LIST OF ACRONYMS

The following table lists some of the acronyms used in this report.

bbreviations	Definition
EP	Annual Energy production
ЗоР	Balance-of-Plant
CFD	Computational Fluid Dynamics
осо	Development Consent Order
EPA	Energy Production Assessment
ERA5	ECMWF Reanalysis 5th Generation
ECMWF	European Centre for Medium-Range Weather Forecasts
EPSG	European Petroleum Survey Group Geodetic Parameter Database
EL	Floating Lidar
EC	International Electrotechnical Commission
им	Meteorological (Met.) Mast
MERRA	Modern-ERA Retrospective analysis for Research and Applications
иомм Иомм	Mean of Monthly Means
CAPEX	Capital Expenditure
EIA	Environment Impact Assessment
D&M	Operation and Maintenance
250	Exceedance probability: The probability of exceeding the reported P50 value for annual energy production is 50%
90	Exceedance probability: The probability of exceeding the reported P90 value for annual energy production is 90%
PBE	Production Based Estimate
PC	Power Curve
PPA	Power Purchase Agreement
A&Q	Questions and Answers
SPV	Special Purpose Vehicle
SCADA	Supervisory Control and Data Acquisition
П	Turbulence Intensity
"SA	Turbine Supply Agreement
WAsP	Wind Atlas Analysis and Application Program
WF	Wind Farm
WRF	Weather Research and Forecasting
WSBE	Wind Speed Based Estimate
WSM	Wind Sector Management
WTG	Wind Turbine Generator
WT	Wood Thilsted

EXECUTIVE SUMMARY

Ørsted (the "Client") has retained Wood Thilsted Partners Ltd (WT) to develop an independent wake impact assessment for their operational offshore wind farm assets in the Irish Sea. These assets are anticipated to be impacted by the proposed neighbouring wind farms, including Mona¹, Morgan² and Morecambe³ (abbreviated as MoMoMo).

Apart from the individual impacts of the wakes of each of the wind farms given above, the cumulative impact caused by all three wind farms on the Client's assets will also be assessed. Along with the MoMoMo wind farms, WT has also considered the effect of existing neighbouring operational wind farms including Gwynt y Môr, Rhyl Flats, North Hoyle and Ormonde, and the future wind farm Awel y Môr.

A range of publicly available datasets has been utilized for the assessment of future wind farm parameters, including the development phase, possible turbine configurations, turbine type and hub height. Sources for this include the 4C Offshore Wind Market Intelligence [1], submissions to the National Infrastructure Planning Portal [3], along with correspondence with the Client [2]. It should be noted that due to the early stage of some of the projects, the information compiled for the future projects are not considered final, therefore the impacts will be subject to change – this report should be considered as being based on the best available information at the time of preparation.

The wind farms belonging to Ørsted, namely Barrow, Walney 1, Walney 2, Walney Extension 3 and 4, West of Duddon Sands, Burbo Bank and Burbo Bank Extension are situated in the wider Liverpool Bay area, close to the UK coastline of the Irish Sea, ranging from 20-30 km from the shore.

This report provides a summary of the data used along with the industry standard methodologies for deriving the impact of wakes between operational wind farms. The primary objective of the study is to estimate the comparative loss in energy for the Ørsted assets due to wakes caused by the addition of new wind farms, and not estimating the absolute values for energy production and wakes. A short description of wind farm wakes, their effects and methodologies for their modelling is also included in Section 1.2.

WT has assessed the effects of future wind farms by utilizing different scenarios. Table 1 below summarizes the main scenarios used and Table 2 summarizes the magnitudes of additional losses with respect to the baseline scenario.

³ Morecambe Windfarm, https://morecambeandmorgan.com/morecambe/en/ a joint venture of Cobra Instalaciones y Servicios, S.A. - Flotation Energy Limited

¹ Mona Windfarm, https://www.morganandmona.com/en/ a joint venture of EnBW - BP

² Morgan Windfarm, https://morecambeandmorgan.com/morgan/ a joint venture of EnBW - BP

Table 1 External Wakes Scenarios

Scenario	Included Wind Farms	Comments / Assumptions
Baseline	Ørsted assets ¹ + Neighbouring operational wind farms ^{2.}	Existing operational conditions
Scenario 1	Baseline + proposed Mona³ Wind Farm	Mona Wind Farm capacity will be up to 1500 MW, to start construction in 2026, and owned by a joint venture of EnBW - BP
Scenario 2	Baseline + proposed Morgan³ Wind Farm with	Morgan Wind Farm capacity will be up to 1500 MW, to start construction in 2027, and owned by a joint venture of EnBW - BP
Scenario 3	Baseline + Morecambe ³ Wind Farm	Morecambe Wind Farm capacity will be up to 480 MW, to start construction in 2027/2028, and owned by a joint venture of Cobra - Flotation Energy
Scenario 4	Baseline + all MoMoMo³ assets	-
Scenario 5	Scenario 4 + Awel y Môr ³	Awel y Môr Wind Farm capacity will be approximately 576 MW and will be operational by 2030.

¹ Barrow, Walney 1, Walney 2, Walney Extension 3 and 4, West of Duddon Sands, Burbo Bank and Burbo Bank Extension

Based on these scenarios the additional wake loss in individual wind farms varies between **-0.16** % and **-5.30** % depending on the scenario and the existing Ørsted assets under consideration. Considering the total effect on all the existing Ørsted Irish Sea Portfolio, the effect varies between **-0.68** % (considering if only Morecambe OWF is consented) to **-3.80** % (considering if all future wind farms considered in this study are consented), depending on the scenario.

As such, if all the proposed development takes place, the cumulative impact on the Ørsted Irish Sea Portfolio is just under **-4** %. Whilst this may only be following the total build out (with completion timelines post 2030), the impact on annual energy production (AEP) of individual future wind farms has been seen to be between **-0.68** % and **-1.64** % on the existing Ørsted Irish Sea Portfolio.

Considering the engineering wake model approaches used and distances between the Client assets and proposed neighbouring wind farms, WT considers the assessed additional wake loss numbers to be commensurate with WT's expectations. WT also finds the above results comparable with recent studies conducted by DNV and RWE [7] about cluster wakes and their effects on wind farm annual energy production, where values of -3.0% to -3.6% additional wake losses arising from neighbouring wind farms which are 5-30 km away from the projects under interest.

² Gwynt y Môr, Rhyl Flats, North Hoyle and Ormonde

^{3. 15} MW capacity turbines (each), 150 m hub height and 236 m rotor diameter turbine

Subject to specific criteria on each wind farm site, including capacity factor, age of the wind farm, turbine type/size and the agreed electricity sale price, the financial and technical consequences of additional wake losses could be considerable. WT also notes that increased turbulence levels due to the added wake may increase the fatigue / structural loading and may cause additional downtime for the turbines, where electricity production is halted.

Due to uncertainty on the ultimate turbine selection, WT has also undertaken a series of sensitivity scenarios for the future wind farm assets, based on an assumption of 22.6 MW 276 m diameter wind turbines (instead of 15 MW 236 m rotor diameter turbines). The results of this sensitivity test (shown in Table 5-2) suggest that the additional wake losses will typically be reduced with larger turbines.

