1. OPERATION PHASE AIR QUALITY ASSESSMENT RESULTS TABLES: HUMAN RECEPTORS

1.1. BACKGROUND POLLUTANT VALUES USED IN MODELLING: HUMAN RECEPTORS

- 1.1.1. The respective pollutant background concentrations applied to the post-processing of the dispersion model outputs, for each averaging period and discrete human receptor, are presented in **Table 1.1**.
- 1.1.2. Details of the sources of the pollutant background data are provided in Chapter 6 (Air Quality). For background levels of NH₃, SO₂, and HCl, monitored data were used in the absence of spatially varying background data across the operation phase Study Area. For SO₂, the monitored maximum hourly value is used as the background level across the Study Area based on 2020 data. For NH₃ and HCl, the monitored maximum monthly value is used based on 2020 data.
- 1.1.3. For amines and nitrosamines, there are currently no published background data for the UK.

Table 1.1 - Modelled Background Pollutant Concentrations – Human Receptors

Notes:

Receptor	Pollutant Background Concentration ($\mu\text{g}/\text{m}^3$)				
	Annual Mean NO ₂	Annual Mean PM ₁₀	Hourly Max SO ₂ *	Monthly Max NH ₃ **	Monthly Max HCl ***
(1) For purposes of providing a conservative assessment within the Selby AQMA, the 2019 annual mean monitored concentration from diffusion tube site ID S7 (21 New Street) was used as the background for this receptor (Source: Selby District Council (June 2021) 2021 Air Quality Annual Status Report)					
(2) For purposes of providing a conservative assessment of impacts in Goole, the 2019 annual mean monitored concentration from diffusion tube site ID S5 (Boothferry Rd / Airmyn Rd, Goole) was used as the background for this receptor (Source: East Riding of Yorkshire Council (June 2021) 2021 Air Quality Annual Status Report)					
(3) For purposes of providing a conservative assessment of impacts in Thorne, the 2019 annual mean monitored concentration from diffusion tube site ID DT50 (King Street, Thorne) was used as the background for this receptor (Source: Doncaster Council (June 2021) 2021 Air Quality Annual Status Report)					
* Maximum hourly monitored SO ₂ used to represent short-term averaging period background level					
** Maximum monthly monitored NH ₃ used to represent annual mean level, with each concentration doubled to represent short-term averaging period background level					
*** Maximum monthly monitored HCl doubled to represent short-term averaging period background level					

1.2. IMPACTS ON HUMAN RECEPTORS

- 1.2.1. The results of the modelling assessment at each modelled discrete human receptor are presented in the below tables for each relevant pollutant and averaging period applicable to the study. For each receptor, the maximum modelled concentration is presented, which is based on modelling over all five years of meteorological data (2016-2020). In addition, the maximum modelled concentration from across the entire 30 km x 30 km grid is provided. The associated IAQM impact descriptor is reported for each receptor, as per the significance criteria detailed in **Chapter 6 (Air Quality)** ([document reference 6.1.6APP-042](#)).
- 1.2.2. Both the process contribution (PC) and predicted environmental concentration (PEC), which comprises the PC in addition to the receptor-specific background concentration, are presented for each receptor. For PEC's relating to short-term averaging periods (i.e. sub-hourly, hourly, daily means), the respective annual mean background concentration has been doubled in line with EA guidance (Environment Agency, 2021).
- 1.2.3. For SO₂, PM₁₀ (dust), NH₃, and HCl, only the maximum PC impacts are presented given that they represent an insignificant contribution relative to the air quality objective / EAL and the respective background concentration (see **Table 1.9**).
- 1.2.4. It is important to note that the maximum PC impact is the maximum difference between Baseline and With Proposed Scheme concentrations, and may not coincide with the specific geographic point at which either the maximum Baseline or maximum With Proposed Scheme value occurs.
- 1.2.5. The human receptor results are presented in sub-sections relating to:
- Core model scenarios (Baseline and With Proposed Scheme)
 - Cumulative impacts (With Proposed Scheme & Other Projects)
 - Worst case emissions profile sensitivity test (Baseline and With Proposed Scheme); and
 - Amine sensitivity testing (With Proposed Scheme).

CORE MODEL SCENARIOS

- 1.2.6. Results pertaining to the core model scenarios are presented in **Tables 1.2 to 1.10**.

Notes:

⁽¹⁾ Maximum modelled amine concentrations based on sum of 'Amine 1' + 'Amine 2' maxima, which is potentially conservative because the 'Amine 1' maximum concentration could occur at a different time (hour/day) to the 'Amine 2' maximum concentration at any given receptor or grid point. Results based on proposed daily average AELs for 'Amine 1' and 'Amine 2'.

