and reducing the beryllium content in the secondary neutron sources.

21.7.24 The recombination unit may help to ensure that tritium in the purge gas in the gaseous effluent treatment system is returned to and retained in the liquid phase, although to date this effect has not been quantified. The majority of tritium is discharged into the environment in liquid discharges. Discharge of tritium in liquid form has a lower radiological impact than the discharge of tritium in gaseous effluent.

21.7.25 As part of the overall design philosophy for the UK EPR, an extensive assessment of potential methods for the abatement of tritium in liquids and gases has been carried out, including reference to IAEA Technical Report 421 (Ref. 21.72).

21.7.26 The overall conclusion is that that the containment and minimisation at source implemented in the UK EPR represents the BAT for this radioactive isotope. This is consistent with the conclusion drawn in the Environment Agency Draft Decision Document on the GDA (Ref. 21.43). The final discharges of tritium have a low radiological impact and are a small fraction of the overall site radiological impact, which has been assessed as very low.

iii. Iodine

21.7.27 Isotopes of radioactive iodine have a relatively short half-life, ranging up to 8 days for iodine-131 (the most significant isotopes of iodine from a dose assessment perspective). Isotopes of iodine are fission products and are largely contained within the fuel by the fuel cladding. Very small quantities of iodine can transfer into the reactor coolant by passing through minute defects in the fuel cladding. Alternatively if there is any contamination on the outside of the fuel this can result in the generation of isotopes of iodine.

21.7.28 The high-quality manufacturing and inspection of fuel is therefore a very important stage in minimising the amount of radioactive iodine that occurs in the reactor coolant. However, once generated iodine is generally retained in the liquid phase. Any isotopes of iodine that are found in the gaseous effluents are effectively abated through the use of charcoal adsorption plant which delay the gaseous effluent long enough for the majority of the radioactivity to decay. Isotopes of iodine are also retained in the iodine traps installed in the building ventilation circuits (these iodine traps are brought into service as required).

21.7.29 Due to the treatment and recycling of primary effluents most isotopes of iodine decay within the primary system and therefore are not discharged. Effluents that do contain isotopes of iodine are treated with abatement systems, including ion exchange resins which effectively remove the activity from the liquid effluent.

e) Mitigation for Direct Radiation and Transport

21.7.30 Doses from direct radiation ‘shine’ to members of the public from the storage of ILW or ISFS on the HPC site have been assessed as very low. Ensuring that these radiation exposures remain ALARA will be by:

- engineering controls, such as the design of the buildings to optimise the thickness of radiation shielding; and
- administrative controls, such as the routine monitoring of the externals of the building to verify that the external radiation doserate is suitable for the area around the building to be 'undesignated'.

21.7.31 Estimated doses to members of the public from the transport of radioactive materials to and from the proposed HPC site are dominated by the transport of spent fuel. As noted in Section 12.5, this was based on the assumption in the assessment that the spent fuel would require movement off-site. Whilst this predicted annual dose is negligible (up to 2 µSv y^{-1}) doses will be mitigated by retaining an on-site ISFS, as is currently described in **Chapters 6** and **7** of this volume.

21.8 Residual Impacts

21.8.1 As described in section 21.2 there will be no radiological impacts associated with construction, and discharges from commissioning of HPC will be no greater than those expected during operations. It has also been assumed that techniques employed to mitigate impacts will be operating during commissioning.

21.8.2 The UK EPR is an evolutionary design which has been developed taking advantage of operational feedback and the wide experience of the EDF Group and AREVA NP. The design and operation of the UK EPR will ensure that the formation of solid radioactive waste (in terms of volume and activity) and the discharge of liquid and gaseous effluents per unit generation of electricity is amongst the best performing compared with current operating PWR plants.

21.8.3 The following overarching goals were included in the design optimisation:

- minimise the generation of radioactive effluents and wastes at source;
- select the best materials of construction to minimise the generation and transfer or wastes, including the design of fuel;
- reduction and control of tritium liquid discharges;
- reduction and control of C-14 liquid discharges;
- reduction of discharges of other radionuclides;
- maximum recycling of boron (used in the primary circuit coolant);
- optimisation of the primary circuit coolant quality (that can affect discharges); and
- overall reduction of chemical discharges.

21.8.4 This chapter has outlined the radiological assessments that have been undertaken for the impact associated with the construction and routine operation of the HPC Power Station and the cumulative radiological impacts due to this new facility and the existing HPA and HPB sites. The receptor groups, details and the overall outcomes of the assessment for the planned development are summarised in subsequent paragraphs.

21.8.5 The dose to the most exposed person from radioactive discharges from HPC and therefore considered to represent the Critical Group, with a calculated dose of

4.5 µSv y^{-1}, was infant members of the 'farming family with marine and gaseous exposure'. This dose can be compared with the average dose to the UK population of 2,700 µSv y^{-1} from all sources of radioactivity (Ref. 21.48).

21.8.6 The Critical Group dose from discharges and direct radiation from HPC was calculated as 4.5 µSv y^{-1}. This Critical Group dose is compared against the source constraint (300 µSv y^{-1}) and represents 1.5% of the value.

21.8.7 All individual doses from HPC from continuous or short-term discharges and direct radiation are considered to be very low and below the Statutory Guidance dose constraint of 10 µSv y^{-1} below which progressive reductions in discharges will not be pursued as long as the application of BAT can be demonstrated (Ref. 21.35).

21.8.8 Collective doses, resulting from HPC discharges, to populations of the UK, Europe and the world truncated at 500 years have been calculated (Ref. 21.46). A more informative presentation of this data is in the form of per caput doses, which provide an estimate of the average dose to individual members of a given population. The 'per caput' dose from all discharges from HPC to the UK population was calculated to be less than seven nano-sieverts per year. The Health Protection Agency has stated that discharges giving rise to per caput doses of less than a few nano-sieverts per year of discharge can be regarded as "*minuscule*" (Ref. 21.46).

21.8.9 The freshwater habitat represented the most affected based on estimated dose rates for non-human species. The species most affected was calculated to be insect larvae, which would experience a dose rate of less than 3 µGy h^{-1}. This is below the default screening value of 10 µGy h^{-1} and well below the Environment Agency biota dose screening values listed in Section 21.4.

21.8.10 The highest estimated annual dose to an individual (2 µSv y^{-1}) due to transport of radioactive materials from HPC is associated with the transport of spent fuel. This value can be compared to the dose limit for members of the pubic from the Ionising Radiations Regulations 1999 of 1,000 µSv y^{-1} which is applicable to transport operations (Ref. 21.18). It should be noted that the ISFS is proposed to be on the HPC site so this estimated dose is conservative.

21.8.11 The combined impacts of discharges from the Hinkley Point Sites, including gaseous and liquid effluents are compared against the site dose constraint of 500 µSv y^{-1}. The highest dose (17.2 µSv y^{-1}) represents less than 3.5% of the site constraint.

21.8.12 The assessments all show that, when judged against a range of stringent internationally agreed criteria on the Radiological Protection of Human and Non-human species, the assessed impacts from radioactive liquid and gaseous discharges from HPC and other impacts due to site operations such as waste storage and transport are all considered negligible without additional mitigation being required over and above that already contained in the current design. Therefore, the residual impacts remain very low and a small percentage of the relevant dose limits and constraints.

22. LANDSCAPE AND VISUAL

22.1 Introduction

22.1.1 This chapter of the Environmental Statement (ES) provides an assessment of the potential landscape and visual impacts associated with the construction and operation of the proposed Hinkley Point C (HPC), the on-site campus accommodation, associated leisure facilities, temporary jetty and the National Grid substation (together referred to as the HPC proposed development). Consideration is also given to the HPC highway improvement works off-site which also form part of the project.

22.1.2 A detailed description of the proposed development is provided in **Chapter 2** of this volume. The construction and operation of HPC is described in **Chapter 3** and **Chapter 4** of this volume, respectively. A summary of issues arising from construction and operation of the HPC proposed development and associated off-site HPC highway improvement works relevant to the assessment of landscape and visual impacts is presented in Section 22.6 of this chapter. A site location plan is shown on **Figure 22.1**.

22.2 Scope and Objectives of Assessment

22.2.1 The scope of this assessment has been determined through a formal Environmental Impact Assessment (EIA) scoping process undertaken with the Infrastructure Planning Commission (IPC) and informed by consultation with statutory consultees, including English Heritage, Natural England, Exmoor National Park Authority, and West Somerset Council (WSC), Sedgemoor District Council (SDC) and Somerset County Council (SCC) as the relevant authorities. Consideration has also been given to comments from non-statutory consultees including the Quantock Hills AONB Service, local residents and members of the general public, notably in response to the Stage 1, Stage 2, Stage 2 Update and M5 Junction 24 and Highway Improvements consultations.

22.2.2 Specifically, this chapter addresses the following:

- landscape planning context for the project including a review of the key designations and the planning policies relevant to the proposed development;
- landscape character and condition of the site and its relationship with the surrounding area;
- visual prominence of the proposed development within the surrounding landscape and the identification of representative visual receptors;
- the significance of the impacts arising from the HPC proposed development on landscape character and landscape elements and features within the HPC development site boundary;
- the significance of the impacts arising from the HPC proposed development on representative visual receptors from locations within the short, middle and long distance during the day and under night time conditions; and

- the significance of impacts on landscape and representative visual receptors arising from the associated off-site highway improvement works.

22.2.3 This chapter has influenced and has been informed by terrestrial ecology and ornithology (**Chapter 20** of this volume), historic environment (**Chapter 23** of this volume), amenity and recreation (**Chapter 25** of this volume) and transport matters (**Chapter 10** of this volume) due to the strong inter-relationship between these topics with landscape and visual issues. Further topic specific baseline information is included in these chapters.

22.2.4 The assessment of landscape and visual impacts has been undertaken adopting the methodologies described in section 22.4.

22.2.5 The existing baseline conditions, against which the landscape and visual impacts of the HPC proposed development and associated off-site highway improvement works are assessed, have been determined through a desk-based assessment, field surveys and modelling, and are described in section 22.5. The assessment of landscape and visual impacts is presented in section 22.6 and assumes that proposed mitigation located within the HPC development site is embodied in the project. Section 22.7 describes the proposed landscape mitigation, including off-site landscaping and a temporary screening bund along the north-western boundary during construction. An assessment of residual impacts is presented in section 22.8. Section 22.9 provides a summary of landscape and visual impacts assessed in this chapter.

22.2.6 An assessment of the landscape and visual impacts arising from HPC off-site associated development is presented in separate ES chapters. Cumulative impacts relating to landscape and visual matters arising from the HPC proposed development in combination with other elements of the HPC project and other relevant plans and projects are identified and assessed in **Volume 11** of this ES.

22.3 Legislation, Policy and Guidance

22.3.1 Guidelines for Landscape and Visual Assessment (GLVIA) produced by the Landscape Institute (LI) and Institute of Environmental Management and Assessment (IEMA) (Ref. 22.1) states that

> *"It is important for landscape assessments to consider the ecological, historical or cultural associations that contribute to the character and importance of a landscape."*
>
> and,
>
> *"planning policies for nature conservation and landscape are generally linked through a common approach to land use… there are also numerous interrelationships between landscape and cultural heritage and it is important that these links are not overlooked."*

22.3.2 In accordance with best practice guidance, this assessment takes into account legislation and policy relevant to landscape and visual amenity, ecology and cultural heritage. Reference should also be made to **Chapter 20** of this volume (terrestrial ecology and ornithology) and **Chapter 23** of this volume (historic environment) for details on specific heritage and biodiversity policy.

22.3.3 This section reviews relevant European and national legislation and policy, as well as guidance from Natural England and published materials prepared by statutory and non-statutory bodies, such as Exmoor National Park authority and the Quantock Hills AONB Service.