Table 2 Summary of the results of the main scenarios, normalized to the baseline

Scenario	Additional wake loss on each wind farm (%)								
	Barrow	Walney 1	Walney 2	Walney Extension 3	Walney Extension 4	West of Duddon Sands	Burbo Bank	Burbo Bank Extension	Total additional wake loss on all Ørsted Irish Sea assets
Baseline	0	0	0	0	0	0	0	0	0
Scenario 1 - Addition of Mona OWF	-1.55%	-1.67%	-1.22%	-0.83%	-1.58%	-1.57%	-0.96%	-1.22%	-1.38%
Scenario 2 – Addition of Morgan OWF	-0.49%	-1.44%	-2.09%	-3.39%	-3.09%	-1.29%	-0.23%	-0.16%	-1.64%
Scenario 3 – Addition of Morecambe OWF	-1.37%	-0.53%	-0.32%	-0.40%	-0.56%	-1.01%	-0.46%	-0.45%	-0.68%
Scenario 4 – Cumulative addition of MoMoMo	-3.13%	-3.64%	-3.64%	-4.22%	-5.16%	-3.86%	-1.63%	-1.83%	-3.63%
Scenario 5 – Cumulative addition of MoMoMo and Awel y Môr	-3.40%	-3.70%	-3.68%	-4.27%	-5.30%	-3.97%	-2.15%	-2.43%	-3.80%

1. INTRODUCTION

1.1. Background to the study

Ørsted (the "Client") has retained Wood Thilsted Partners Ltd (WT) to complete an independent assessment of the possible additional external wake losses for their operational wind farms located in Irish Sea. The starting hypothesis is that these additional losses will be incurred from the proposed future neighbouring wind farms, including Morgan, Mona and Morecambe (abbreviated as MoMoMo) and Awel y Môr.

The Client's operational wind farms are considered to include:

- Barrow (90 MW, commissioned in 2006)
- Walney Phase 1 (183.6 MW, commissioned in 2011)
- Walney Phase 2(183.6 MW, commissioned in 2012)
- West of Duddon Sands (389 MW, commissioned in 2014)
- Walney Extension (Walney Phases 3 & 4) (659 MW, commissioned in 2018)
- Burbo Bank (90 MW, commissioned in 2007)
- Burbo Bank Extension (256 MW, commissioned in 2017)

The Client is interested in the potential differences in annual energy production driven by the external wake effects from the proposed future MoMoMo wind farms. These future farms are at the stage of having their Development Consent Orders examined. Apart from the individual impacts of the wakes on each wind farm listed above, the Client has also requested the cumulative impact caused by all three wind farms on each of the Client's Irish Sea assets. It should be noted that due to the physical complexity of wind turbine wake phenomena (as explained in Section 1.2 below), the cumulative assessment will not be as high as the sum of impact of each individual wind farm added together. This is something expected, considering the complexity of flow and interaction & recovery processes of wakes downstream of a wind turbine. Therefore, in order to have a fairer view of the wake impacts, it is considered appropriate to assess their effects on both individual and cumulative basis, considering that these wind farms will be built in successive manner between the years 2026-2028, as given in Table 1.

The project area has a range of proposed and operational wind farms as noted in Figure 1-1. WT has modelled the existing operational wind farms including Gwynt y Môr, Rhyl Flats, North Hoyle and Ormonde. It should be noted that, apart from the Morgan, Mona & Morecambe wind farms given above, there are other future projects around the Client Irish Sea assets which are in earlier phases of their

development, including Awel y Môr and Mooir Vannin. WT notes that Awel y Môr wind farm will also affect the energy production of Client Irish Sea assets when it becomes operational. Consequently, WT will include this wind farm in its wake estimations in Scenario 5. It should be noted that the Mooir Vannin wind farm is excluded from the assessment since it hasn't obtained consent at the time of writing, though would likely have an additional impact on the results of this assessment.

Figure 1-1 Location of the Client's operational Irish Sea Portfolio assets (shown as the site boundaries in blue). The existing wind farms (green site boundaries) and the future proposed wind farms (shown as orange and red boundaries).

By way of introduction, WT finds it appropriate to briefly explain the issue of wind farm wakes and industry methodologies to model them.

1.2. Wind Farm Wakes

Wind turbines generate electricity by extracting the useful kinetic energy within the wind. This energy conversion process leaves a slower-moving and highly chaotic, therefore less-useful wind downstream of the wind turbine. This downstream region is characterized by lower wind speeds and higher turbulence and is referred as the wind turbine wake. The turbulence in the wake is driven by tip vortices generated at the turbine blade tips and turbulent eddies just behind the turbine, which is a region with intense swirling motions of air. Wakes both affect

the performance of the downstream turbines, and they also increase the mechanical stress in the turbines, reducing the useful life of the turbines.

As the flow propagates downstream, the highly chaotic state of the wake recovers gradually to the original airflow state, by mixing of the slower, turbulent air within the wake with the undisturbed air in the surroundings. This recovery is affected by factors such as the atmospheric turbulence, which is the natural turbulence of the background atmosphere; wind shear, which describes the change in wind speed with height; and the atmospheric stability, which is the resistivity of the atmosphere to the disturbances. The full recovery behind a single turbine usually requires distances such as 10-12 turbine rotor diameters. However, wake effects from entire wind farms have been shown to persist for much greater distances > 30km and potentially up to 100km downstream [7], potentially affecting wind farms located further away.

Modelling the effects associated with wakes and designing the wind farm turbine layouts in such a way to minimize these effects are essential in the realisation of wind farms. Industry best practices often apply constraints of 4-6 rotor diameters between the turbines in non-significant wind directions and 7-8 rotor diameters between the turbines in prevailing wind directions.

There are several methodologies in the industry for modelling the wakes, ranging from simple analytical / empirical models to more advanced CFD based models, which have trade-offs in terms of accuracy and computational cost. As covered in Section 5, WT's typical best practice is to use the WindFarmer: Analyst Eddy Viscosity with large wind farm correction model to estimate offshore wake and turbine interaction effects. This model has been validated by DNV in 2019, and results in lower errors across a number of operational offshore wind farms compared to other wake models [8], [9].

2. DESCRIPTION OF THE ASSESSED PROJECTS

2.1. Location of the client assets & data

The Client assets are situated in the wider Liverpool Bay area, close to the UK coastline of the Irish Sea, ranging from 20-30 km from the shore.

A map showing available wind climate locations at West of Walney (WOW) Extension FL, Shell Flats MM and Burbo Bank FL, as well as boundaries of existing Client assets are presented in Figure 2-1. Further information related to the wind climate files can be found in Section 3.

Figure 2-1 Map of the existing projects along with the available measured wind data locations used to derive wind climates

2.2. Turbine Layouts and Configurations

2.2.1. Power Curves

Turbine configurations for the Client assets and neighbouring and future wind farms, including the turbine model and associated wind farm, rated power, hub height, peak power coefficient, number of turbines and total installed capacity, are provided in Table 2-1. The information related to the Client assets and neighbouring operational wind farms were provided by the Client [2]. For the future MoMoMo assets and Awel y Môr, WT has made reasonable assumptions including designing layouts with a set of constraints as described in Section 2.2.2..