Receptor Grid Max	0.0002	0.020	0.020	0.020	Slight adverse (10.2% of EAL)
EAL	0.2				

⁽¹⁾ Based on direct mass emissions of 'Nitrosamine 1' and 'Nitrosamine 2' from Main Stack only. PC to ground level is insignificant (<0.1% of the EAL for NDMA). There is no requirement to propose an annual average ELV for direct nitrosamine emissions.

⁽²⁾ Accounts for application of ADMS Amine Chemistry Module and relates to indirect formation of nitrosamines and nitramines through atmospheric reactions.

⁽³⁾ Equal to sum of modelled direct and indirect nitrosamine + nitramine concentrations.

CUMULATIVE IMPACTS (WITH PROPOSED SCHEME & OTHER PROJECTS)

1.2.7. Results pertaining to the cumulative impacts are presented in **Tables 1.11 to 1.13**.

SENSITIVITY TEST: WORST CASE EMISSIONS PROFILE

- 1.2.8. Results pertaining to the worst-case emissions profile sensitivity test are presented in **Tables 1.14 to 1.22**.
- 1.2.9. It is evident that, for the annual mean averaging period, modelled maximum PC concentrations increase in the Baseline scenario under worst case emission conditions, relative to the core modelling scenario equivalents (see **Table 1.2** for NO₂ annual mean). Whereas, in the With Proposed Scheme scenario, there is no or very small change in modelled annual mean concentrations when comparing the core and worst-case emissions modelling.
- 1.2.10. This is a function of all four biomass units in the Baseline scenario switching from 'mid-merit' operation (full load for 4,000 hours per year) to continuous operation (full load for 8,760 hours per year), resulting in more pollutants being emitted and thus more pronounced changes in annual mean concentrations relative to the With Proposed Scheme, where operation changes from 'mid-merit' to continuous full load at the two non-BECCS biomass units only (BECCS units already assumed to operate at continuous full load in core modelling scenario). As the non-BECCS units emit flue gas at a higher temperature relative to the BECCS units, there is enhanced plume buoyancy when all units operate continuously, resulting in some minor reductions in maximum PC annual mean concentrations.
- 1.2.11. The net outcome of the above effects, under worst case emissions conditions, is that the majority of modelled Baseline annual mean concentrations increase, whilst With Proposed Scheme concentrations remain largely unchanged or reduce slightly. Therefore, the maximum impacts on annual mean concentrations are reported to decrease at the majority of receptors relative to the core modelling equivalents.
- 1.2.12. For short-term averaging periods, under worst case emissions conditions, the modelled maximum PC concentrations in the Baseline scenario are shown to be identical to the core modelling equivalents (see **Table 1.3** for NO₂ hourly mean). This is because modelling was undertaken with all biomass units at full load for all hours in the year in both core and worst-case Baseline scenarios, to capture all potential meteorological conditions in any given hour or day.
- 1.2.13. In the With Proposed Scheme scenario, under worst case conditions, the maximum short-term PC concentrations are lower at receptors closer to the Main Stack relative to the core modelling results. This is due to the effect of enhanced plume buoyancy when the non-BECCS units operate continuously with the BECCS units (as discussed above). At distances further from the Main Stack, the effect of enhanced buoyancy on short-term maxima diminishes, resulting in no or very small changes in maximum PC concentrations relative to the core modelling.
- 1.2.14. The net outcome of the above, under worst case emissions conditions, is that the majority of modelled Baseline short-term averaged concentrations are unchanged, whilst With Proposed Scheme maximum concentrations are largely unchanged or reduce slightly. Therefore, the maximum impacts on short-term averaged

concentrations are reported to decrease at the majority of receptors relative to the core modelling equivalents.

- 1.2.15. Whilst the maximum short-term grid PC concentrations do not change in the worst case modelling relative to the core modelling (excluding amines), in both the Baseline and With Proposed Scheme scenarios, the maximum modelled impacts are lower. This is a function of the location of the maximum impact shifting under worst case emissions, again due to the change in Main Stack plume buoyancy (i.e. the maximum impact does not occur at the same location as the maximum PC concentration in the With Proposed Scheme scenario).
- 1.2.16. Given that the results of the core scenario modelling represent the highest modelled impacts associated with the Proposed Scheme operation, there was no need to repeat this sensitivity test in relation to ecological receptors.

EAL	0.2				

(¹) Based on direct mass emissions of 'Nitrosamine 1' and 'Nitrosamine 2' from Main Stack only. PC to ground level is insignificant (<0.1% of the EAL for NDMA). There is no requirement to propose an annual average ELV for direct nitrosamine emissions.

(²) Accounts for application of ADMS Amine Chemistry Module and relates to indirect formation of nitrosamines and nitramines through atmospheric reactions.

(³) Equal to sum of modelled direct and indirect nitrosamine + nitramine concentrations.