22.3.4 The overall legislative and planning policy context for the HPC project is set out in **Volume 1 Chapter 4**.

a) International Legislation

i. European Landscape Convention (Ref. 22.2)

22.3.5 The European Landscape Convention (ELC), which was signed by the UK in February 2006 and became binding in 2007, is the first international convention to focus specifically on landscape issues and aims to protect, manage and plan landscapes in Europe. The ELC defines landscape as:

> *"An area, as perceived by people, whose character is the result of the action and interaction of natural and/or human factors."*

b) UK Legislation

i. National Parks and Access to the Countryside Act 1949 as amended by the Environment Act 1995 (Ref. 22.3)

22.3.6 The National Parks and Access to the Countryside Act provides for the designation of National Parks to conserve and enhance their natural beauty, wildlife and cultural heritage and promote opportunities for the understanding and enjoyment of the special qualities of those areas by the public. References in the Act to the preservation or the conservation of the natural beauty of an area are to be construed as including references to the preservation or, as the case may be, the conservation of its flora, fauna and geological and physiographical features.

22.3.7 Areas of Outstanding Natural Beauty (AONB) are designated under the provisions of the 1949 National Parks and Access to the Countryside Act, in order to secure their permanent protection against development that would damage their special qualities. AONBs are designated solely for their landscape qualities, for the purpose of conserving and enhancing their natural beauty.

ii. Countryside and Rights of Way (CRoW) Act 2000 (Ref. 22.4)

22.3.8 The CRoW Act provides a statutory framework for AONBs, provides further measures to protect the AONBs, and clarifies the role of local authorities which now includes the preparation of management plans to set out how they will care for their AONBs.

iii. Hedgerow Regulations 1997 (Ref. 22.5)

22.3.9 The Hedgerow Regulations aim to protect hedgerows, which play an important role in supporting and enhancing biodiversity, as well as defining the character of the English countryside.

22.3.10 According to the regulations, a hedgerow is important if it has existed for 30 years or more and it satisfies various wildlife, landscape or historical criteria specified in the regulations.

iv. Ancient Monuments and Archaeological Areas Act 1979 (Ref. 22.6)

22.3.11 Scheduled Monuments are designated under the Ancient Monuments and Archaeological Areas Act for archaeological sites or historic buildings that are considered to be of national importance by English Heritage. They are given protection against unauthorised change including changes to their visual setting.

c) National Planning Policy

i. Overarching National Policy Statement for Energy (EN-1) (Ref. 22.7)

22.3.12 The overarching National Policy Statement (NPS) for Energy (EN-1) sets out national policy for energy infrastructure. The policy, together with the relevant technology-specific NPS, effects decisions by the Infrastructure Planning Committee (IPC) on applications for energy developments that fall within the scope of the NPSs.

22.3.13 Part 4 of EN-1 titled 'Assessment Principles' sets out the key principles for examining and determining applications for energy infrastructure. In relation to good design, EN-1 states in paragraph 4.5.1 that *"applying 'good design' to energy projects should produce sustainable infrastructure sensitive to place, efficient in the use of natural resources and energy used in their construction and operation, matched by an appearance that demonstrates good aesthetic as far as possible"*. However, it is acknowledged that the nature of much of the infrastructure development will often limit the extent to which it can contribute to the enhancement of the quality of the area.

22.3.14 In relation to landscape and visual impacts, EN-1 specifies that *"applicants should carry out a landscape and visual assessment and report it in the ES"*, adding that it should *"include reference to any landscape character assessment and associated studies as a means of assessing landscape impacts relevant to the proposed project… [and] …also take account of any relevant policies based on these assessments in local development documents…"*. EN-1 adds that *"the applicants' assessment should include the effects during construction of the project and the effects of the completed development and its operation on landscape components and landscape character"*. It should be noted that EN-1 Specifies that *"in this context, references to landscape should be taken as covering seascape and townscape where appropriate."*

22.3.15 It acknowledges that *"Virtually all nationally significant infrastructure projects will have effects on the landscape. Projects need to be designed carefully, taking account of the potential impacts on the landscape. Having regard to siting, operational and other relevant constraints the aim should be to minimise harm to the landscape, providing reasonable mitigation where possible and appropriate."*

22.3.16 Reference is made to development within nationally designated landscape, noting in particular that:

> *"National Parks, the Broads and AONBs have been confirmed by the Government as having the highest status of protection in relation to landscape and scenic beauty. Each of these designated areas has specific statutory purposes which help ensure their continued protection and which the IPC should have regard to in its decisions. The conservation of the natural beauty of the landscape and countryside should be given*

substantial weight by the IPC in deciding on applications for development consent in these areas.

Nevertheless, the IPC may grant development consent in these areas in exceptional circumstances. The development should be demonstrated to be in the public interest and consideration of such applications should include an assessment of:

- *The need for the development, including in terms of national considerations, and the impact of consenting or not consenting it upon the local economy;*
- *the cost of, and scope for, developing elsewhere outside the designated area or meeting the need for it in some other way, taking account of the policy on the alternatives set out in Section 4.4; and*
- *any detrimental effect on the environment, the landscape and recreational opportunities, and the extent to which that could be moderated.*

The IPC should ensure that any projects consented in these designated areas should be carried out to high environmental standards, including the application of appropriate requirements where necessary."

22.3.17 It should be noted that the HPC development site is not located within an AONB designation. The nearest AONB, Quantock Hills, is located approximately 3.7km south west of the HPC development site boundary.

ii. National Policy Statement for Nuclear Power Generation (EN-6) (Ref. 22.8)

22.3.18 The National Policy Statement (NPS) for Nuclear Power Generation (EN-6), together with the overarching NPS for Energy (EN-1) provides the primary basis for decisions taken by the IPC on applications for nuclear power stations.

22.3.19 All of the NPSs have been subject to an Appraisal of Sustainability (AoS). EN-6 reports that: *"possible significant adverse effects on nationally important nature conservation sites and designated landscapes were identified by the Nuclear AoS"*, adding that *"further studies will need to be carried out, as part of the project EIA process for individual development consent applications, to determine significance of the effects and the effectiveness of any mitigation measures."*

22.3.20 EN-6 re-emphasises EN1 by noting the need for the consideration of good design. It states that the *"IPC should consider how good design can act to mitigate the impacts of nuclear power stations, such as landscape and visual impacts."*

22.3.21 Part 4 of the NPS identifies the potentially suitable sites for the development of nuclear power stations in England and Wales before the end of 2025. Hinkley Point is one of the eight sites identified.

22.3.22 All the potentially suitable sites are recognised as sharing the following landscape issues:

"The sites are generally in less populated areas that may have value for their visual amenity and as landscape resources; they are coastal/estuarine sites; and the scale of the facilities means that the scope for visual mitigation is quite limited."

22.3.23 It is recorded that there can be uncertainty over future land uses once the sites are decommissioned due to the timescales involved in the projects. The potential long term impacts on visual amenity are also recognised.

iii. Planning Policy Statement 1: Delivering Sustainable Development (PPS1) (2005) (Ref. 22.9)

22.3.24 PPS1 was published in 2005 and sets out the Government's overarching planning policies on the delivery of sustainable development through the planning system. It advises that planning should facilitate and promote sustainable and inclusive patterns of urban and rural development by, amongst other things: protecting and enhancing the natural and historic environment; the quality and character of the countryside and existing communities; and ensuring high quality development through good and inclusive design; and the efficient use of resources (paragraph 5).

22.3.25 Paragraph 17 of PPS1 states:

> *"The Government is committed to protecting and enhancing the quality of the natural and historic environment, in both rural and urban areas. Planning policies should seek to protect and enhance the quality, character and amenity value of the countryside and urban areas as a whole. A high level of protection should be given to most valued townscapes and landscapes, wildlife habitats and natural resources. Those with national and international designations should receive the highest level of protection."*

iv. Planning Policy Statement 5: Planning for the Historic Environment (2010) (PPS5) (Ref. 22.10)

22.3.26 PPS5 sets out the role of planning in conserving and enhancing the historic environment, and establishes those elements which constitute the historic environment.

22.3.27 Landscapes of historic interest are considered to be 'heritage assets' and PPS5 makes reference to 'historic environment characterisation', the process of combining assessments of archaeological, architectural and historic landscape character to define the overall historic character of a place or landscape. PPS5 also stresses the importance of understanding of the cultural processes shaping the present landscape in coastal and marine areas.

v. Planning Policy Statement 7: Sustainable Development in Rural Areas (PPS7) (2004) (Ref. 22.11)

22.3.28 PPS7 was published in 2004 and sets out Government policy on the conservation of the natural beauty of the landscape and countryside and the Government's objectives for rural areas. The key objectives of PPS7 in the context of landscape and visual amenity are:

- *"good quality, sustainable development that respects and, where possible, enhances local distinctiveness and the intrinsic qualities of the countryside; and,*

- *continued protection of the open countryside for the benefit of all, with the highest level of protection for our most valued landscapes and environmental resources."*

22.3.29 PPS7 also states that protection of the countryside for the sake of its intrinsic character and beauty is the Government's overall aim and that all development in rural areas should be sensitive to the character of the countryside and local distinctiveness.

22.3.30 Paragraph 21 of PPS7 states:

> *"Nationally designated areas comprising National Parks, the Broads, the New Forest Heritage Area and Areas of Outstanding Natural Beauty (AONB), have been confirmed by the Government as having the highest status of protection in relation to landscape and scenic beauty. The conservation of the natural beauty of the landscape and countryside should therefore be given great weight in planning policies and development control decisions in these areas. The conservation of wildlife and the cultural heritage are important considerations in all these areas. They are a specific purpose for National Parks, where they should also be given great weight in planning policies and development control decisions. As well as reflecting these priorities, planning policies in LDDs and where appropriate, RSS, should also support suitably located and designed development necessary to facilitate the economic and social well-being of these designated areas and their communities, including the provision of adequate housing to meet identified local needs."*

22.3.31 Paragraph 22 advises that major developments (including major development proposals that raise issues of national significance) should not take place in these designated areas, except in exceptional circumstances.

vi. Planning Policy Statement 9 (PPS9): Biodiversity and Geological Conservation (2005) (Ref. 22.12)

22.3.32 PPS9 was published in 2005 and sets out planning policies on the protection of biodiversity and geological conservation through the planning system. The broad aim of the policies is to ensure that planning, construction, development and regeneration should have minimal impacts on biodiversity and enhance it wherever possible.

22.3.33 Key objectives of PPS9 include:

- *"to promote sustainable development by ensuring that biological and geological diversity are conserved and enhanced as an integral part of social, environmental and economic development, so that policies and decisions about the development and use of land integrate biodiversity and geological diversity with other considerations.*
- *conserve, enhance and restore the diversity of England's wildlife and geology by sustaining and where possible improving the quality and extent of natural habitat and geological and geomorphological sites; and to conserve, enhance and restore the diversity of England's wildlife and geology by sustaining, and where possible improving, the quality and extent of natural habitat and geological and geomorphological sites; the natural physical processes on*

which they depend; and the populations of naturally occurring species which they support."

22.3.34 Paragraph 8 states that, where a proposed development on land within or outside an SSSI is likely to have an adverse effect on an SSSI (either individually or in combination with other developments), planning permission should not normally be granted. Where an adverse effect on the site's notified special interest features is likely, an exception should only be made where the benefits of the development, at this site, clearly outweigh both the impacts that it is likely to have on the features of the site that make it of special scientific interest and any broader impacts on the national network of SSSIs.

22.3.35 Paragraph 9 states that sites of regional and local biodiversity and geological interest, which include Regionally Important Geological Sites, Local Nature Reserves and Local Sites, have a fundamental role to play in meeting overall national biodiversity targets; contributing to the quality of life and the well-being of the community; and in supporting research and education.