It should be noted that for the MoMoMo wind farms, WT has made reasonable assumptions for the turbine models including the parameters such as rotor diameter, hub height, and power and thrust curves considering the project timelines, current sector trends and best practices. The information compiled for the future projects are not certain at this stage, and the impacts will be subject to change; therefore, this report should be considered as being based on the best available information at the time of preparation.

The power curves of the turbine models for the Ørsted Irish Sea Portfolio assets and operational neighbouring assets have been provided by the Client [2]. WT has derived two turbine models to be used for the future farms, namely WT 15MW-236m and WT 22.6MW-276m. The characteristics and performance data of the turbines are presented in Appendix B. It should be noted that the characteristics and performance data of the neighbouring operational wind farms are redacted for confidentiality reasons.

WT has obtained historical pressure and temperature records from eight nearby meteorological stations within a maximum radial distance of 90 km and maximum elevation difference of 150 m from the site. Using standard lapse rate assumptions, WT has derived air density values between 1.221 kg/m³ and 1.223 kg/m³ at an elevation of 155 mMSL. Based on these data, WT has estimated the long-term air density at the site to be 1.222 kg/m³ at an average elevation of 155 mMSL for all the wind farms.

The supplied power curves used in this analysis have been adjusted to the predicted site air density, in accordance with the recommendations of IEC [10]. This has been undertaken on an individual turbine basis.

2.2.2. Layouts

The layouts related to the Client assets and neighbouring operational wind farms were provided by the Client [2]. However, for the future wind farms, Mona, Morgan, Morecambe and Awel y Môr, WT has designed preliminary wind turbine layouts based on guidelines and constraints described in the project submissions available in the Planning Inspectorate Portal [3], and Development Consent Order (DCO)

documents for Mona [4], Morgan [5] and Morecambe [6], which include a number of constraining parameters, including minimum and maximum number of turbines, maximum rotor diameter, maximum blade tip height and minimum tip clearance, and minimum distance between turbines.

Due to the preliminary nature of the future wind farms, WT did not consider additional constraints including foundation type or seabed properties such as depth and slope. WT would expect that micrositing or additional layout considerations would ultimately alter the results, however these are likely to be small compared to the changes due to turbine selection. As such, WT has designed two layouts for each MoMoMo site considering the WT 15MW-236m and WT 22.6MW-276m wind turbines, and one layout for the Awel y Môr site considering the WT 15MW-236m turbine. The allowable number of turbines for each of the MoMoMo sites has been obtained from the DCO documents [4], [5], [6] and applied to the above turbine models. Using WT 15MW-236m turbines, the resulting capacities for these sites are all within the upper limits stated in Table 1. However, for the sites with the WT 22.6MW-276m turbines, the minimum number of turbines results in site capacities that exceed the site capacity limits and are therefore not compliant with the DCO project descriptions. These layouts have been provided for completeness and to demonstrate the effect of using larger turbines.

Based on the derived wind climates (see Section 4), WT has estimated the prevailing wind direction at each site in order to define acceptable minimum turbine separation distances in the prevailing and non-prevailing wind directions, and to align the layout grid such that the wake impacts from a row of turbines on the rows behind them are minimised. Typical offshore wind farms currently under development maintain an average inter-turbine spacing of approximately 7-8 rotor diameters in prevailing wind directions, and 4-6 rotor diameters in non-prevailing wind directions.

Given the wind regimes at the wind climate locations, which can be seen in Appendix D-3, WT considers that inter-turbine spacings of 8 rotor diameters in the prevailing wind directions and 6 rotor diameters in the non-prevailing wind directions can be accommodated for the MoMoMo wind farms for most scenarios. The exception to this is the Awel y Môr site when using 15 MW turbines, and in order to achieve the desired wind farm capacity, layouts using 7 and 5 rotor diameters have been applied in the prevailing and non-prevailing wind directions, respectively. As such, the minimum inter-turbine separation distances applied are considered to be consistent with those defined in the DCO project descriptions [4], [5], [6].

The grid coordinates of the turbines for all the wind farms under consideration are given in Appendix A.

Table 2-1 Turbine model parameters and turbine configurations.

Turbine	Associated wind farm	Rated power (MW)	Hub height (mMSL)	Number of turbines	Installed Capacity
Siemens Gamesa SWT-3.6-107	Burbo Bank	3.6	83.4	25	90
Vestas V164-8.0 MW	Burbo Bank Extension	8.3	108.0	32	265.6

3. DESCRIPTION OF THE AVAILABLE WIND DATA

3.1. Wind Climate Files

The Client has provided the long-term corrected time series at the hub heights of all Ørsted assets from the following wind measurements in the vicinity of the sites [2] (denoted as "wind climates") as summarized in Table 3-1 below and shown in Figure 2-1.

Device	Provided long term time series heights		Period of time series	Location	
	Wind speed (m)	Wind direction (m)		Latitude	Longitude
WOW Extension Floating LiDAR (FL)	75.0, 78.4, 83.4, 84.9, 85.77, 106.7, 108.0, 112.3	108.0	01/01/1999 – 30/06/2023	54.13619°	-3.91969°
Shell Flats Met. Mast (MM)	75.0, 78.4, 83.4, 84.9, 85.77, 106.7, 108.0, 112.3	80.0	01/01/2002 – 30/06/2023	53.85979°	-3.28329°
Burbo Bank Floating LiDAR (FL)	75.0, 78.4, 83.4, 84.9, 85.77, 106.7, 108.0, 112.3	108.0, 76.0	01/01/1999 – 30/06/2023	53.48829°	-3.35809°

Table 3-1 Wind climates summary.

Further details of the individual wind climate files provided by the Client, including monthly data statistics at selected heights, can be found in Appendix C.

The WOW Extension FL system is located in the northern part of the Irish Sea, approximately 30 km east of the Isle of Man and 40 km west of UK shores, in the vicinity of Walney 1, Walney 2, Walney Extension and West of Duddon Sands Wind Farm project areas.

The Shell Flats MM is located in the eastern part of the Irish Sea, approximately 15 km west of the city of Blackpool and approximately 15 km south of Barrow Wind Farm project area.

The Burbo Bank FL system is located in the south-eastern part of the Irish Sea, approximately 20 km west of the city of Liverpool and in the close vicinity of Burbo Bank and Burbo Bank Extension Wind Farm project areas.

It should be noted that the Client has provided the wind climates in the form of long-term corrected time series from the measurement devices. Therefore, further details about the measurement devices including the device type, configuration, installation and maintenance records and raw wind data is not available to WT. WT has discussed the process followed by the Client while producing these wind climates and also conducted quality checks of this data, including comparisons of WT's assessment of publicly available data and Client-provided data for the Shell

Flats Met Mast, and have deemed this wind climate data acceptable as input for the wake assessment. Further details can be found in Section 4.

3.2. Reference Data

WT has used reference data in the form of wind speed maps for the derivation of horizontal wind speeds across the turbine locations. These include the New European Wind Atlas (NEWA) [11], Global Wind Atlas (GWA) [12] and Vortex proprietary data. Vortex data has been provided by the Client [2] and publicly available data including NEWA and GWA, have been obtained by WT.

