Version 1

June 2024

APFP Regulation 5(2)(a)

Planning Act 2008

The Infrastructure Planning (Applications: Prescribed Forms and Procedure) Regulations 2009

## Appendix 11.4: Revised Conceptual Site Model

### 1 INTRODUCTION

1.1 This Revised Conceptual Site Model has been prepared on behalf of EPL 001 Limited ('the Applicant') to summarise the findings of the **ES Volume 4, Appendix 11.2: Phase I Geoenvironmental and Geotechnical Desk Study (Doc Ref 5.4)** and the **ES Volume 4, Appendix 11.3: Ground Investigation Report (Doc Ref 5.4)** in relation to potential contaminated land risk posed to the Development Consent Order ('DCO') application for Stonestreet Green Solar ('the Project').

#### 1.2 The Project

1.2 The Project comprises the construction, operation, maintenance, and decommissioning of solar photovoltaic ('PV') arrays and energy storage, together with associated infrastructure and an underground cable connection to the existing Sellindge Substation.

1.3 The Project will include a generating station (incorporating solar arrays) with a total capacity exceeding 50 megawatts ('MW'). The agreed grid connection for the Project will allow the export and import of up to 99.9 MW of electricity to the grid. The Project will connect to the existing National Grid Sellindge Substation via a new 132 kilovolt ('kV') substation constructed as part of the Project and cable connection under the Network Rail and High Speed 1 ('HS1') railway.

1.4 The location of the Project is shown on **ES Volume 3, Figure 1.1: Site Location Plan (Doc Ref. 5.3)**. The Project will be located within the Order limits (the land shown on the **Works Plans (Doc Ref. 2.3)** within which the Project can be carried out). The Order limits plan is provided as **ES Volume 3, Figure 1.2: Order Limits (Doc Ref. 5.3)**. Land within the Order limits is known as the 'Site'.

#### 1.3 Purpose

1.5 This Revised Conceptual Site Model is based upon the Initial Conceptual Site Model presented in the **ES Volume 4, Appendix 11.2: Phase I Geoenvironmental and Geotechnical Desk Study (Doc Ref 5.4)** and has been revised following the findings of the intrusive ground investigation works presented in **ES Volume 4, Appendix 11.3: Ground Investigation Report (Doc Ref 5.4)**.

- 1.6 This Revised Conceptual Site Model forms the basis for the assessment provided in the **ES Volume 2, Chapter 11: Land Contamination (Doc Ref 5.2)**.
- 1.7 In support of the proposed DCO application, the **ES Volume 4, Appendix 11.2: Phase 1 Geoenvironmental and Geotechnical Desk Study (Doc Ref. 5.4)** was included as part of the EIA Scoping Report (**ES Volume 4, Appendix 1.1 (Doc Ref. 5.4)**). Whilst the Planning Inspectorate agreed that contamination is unlikely to be significant, given there is potential for Made Ground across the Site, further assessment in the form of intrusive ground investigation works was required to confirm the risks were very low to low.
- 1.8 The primary purpose of the intrusive ground investigation works was to investigate the potential presence of Made Ground beneath the Site identified in the **ES Volume 4, Appendix 11.2: Phase 1 Geoenvironmental and Geotechnical Desk Study (Doc Ref. 5.4)** and provide an assessment of the geo-environmental suitability of the ground conditions.
- 1.9 In the UK, contaminated land is regulated by the planning and development control system and the contaminated land regime set out in Part 2A of the Environmental Protection Act (EPA) 1990<sup>1</sup>.
- 1.10 Environment Agency guidance 'Land Contamination Risk Assessment (LCRM)<sup>2</sup>' provides advice on the approach for the investigation and assessment of contamination on a site. This approach includes the production of a conceptual site model depicting the environmental processes that occur on and in the vicinity of the site and identifying the potential pollution linkages. The assessment of the significance of these pollution linkages can then be carried out through the risk assessment process.

## 2 GROUND INVESTIGATION WORKS SUMMARY

2.1 The ground investigation works were undertaken between the 15<sup>th</sup> and 17<sup>th</sup> February 2023, and comprised the following:

- 5 No. Trial pits (TP) were excavated across the Site excavated to a maximum depth of 2.30 mbgl.
- 11 No. windowless sampler boreholes (WS) were drilled to a maximum depth of 5.00 mbgl.
- 32no. solid soil samples were subject to laboratory chemical analysis.