22.3.36 Paragraph 10 states that planning authorities should not grant planning permission for any development that would result in the loss or deterioration of ancient woodland, unless the need for, and benefits of, the development in that location outweigh the loss of the woodland habitat.

22.3.37 Paragraph 12 states that networks of natural habitats provide a valuable resource and should be protected from development, and, where possible, strengthened by or integrated within it.

22.3.38 Paragraph 16 states that planning authorities should ensure that protected species are protected from the adverse impacts of development and refuse permission where harm to the species or their habitats would result, unless the need for, and benefits of, the development clearly outweigh that harm.

vii. **Planning Policy Statement 25 Supplement: Development and Coastal Change (PPS25)** (Ref. 22.13)

22.3.39 PPS25 Supplement describes coastal change as *"physical change to the shoreline, i.e. erosion, coastal landslip, permanent inundation and coastal accretion"*. It states that the Government's aim is to ensure that coastal communities adapt to coastal change, and that policies and decisions are based on an understanding of coastal change over time. It adds that local planning authorities should therefore ensure that they have an appropriate evidence base on coastal change. Specifically, local planning authorities should *"identify areas likely to be affected by physical changes to the coast and refer to this area as the Coastal Change Management Area (CCMA)".* This should include details of the character of the coast and any relevant designations.

viii. **Planning Policy Statement: Planning for a Low Carbon Future in a Changing Climate (Consultation Paper) (March 2010)** (Ref. 22.14)

22.3.40 The draft PPS sets out a planning framework for securing progress towards meeting the UK's targets to cut greenhouse gas emissions and use more renewable and low carbon energy, and to plan for climate change.

22.3.41 The document sharpens the policy on locating renewable and low carbon energy projects and states that *"depending on their scale and impact, renewable and low carbon energy developments should be capable of being accommodated in most locations"*. It goes on to state that *"planning should ensure that adverse impacts on the environment are addressed satisfactorily but applications for cutting edge, well designed buildings should not be turned down simply because they do not look familiar".* The document sets this out in proposed policy LCF 13.4 which states that *"Local planning authorities should support innovation which secures well designed, sustainable buildings."*

ix. Consultation Paper on a New Planning Policy Statement: Planning for a Natural and Healthy Environment (Ref. 22.15)

22.3.42 In March 2010, the Government published a Consultation Paper for a new Planning Policy Statement: Planning for a Natural and Healthy Environment. The consultation period expired in June 2010.

22.3.43 At the outset, the document makes clear that in its final form, the PPS would replace paragraphs 21 to 23 in PPS7 which relate to landscape protection.

22.3.44 With specific reference to landscape protection, proposed Policy NE8.5 maintains the approach set out in Paragraph 21 of PPS7. In addition, proposed Policy NE8.5 advises that, in consideration of applications for major development proposals should include an assessment of:

(i) "the need for the development, including in terms of any national considerations, and the impact of permitting it, or refusing it, upon the local economy;

(ii) the cost of, and scope for, developing elsewhere outside the designated area, or meeting the need for it in some other way; and

(iii) any detrimental effect on the environment, the landscape and recreational opportunities, and the extent to which that could be moderated."

d) Regional Planning Policy

22.3.45 The Government's revocation of regional strategies was quashed in the High Court on 10 November 2010. However, on the same date the Government reiterated in a letter to Chief Planners its intention to revoke regional strategies through the Localism Bill. This letter was also challenged but, on 7 February 2011, the High Court held that the Government's advice to local authorities that the proposed revocation of regional strategies was to be regarded as a material consideration in their planning decisions should stand. Therefore, the regional strategies remain in place but it is for planning decision makers to decide on the weight to attach to the strategies taking into account, as a material consideration, the Government's stated intention to revoke them (see **Volume 1, Chapter 4** for a full summary of the position regarding the status of regional planning policy). Consequently, the following policies are of relevance:

i. Regional Planning Guidance 10 for the South West 2001 – 2016 (RPG10) (2001) (Ref. 22.16)

22.3.46 RPG 10 sets out the broad development strategy for the period to 2016 and beyond. With specific reference to landscape character, paragraph 4.5 explains that the Countryside Agency and English Nature have identified and mapped the distinctive "character areas" for the South West as part of the testing of a new approach to "environmental capital" being promoted by the Countryside Agency, English Heritage, English Nature and the Environment Agency.

22.3.47 Policy EN 1 relates to Landscape and Biodiversity. It states that local authorities and other agencies, in their plans, policies and proposals, should, amongst other things:

- *"provide for the strong protection and enhancement of the region's internationally and nationally important landscape areas and nature conservation sites;*
- *indicate that the protection and, where possible, enhancement of the landscape and biodiversity should be planned into new development;*
- *have regard to the significant landscape joint character areas of the region set out in this RPG (…)and aim to conserve and enhance local character;*
- *take measures to protect the character of the countryside and the environmental features that contribute towards that character, including minimisation of light pollution."*

ii. Draft Revised Regional Spatial Strategy (RSS) for the South West Incorporating the Secretary of State's Proposed Changes for Public Consultation (July 2008) (Ref. 22.17)

22.3.48 Chapter 7 deals with Enhancing Distinctive and Cultural Life. Policy EN1 states;

"The quality, character, diversity and local distinctiveness of the natural and historic environment in the South West will be protected and enhanced, and developments which support their positive management will be encouraged. Where development and changes in land use are planned which would affect these assets, Local Authorities will first seek to avoid loss of or damage to the assets, then mitigate any unavoidable damage, and compensate for loss or damage through offsetting actions. Priority will be given to preserving and enhancing sites of international or national landscape, nature conservation, geological, archaeological or historic importance. Tools such as characterisation and surveys will be used to enhance local sites, features and distinctiveness through development, including the setting of settlements and buildings within the landscape and contributing to the regeneration and restoration of the area."

iii. Somerset & Exmoor National Park Joint Structure Plan Review 1991-2011 (2000) (Ref. 22.18)

22.3.49 The Somerset & Exmoor National Park Joint Structure Plan was adopted in 2000 with relevant policies saved from 27 September 2007. All policies have been saved with the exception of Policy 53 which is unrelated to landscape and visual impacts. The Plan provides a strategic base for all land use planning within the plan area for the period up to 2011.

22.3.50 The Somerset and Exmoor National Park Joint Structure Plan contains policies which aim to protect the local area.

22.3.51 Nature Conservation (Policy 1) states;

> *"The biodiversity of Somerset and the Exmoor National Park should be maintained and enhanced. The greatest protection will be afforded to nature conservation sites of international and national importance.*
>
> *In addition, Local Plans should include policies to maintain and enhance sites and features of local nature conservation importance including landscape features which provide wildlife corridors, links or stepping stones between habitats."*

22.3.52 Exmoor National Park (Policy 2) states;

> *"In the Exmoor National Park;*
>
> - *the conservation and enhancement of the natural beauty, wildlife and cultural heritage;*
> - *the promotion of opportunities for public understanding and enjoyment of the special qualities of the area,*
>
> *should be given priority over other planning considerations. In cases of conflict between these purposes, greater weight should be attached to the first."*

22.3.53 Areas of Outstanding Natural Beauty (Policy 3) states;

> *"In Areas of Outstanding Natural Beauty the conservation of the natural beauty of the landscape should be given priority over other planning considerations….Provision should only be made for major industrial or commercial development where it is in the national interest and there is a lack of alternative sites. Particular care should be taken to ensure that any development proposed does not damage the landscape character of the area."*

22.3.54 Landscape Character (Policy 5) states;

> *"The distinctive character of the countryside of Somerset and Exmoor National Park should be safeguarded for its own sake. Particular regard should be had to the distinctive features of the countryside in landscape, cultural heritage and nature conservation terms in the provision for development."*

22.3.55 Historic Landscapes (Policy 10) states;

> *"Development proposals which affect a registered historic landscape (historic parks, gardens and battlefields) should take account of their impact on the character of that landscape."*

22.3.56 Coastal Development (Policy 15) states;

"Provision for any development along the coast, including the Exmoor Heritage Coast, should be made within towns, Rural Centres and Villages. Where development requires an undeveloped coastal location it should respect the natural beauty, biodiversity and geology of the coast and be essential in that location…."

iv. Strategy for the Severn Estuary (2001) (Ref. 22.19)

22.3.57 Whilst not forming part of the statutory development plan for the proposed development site, the Strategy for the Severn Estuary was published by the Severn Estuary Partnership in 2001 and sets out policies and proposals for action for the estuary. Chapter 12 deals with Landscape and Seascape and aims to conserve, promote and enhance and, where necessary, restore the special and distinctive character and quality of the estuary's landscape and seascape.

22.3.58 Strategy for the Severn Estuary influences the design of infrastructure and transport projects in relation to the estuary's landscape and seascape through Policy L1c, which states;

"Plan and design all new developments including infrastructure and transport so that they conserve and enhance the character of the Severn Estuary landscape and seascape across authority boundaries."

e) Local Planning Policy

22.3.59 Although the site is not located within any local landscape policy designation, several general policies related to landscape issues exist within the West Somerset District Local Plan 2006; the Exmoor National Park Local Plan 2001-2011, Sedgemoor District Local Plan 1991-2011; and North Somerset District Replacement Local Plan (RLP). Details follow below.

i. West Somerset Local Plan (2006) (Policies 'saved' from 17 April 2009) (Ref. 22.20)

22.3.60 The West Somerset Local Plan forms part of the development plan for West Somerset. The Local Plan was adopted in April 2006. The Proposals Map indicates that the site is not subject to any specific landscape designations. The site lies outside of the defined Development Boundary.

22.3.61 The following policies are considered to be potentially relevant:

22.3.62 Areas of Outstanding Natural Beauty (Policy LC/2) states;

"Development which would harm the natural beauty and character of the Quantock Hills Area of Outstanding Natural Beauty will not be permitted. Major industrial or commercial development will only be permitted where justified by a proven national interest and a lack of alternative sites."

22.3.63 Landscape Character (Policy LC/3) states:

"Where development is permitted outside development limits, particular attention will be given to the protection of the scenic quality and distinctive local character of the landscape. Development which does not respect the character of the local landscape will not be permitted."

22.3.64 Trees and Woodland Protection (Policy TW/1) states;

"Development proposals that would adversely affect woodlands, groups of trees or individual trees of significant landscape, wildlife or amenity value will only be permitted where conditions can be attached to planning permissions to protect trees and, where appropriate, to require replacement and/or additional planting."

22.3.65 Hedgerows (Policy TW/2) states;

"Development or land management proposals will be required to show that an allowance has been made for the retention and protection of existing hedgerows and hedgerow trees unless they are not considered to be of value to the area's landscape, character or wildlife."

22.3.66 Sites of Local Nature Conservation or Geological Importance (Policy NC/3) states;

"Planning permission will not be granted for development which has a significant adverse effect on local nature conservation/geological interests or integrity of landscape features, unless the importance of the development outweighs the value of the substantive interests present.*

Where development is permitted which would damage the nature conservation value of the site, such damage will be kept to a minimum. The use of conditions and/or Planning Obligations to provide appropriate compensatory measures will be considered.

**Landscape features include:*

- river, streams and ponds,

- species rich hedgerows, field margins and road verges,

- broad leafed woodlands and orchards,

- wood pasture, parkland and veteran trees present."

22.3.67 River Corridor Protection (Policy W/7) states;

"Development which would harm the landscape, nature conservation, fisheries or the recreational interest of water courses, wetlands and the surrounding landscape will only be permitted where suitable mitigation measures are undertaken to ensure that any damage is kept to a minimum and compensatory measures, including enhancement and habitat restoration, are secured."

22.3.68 Development in the Coastal Zone (Policy CO/2) states;

"Development proposals in any part of the Coastal Zone, including those areas of existing developed coast, will only be permitted where;

(i) the development and its associated activities are unlikely to have an adverse effect, either directly or indirectly on;

a. heritage features,

b. landscape character areas,

c. nature conservation interests, including sub-tidal and marine habitats, and;

d. residential amenities.