WT has undertaken checks regarding the variation of wind speeds on those wind speed maps and compared the cross predictions of the wind climate files summarised in Section 3.1. Based on these checks WT has developed an approach for the prediction of the wind conditions at the turbine locations. Further information on the approach can be found in Section 4.3.1.

3.2.1. New European Wind Atlas (NEWA)

The New European Wind Atlas (NEWA) [11] uses the Weather Research and Forecasting (WRF) model, forced with ERA5 reanalysis data, to generate a regional map of wind speed variation across Europe and Turkey, including offshore.

Data are available at seven heights between 50 m and 500 m. Both mesoscale and microscale modelling has been performed, and WT has obtained data from the mesoscale model. The mesoscale data is based on a simulation period of 30 years and has a horizontal grid resolution of 3 km. WT used wind map data at a height of 100 mMSL for the horizontal wind speed variation. The wind map at 100 m can be seen in Figure 3-1 along with the site boundaries.

WT has further extracted timeseries data at a height of 100 mMSL, covering an approximately 13-year period from January 2005 to December 2018 from the nodes nearest to all the centroids of the wind farms listed in Table 2-1.

Figure 3-1 New European Wind Atlas (NEWA) 100 m wind map for the site area.

3.2.2. Global Wind Atlas (GWA)

The Global Wind Atlas (GWA) [12], uses the Weather Research and Forecasting (WRF) model forced with ERA5 reanalysis data to generate a global map of wind speed variation (including offshore). The model is based on a simulation period of 58 years (from 1961 to 2019).

Data are available at five heights between 10 m and 200 m at a horizontal grid resolution of 3 km that has then been downscaled to a horizontal resolution of 250 m using microscale modelling [12].

WT has obtained wind map data at a height of 100 mMSL to inform the horizontal wind speed variation across the site area. The wind map at 100 m can be seen in Figure 3-2 along with the site boundaries.

Figure 3-2 Global Wind Atlas (GWA) 100 m wind map for the site area.

3.2.3. Vortex Wind Map

To assess the horizontal wind speed variation across the sites, WT has further considered the Vortex MAP product, purchased on behalf of the Client from Vortex [13]. This has been provided at several heights ranging from 50 m to 200 m, and uses the Weather Research and Forecasting (WRF) model forced with ERA5 and downscaled to the site. The wind map at 100 m can be seen in Figure 3-3 along with the site boundaries.

Figure 3-3 Vortex 100 m wind map for the site area.

4. LONG-TERM WIND REGIME AT THE SITE

4.1. Choice of primary source of wind climate files and wind maps

WT has evaluated the long-term wind climate files of Shell Flats MM, Burbo Bank FL system and WOW Extension FL system, which are summarized in Section 3.1, and using the wind maps summarized in Section 3.2 has developed an approach to predict the long term wind speeds at each wind turbine, which were used as inputs for the wake modelling runs.

WT has correlated the time series in wind climate files with each other and observed that there is generally good agreement among the wind climates at the three locations. The correlation results can be seen in Appendix D-1. WT has further compared the frequency distributions derived from each of the wind climate files to see if any differences in the wind roses across the sites are observed. The results of this comparison can be seen in Appendix D-3. It can be seen in these comparisons that while the Shell Flats MM and Burbo Bank FL system seem in good agreement, there is some difference between the Shell Flats MM and WOW Extension FL system, especially in the 210-, 270-, and 300-degree wind direction sectors, implying that there might be changes in the wind roses within the site, according to the differences between Shell Flats MM and WOW Extension FL system.

Furthermore, WT has checked the wind speed predictions of each wind map at the locations of the wind climate files, which can be seen in Table 4-4, and compared these predictions with the long-term mean wind speeds of the time series given in the wind climate files. WT has further cross-predicted the wind speeds at the wind climate locations using the speedups derived from each of the wind speed maps and evaluated the consistency of the wind climate files and performance of wind speed files. The results of this check can be seen in Table 4-5.

WT observed that there is good consistency among the wind climate files and the wind speed predictions of the wind maps. Due to its superior performance compared to Global Wind Atlas and Vortex, WT has decided to use the New European Wind Atlas map for the predictions of wind speeds at the turbine locations.

For specifying the wind climate files to be used in turbine location wind speed predictions, due to their proximity to the project areas and similar expected wind climate exposure, and in order to mitigate the possible effects of the change of wind rose across the site, WT has used the predictions of Burbo Bank FL system data for the southern wind farms (namely Burbo Bank, Burbo Bank Extension, Gwynt y Môr, Rhyl Flats, Mona, Awel y Môr and North Hoyle Wind Farms) and the predictions of WOW Extension FL system for the northern wind farms (namely Walney 1-2, Walney

Extension 3-4, West of Duddon Sands, Barrow, Morgan, Morecambe and Ormonde). This is considered the most robust and lowest uncertainty route to defining the wind regime over the wind farm sites. WT did not consider use of Shell Flats Met Mast as explained in Section 4.3.1. The approach discussed above is also summarized in Table 4-1.

Long term wind speed and direction frequency distributions of each wind climate file can be inspected in Appendix D-2.

Table 4-1 Summary of wind speed prediction route for the wind farms under consideration.

Wind farms	Wind climate file used for predicting wind climate at turbine locations	Reference wind map used
Walney 1-2, Walney Extension 3-4, West of Duddon Sands, Barrow, Morgan, Morecambe and Ormonde	WOW Extension FL system	Now European Wind Atlas
N/A	Shell Flats MM	New European Wind Atlas
Burbo Bank, Burbo Bank Extension, Gwynt y Môr, Rhyl Flats, Mona, Awel y Môr and North Hoyle	Burbo Bank FL system	(NEWA)

4.2. Long term hub height wind regime at the site

4.2.1. Derivation of long-term wind speed at the wind climate locations

As discussed in Section 3, since the wind climate files contain wind time series already adjusted according to the long-term wind speed and extrapolated to some of the hub heights of 75.0 m, 78.4 m, 83.4 m, 84.9 m, 85.77 m, 106.7 m, 108.0 m and 112.3 m, WT has directly used them in order to derive the wind speed and direction distributions for the other hub heights and derived the time series in all hub heights.

The variations in wind speed with height at the wind climate locations have been defined using the power law shear exponents which are calculated for each wind climate file and have been used to predict the wind resource at the proposed hub heights for the respective device.

The power law wind shear exponent is defined by Equation 1:

$$\frac{\overline{U}(z_1)}{\overline{U}(z_2)} = \left(\frac{z_1}{z_2}\right)^{\alpha} \tag{1}$$

Where:

 α is power law wind shear exponent (-)

 \overline{U} is the wind speed (m/s)

z is the height above ground level (m)

The shear exponents at the wind climate locations have been derived and used to extrapolate the long-term wind speeds at the respective wind climate files to all the hub heights. The estimated shear exponents are given in Table 4-2 while the long-term wind speeds at all the hub heights are provided in Table 4-3 with associated wind farm for each hub height.

We note that the estimated wind shear exponents are in line with WT's expectations for such offshore locations.

Table 4-2 Summary of the predicted wind shear exponents.