SENSITIVITY TESTING: AMINE CHEMISTRY

- 1.2.17. Results pertaining to the amine chemistry sensitivity testing are presented in **Tables 1.23** (MEA) and **1.24** (NDMA). The grid receptor reporting the maximum modelled process contributions are presented, based on the results of modelling completed for low and high range values relating to the atmospheric reaction kinetics detailed in **Table 1.8 of Appendix 6.3 (Atmospheric Dispersion Modelling)** ([document reference 6.3.6.3APP-127](#)) for the proxy compounds.
- 1.2.18. As stated in **Table 1.8 of Appendix 6.3 (Atmospheric Dispersion Modelling)**, amine sensitivity modelling was based on initial design mass emission data that is no longer representative of the proposed BECCS plant. However, the initial design emissions represent higher mass emissions of the amine compounds relative to the proposed permit ELVs used in the core scenario modelling. As such, the initial design emission rates were used and also applied to the proprietary solvent (confidential) data as part of the sensitivity testing to allow a direct comparison with the proxy compound modelling results, whilst also providing a conservative assessment of amine mass emissions from the Main Stack. The maximum modelled PCs for the proprietary amine compounds are also presented in the below tables alongside the proxy compound results.
- 1.2.19. Therefore, the results of the amine sensitivity modelling are self-contained and should not be compared to the core scenario modelling results.
- 1.2.20. The maximum hourly ($0.10 \mu\text{g}/\text{m}^3$) and daily mean ($0.02 \mu\text{g}/\text{m}^3$) MEA concentrations from the sensitivity tests were modelled to be equivalent to the concentrations reported for the proprietary amine solvent ($0.10 \mu\text{g}/\text{m}^3$ and $0.02 \mu\text{g}/\text{m}^3$ respectively), when modelling an identical mass emission rate for amines in all tests.
- 1.2.21. The maximum annual mean NDMA concentrations reported from the sensitivity tests ($0.03 \text{ ng}/\text{m}^3$) was modelled to be 67% higher than the equivalent concentration reported for the proprietary amine solvent ($0.02 \text{ ng}/\text{m}^3$). However, the maximum concentration from the sensitivity tests still remains well below the annual mean EAL for NDMA, equating to 14% of the EAL.
- 1.2.22. Therefore, the results of the sensitivity testing do not affect the outcome of the core assessment results, such that emissions in the With Proposed Scheme scenario would still not result in significant air quality effects at human receptors in terms of amine (MEA) and nitrosamine (NDMA) concentrations.

Table 1.23 - Modelled Minimum and Maximum Operational Impacts at Human Receptors – Amines (as MEA) Concentrations (amine sensitivity testing)

1.3. IMPACTS ON HUMAN RECEPTORS (WITH MITIGATION)

- 1.3.1. Equivalent results tables are presented below for the core model scenarios and sensitivity testing scenarios (worst case emissions profile), inclusive of all mitigation measures outlined in **Section 6.10 of Chapter 6 (Air Quality)** as updated by Air Quality Technical Note 2 (document reference 8.9.5).

CORE MODEL SCENARIOS (WITH MITIGATION)

- 1.3.2. Results pertaining to the core model scenarios, including mitigation, are presented in **Tables 1.25 to 1.33**.

Notes:
⁽¹⁾ Maximum modelled amine concentrations based on sum of 'Amine 1' + 'Amine 2' maxima, which is potentially conservative because the 'Amine 1' maximum concentration could occur at a different time (hour/day) to the 'Amine 2' maximum concentration at any given receptor or grid point. Results based on proposed daily average AELs for 'Amine 1' and 'Amine 2'

⁽¹⁾ Based on direct mass emissions of 'Nitrosamine 1' and 'Nitrosamine 2' from Main Stack only. PC to ground level is insignificant (<0.1% of the EAL for NDMA). There is no requirement to propose an annual average ELV for direct nitrosamine emissions.

⁽²⁾ Accounts for application of ADMS Amine Chemistry Module and relates to indirect formation of nitrosamines and nitramines through atmospheric reactions.

⁽³⁾ Equal to sum of modelled direct and indirect nitrosamine + nitramine concentrations.

SENSITIVITY TEST: WORST CASE EMISSIONS PROFILE (WITH MITIGATION)

- 1.3.3. Results pertaining to the worst-case emissions profile sensitivity test, including mitigation, are presented in **Tables 1.34 to 1.42**.

EAL	0.2				

(¹) Based on direct mass emissions of 'Nitrosamine 1' and 'Nitrosamine 2' from Main Stack only. PC to ground level is insignificant (<0.1% of the EAL for NDMA). There is no requirement to propose an annual average ELV for direct nitrosamine emissions.

(²) Accounts for application of ADMS Amine Chemistry Module and relates to indirect formation of nitrosamines and nitramines through atmospheric reactions.

(³) Equal to sum of modelled direct and indirect nitrosamine + nitramine concentrations.