(ii) the development is unlikely to have an adverse effect on the character of the coast and maintains and where possible, enhances, improves or upgrades the environment particularly in derelict and/or despoiled coastal areas; and

(iii) the development requires a coastal location."

22.3.69 Historic Parks and Gardens (Policy LB/3) states;

"Development which would harm any part or setting of a registered historic park or garden will not be permitted."

22.3.70 New Development and Conservation Areas (Policy CA/1) states;

"Development proposals in conservation areas will be permitted only where they are compatible with the preservation or enhancement of the architectural and historic character or appearance of the conservation area. In particular, proposals should meet the following requirements:

i) The proposal must be in keeping with the scale, architectural quality and features of the area and not detract from the setting of historic or architecturally important buildings.

ii) External building materials must be appropriate to those that are traditional in the conservation area.

iii) The proposal should not detract from the existing landscape elements of the conservation area including trees, hedgerows, walls, banks, footpaths and open spaces."

ii. **Exmoor National Park Local Plan 2001-2011 (2005) (Policies 'saved' from 14 February 2008)** (Ref. 22.21)

22.3.71 Aspects of planning policy and guidance of relevance to the site and to the landscape and visual amenity are presented below, as detailed in the Exmoor National Park Local Plan.

22.3.72 Lighting (Policy LNC 2) states;

"Applications for development which include lighting will not be permitted where:

(i) The lighting scheme proposed is excessive to achieve its purpose;

(ii) There would be sky glow, light spillage from the site or unacceptable glare;

(iii) There would be an adverse impact on local amenity, landscape, wildlife or the historic environment of the National Park."

22.3.73 Landscapes Covered by Section 3 Conservation Map (Policy LNC 3) refers to Section 3 of the Wildlife and Countryside (Amendment) Act 1985 and states;

"Development proposals which adversely affect the natural beauty of areas shown on the Proposals Map as Section 3 Moor, Heath, Woodland, Cliff and Foreshore will not be permitted."

22.3.74 Important Trees, Woodlands and Hedgerows (Policy LNC 4) states;

"Development proposals that would adversely affect woodlands, groups of trees, hedgerows or individual trees of significant landscape or amenity value will not be permitted unless acceptable conditions can be attached to protect trees and, where appropriate to require replacement or additional planting."

22.3.75 Coastal Zone (Policy LNC 6) states;

"Permission for development proposals within the coastal zone defined on the Proposals Map will be restricted to those which:

(i) Are appropriate to the coastal location and do not adversely affect coastal interests;

(ii) Involve changes in use or alterations or additions to buildings, or improvements to facilities on permanently established caravan and camping sites, without substantial impact on the coastal character of the surroundings."

22.3.76 Rivers and their Corridors (Policy LNC 7) states;

"Development proposals which harm the landscape, nature conservation, fishing or recreational interest of rivers and adjacent banks and valley sides associated with their landscape and amenity value will not be permitted."

22.3.77 Sites of Local Nature Conservation Importance (Policy LNC 11) states;

"In considering proposals which affect sites of local nature conservation importance the Authority will have full regard for their scientific significance and nature conservation value…"

22.3.78 Historic Parks and Gardens (Policy CBS 11) states;

"Development which would harm the special features and qualities of historic parks or gardens, or their settings will not be permitted."

iii. Sedgemoor District Local Plan (1991-2011 Adopted Version) (2004) (Ref. 22.22)

22.3.79 The Sedgemoor District Local Plan forms part of the development plan for the proposed development site. The Local Plan was adopted in 2004 with relevant policies saved from 27 September 2007. The Inset Map (Map No. 1) indicates that the entire proposed development site is not subject to any specific landscape, heritage or biodiversity designations.

22.3.80 The relevant saved policies relating to landscape and visual impacts are as follows.

22.3.81 Policy CNE2 (Landscape Character) states;

"Development which adversely affects local landscape character or scenic quality will not be permitted. In particular:

a) siting and landscaping should take account of visibility from publicly accessible vantage points; and

b) the form, bulk and design of buildings should have proper regard to their context in respect of both the immediate setting and the defining characteristics of the wider local area.

In determining planning applications the important characteristics of landscape character areas described in the Sedgemoor Landscape Assessment and Countryside Design Summary and/or AONB Landscape Assessments will be a material consideration."

22.3.82 Policy CNE4 (Countryside Around Settlements) states;

"Areas of land which have particular importance as Green Wedge, Green Edge or Strategic Gap are defined on the Proposals Map. Whatever their individual character and function, these are predominantly open areas, mostly outside development boundaries, which retain a largely rural character and appearance. Positive land management which benefits the landscape, countryside access, amenity, nature conservation or urban area containment/enhancement functions of these areas will be encouraged and developments which would have a detrimental effect on these functions will not be permitted."

22.3.83 Policy CNE7 (Internationally Important Sites) states;

"Development which is likely to have a significant adverse effect on the conservation objectives or the integrity of a site of international importance (i. e. Ramsar sites, potential and classified Special Protection Areas, or candidate and designated Special Areas of Conservation) will not be permitted."

22.3.84 Policy CNE12 (Trees, Hedgerows and Woodlands) states;

"In considering proposals for development, the Council will seek to protect important trees and hedgerows. Planning permission may be refused where these would not be retained, or acceptably replaced. The Council will also encourage the planting and proper management of new trees and shrubs."

iv. Sedgemoor District Local Development Framework Core Strategy (Proposed Submission) (September 2010) (Ref. 22.23)

22.3.85 The Sedgemoor Core Strategy Proposed Submission was consulted on from September to November 2010. Changes prior to submission, proposed as a result of the consultation process were recently reported and endorsed by the Council's Executive Committee on 9 February 2011. This was submitted to the Secretary of State on 1 March 2011.

22.3.86 Chapter 3 outlines the overarching strategy for the plan area. Policy D4 relates to proposals for Renewable or Low Carbon Energy Generation. It states the Council will support proposals that maximise the generation of energy from renewable or low carbon sources, provided that the installation would not have significant adverse impact taking into account, amongst other factors:

"The impact of the scheme, together with any cumulative impact (including associated transmission lines, buildings and access roads), on landscape character, visual amenity, historic features and biodiversity."

22.3.87 Policy D14 (Natural Environment) deals with landscape and visual impacts more generally. It states:

"Development proposals within the Mendip Hills AONB or the Quantock Hills AONB will only be supported where they enhance or maintain the natural beauty, or the exceptional character or quality of the landscape in these areas.

Elsewhere in the District proposals should ensure that they enhance the landscape quality wherever possible or that there is no significant adverse impact on local landscape character, scenic quality and distinctive landscape features as identified in the Sedgemoor Landscape Assessment and Countryside Design Summary. In particular through:

a) siting and landscaping that takes account of visibility from publicly accessible vantage points;

b) the form, bulk and design of buildings having proper regard to their context in respect of both the immediate setting and the defining characteristics of the wider local area.

Where there are reasonable grounds to suggest that a development proposal may result in a significant adverse impact on the landscape, the Council will require planning applications to be supported by landscape impact assessments.

In exceptional circumstances, where development is necessary and could result in significant impact on the landscape, appropriate mitigation and compensation measures should be provided."

v. Supplementary Planning Guidance

22.3.88 Sedgemoor District Council and West Somerset Council have jointly prepared draft supplementary planning guidance in relation to the HPC Project. Public consultation on the Consultation Draft version of the Hinkley Point C Project Supplementary Planning Document (the draft HPC SPD) commenced on 1 March 2011 and concluded on 12 April 2011. EDF Energy has submitted representations which object to the draft HPC SPD. See **Volume 1, Chapter 4** for a full summary of the position regarding the status of the draft HPC SPD.

22.3.89 With regards to the approach to masterplanning and design of the Main Site, Box 19 in the draft HPC SPD states that the HPC project promoter will be expected, amongst other things:

- *"To undertake an assessment of the individual and cumulative visual impacts of the proposals taking into account the impacts of off-site associated development proposals and impacts during the construction stage of the project;*
- *To minimise the individual and cumulative visual impacts on the landscape and setting of designated areas, buildings and monuments, including Exmoor National Park, AONBs, Conservation Areas, Outstanding Heritage Settlements, Listed Buildings and Scheduled Ancient Monuments and where it has been demonstrated by the HPC project promoter that the impacts are unavoidable provide appropriate levels of mitigation and compensation;*
- *To ensure a partnership approach to the master-planning of the site involving local authorities and the local communities with the objective of securing a coherent and high quality design solution;*
- *To identify landscape treatments, habitat creation and public rights of way connections and improvements that integrate appropriately with the surrounding area and sufficiently mitigate and compensate for the impacts on these features at the construction, operation and decommissioning stages. Landscape and green infrastructure works and enhancements that extend beyond the power station main site boundary will be expected to mitigate and compensate the impacts of the project;*
- *Protect valuable landscape assets through careful construction practices;*
- *To prepare a landscape legacy plan (in consultation with the Council and local communities) to demonstrate how the landscape and rights of way proposals on and off site can integrate effectively with the area in the long term…" (page 36-37)'.*

22.3.90 Further planning policy context is provided in the Legislative Planning Policy Context chapter (**Volume 1 Chapter 4**) and the Introduction chapter (**Volume 1 Chapter 1**).

vi. North Somerset District Replacement Local Plan (RLP) (Ref. 22.24)

22.3.91 The North Somerset Replacement Local Plan (RLP) adopted in March 2007 is the most important local planning document as it sets out the local planning context up to 2011. It applies and implements all national and regional planning policies interpreting them into specific planning guidelines for North Somerset district. Work has also begun on the Local Development Framework (LDF) a new suit of documents which will provide local planning guidance to replace the North Somerset Local Plan.

22.3.92 The North Somerset Replacement Local Plan (RLP) is part of North Somerset's Local Development Framework. The policies in the plan remain in force until they are superseded by forthcoming Development Plan Documents.

22.3.93 Landscape Character Areas (Policy ECH/7) states;

"Within the Landscape Character Areas, development will be permitted if it will not adversely affect the particular character of the landscape."

22.3.94 Mendip Hills Area of Outstanding Natural Beauty (Policy ECH/8) states;

"(…) Major development which would affect the environment and landscape of the Mendip Hills AONB will only be permitted where:

i. there is a need for the development in terms of national considerations; and

ii. there is no adverse effect on the local economy; and

iii. there is a lack of an alternative site outside the area, having regard to the cost or means of meeting the need for it in some other way; and

iv. any harm to the environment and natural beauty of the landscape of the AONB can be kept to a minimum and the development is carried out to high environmental standards.

Wherever possible new roads should be kept away from the AONB and, where they would be likely to affect it, proposals should demonstrate the need for the road and that the route and design would do as little damage to the environment as practicable."

f) Designated Area Management Plans and Guidance

i. Quantock Hills Area of Outstanding Natural Beauty Management Plan 2009-2014 (2009) (Ref. 22.25)

22.3.95 Whilst not forming part of the statutory development plan for the HPC development site, the Quantock Hills Area of Outstanding Natural Beauty (AONB) Management Plan was published by the Quantock Hills AONB Joint Advisory Committee in 2009 and sets out policies, objectives and action points over a range of subjects, including landscape, wildlife, historic environment and cultural influences, development and planning. Of particular relevance are the following policies:

- Policy D1 – *"To protect the wild character, wildlife sites and species, cultural landscape and architectural heritage of the AONB."*
- Policy D2 – *"To ensure AONB involvement and influence in planning processes affecting the AONB."*
- Policy D3 – *"To protect the views out from the AONB through involvement in the planning process."*
- Policy D4 – *"To support the local distinctiveness in AONB settlements."*

ii. Mendip Hills Area of Outstanding Natural Beauty Management Plan 2009-2014 (Ref. 22.26)

22.3.96 The Mendip Hills AONB Management Plan was published by the Mendip Hills AONB Partnership in 2009 and sets out the special qualities of the Mendip Hills AONB; considers current issues and future trends; pressures and challenges; and suggests what needs to happen in the future to conserve and enhance the AONB.

g) Other Relevant Guidance

i. Lighting in the Countryside: Towards Good Practice (Ref. 22.27)

22.3.97 The Department for Communities and Local Government (DCLG) and the former Countryside Commission (CC) 1997 guidance on lighting, Lighting in the Countryside: Towards Good Practice provides advice on developing lighting strategies, lighting design and how to mitigate adverse impacts associated with lighting on landscape and visual amenity.