Wind Climate File	Predicted wind shear exponent from the time series
WOW Extension FL system	0.090
Shell Flats MM	0.093
Burbo Bank FL system	0.071

Table 4-3 Summary of the long-term hub height wind speeds

Hub Height in ascending order (m)	Associated wind farm	WOW Extension FL system (m/s)	Shell Flats MM (m/s)	Burbo Bank FL system (m/s)
67	North Hoyle (neighbouring)	9.5	9.0	8.9
75	Barrow	9.6	9.1	8.9
78.4	Walney 1	9.7	9.1	9.0
80	Rhyl Flats (neighbouring)	9.7	9.2	9.0
83.4	Burbo Bank	9.7	9.2	9.0
84.4	Gwynt y Môr (neighbouring)	9.7	9.2	9.0
84.9	Walney 2	9.7	9.2	9.0
85.77	West of Duddon Sands	9.7	9.2	9.0
90	Ormonde (neighbouring)	9.8	9.3	9.0
106.7	Walney Extension 4	9.9	9.4	9.1
108	Burbo Bank Extension	9.9	9.4	9.2
112.3	Walney Extension 3	10.0	9.4	9.2
150	MoMoMo cluster and Awel y Môr	10.2	9.7	9.4
170	MoMoMo cluster ¹	10.4	9.8	9.5

¹⁻ Considered for sensitivity scenarios, see Table 5-2

4.2.2. Derivation of the long-term hub height wind speed and direction frequency distribution

As indicated in Section 4.1, the primary measurement devices are specified as Burbo Bank FL system for the southern and WOW Extension FL system for the

northern wind farms for the prediction of long-term wind speeds at the turbine locations, in order to take the possibility of the changes in the wind roses into account.

The measurement time series at the wind climate locations have been extrapolated to the turbine hub heights based on the estimated shear profile of the respective wind climate. The resulting hub height time series has been used to define the wind speed and direction frequency distributions.

The resulting time series has been used to derive the wind speed and direction frequency distribution at the wind climate locations using the following procedure to avoid the introduction of bias into the annual mean wind regime prediction from seasonally uneven data coverage:

- The mean wind speed and direction frequency distribution for each month
 was determined from the valid data recorded in that month over the period.
 The frequency distribution for each month considered to be representative
 of the long term for that month thereby assuming the valid data are
 representative of any missing data.
- The frequency distributions for each of the twelve months were averaged, weighted by the number of days in each month, to determine the long-term annual frequency distribution.

The resulting hub height wind rose and frequency distributions at the wind climate locations at 100 m height can be seen in Appendix D, where the wind rose shapes are considered as representative for the sites under consideration.

4.3. Wind regime across the site

4.3.1. Wind flow modelling

To assess the horizontal wind speed variation across the turbine locations at the sites, as explained in Section 3.2, WT has considered use of the Vortex MAP product, New European Wind Atlas and Global Wind Atlas, at 100 m height for reference.

Wind model validation

Given that wind climate files are available at three different locations across the wind farms, WT has undertaken a performance check utilizing all three-wind maps to understand the agreement. The results of this check are given in Table 4-4 below, including the percentage differences with the predicted long term hub height wind speeds in parentheses.

Table 4-4 Comparison of wind map wind speeds and long term wind speeds at 100 m height.

Wind Climate File	Wind speed derived on Vortex wind map [m/s]	Wind speed derived on GWA [m/s] ¹	Wind speed derived on NEWA [m/s] ¹	Predicted long term hub height wind speed [m/s] ¹
Burbo Bank FL SYSTEM	9.2 (1.5%)	9.5 (4.6%)	8.9 (-2.8%)	9.1
Shell Flats MM	9.6 (3.3%)	9.7 (3.6%)	9.1 (-2.4%)	9.3
WOW Extension FL SYSTEM	10.1 (2.0%)	9.9 (0.6%)	9.6 (-2.8%)	9.9

¹⁻ Values in the parentheses indicate the percentage difference between the wind speeds derived from the wind map and long-term hub height frequency distribution.

Whilst WT considers this exercise beneficial to inform the relative performance and agreement of wind maps and measurements, it is acknowledged that there are limitations and elevated uncertainty in performing this validation because of the nature of measurement devices as two are floating lidars and other one is a meteorological mast, in which the measurements may be affected by lattice structure of the mast at certain wind sectors, as well as the modelling inputs & methodology used in generation of the wind maps, which are summarized in Section 3.2.

Notwithstanding the uncertainties discussed above, it is considered that uncertainties in the wind regime across the site have a lower impact on the analysis conducted in Section 5 due to it being a delta on wake impact, which is not as sensitive to wind speed errors as a traditional energy yield analysis.

Whilst the measurements predict relatively similar wind speeds on all wind climate locations and they also indicate a similar variation in wind speed, WT considers the results of the validation to be inconclusive. Therefore, WT also conducted a cross-prediction check across the measurement devices and the results are given in Table 4-5, Table 4-6 and Table 4-7, which offers wind speed differences on the order of 0.5% between the predictions of NEWA and long-term hub height mean wind speed estimations.

Table 4-5 Wind speed cross-predictions at 100 m height for Vortex.

Predicted from wind climate file	Long term hub height mean wind	Predicted from Vortex MAPS at 100 m [m/s]				
	speed at 100 m [m/s]	Burbo Bank FL	Shell Flats MM	WOW Extension FL		
Burbo Bank FL	9.1		9.0 (-1.7%)	9.1 (-0.5%)		
Shell Flats MM	9.3	9.5 (1.7%)		9.5 (1.2%)		
WOW Extension FL	9.9	9.9 (0.5%)	9.7 (-1.2%)			

Table 4-6 Wind speed cross predictions at 100 m height for GWA.

Predicted from wind climate file	Long term hub height mean wind	Predicted from GWA at 100 m [m/s]				
	speed at 100 m [m/s]	WOW Extension FL	Shell Flats MM	Burbo Bank FL		
WOW Extension FL	9.1		9.2 (0.9%)	9.5 (4.0%)		
Shell Flats MM	9.3	9.3 (-0.9%)		9.6 (3.0%)		
Burbo Bank FL	9.9	9.5 (-3.8%)	9.6 (-2.9%)			

Table 4-7 Wind speed cross predictions at 100 m height for NEWA.

Predicted from wind climate file	Long term hub height mean wind	Predicted from NEWA at 100 m [m/s]				
	speed at 100 m [m/s]	WOW Extension FL	Shell Flats MM	Burbo Bank FL		
WOW Extension FL	9.1		9.1 (-0.4%)	9.1 (0.0%)		
Shell Flats MM	9.3	9.4 (0.4%)		9.4 (0.4%)		
Burbo Bank FL	9.9	9.9 (0.0%)	9.8 (-0.4%)			

Wind speed variation across the sites

As noted in Section 4.1, the WOW Extension FL and Burbo Bank FL have been chosen as the primary sources of data for the analysis and therefore have been used to initiate the wind flow model from which the wind speeds at the proposed turbine locations have been predicted.

The reasoning behind this selection was the slight change in the wind roses across those wind climate files so that WT found it more sensible to predict the northern wind farms from WOW Extension FL and southern wind farms from Burbo Bank FL. Also as given in Table 4-7 the cross-predictions between Burbo Bank and WOW Extension are also minimal. Also, as seen in Appendix D-4, the turbine location predictions of these two wind climates are very close to each other with a difference level of lower than 0.5%.