The following suite of laboratory chemical testing was undertaken:

- Heavy Metals (Arsenic, Boron, Cadmium, Copper, Chromium III, Chromium VI, Lead, Mercury, Nickel, Selenium, and Zinc);
- Total Organic Carbon (TOC);
- Soil Organic Matter (SOM);
- Water Soluble Sulphate;
- pH;
- USEPA 16 Polycyclic Aromatic Hydrocarbons (PAH's);
- Total Petroleum Hydrocarbons (TPH's) (TPH total >C6-C40); and
- Asbestos identification.

### 2.2 Human Health

2.2 The significance of the recorded concentrations has been determined through a comparison with published Generic Assessment Criteria (GACs).

2.3 GACs are derived based on generic conceptual site models for a number of land-uses and making generic assumptions about receptor type and behaviour and building and soil properties.

2.4 The land uses included under the GAC include residential development, with and without the consumption of homegrown vegetables, allotments, commercial and industrial, open space and parks and playing fields. The assessment for this development i.e., construction of a solar farm, infrastructure and associated switch & storage rooms, will therefore be undertaken using the values for “Commercial” land use. It is also assumed that the future site users will be involved only in the operation and maintenance and decommissioning of the Site, and there will be no full-time occupation of any Site buildings.

2.5 There is no one source that publishes values for all contaminants and so the following sources have been used in the following order of preference.

Results that are reported lower than the limit of detection have been discounted.

#### *Category 4 Screening Levels (C4SL)*

- 2.6 In March 2014, the Department for Environment, Food and Rural Affairs published six Category 4 Screening Levels within their report “*Development of Category 2 Screening Levels for Assessment of Land Affected by Contamination*”<sup>3</sup>. These GACs are generated using the CLEA model, although the toxicology and exposure parameters have been modified so that the values represent “*a more pragmatic approach to contaminated land risk assessment (albeit still strongly precautionary)*”. DEFRA state that the Category 4 Screening Levels will be used as generic screening criteria.

#### *Suitable For Use Levels (S4UL)*

- 2.7 Land Quality Management (LQM) and Chartered Institute of Environmental Health (CIEH) have published Suitable For Use Levels (S4UL’s) for 82 substances. These values, contained within the publications “*LQM/CIEH S4ULs for Human Health Risk Assessment*” (2015)<sup>4</sup>, replace the previous values contained within “*Generic Assessment Criteria for Human Health Risk Assessment (2<sup>nd</sup> Edition)*” dated 2009, and reflect the greater knowledge of relevant toxicology and further consideration of exposure scenarios.
- 2.8 Separate S4UL values have been published for three soil organic matter (SOM) contents (i.e. 1%, 2.5% and 6%). The SOM across the site ranged from 0.1% to 3.9%. Due to the variable nature of the SOM a value of 1% has been chosen for the initial screen as it is the most conservative approach.

#### *Laboratory Chemical Analysis*

- 2.9 The comparison of the results of the solid laboratory chemical testing with the GACs discussed above showed no exceedances against the relevant screening criteria.

#### *Asbestos*

- 2.10 During the ground investigation works, no asbestos or asbestos containing material (ACMs) were recorded.

- 2.11 Asbestos identification analysis was undertaken on 32no. samples taken from across the Site and asbestos was not detected within any of these samples, therefore the risk from asbestos is considered to be low.
- 2.12 Prior to any excavation taking place all workers should be informed by a toolbox talk of the potential for ACMs to be present and what to do if encountered. During the construction phase, construction workers shall remain vigilant to the possible risk of encountering isolated areas of contaminated material. Should potentially contaminated material be encountered, works in this area will immediately cease and the procedure set out in the **Outline CEMP (Doc. Ref. 7.8)** will be followed.