22.3.98 Guidance relevant to the landscape and visual impact assessment and landscape character assessment is referred to in section 22.4 of this chapter (methodology).

22.4 Methodology

22.4.1 The Landscape and Visual Impact Assessment (LVIA) and supporting studies and surveys were conducted for all phases of the proposed development, in accordance with the principles set out by the Landscape Institute (LI) and Institute of Environmental Management Assessment (IEMA) in the Guidelines for LVIA (GLVIA) (Ref. 22.1) and guidance on Landscape Character Assessment from the Countryside Agency (now Natural England) and Scottish Natural Heritage (Ref. 22.28).

22.4.2 Landscape and visual impact assessment (LVIA) comprises firstly the identification, understanding and description of the existing ('baseline') landscape and visual receptors (viewers of varying types) likely to be impacted by the proposed HPC development within a defined study area and secondly the identification and description of the impacts arising from the development on the landscape and the visual receptors. The assessment examines both construction phase impacts and operational phase impacts. The impacts are assessed based on an understanding of the construction and operation phases which are fully described in earlier ES chapters but summarised in this section and include all landscape mitigation works within the red line application boundary, except for a temporary screening bund along the north-western boundary during the construction phase, and off-site planting works. Landscape impacts can be both indirect (essentially visual issues that contribute to the appreciation and understanding of landscape character) or direct, physical impacts resulting from development where elements of the landscape are lost i.e. tree cover is removed or farmland is lost to development. Visual impact is an indirect impact resulting in the alteration in a view resulting from development, as seen by varying types of visual receptors. Residual Impacts are recorded in section 22.8. These record the benefits of permanent off-site planting and a temporary screening bund during the construction phase for receptors in close proximity to the HPC development site.

22.4.3 The structure of this chapter broadly comprises the following:

- description of the LVIA study area;
- baseline and assessment methodology;
- landscape baseline;
- visual baseline;
- summary of construction and operational phases;
- landscape impact assessment;
- visual impact assessment; and
- residual impact assessment.

a) LVIA Study Area

22.4.4 The LVIA study area defines the geographic extent of the landscape and visual impact assessment of the HPC proposed development and associated off-site highway improvement works.

22.4.5 The LVIA study area has been defined through a staged process which has included desk study, Zone of Theoretical Visibility (ZTV) analysis, modelling and field survey, including verification and refinement of ZTV results. Consultation has also been undertaken with a range of statutory and non-statutory consultees on the extents of the LVIA study area. The ZTV methodology is presented in **Appendix 22A**.

22.4.6 The geographic area for the assessment of landscape and visual impacts was initially set to 25km from the HPC development site. This distance was considered by the statutory consultees in the Stage 2 consultation as an appropriate basis for initial modelling and assessment.

22.4.7 Following the analysis of Bare Ground ZTVs of early iterations of the HPC proposed development, Ordnance Survey mapping at a range of scales, field surveys and consultation this initial 25km study area was refined to exclude areas from which the proposed development would not be visible or was judged not to have a potential to cause significant landscape and visual impacts due to the screening provided by landform, vegetation or urban form, distance from the HPC proposed development, or combination of some of these factors.

22.4.8 For example it was confirmed during site visits and consultation that in lowland inland areas the HPC proposed development would not be visible beyond 18km. In more elevated areas, or in exposed coastal locations with no intervening visual barriers, the maximum extents of the LVIA study area were assessed to be either 21km or 25km from the HPC proposed development. A summary of the maximum extent of the study area is described below:

- Lowland Somerset – up to 18km from the HPC development site;
- Exmoor National Park – up to 25km from the HPC development site;
- Mendip Hills AONB – up to 21km from the HPC development site; and
- Welsh coastline – up to 21km of the HPC development site.

22.4.9 The Bare Ground ZTV for the HPC proposed development and buffer zones used to define the maximum extents of the LVIA study area for different topographies are presented on **Figure 22.2**. The final LVIA study area is illustrated on **Figure 22.3**.

b) Baseline and Assessment Methodology

22.4.10 The approach to assessing and describing the impacts on landscape and visual receptors is similar to that used for other environmental topics in this ES and is based on determining impact significance through consideration of the potential magnitude of change in relation to the sensitivity of a particular receptor to change. As such the LVIA is similar to the overall assessment approach set out in **Volume 1 Chapter 7**.

22.4.11 There are, however, some differences, which largely relate to the landscape and visual impact assessment process being more complex than other environmental topics (such as water or air quality), since *"it is determined through a combination of quantitative and qualitative elements"* (Ref. 22.1). Therefore, the assessment adopts a structured and consistent approach, incorporates consultation findings and has been undertaken by experienced landscape architecture and assessment professionals.

22.4.12 The methodology used in the assessment of landscape and visual impacts draws significantly upon professional judgment to accurately establish an understanding of baseline conditions, the sensitivity of landscape and visual receptors the magnitude of impacts arising from the proposed development and the significance of impacts arising.

22.4.13 The methodology for this assessment, as described below, was subject to consultation with statutory and non-statutory consultees.

22.4.14 There are four key stages in the assessment process:

- Stage 1: Baseline data collection and analysis.
- Stage 2: Assessment of the sensitivity of landscape and visual receptors.
- Stage 3: Assessment of the magnitude and nature of impacts.
- Stage 4: Assessment of the significance of impacts on landscape and representative visual receptors.

i. Stage 1: Baseline Data Collection and Analysis

22.4.15 This stage establishes the baseline conditions for the LVIA study area and identifies the relevant landscape and visual receptors. Key activities during the baseline data collection and analysis stage included:

- preparation of a ZTV; a theoretical area from which part or all of the proposed HPC proposed development is potentially visible, based on evolving project design;
- preparation of draft photomontages from several locations to illustrate the anticipated view of the operational scheme and including maturing vegetation associated with the landscape strategy to inform evolving project design iterations;
- desk study to identify potential representative viewpoints and photomontage locations;
- desk study of national landscape character within the LVIA study area to understand the broad landscape character context for the project;

- desk study of local (district and designated landscape) character assessments to gain a detailed understanding of the landscape character context of the LVIA study area;
- field survey to review the selection of representative viewpoints to gain a broad understanding of the visual context of the LVIA study area;
- field work to verify the desk study of national and local landscape character assessments and to gain a detailed understanding of the landscape character of the HPC development site and its immediate landscape context, including analysis of landscape elements and features for the HPC development site; and
- consultation with key statutory and non-statutory consultees to review the findings of initial desk study and field work and to agree representative viewpoints, and baseline descriptions of landscape character and visual context.

22.4.16 Representative viewpoints have been selected on the basis of locations that represent a receptor type (such as a group of residential properties). To ensure that selected viewpoints represent the 'worst-case scenario' view for a given receptor, viewpoints were selected which provide the clearest views of the proposed development, for example because of their proximity to the proposed development or the absence of visual barriers between the viewpoint and the proposed development. All representative viewpoints have been agreed during consultation. The majority of viewpoints are publicly accessible, except Principal Viewpoints 10 and 17, which are located on private farmland, and Principal Viewpoints 7 and 23, which are located on private land around historic residences seasonally open to public.

22.4.17 In this LVIA a distinction is made between 'Principal' and 'Secondary' Viewpoints to indicate viewpoints for which Visually Verifiable Images (VVI) were prepared (Principal Viewpoints) and those that have restricted views of the proposed development and for which VVIs were not considered appropriate (Secondary Viewpoints) due to a range of factors such as the long distance from the viewpoint to the site, elevation or landscape elements/features obscuring the views.

22.4.18 A total of 42 Principal and 6 Secondary Viewpoints were selected and agreed with statutory and non-statutory consultees. Initial baseline photographs illustrating views from all viewpoints were taken using a Nikon D100 digital camera, set to the equivalent of a 35mm focal length, which is the equivalent of 50mm film camera lens (equivalent of human eye). Where viewpoints consisted of more than one frame, the relevant frames were merged together using Photovista software (version 2.0).

22.4.19 Photographs for all agreed Principal Viewpoints were retaken with a high resolution camera between February and April 2011. The method for recording high resolution photography, stitching full resolution panoramas and creating VVIs is set out in **Appendix 22B**.

22.4.20 For the purpose of the assessment of lighting impacts dusk views were recorded for 13 viewpoints covering selected and agreed locations up to approximately 7km from the HPC development site. The viewpoints were selected based on their accessibility at dusk, potential visibility of lighting proposals and their distribution across the study area. The dusk views locations were agreed with Statutory and non-statutory consultees in April 2011. The methodology for recording dusk views is available in **Appendix 22B**.

22.4.21 The viewpoint panoramas were scaled according to the Advice Note 01/11 from the Landscape Institute, Photography and Photomontage in Landscape and Visual Impact Assessment (Ref. 22.29). The panoramas on the viewpoint sheets have been scaled to be viewed at a distance of 400mm. Further details on the photographic scaling method are available in **Appendix 22B**.

22.4.22 Where possible, the selected photographs were taken in winter and show the 'worst-case scenario' (views without foliage). For some views, where vegetation does not obscure views of the proposed HPC development site, or it has limited screening effect, views with foliage were considered sufficient. In relation to the Quantock Hills AONB, summer views were preferred by the consultees (notably the Quantock Hills AONB Service), due to the better visibility of the HPC development site and the more representative character of the photographs due to higher number of visual receptors likely to experience such views during summer months.

22.4.23 Representative viewpoints have been classified according to their distance from the HPC development site. Short distance viewpoints are located up to 1.5km from the site, medium distance viewpoints are between 1.5km - 5km from the site and viewpoints beyond 5km from the site are classified as long distance views.

ii. Stage 2a: Receptor Sensitivity – Landscape

22.4.24 The determination of landscape sensitivity is an important part of the landscape and visual impact assessment process. Sensitivity combined with the potential magnitude of impact allows assessment of the overall significance of the landscape impacts to be made.

22.4.25 According to GLVIA (Ref. 22.1), the sensitivity of the landscape resource is described as *"The degree to which a particular landscape type or area can accommodate change arising from a particular development without detrimental effects on its character (…)".* The overall sensitivity of the existing landscape resource will vary with:

- *"existing land use;*
- *the pattern and scale of the landscape;*
- *visual enclosure/ openness of the views, and distribution of visual receptors;*
- *the scope for mitigation, which would be in character with the existing landscape;*
- *the value placed on the landscape."*

22.4.26 In addition to the above list of considerations, GLVIA also considers that sensitivity of the landscape resource is based on evaluation of factors such as quality, value, contribution to landscape character and degree to which elements can be replaced or substituted.

22.4.27 Evaluation of the value or importance of a landscape often refers to policy or designations as an indicator. Importance also relates to the contribution of the landscape element/feature to the character or views within the local area and is a factor of its scenic quality, condition, sense of place, visibility, accessibility and special qualities such as remoteness. Not all characteristics are uniformly spread throughout designated landscapes so the importance of the proposed development site is considered within the designated area.