Due to its superior performance compared to Global Wind Atlas and Vortex as shown above, WT has decided to use the New European Wind Atlas map for the predictions of wind speeds at the turbine locations.

4.4. Turbulence Intensity

It is widely accepted in the wind industry that turbulence intensity measurements from Lidar devices (volume measurements) are not directly comparable to turbulence intensity measurements from meteorological masts using cup anemometers (point measurements), which is currently what the wind industry standards are based on.

In addition to the difference in turbulence intensity measurements from Lidars due to the volume to point measurement issue, floating Lidar systems have the added complication of motion impacting the measurements, which artificially increases the measured turbulence intensity.

Due to these reasons, and due to the fact that the standard deviation data is not included in the provided wind climate files, WT finds it appropriate to calculate the turbulence intensity from its own independent assessment of the publicly available Shell Flats Met Mast data.

WT has adjusted the turbulence profile measured at the Shell Flats MM to be representative of the expected long-term hub height wind speeds at the WOW Extension FL and Burbo Bank FL. As standard deviation is assumed constant, the turbulence intensity can be scaled from the Shell Flats MM location to the turbine locations using the ratio in long-term wind speed between the Shell Flats MM and the long-term wind speed of the site in question.

Figure 4-1 and Figure 4-2 show the assumed turbulence intensity profile at the WOW Extension FL and Burbo Bank FL respectively, derived at the turbine hub height of 112.3 m, which is considered as representative for the turbine locations at 112.3 m, along with profiles for IEC turbulence subclasses A, B and C [10].

Table 4-8 shows the tabulated ambient turbulence intensity profiles for the mentioned combinations of sites and hub heights. WT notes that the magnitude of derived turbulence intensity values is in line with WT's experience, considering the expected offshore wind conditions at sites around the UK, with similar hub height.

Figure 4-1 Ambient Turbulence Intensity profile assumed at the WOW Extension FL location at 112.3 m height, as derived from measurements made at the Shell Flats MM.

Figure 4-2 Ambient Turbulence Intensity profile assumed at the Burbo Bank FL location at 112.3 m height, as derived from measurements made at the Shell Flats MM.

Table 4-8 Ambient Turbulence Intensity profile assumed at Burbo Bank FL and WOW Extension FL at selected hub heights.

Wind speed bin centre (m/s)	Mean TI at WOW Extension FL at 75 mMSL hub height (%)	Mean TI at WOW Extension FL at 112.3 mMSL hub height (%)	Mean TI at WOW Extension FL at 150 mMSL hub height (%)	Mean TI at Burbo Bank FL at 75 mMSL hub height (%)	Mean TI at Burbo Bank FL at 112.3 mMSL hub height (%)	Mean TI at Burbo Bank FL at 150 mMSL hub height (%)

5. METHODOLOGY & RESULTS OF THE WAKE ASSESSMENT

The Energy Yield and the subsequent impact of the wakes produced by the individual wind farms have been calculated using WindFarmer: Analyst software. Of concern in any Energy Yield study is the effect of wake and turbine interaction losses (including blockage effect) from inside the farm and from adjacent farm sites. WT's typical best practice is to use the WindFarmer: Analyst Eddy Viscosity with large wind farm correction model to estimate offshore wake and turbine interaction effects, as validated by DNV in 2019, which results in lower errors across a number of operational offshore wind farms compared to other wake models [8], [9].

As noted in Appendix E-4.1a, the blockage effects have also been calculated using the Blockage Effect Estimator Tool (BEET) implemented within WindFarmer: Analyst software, which is based on a validation study incorporating more than 50 CFD simulations. The wind farm blockage is defined as the slowing-down effect caused by the wind farm itself, as it presents an obstacle to the incoming wind flow. This effect is usually not estimated in many standard industry wake models. According to WT's estimates, the wind farm blockage based on the BEET is found to be around 1.3% for all the scenarios considered and this figure is also inherent in the wake effect estimations given in Table 5-4 and Table 5-5.

No specific sensitivity assessment of the available range of wake models has been undertaken as the intention is to provide an "industry standard" independent assessment.

A series of scenarios have been established to assess the relative impact of the build out of the proposed wind farms in this part of the Irish Sea. Table 5-1 and Table 5-2 below summarises the scenarios applied in this assessment.

The Baseline scenario represents the current situation of the project area, such that all existing assets from Ørsted with the full ownership details provided by Client [2], plus other existing assets are assessed, as listed in Table 5-3.

The MoMoMo wind farms were added in the order in which it is currently understood they will be constructed, such that Mona is going to begin construction in 2026 (Scenario 1), Morgan in 2027 (Scenario 2) and Morecambe in 2027/8 (Scenario 3) [1]. The impact from the entire MoMoMo cluster is also considered (Scenario 4), whilst the commissioning of Awel y Môr, which is planned for construction at a later stage, is considered in Scenario 5.

For Scenarios 1, 2 and 3 it is assumed that a 15 MW turbine with 236 m rotor diameter at a hub height of 150 m will be used for MoMoMo. This size turbine is typically being planned for other wind farms due for installation in the period. Some uncertainty remains over the selection of this turbine, therefore in order to estimate the impact of installing bigger turbines at the MoMoMo sites e.g. 22.6 MW capacity, 276 m rotor

diameter and 170 m hub height, WT has considered Scenarios 1b, 2b and 3b as variations on the assessment.

No changes to the existing wind farms e.g. repowering/ extended maintenance or non-operational turbines were assumed.

The projected decrease in potential energy production due to additional wake and turbine interaction losses from each scenario on each of the Client assets are shown in Table 5-4 and Table 5-5.

The results of the turbine basis analysis are presented in Appendix D. A detailed definition of turbine interaction loss factors applied to all scenarios is included in Appendix E-4.

Table 5-1 External Wake Main Scenarios

Scenario	Included Wind Farms	Comments / Assumptions
Baseline	Ørsted assets ¹ + Neighbouring operational wind farms ^{2.}	Existing operational conditions

¹⁻ The ownership details of Client operational offshore wind farm assets (Barrow, Walney Phase 1 & 2, West of Duddon Sands, Walney Extension, Burbo Bank and Burbo Bank Extension) were provided by the Client [2]. For the neighboring assets, publically available datasets were used [1].

It should be noted that the scope of work presented in this report has been focused on the potential difference in annual energy production due to wake impacts of each future wind farm scenario. As this is not a complete EPA study, WT did not undertake a comprehensive technical loss assessment, which is typically required in order to estimate a realistic annual energy production for any wind farm, and as such Table 5-4 presents the results as a percentage difference normalised to the baseline.

It should be noted that along with the increased wakes with the commissioning of the future wind farms, the turbine performance losses (including generic and site-specific power curve adjustments and hysteresis losses) may undergo changes with the different waked wind regime expected on the Client's operational wind farms, along with the possibility of increased fatigue. Assessment of these effects is not in the scope of this report. Nevertheless, these effects are considered of second order with relation to the wake impacts on annual energy production.