### 2.3 Controlled Waters Risk Assessment

- 2.13 The Phase I Desk Study (**ES Volume 4, Appendix 11.2 (Doc Ref. 5.4)**) indicates that the Site is predominantly underlain by the Atherfield and Weald Clay Formations, covering approximately 17.3% and 68.3% respectively, which are both classified as Unproductive groundwater aquifers. The Hythe Formation, which constitutes the remaining 14.4% of bedrock geology covering the Site, is classified as a Principal Aquifer; however, no source protection zones, or abstraction licences were identified across or within 250m of the Site. The Alluvium superficial deposits are present across the northern fields of the Site (Fields 25-29) and cover approximately 19.8% of the Site area. The Alluvium deposits are associated with the East Stour River and are classified as a Secondary A aquifer.
- 2.14 The Ground Investigation Report (**ES Volume 4, Appendix 11.3 (Doc Ref. 5.4)**) has proven the near surface deposits are relatively low permeability in nature (clay) which consequently reduces the hydraulic conductivity of potential contaminants present beneath the Site and therefore unlikely to support the infiltration and migration of groundwater. In addition, the results of the solid analysis concluded that there were no exceedances of GACs for commercial land use and this indicates that the reservoir of contaminants present beneath the Site is low.
- 2.15 Given that the materials tested were first generation material with no definable made ground having been encountered, the low permeability nature of the near surface deposits and the reservoir of contaminants being low, the overall risk to controlled waters is concluded to be low.

2.16 It is recommended that the main area of focus for the protection of controlled waters receptors is through ensuring environmental best practice throughout the lifespan of the Project but primarily during earthworks associated with construction and decommissioning phase works. The use of environmental best practice (e.g control of run off, stockpiling etc.) is detailed in the **Outline CEMP** and **Outline DEMP (Doc Ref. 7.8 and Doc Ref. 7.12)**.

## 2.4 Preliminary Ground Gas Risk Assessment

2.17 The records of the environmental monitoring visit undertaken on 6<sup>th</sup> April 2023 indicate that the majority of the Site would provisionally be classified as Gas Characteristic Situation (CS) 2, as per CIRIA C665<sup>5</sup>. This is due to elevated carbon dioxide concentrations of > 1% v/v (WS01, WS07 and WS09) or gas screening value of greater than 0.07l/hour (WS06). The remaining two monitoring boreholes (WS05 and WS10) were classified as Gas CS1.

2.18 The Project Substation, and Intermediate Substations, are situated in Field 26. This is where WS10 and the Gas CS1 area is located, indicating that any proposed enclosed spaces across the area are unlikely to require ground gas protection measures.

2.19 The development proposed across the areas classified as Gas CS 2 comprise the PV Arrays, Inverter Stations (including BESS), Intermediate Substations, Project Substation and Sellindge Substation Extension.

2.20 As the PV Arrays are in the open-air with no confined areas for the potential accumulation of gases, this therefore removes the pathway for ground gas migration and accumulation.

2.21 All other infrastructure (e.g. Inverter Stations, Intermediate Substations, Project Substation and Sellindge Substation Extension) will be sited on concrete or skid foundations which will help to break the pollutant pathway between ground and containers.

2.22 It is understood that any works during the operational phase involving containerised Inverters, will be undertaken outside of the units in the open air therefore removing the potential for inhalation pathway by human health receptors.

- 2.23 The BESS, the Intermediate Substations and the Project Substation buildings will have active and/or passive ventilation systems installed thereby removing the potential for ground gas accumulation.
- 2.24 Additionally, the Project Substation buildings are expected to be raised to allow cable infrastructure to enter from beneath. The void space between the foundations and the Project Substation building will allow for dispersion and prevent potential accumulation of any ground gases.
- 2.25 It is considered unlikely that the proposed buildings located across the areas provisionally designated as Gas CS 2 would require any additional ground gas protection measures.

## 2.5 Ecological Receptors

- 2.26 The results of the solid laboratory chemical testing indicate that the preliminary risk assessment of Very Low to Low for ecological receptors (local fauna and flora) presented in the **ES Volume 4, Appendix 11.2: Phase 1 Geoenvironmental and Geotechnical Desk Study (Doc Ref. 5.4)** has been downgraded to Very Low.

**REVISED CONCEPTUAL SITE MODEL & QUANTITATIVE RISK ASSESSMENT**