22.4.28 For assessment purposes, the sensitivity of a landscape receptor is based on the application of the above criteria, informed by field surveys undertaken by landscape professionals, professional judgement of the assessor and consultation with statutory and non-statutory consultees.

22.4.29 **Table 22.1** shows the potential gradations of sensitivity of landscape receptors (high, medium, low or very low).

Table 22.1: Guidelines for the Assessment of Landscape Sensitivity

Sensitivity	Description
High	A landscape of particularly distinctive character and scenic quality. Nationally and regionally designated landscape for its scenic quality and character.
Medium	A landscape of moderately distinctive character and scenic quality. Locally designated landscape for its scenic quality and character.
Low	A landscape of no distinctive character and scenic quality. A landscape not subject to any form of landscape designation.
Very low	A landscape that is damaged, neglected or poor character and lacking scenic quality. A landscape not subject to any form of landscape designation.

22.4.30 By way of an example, a landscape that is nationally designated, such as an AONB, is regarded as being the most sensitive to change. A landscape that is relatively intact, of some scenic quality, and locally designated would be judged to be of medium sensitivity. A landscape that is neglected and damaged, or lacking scenic quality, such as a brownfield site, might be judged to be of low or very low sensitivity.

iii. Stage 2b: Receptor Sensitivity – Visual

22.4.31 Visual sensitivity is established in relation to visual receptors. Visual receptors are interest or viewer groups that may experience an effect arising from the proposed development. According to GLVIA (Ref. 22.1), the sensitivity of visual receptors depends on:

- *"The location and context of the viewpoint;*
- *The expectations and occupation or activity of the receptor;*
- *The importance of the view (which may be determined with respect to its popularity or numbers of people affected, its appearance in guidebooks, on tourist maps, and in the facilities provided for its enjoyment and references to it in literature or art)."*

22.4.32 **Table 22.2** shows the potential gradations of sensitivity of visual receptors (high, medium, low or very low).

Table 22.2: Guidelines for the Assessment of Visual Receptor Sensitivity

Sensitivity	Description
High	Viewers with a proprietary interest, specific interest in the view and prolonged viewing opportunities. Examples include: Occupiers of residential properties. Visitors to tourist attractions. Recreational receptors using recreational facilities such as National Cycle Routes, National Trails, and designated long distance footpaths. Recreational receptors using PRoW or viewpoints in nationally or locally designated landscapes.
Medium	Viewers with a moderate interest in their surroundings such as : Users of schools. Users of outdoor recreational facilities where landscape appreciation is unlikely to be a primary motive. Local viewpoints. Users of local PRoW.
Low	Viewers with a passing interest in their surroundings such as: Road or other transport users.
Very low	Viewers with no interest in their surroundings such as: People at their place of work.

22.4.33 By way of an example residential receptors are generally considered to be the most sensitive receptor group owing to their propriety interest and their prolonged exposure. Recreational receptors such as people engaged in outdoor sports are considered of medium sensitivity although recreational receptors whose attention or interest is focused on the landscape may also be considered to be highly sensitive.

22.4.34 The least sensitive group are those with no interest in their surroundings or that are already affected by similar types of visual impact to that arising from the proposed development or have a passing interest in the surroundings, such as motorists on a busy motorway.

22.4.35 It should be noted that for each of the representative visual receptors used in the assessment, a range of visual receptor types may be represented. In all cases the highest sensitivity is taken forward to the assessment of significance.

22.4.36 For assessment purposes, the sensitivity of representative visual receptors is based on the application of the above criteria, informed by field surveys undertaken by landscape professionals, professional judgement of the assessor and consultation with statutory and non-statutory consultees.

iv. Stage 3: Magnitude of Impacts

22.4.37 According to GLVIA (Ref. 22.1), the magnitude of impacts is described as a *"combination of the scale, extent and duration of an effect."* The magnitude of landscape and visual impacts are judged using the criteria set out below.

v. Stage 3a : Magnitude of Landscape Impacts

22.4.38 The magnitude of landscape impacts is defined as high, medium, low or very low depending on the following factors:

- scale or degree of change to the existing landscape resource;
- nature and duration of the change caused by the proposed development (for example beneficial or adverse); and
- timescale or phasing of the proposed development.

22.4.39 Guidelines for the assessment of magnitude of landscape impacts are presented in **Table 22.3**:

Table 22.3: Guidelines for the Assessment of Magnitude of Landscape Impacts

Magnitude	Description
High	Total or widespread loss or major alteration to key landscape elements/characteristics.
Medium	Partial loss or alteration to one or more key landscape elements/characteristics.
Low	Limited loss or alteration to one or more key landscape elements/characteristics.
Very low	Extremely limited loss or alteration to one or more key landscape elements/characteristics.

vi. Stage 3b: Magnitude of Visual Impacts

22.4.40 The magnitude of visual impacts is defined as high, medium, low or very low and depends upon the following factors:

- the scale of change or proportion of the existing view that would change as a result of the proposed development;
- the loss or addition of features or elements within the view;
- the degree of contrast or integration of the proposed development with the existing or remaining landscape elements and characteristics within the view;
- the nature and duration of the impact and whether it is temporary or permanent, continuous or intermittent;
- the angle of the view in relation to the main activity of the receptor; and
- the distance of the viewpoint from the proposed development.

22.4.41 Guidelines for the assessment of magnitude of visual impacts are presented in **Table 22.4**:

Table 22.4: Guidelines for the Assessment of Magnitude of Visual Impacts

Magnitude	Description
High	Complete change or widespread alteration to the existing view.
Medium	Noticeable but localised alteration to the existing view.
Low	Partial and very localised alteration the existing view.
Very low	Barely perceptible change to the existing view. It may be difficult to differentiate the proposed development from its surroundings.

vii.Nature and Duration of Impacts

22.4.42 The nature of impacts contributes to the assessment of magnitude of landscape and visual impacts.

22.4.43 The nature of impacts can be adverse, beneficial or neutral. The impact is assessed as neutral in situations where little or no change is predicted, or it is impossible to objectively establish whether the change would be adverse or beneficial.

22.4.44 With regard to the duration of landscape and visual impacts, short to medium-term impacts are normally considered to be temporary and associated with the construction of the proposed development, and long-term impacts are normally associated with a fully occupied and operational scheme. Permanent impacts are those which result in an irreversible change to baseline conditions or will last for the foreseeable future.

22.4.45 The duration of landscape and visual impacts assessed in this chapter takes account of possible project delays and is typically categorised as follows:

- long-term – 15 years plus;
- medium-term – 5 to 15 years;
- short-term – 0 to 5 years.

22.4.46 Landscape impacts can be both indirect (essentially visual issues that contribute to the appreciation and understanding of landscape character) or direct, physical impacts resulting from development where elements of the landscape are lost i.e. tree cover is removed or farmland is lost to development, or new elements and features, such as woodland areas or buildings, are introduced. Visual impact is an indirect impact resulting in the alteration in a view resulting from development, as seen by varying types of viewers.

22.4.47 Section 9 of this chapter provides a summary of impacts and their classification as temporary (short-term or medium-term) or permanent (long-term).

viii. Stage 4: Assessment of Significance

22.4.48 The potential significance of landscape and visual impacts is determined by assessing the magnitude of the identified impacts against the sensitivity of the landscape and visual receptors affected. The significance matrix presented in **Volume 1 Chapter 7** provides a guide to decision-making but is not a substitute for professional judgement and interpretation, particularly when sensitivity or impact magnitude levels are not clear or are borderline between categories.

22.4.49 **Table 22.5** provides a brief definition of the significance criteria which are specific to landscape and visual impact assessment and are in accordance with the overall EIA sensitivity criteria outline in **Volume 1 Chapter 7**.

Table 22.5: Significance Criteria

Level of Significance	Description
Major	Very important or substantial change in landscape and visual conditions. Impacts may be adverse or beneficial.
Moderate	Noteworthy or medium change in landscape and visual conditions. Impacts may be adverse and beneficial.
Minor	Inconsiderable or small change in landscape and visual conditions. Impacts may be adverse, neutral or beneficial.
Negligible	No discernable change in landscape and visual conditions. Impact is likely to have a negligible (neutral) influence, irrespective of other impacts.

22.4.50 By way of an example, major landscape and visual impact may occur where a large scale development is proposed within a nationally designated landscape leading to widespread loss or alteration to one or more key landscape elements/characteristics. In visual terms, a major impact may arise where large number of residential receptors would experience complete alteration to the existing view.

22.4.51 With reference to the EIA Methodology (see **Volume 1 Chapter 7**), predicted impacts of major and moderate significance equate to a significant impact in planning terms.

ix. Illustration of the HPC Proposed Development

22.4.52 As described above, the extent to which the HPC proposed development is visible in the surrounding landscape has been established through a combination of ZTV modelling, desktop analysis, and field survey. Forty eight viewpoints were agreed with consultees to be representative of views within the LVIA study area and as an appropriate basis on which to assess and describe visual impacts arising from the HPC proposed development on a diverse range of receptors at locations in the short, middle and long distance from the HPC development site.

22.4.53 Photograph panels (full list presented on **Figure 22.9b**) illustrate the existing view from each of the representative viewpoints and, where appropriate, indicate the location of the HPC development site in the view as well as other major landscape features to help orientate the viewer. Forty two of the representative viewpoint locations have been agreed with consultees as appropriate for the preparation of photo-realistic photomontages to illustrate the nature of visual effects arising from the HPC development during its operational phase.

22.4.54 The photomontages, referred to throughout the ES as Visually Verifiable Images (VVIs), illustrate the HPC proposed development at year 15 of the operational phase and as such include all proposed HPC structures, associated infrastructure such as access roads and lighting and mitigation proposals developed iteratively as part of the design process such as landform and screen planting. In addition to the 42 VVIs illustrating day time views, 13 additional VVIs have been prepared to illustrate the HPC proposed development at night. Additional VVIs from 11 Principal Viewpoints have also been prepared to illustrate the HPC proposed development in combination with National Grid proposals (see **Volume 11 Chapter 6**).

22.4.55 The methodology for the preparation of the VVIs (see **Appendix 22B**) states that the surveying techniques used in the preparation of the VVIs have recorded information based on Ordnance Survey National Grid with a relative accuracy of 10-50mm. It should be noted, whilst position, height and scale are objectively accurate, subjective judgement must be used when lighting is being assessed in VVI imagery. The lighting used in the preparation of the dusk VVI's has been constructed and placed based on manufacturers specifications and industry guidelines however technology is not sufficiently advanced to produce definitive reproduction of lighting and therefore a definitive and objectively verified agreement on lighting is not possible.

22.4.56 The computer can accurately assess the relative contrast between the faces of a building at a particular time. The computer can also render approximate material definitions. However, not every aspect of what is seen visually on screen is able to be simulated using an automatic or wholly objective process. Reflected light, local lighting conditions, detailed material definitions, and climatic conditions including moisture content of the air both across the scene as a whole and locally cannot be accurately assessed or simulated by current computer technology. In these cases it is necessary to refer to the scene for visual clues in order to set the render of the proposed development into the photograph.

22.4.57 Some elements of the HPC proposed development are yet to be finalised, and as such several parameters have been established and used as a basis to model and render the proposed development in the VVIs. By way of an example, parameters are specified for the building heights that are modelled, and the materials, finishes and colours that are used to render the buildings in the VVI views. **Appendix 22B** also describes the parameters used to model the landform and planting proposed as part of the landscape strategy, taking into account assumptions regarding how the selected species will grow over the period from planting to year 15 of operation. It should be noted that vegetation growth is modelled only for planting proposed as part of the landscape restoration plan within the HPC development site. Existing planting visible in the VVIs has not been amended in the VVIs to illustrate 15 years of additional growth.

22.4.58 The effects of natural lighting were also modelled into the VVIs to replicate the lighting conditions in which the original photograph was taken. For the dusk VVIs, the effects of proposed lighting were modelled in accordance with the methodology described in **Appendix 22B**.