Table 5-4 Summary of the results of the main scenarios normalized to the baseline

Scenario	Additional wake loss on each wind farm (%)								
	Barrow	Walney 1	Walney 2	Walney Extension 3	Walney Extension 4	West of Duddon Sands	Burbo Bank	Burbo Bank Extension	Total additional wake loss on all Ørsted Irish Sea assets
Baseline	0	0	0	0	0	0	0	0	0
Scenario 1 - Addition of Mona OWF	-1.55%	-1.67%	-1.22%	-0.83%	-1.58%	-1.57%	-0.96%	-1.22%	-1.38%

Scenario 3 – Addition of Morecambe OWF	-1.37%	-0.53%	-0.32%	-0.40%	-0.56%	-1.01%	-0.46%	-0.45%	-0.68%
Scenario 4 – Cumulative addition of MoMoMo	-3.13%	-3.64%	-3.64%	-4.22%	-5.16%	-3.86%	-1.63%	-1.83%	-3.63%
Scenario 5 – Cumulative addition of MoMoMo and Awel y Môr	-3.40%	-3.70%	-3.68%	-4.27%	-5.30%	-3.97%	-2.15%	-2.43%	-3.80%

Table 5-5 Summary of the difference of results of the sensitivity scenarios and each main scenario

Scenario	Difference	Difference with respect to the main scenarios, for each wind farm (%)							
	Barrow	Walney 1	Walney 2	Walney Extension 3	Walney Extension 4	West of Duddon Sands	Burbo Bank	Burbo Bank Extension	Total additional wake loss on all Ørsted Irish Sea assets
Scenario 1b - Addition of Mona OWF	0.06%	0.14%	0.08%	0.04%	0.12%	0.13%	-0.11%	0.04%	0.09%
Scenario 2b – Addition of Morgan OWF	0.03%	0.18%	0.13%	0.34%	0.29%	0.10%	-0.09%	-0.11%	0.13%
Scenario 3b – Addition of Morecambe OWF	0.16%	0.05%	0.04%	0.04%	0.04%	0.16%	0.03%	0.01%	0.08%

6. CONCLUSIONS

A differential energy yield assessment approach has been undertaken using the industry standard WindFarmer:Analyst software, to provide an independent evaluation of the possible external wake losses for the existing Ørsted Irish Sea Portfolio assets located in the Irish Sea.

The following conclusions are noted:

- Based on the approach detailed in this report, WT has conducted a series of wake model runs according to the selected scenarios given in Table 5-1 and compared the results with a baseline scenario whose details are provided in Table 5-3. Table 5-4 provides the additional wake effect results at all Ørsted assets for each of the future scenarios. It was assumed that there are no changes to the existing wind farms e.g. repowering/ extended maintenance or non-operational turbines.
- 2. Based on those results the additional wake loss in individual wind farms varies between **-0.16** % and **-5.30** % depending on the scenario and the Ørsted assets under consideration. Considering the total effect on all Ørsted assets, the effect varies between **-0.68** % (considering only if Morecambe OWF is consented) to **-3.80** % (considering if all future wind farms considered in this study are consented), depending on the scenario.
- 3. As such, if all of the proposed development takes place, the cumulative impact on the Ørsted Irish Sea Portfolio is just under -4%. Whilst this may only be following the total build out (with completion timelines post 2030), the impact on annual energy production (AEP) of individual future wind farms has been seen to be between -0.68 % and -1.64 % on the existing Ørsted Irish Sea Portfolio.
- 4. Morgan has the largest impact on the total additional wake loss of the Ørsted assets, particularly on the nearby Walney 2 and Walney Extension sites. Due to the south-westerly prevailing direction, it has less impact on the other sites in this northern cluster of Ørsted wind farms. Because of its more central location in the area, Mona has a large impact on all surrounding Ørsted assets, and Walney 1, Barrow, West of Duddon Sands, Burbo Bank and Burbo Bank Extension experience the highest added wake loss due to this site. Morecambe is the smallest of the sites and in a location that has less impact on Ørsted assets, with only West of Duddon Sands and Barrow experiencing additional losses of > 1 %. The inclusion of Awel y Môr sees a very small increase in additional wake loss, as it is situated a large distance from the majority of Ørsted assets. Its largest impact is on Burbo Bank and Burbo Bank Extension, which are located approximately 20 km to the east, which experience an additional ~0.5 % wake loss.

- 5. Considering the engineering wake model approaches used and distances between the Client assets and proposed neighbouring wind farms, WT considers the assessed additional wake loss numbers to be commensurate with WT's expectations. WT also finds the results comparable with a recent study conducted by DNV and RWE [7], where values of -3.0% to -3.6% additional wake losses arising from neighbouring wind farms with similar distances to the ones evaluated in this report, which are 5-30 km away from the projects under consideration. Subject to specific criteria on each wind farm site, including capacity factor, age of the wind farm, turbine type/size and the agreed electricity sale price, the financial and technical consequences of additional wake losses could be considerable. WT also notes that increased turbulence levels due to the added wake may increase the fatigue / structural loading and also may cause additional downtime for the turbines, where electricity production is halted.
- 6. WT has undertaken a sensitivity test based on the assumption of the potential for larger wind turbines to be installed for MoMoMo assets (instead of 15 MW 236 m rotor diameter turbines, WT assumed that 22.6 MW, 276 m rotor diameter turbines will be used). According to the results of this sensitivity test, WT found that the additional wake losses are reduced when using the larger turbine.
- 7. The wind farms in the vicinity of the Client assets are either operational or at an early stage of development. For the operational wind farms in the vicinity of Client assets, basic turbine and layout parameters are known to WT and summarized in Table 5-3, and as such modelling of these assets contains reduced uncertainty. For the wind farms at an early stage of development, there is currently limited information available about the turbine types, layouts and hub heights. For the prediction of current status of those future wind farms, including the development phase and possible turbine configurations, a range of publicly available datasets has been utilized including TGS Wind, 4C Offshore Wind Market Intelligence [1], and Development Consent Order documents for Mona [4], Morgan [5] and Morecambe [6]. As such, as some of the information compiled for the future projects is uncertain at this stage, the impacts will be subject to change this report should be considered as being based on the best available information at the time of preparation.
- 8. It should also be noted that WT has utilized industry standard WindFarmer: Analyst Eddy Viscosity wake model with large wind farm and blockage correction.

APPENDIX B: WIND TURBINE INFORMATION

Table B-1 Turbine data for the Siemens Gamesa SWT-3.6-107 at Burbo Bank

Manufacturer	Siemens Gamesa
Turbine	SWT-3.6-107
Power Control	Pitch
Rated power	3,600 kW
Diameter	107 m
Hub height	83.4 mMSL
Rotor speed	8.0 – 17.5 rpm (assumed)
Air Density	1.225 kg/m3
Turbulence intensity	Unknown
Peak C _p	*
Cut out ten-minute mean wind speed	25.0 m/s
Restart ten-minute mean wind speed	20.0 m/s (assumed)

^{*} It should be noted that the characteristics and performance data of the neighbouring operational wind farms are redacted for confidentiality reasons.