22.4.59 Whilst every effort has been made to ensure the accuracy of the VVIs within the parameters defined and described, several factors are not, and in many instances cannot be, modelled into static photo-realistic montages of the type presented in the ES. For example, the dynamic effects of lighting (such the shifting patterns of light and shade created by clouds moving across the view) and atmospheric conditions (created by mist, rain and snow) on the main HPC structures are not illustrated. Similarly, movement within the site and in the surrounding landscape, perhaps from vehicles on roads evident in the view, is not illustrated. Similarly, the VVIs do not illustrate changes to elements in the view that are outside the HPC development site, such as the introduction of new structures or planting arising from other developments; changes to land management regimes; or the removal of features in the existing view such as buildings or woodlands. In addition, the VVIs illustrate static views of a field of view centred upon the HPC application site, and as such they cannot replicate the effects of the movement of the viewer or the true nature of the view which in reality will include an awareness of the wider landscape.

22.4.60 In addition, the VVIs do not seek to portray a subjective representation of the proposed development. It is acknowledged that individual viewers will each have their own particular emotional response to the change in view arising from the HPC proposed development that is illustrated. However, and as with the assessment of landscape and visual impacts described, the preparation of VVIs is an objective process based on best practice methodologies.

22.4.61 Therefore, and whilst representing an accurate objective representation of the proposed HPC development, the VVIs must be regarded as representative and illustrative. They are not intended to be a definitive illustration of how the project will appear at year 15 of operation or seek to influence the viewer's emotional or subjective reaction to the proposals.

x. Residual Impact Assessment

22.4.62 The initial assessment of landscape and visual impacts assumes that the proposed mitigation within the HPC development site boundary is embodied within the HPC scheme.

22.4.63 The assessment of the residual impacts takes account of the proposed off-site mitigation measures and is undertaken using the same assessment methodology as outlined above.

xi. Cumulative Impacts

22.4.64 The assessment of site-specific additive and interactive impacts on landscape and visual receptors as a result of the HPC proposed development is included in the assessment of impacts in this LVIA. The methodology for assessing these impacts is described in **Volume 1 Chapter 7**.

22.4.65 Project-wide cumulative impacts and in-combination impacts with other proposed or reasonably foreseeable development or projects are assessed in **Volume 11**.

b) Consultation

22.4.66 The HPC consultation process is outlined in **Volume 1 Chapter 7**. Comments from formal stages of consultation (Stage 1, Stage 2, Stage 2 Update and M25 Junction 24 and Highway Improvements) have been taken into account within the assessment (see **Consultation Report**).

22.4.67 Consultation undertaken outside the Stage 1, Stage 2 and Stage 2 Update and M25 Junction 24 and Highway Improvements consultation (informal consultation) was also carried out and included meetings and correspondence exchanged with a variety of organisations to discuss the extents of study area, landscape and visual baseline, landscape and visual impacts including lighting, development footprint and design, and mitigation proposals.

22.4.68 Informal consultation has been carried out with the following organisations and consultees:

- Local residents;
- Natural England;
- Exmoor National Park Authority;

- Somerset County Council (SCC);
- West Somerset District Council (WSC);
- Sedgemoor District Council (SDC);
- Quantock Hills AONB Service;
- English Heritage; and
- Fairfield Estate.

c) Limitations, Constraints and Assumptions

22.4.69 The principal assumptions and limitations for the LVIA are described below:

- The baseline assessment is set for spring 2011 and is focused on landscape conditions prior to any major HPC works on the HPC development site (including the proposed HPC preliminary works, comprising the site preparation works and the temporary jetty).
- The landscape character baseline was informed by landscape character desk studies and existing Landscape Character Assessments, whose findings were verified and, where necessary, extended during field surveys carried out by qualified landscape professionals.
- Landscape and visual surveys that contribute to the assessment were undertaken between December 2008 and May 2011.
- The assessment of impacts has been undertaken for the following phases of the HPC proposed development:
  - construction of the HPC (including all phases of the on-site accommodation campus and leisure facilities, temporary jetty and site preparation works, which are entirely located within the HPC development site);
  - operation of the HPC at year 1 (including fully implemented landscape strategy);
  - operation of the HPC at year 15 (including fully implemented and maturing landscape strategy); and
  - Highway Improvements were assessed during all phases of the HPC proposed development according to the HPC project programme.
- All photographs used for VVIs within this ES were taken between February and April 2011.
- The assessment of construction impacts is based on construction parameters described in **Chapter 3** of this volume. The assessment is based on likely construction activities and takes account of the potential exceptional conditions, such as temporary tall crane operations.
- The assessment of operational impacts on landscape and visual receptors is based on the parameters of the project described in **Chapter 2** of this volume and includes an allowance for the proposed height of the buildings and structures (illustrated on **Figure 2.3** in **Chapter 2** of this volume) to increase by an additional 3m above stated roof heights to permit additional roof plant or machinery to be secured. Visually Verifiable Images (VVIs) are based on building height parameters without the 3m additional height allowance.

- The landscape restoration plan involves extensive bulk earthworks, excavation, earth placement and modelling. At this stage the final detail of the formation levels across the landscape restoration area is not known, but illustrative information is provided in the landscape restoration plan (see **Figure 22.59**), setting out the likely finished ground levels. Details regarding the finished ground levels will be submitted as part of the detailed landscape scheme, submitted pursuant to a requirement in the DCO.
- The impact assessment has therefore been based on the likely ground levels across the site and has factored into the assessment potential changes to ground levels that may arise in the design development process, allowing for a potential variation in the stated heights of +1m to +1.5m has been assumed. Such variations have been assessed and it is considered that such change across the site would not give rise to any additional significant impact on landscape or visual receptors than that already identified. The effectiveness of the proposed screening earthworks and planting mitigation proposed and illustrated in the VVIs will not be materially altered.
- The mitigation of landscape and visual impacts has been considered from an early stage in the project. As such, consideration of landscape and visual impacts comprising both the construction and operational phases has been an important part of the design process, including architectural and landscape design, and development of the lighting strategy. Further details of the iterative design process are provided within the description of the HPC proposed development (see **Chapter 2** of this volume), and the alternatives chapter (see **Chapter 6** of this volume), which describes the alternative design options which have been considered with respect to the potential environmental impact.
- The assessment of the lighting impacts of the proposed development on visual amenity is based on construction and operational lighting strategies and health and safety requirements. The lighting strategy is considered inherent mitigation within the design of the proposed development and as such is not part of further or additional mitigation measures. The HPC Construction Lighting Strategy is appended to the **Construction Method Statement** and **HPC Operational Lighting Strategy** is appended to **Chapter 2** of this volume.
- The principles of mitigation adopted for this EIA are consistent with the guidance on landscape mitigation provided within the consultation document EIA: A Guide to Good Practice and Procedures produced by the Department for Communities and Local Government (DCLG) (Ref. 22.30).

22.5 Baseline Environmental Characteristics

a) Introduction

22.5.1 This section describes the landscape and visual baseline environmental conditions for the HPC proposed development.

b) Study Area Description

22.5.2 The HPC development site is located to the west of and adjacent to the existing Hinkley Point Power Station Complex. It occupies farmland extending westwards up to Benhole Lane, and southwards to Holford Stream and the village of Shurton. The on-shore part of the HPC development site is bounded to the north by Bridgwater

Bay, from which it is separated by a low cliff. The site then extends into the Bridgwater Bay to accommodate off-shore construction activities. The on-shore part of the HPC development site is bisected by Green Lane, a local ridge running east-west up to a maximum elevation of approximately 35m AOD. A detailed description of the HPC development site is presented in **Chapter 1** of this volume.

22.5.3 The LVIA study area is shown on **Figure 22.3**. The maximum extents of the LVIA study area are as follows:

- Lowland Somerset – up to 18km from the HPC development site;
- Exmoor National Park – up to 25km from the HPC development site;
- Mendip Hills AONB – up to 21km from the HPC development site; and
- Welsh coastline – up to 21km of the HPC development site.

c) Environmental Designations

i. International and National Designations

22.5.4 There are no national or international landscape designations within the HPC development site.

22.5.5 However, there are several important international or national landscape and environmental designations within the LVIA study area which are illustrated on **Figure 22.4**. These designations are:

- Exmoor National Park;
- Quantock Hills and Mendip Hills AONB;
- The Severn Estuary Ramsar site;
- The Severn Estuary Special Protection Area (SPA);
- The Severn Estuary Special Area of Conservation (SAC);
- The Bridgwater Bay Site of Special Scientific Interest (SSSI), Blue Anchor to Lilstock Coast SSSI, and the Quantocks SSSI;
- The Bridgwater Bay National Nature Reserve (NNR);
- Scheduled Monuments;
- Registered Parks and Gardens; and
- Area of outstanding scenic interest.

22.5.6 Exmoor National Park is situated within the counties of Somerset (71% of the park) and Devon. The boundary of the National Park is located approximately 14km to the west of the HPC development site.

22.5.7 The Quantock Hills AONB was designated in 1956 under the National Parks and Access to the Countryside Act 1949 and was the first AONB designated in England. It is approximately 9,900ha in area and at its closest is located approximately 3.7km away from the HPC development site. It falls within the boundary of three local planning authorities, namely: WSC, SDC and Taunton Deane Borough Council (TDBC). The Mendip Hills AONB lies approximately 19.5km north-east of the HPC development site.

22.5.8 The Bridgwater Bay NNR is approximately 5km north of the town of Bridgwater and comprises the lower reaches of the River Parrett and its estuary where it flows into the Bristol Channel. Along the coast the site extends north to the town of Burnham on Sea and as far west as the village of Lilstock. The area is also designated as the Bridgwater Bay SSSI, the Severn Estuary SPA and part of the area is in the process of being designated as a SAC. The area comprises a succession of habitats ranging through extensive intertidal mudflats, saltmarsh, shingle beach and grazing marsh intersected by a complex network of freshwater and brackish ditches. The ditches and ponds contain a diverse invertebrate fauna including six nationally rare species and eighteen nationally scarce species. The site is an integral part of the Severn Estuary system and is ecologically linked to the Somerset Levels which provide alternative winter feeding grounds for waders and wildfowl.

22.5.9 A Scheduled Monument (Wick Barrow, commonly known as Pixies Mound), dating from the Neolithic and Bronze Age, is located immediately to the east of the HPC development site. The visual impact on Pixies Mound is considered in this assessment. The full list of Scheduled Monuments and the assessment of impact of the HPC proposed development on their setting are included in **Chapter 23** of this volume (historic environment).

22.5.10 There are a number of Registered Parks and Gardens within 10km of the HPC development site. Two are located within the ZTV, namely; Fairfield and St Audries. Both are of historic value and are included by English Heritage in the national Register of Parks and Gardens of special historic interest in England. The full list of Registered Parks and Gardens and the impact of the HPC proposed development on their setting is assessed in **Chapter 23** of this volume (historic environment).

22.5.11 Areas of outstanding scenic interest are described by Natural England as landscape designations aimed to protect landscapes of outstanding, scenic, historic and scientific interest; although they are not a statutory landscape designation as such. An area of outstanding scenic interest covering the historic Fairfield Estate is located adjacent to the HPC development site and extends farther to the west. Two other areas of outstanding scenic interest are located to the west of Fairfield Estate. Areas of outstanding scenic interest located within the LVIA study area are shown on **Figure 22.4**.

ii. Regional and Local Designations

22.5.12 Regional and local designations within 5km of the HPC development site are shown on **Figure 22.4a**.

22.5.13 There are two Conservation Areas within 5km of the HPC development site; Stogursey and Nether Stowey. Baseline descriptions and assessments of the impact of the HPC proposed development on their setting can be found in **Chapter 23** of this volume (historic environment).

22.5.14 The nearest Green Wedge designation is located approximately 11km to the north-east of the HPC development site, adjacent to the coastal settlements between Burnham-on-sea and Brean Down. There are no Green Wedge designations within 5km of the HPC development site.

22.5.15 There is a County Wildlife Site (CWS) within the HPC development site (Hinkley County Wildlife Site). The full list of relevant CWS within the LVIA study area and an assessment of the impact of the HPC development site on these sites are provided in **Chapter 20** of this volume. County Wildlife Sites are shown on **Figure 22.4a**.

d) Landscape Character Baseline

i. Introduction

22.5.16 The assessment of landscape character is an objective process that provides factual information about a particular locality. It does not itself attribute a place with an account of its relative quality, sensitivity or capacity to accommodate particular types of development, and nor does it prescribe whether particular development or landscape change would be appropriate or inappropriate. However, an assessment of landscape character can be used as a basis on which to attribute value, sensitivity and/or capacity at a range of spatial scales - such as at the county, district and site scales of assessment. An understanding of landscape character, and the elements and features that contribute to character can also inform the development of landscape strategies and the iterative design process, in which mitigation proposals are developed in tandem with the design of the HPC proposed development.

22.5.17 In England, a hierarchy exists from the broad scale national character assessment at the top tier, through regional and county scale assessments to those at the district/ local scale. At the most detailed level, site specific landscape character assessments are undertaken, often to provide an accurate and appropriate description of baseline conditions to help inform the siting and design of new development and to provide a basis on which to assess the direct and indirect impacts of new development and changes to land management regimes. Each level in the assessment hierarchy should, in principle, add detail to the layer above, with the broader scale assessment providing a context and framework for more detailed assessments.

22.5.18 Analysis of landscape character at the national and regional scale of assessment is presented for the full LVIA study area, and as such includes reference to broad scale assessments for England and Wales (see **Figure 22.5**). Analysis of local landscape character assessment is presented for the LVIA study area in England and includes reference to seascape character assessment for the coastal element from the coastline up to the low water mark (see **Figures 22.6** and **22.6a**). Site scale assessment has been undertaken for the site and its immediate landscape context within the Quantock Vale local landscape character area (see **Figure 22.7**). An assessment of landscape elements and features is presented for the HPC development site only (see **Figure 22.8**).

22.5.19 The assessment of impacts on landscape character is undertaken at the local and site scales of assessment. An assessment of the impacts of the HPC proposed development on landscape elements and features is also presented for the HPC development site.

22.5.20 Several studies are of relevance to understanding the character of the landscape in the vicinity of the project within the LVIA study area.

22.5.21 In England the national landscape character assessment provides an important overview of landscape character and context within which to understand the HPC development site and its wider setting, extending to the full extent of the LVIA study area and including all locations in which highway improvements associated with the

HPC project are planned. Reference is also made to the draft Landscape Character Map for Wales (Ref. 22.31) which presents character assessment information for the entirety of Wales at a scale similar to National Character Assessment of England.

22.5.22 Local scale landscape character assessments, prepared by local planning authorities, National Park Authorities and AONB Units/Partnerships in England present a more detailed description of landscape character to that contained in the national landscape character assessment in England. It should be stressed that landscape assessments undertaken at the local scale of assessment are often for wide geographic areas, and do not necessarily deal with a specific issue in a particular location. As such their findings can only be used as a basis for understanding landscape character at a broad scale. As such desk study and field survey has been undertaken by LVIA chapter authors to confirm the findings of existing landscape assessments and to attribute sensitivity to the various landscape character areas described for the purposes of undertaking the LVIA. The findings of the local landscape character assessment, and judgments regarding sensitivity of the landscape character types/areas forms the basis of assessing the impacts arising from the HPC proposed development and associated highways works on local landscape character in this assessment.

22.5.23 In addition, a site scale landscape character assessment has been undertaken to describe the HPC development site and its immediate landscape setting and ascribe landscape sensitivity at this detailed scale of assessment. As noted in section 22.4 (methodology) the condition prior to any preliminary works within the HPC development site is taken as the basis of the descriptions of site scale landscape character areas. An assessment has also been undertaken of the key elements and features that combine to create the landscape character of the HPC development site, both to describe in greater detail baseline landscape conditions and also as a basis to assess the impacts of the HPC development site scale landscape character.

ii. Landscape Baseline Summary

22.5.24 An assessment of landscape character from national to site scale is presented in the pages that follow. The analysis identifies the HPC development site as lying within the rolling coastal lowland mixed farming landscape of the Vale of Taunton and Quantock fringes which contrasts with neighbouring upland areas of the Mendips, Exmoor and Quantock Hills, the lower lying Somerset Levels and Moors and the coastal and marine landscape of Bridgewater Bay and the Bristol Channel.

22.5.25 The rolling agricultural landscape in which the HPC development site lies is not designated for its landscape value at a national level. However, the Quantock Hills, located approximately 3.7km from the HPC development site is designated as an AONB and the upland areas of the Mendips and Exmoor, located towards the fringes of the LVIA study area are designated as an AONB and National Park, respectively. The coastal elements of the HPC development site form part of more extensive international and national biodiversity and wildlife designations.

22.5.26 In close proximity to the HPC development site local variations in landscape character are assessed and described. The analysis emphases variations in landform, land cover patterns and land use, and highlights sites and areas that are locally designated for their heritage, landscape and wildlife value and interest. The analysis confirms that the HPC development site is not subject to any form of local landscape designation, but records that areas within the site and in close proximity to it are designated, notably as County Wildlife Site and area of outstanding scenic interest. Stogursey, a nearby village, contains a Conservation Area and several local settlements include Listed Buildings.

22.5.27 The site scale landscape assessment recorded localised variations in character and the elements and features that contribute to the character of the HPC development site.

iii. National Landscape Character

England

22.5.28 At the national scale of assessment, significant work was undertaken in the mid-to-late 1990's by the Countryside Agency and English Nature (together now Natural England) to map and describe the broad variations in character that can be identified across England. The assessment identifies 159 Joint Character Areas (known as National Character Areas) and the findings are presented in eight regional volumes. With reference to Volume 8: South West (Ref. 22.32) all or part of six National Character Areas lie within the LVIA study area (see **Figure 22.5**).

22.5.29 The HPC development site falls within National Character Area (NCA) 146 – Vale of Taunton and Quantock Fringes. The landscape is described as a broad sweep of pastoral lowland landscape which contrasts to the steep moorland-topped character of the Bredon and Quantock Hills to the west and the open character of the clay levels to the east.

22.5.30 The landscape is characterised by irregular, medium sized fields bounded by thick hedgerows, commonly on top of banks. Narrow winding lanes link substantial farmsteads and hamlets, where red sandstone and less commonly, cob are characteristic building materials.

22.5.31 Woodland is described as sparse and the distribution of hedgerow trees variable. Orchards are noted as being a once prominent feature of the Vale but that the older orchards are now in decline.

22.5.32 Within the character area, considerable variety is evident. In the low lying Tone valley the landscape is flat and open displaying something of the character of the nearby Levels. Beyond this, the Vale is described as a patchwork of arable, pasture, market gardening and orchards. Beyond the lower lying parts of the vale, the land rises towards the high moorlands where there are the more steeply undulating hills and valleys of the high vale. Along the coast, to the north of the A39, further local variations are evident. Here the landscape is described as a belt of rolling, open windswept countryside with a few scattered trees and small villages. Field patterns are generally rectilinear and the landscape is broken by blocks of low-lying wet pasture where meandering streams meet the coast. Parts of the coast are described as remote and rather bleak, with the existing Hinkley Point Power Station noted as a prominent feature in the east but with fine views past Steep Holm and Flat Holm to the Welsh coast.

22.5.33 With regard to the observable changes to the countryside, hedgerow removal and a decline in hedgerow management are cited. Small woodlands, described as essential to the character of this sparsely wooded landscape have also been lost, as have hedgerow trees, notably as a result of Dutch Elm Disease. Major development in recent decades is also noted. This has introduced new elements into the landscape such as mineral workings, industrial development and major transport and electricity transmission infrastructure. Hinkley Point is described as a "*very prominent*" feature in the landscape and it is noted that expansion could "*make this impact worse.*" (Ref. 22.32).

22.5.34 The assessment presents broad strategies for shaping the future landscape. It notes that the rural and agricultural character of the landscape, and especially the pattern of irregular fields and thick hedgerows with oak trees, is important and that the retention and appropriate management of hedgerows, hedgerow trees and small copses and woods should be addressed. Additional strategies include the retention, management and replanting of traditional orchards, smaller new buildings in rural locations reflecting the influence of the red sandstones and maintaining the contrast between different parts of the character area i.e. the river floodplains, low vale and high vale.

22.5.35 By way of a summary, the key characteristics of the Vale of Taunton and Quantock Fringes NCA include (Ref. 22.32):

- *"Lowland farmland qualities in sharp contrast to surrounding upland landscapes.*
- *Lowland mixed farming landscape, with dense hedges, sparse woodland and frequent settlement.*
- *Contrast between floodplain, low clay vale and higher sandstone vale edge.*
- *Scattered settlement of farmsteads and hamlets linked by winding lanes.*
- *Scattered villages.*
- *Red sandstone buildings and prominent Perpendicular church towers.*
- *Cider apple orchards.*
- *Variable hedgerow tree cover, with some areas of abundant hedgerow oaks.*
- *Willows on floodplains.*
- *Open and windswept coast with low cliffs."*

22.5.36 Approximately 1km to the east of the HPC development site extends National Character Area 142 – Somerset Levels and Moors. Its characteristics are combined with National Character Area 143 – Mid Somerset Hills, which extends approximately 12km to the east of the HPC development site and beyond.

22.5.37 The landscape is described as a broad area of low-lying farmland and wetland surrounded and divided up by low hills and ridges. The NCA describes the landscape as comprising five distinct elements: hills and islands; the peat moors that lie between them, the clay Levels towards the coast; the dunes and tidal flats of the coast itself; and the sand banks or 'burtles' marking the position of former river channels.

22.5.38 The hills are described as being generally well wooded, with good tree and hedgerow cover, which softens the often frequent settlement. From the hills the assessment notes that expansive views across the Levels and Moors are possible. The Moors lie within the inland basins formed by the hills. Many parts are largely treeless and are dominated by the planned pattern of the rhynes. Near the islands and ridges there is more tree and shrub cover, notably of pollarded willows, marking a transition to a landscape of hedges, farmsteads, villages and orchards as the land rises. While peat extraction has influenced local landscape character, the abiding character of the Moors is centred on a pastoral wetland landscape of long views across a foreground of rhynes, pollards and occasional withy beds. The Levels are a low belt of marine clay which runs parallel to the coast. With its intermittent areas of sinuous lanes and irregular fields, it is an older landscape than the reclaimed moors and more densely populated. The Levels abut a coastline of extensive mudflats around the Parrett estuary and the edge of Bridgwater Bay where sand dunes extend northwards to Brean Down and where caravan parks and camp sites are prominent features.

22.5.39 Despite the distinctions made between these component parts, the landscape character area is described as having a strong unity and a distinctive character. Indeed, a great deal of its charm and interest is described by the writer Hawkins as being because of its paradoxical character; "*at once more wild and primitive and yet more artificial than any other part of England*."

22.5.40 Key characteristics of the Somerset Levels and Moors/Mid Somerset Hills include (Ref. 22.32):

- *"Flat, open landscape of wet pasture, arable and wetland divided up by wet ditches or 'rhynes'.*
- *Absence of dispersed farmsteads or any buildings on levels and moors. Nucleated settlements on ridges/islands.*
- *Surrounded, and divided up, by low hills, ridges and islands which form distinctive skylines.*
- *Peat working and nature reserves contrasting with the rectilinear planned landscape of the Moors.*