APPENDIX E: ANALYSIS METHODOLOGY

- E-1. Wind data analysis process overview
- E-2. Hub-height wind speed and direction distributions
- E-3. Wind flow modelling
- E-4. Gross energy output

E-1 Wind data analysis process overview

The analysis of the wind data involved several steps, which are summarised below:

- The processed and long-term corrected wind speed data from the wind climate locations are processed and evaluated for an estimation of longterm wind speeds extrapolated to hub height using power law wind shear exponent.
- 2. Long-term hub-height wind speed and direction frequency distribution estimates at each wind climate location are derived from the measured and synthesized data.
- **3.** The wind regime at the turbine locations is assessed using wind flow models and WT experience and judgment.

E-2 Hub-height wind speed and direction distributions

E-2.1 Shear power law

The boundary layer power law shear exponents at the measurement locations are derived from the available measurement heights. The power law relates the ratio of measured wind speeds, U_1/U_2 , to the ratio of the measurement heights, z_1/z_2 , using the wind shear exponent, α , as follows:

$$\frac{\overline{U}(z_1)}{\overline{U}(z_2)} = \left(\frac{z_1}{z_2}\right)^{\alpha} \qquad \text{where} \qquad \begin{array}{c} \alpha \text{ is power law wind shear exponent} \\ \overline{U} \text{ is the wind speed} \\ z \text{ is the height above mean sea level} \end{array}$$

The boundary-layer power law shear exponent was derived for each measurement location using the ratios of measured concurrent wind speed data recorded at multiple measurement heights.

E-2.2 Directional shear method

The relationship between two or more heights at a measurement location is established for each of twelve 30° direction sectors, using the technique described in Section E-4.1. These relationships are used to derive the boundary-layer power law shear exponent in each of the twelve direction sectors, which are then used to extrapolate data recorded at the primary measurement height to the target hub height, on a directional basis.

The annual average wind speed frequency and direction distributions at measurement height are determined from the site period wind speed data using the mean of monthly means approach described in Section E-4.4. The resulting distributions in each direction sector are then scaled to the predicted long-term hub height wind speed(s).

E-2.3 Time series method

The boundary-layer power law shear exponent is derived between two measurement heights for each 10 minutes, or hourly, time step. A time series of wind speed at the target hub height is calculated by extrapolating the upper measurement height using the instantaneous boundary-layer power law shear exponent. The Mean of Monthly Means procedure is used to avoid the introduction of bias into the annual wind regime prediction from seasonally uneven data coverage at each mast as discussed in Section E-4.4.

E-2.4 Annual shear method

The relationship between two, or more, heights at a measurement location is established using the concurrent mean of monthly means technique described in Section E-4.4. These relationships are used to derive the boundary-layer power law shear exponent, which is then used to extrapolate data recorded at the upper measurement height to the target hub height.

E-3 Wind flow modelling (offshore)

To calculate the variation of mean wind speed over the site, several techniques are considered:

- ▶ For offshore projects, any site-specific downscaled mesoscale map obtained for the site will be considered.
- ▶ In addition to the above, any publicly available wind maps (global, regional, national) covering the vicinity of the project is considered.

Unless coastal effects are anticipated, speed-up factors between the proposed turbine locations and wind climate locations are derived on an all-directional basis from the different techniques outlined above and compared. Depending on the results of the comparison, and the quality of the validation if multiple measurement locations are available, the most robust technique for predicting the wind speed variation across the site will be identified. This may be an ensemble approach consisting of results from multiple models.

To determine the long-term mean wind speed at any location, the speed-up factor for each location is applied to the long-term wind speed previously derived for the measurement location.

The following sub-sections describe each of the modelling approaches in further detail.

E-3.1 Global Wind Atlas

The Global Wind Atlas is a combined mesoscale and microscale wind flow model which has been run to produce results for the entire global land mass

and coastal areas with a focus on the needs of wind resource and energy assessment. Model outputs are available at elevations of 10, 50, 100, 150 and 200 m above ground/sea at a downscaled horizontal grid spacing of 250 m. Further details of the model can be found at

E-3.2 New European Wind Atlas

The New European Wind Atlas (NEWA) uses the Weather Research and Forecasting (WRF) model, forced with ERA5 reanalysis data, to generate a regional map of wind speed variation across Europe and Turkey, including offshore.

Data are available at seven heights between 50 m and 500 m. Both mesoscale and microscale modelling has been performed. The mesoscale data is based on a simulation period of 30 years and has a horizontal grid resolution of 3 km. Further details of the model can be found at

E-4 Gross energy output / assessment of wakes

The gross energy production is the energy production of the wind farm obtained by calculating the predicted free stream hub height wind speed distribution at each turbine location and the manufacturer-supplied turbine power curve.

In defining the gross energy output, it is assumed that there are no wake interactions between the turbines and no energy loss factors are applied. The Energy Yield and the subsequent impact of the wakes produced by the individual wind farms have been calculated using WindFarmer Analyst computational model. It includes adjustments to the power curve to account for differences between the predicted long-term annual turbine location air density and the air density to which the power curve is referenced.

Of concern in any Energy Yield study is the effect of wake and turbine interaction losses (including blockage effect) from inside the farm and from adjacent farm sites. WT's typical best practice is to use the WindFarmer: Analyst Eddy Viscosity with large wind farm correction model to estimate offshore wake and turbine interaction effects, as validated by DNV in 2019, which results in lower errors across a number of operational offshore wind farms compared to other wake models.

E-4.1 Turbine interaction effect calculations

Wind turbines extract energy from the wind and downstream from each turbine there is a momentum deficit with respect to free stream conditions, which is equal to the thrust force on the machine, referred to as the wake, where the wind speed is reduced. As the flow proceeds downstream there is

a spreading of the wake and the wake recovers towards free stream conditions. Turbulent momentum transfer is important in this process.

The wake effect loss is the aggregated influence on the energy production of the wind farm which results from the changes in wind speed caused by the impact of the turbines on each other. WT uses the WindFarmer: Analyst software – Eddy Viscosity model and implements the Large Wind Farm correction for offshore projects. This software has been developed by DNV and validated using measurements on both full-scale machines and on wind-tunnel models.

The model is employed in a scheme which, taking each wind speed and direction in turn calculates the power production of the wind farm. The important parameters used in this process are:

- array layout
- upstream mean wind speed
- ambient turbulence
- wind turbine thrust characteristic
- wind turbine power characteristic
- rotor speed
- speed-up factors from site wind flow calculations

Any wind speed variations across the site due to coastal or mesoscale effects are accounted for in the model using the speed-up factors calculated by an appropriate wind flow model as described above. The array model is used to calculate the wind speed in the turbine wakes, assuming the terrain is flat, and the wind speed is adjusted by the speed-up factor when the wake reaches a downstream turbine.

E-4.1a Internal wake and blockage effects

This is the effect that the wind turbines within the wind farm being considered have on each other. In addition, the wind farm itself presents an obstacle to the incoming wind flow, which is not accounted for in many standard industry wake models and causes a slow-down effect referred to as wind farm blockage. This effect has also been calculated using the Blockage Effect Estimator Tool (BEET) within WindFarmer:Analyst which is based on more than 50 CFD simulations.

E-4.1b Wake effect external

This is the effect that the wind turbines from neighbouring wind farms (if any) have on the wind farm being considered. These are calculated in the same way as internal wake effects.

E-4.1c Future wake effect

Where future wind farms are to be constructed in the vicinity of the project under consideration, the wake effect of these may be estimated and taken into account if sufficient information is available.
