## 1 Introduction

### 1.1 OVERVIEW

## Road Traffic Emissions Assessment

1.1.1 The traffic data for the Proposed Development demonstrated that during the construction phase, annual average daily traffic (AADT) flows would increase by more than 100 Heavy Goods Vehicles (HGVs) on several road links within the study area, for a period of multiple years during construction. This exceeds the criteria described in current guidance (Ref 14.15) that suggests a detailed assessment of road traffic emissions impacts is required. The links where the criteria would be exceeded are summarised in Table of 14.7 of the Environmental Statement (ES).
1.1.2 The quantification of air quality impacts has been undertaken using the current version of the dispersion modelling software ADMS Roads (v4.1.1.0). ADMS Roads is dispersion modelling software that is commonly used to quantify road traffic emissions contributions to total pollutant concentrations for projects across the UK and overseas.
1.1.3 The scenarios considered within the dispersion modelling exercise for road traffic emissions are:

- Existing baseline situation (representative of 2016) (modelled with 2016 background data, 2016 traffic emission factors and 2016 traffic flows) for use in dispersion model verification against monitoring data that is representative of 2016;
- Peak construction year baseline (representative of 2023) (modelled with 2016 background data, 2016 traffic emission factors and 2023 traffic flows, without the Proposed Development);
- Peak construction year 'with construction' scenario (assuming Tunnel Boring Machine (TBM) tunnelling between Braint and Tŷ Fodol) (representative of 2023) (modelled with 2016 background data, 2016 traffic emission factors and 2023 traffic flows with the Proposed Development during construction).
- Peak construction year 'with construction' scenario (assuming drill and blast tunnelling between Braint and Tŷ Fodol) (representative of

2023) (modelled with 2016 background data, 2016 traffic emission factors and 2023 traffic flows with the Proposed Development during construction).

- Cumulative peak construction year baseline (representative of 2023) (modelled with 2016 background data, 2016 traffic emission factors and 2023 traffic flows, without the Proposed Development, but with major committed development traffic flows);
- Cumulative peak construction year 'with construction' scenario (assuming TBM tunnelling between Braint to Tŷ Fodol) (representative of 2023) (modelled with 2016 background data, 2016 traffic emission factors and 2023 traffic flows with the Proposed Development during construction, and with major committed development traffic flows); and
- Cumulative peak construction year 'with construction' scenario (assuming drill and blast tunnelling between Braint and Tŷ Fodol) (representative of 2023) (modelled with 2016 background data, 2016 traffic emission factors and 2023 traffic flows with the Proposed Development during construction, and with major committed development traffic flows).

## Emergency Generator Emissions Assessment

1.1.4 The Proposed Development would require 12 MVA (or 9.6 MW) in power generation to facilitate the sinking of shafts and the construction of the tunnel beneath the Menai Strait. The primary power source for these works would be an extension to the existing Scottish Power Manweb (SPM). The secondary power source, required only in the event of any failure to the primary power source, would be available from a series of diesel-fired generators.
1.1.5 Emissions from the emergency diesel-fired generator sources have the potential to impact on local air quality and have been modelled using the current version of the dispersion model ADMS 5.2 (v5.2.2). ADMS 5.2 is dispersion modelling software that is commonly used to quantify industrial emissions contributions to total pollutant concentrations for projects across the UK and overseas.
1.1.6 The scenarios considered within the dispersion modelling exercise for emergency generator emissions are:

- Peak construction year 'with construction' scenario (TBM from Braint to Tŷ Fodol) six diesel-fired emergency generators (totalling 9

MVA (7.2 MW)) at the drive shaft at Braint and two diesel-fired emergency generators (totalling 3 MVA (2.4 MW)) at the reception shaft at Ty Fodol; and

- Peak construction year 'with construction' scenario (TBM from Tŷ Fodol to Braint) six diesel-fired emergency generators (totalling 9 MVA (7.2 MW)) at the drive shaft at Tŷ Fodol and two diesel-fired emergency generators (totalling 3 MVA (2.4 MW)) at the reception shaft at Braint.
- Peak construction year 'with construction' scenario (drill and blast between Braint and Tŷ Fodol) assuming up to six diesel-fired emergency generators (totalling 9 MVA (7.2 MW)) at the shaft sites at Braint and Tŷ Fodol.

## 2 Air Quality Sensitive Receptors

1.2.1 The dispersion modelling assessment has predicted the contribution of road traffic emissions and emergency generator emissions to total pollutant concentrations at a number of selected air quality sensitive receptors. These receptors include human health and ecologically sensitive locations that are close to roads used by Proposed Development construction traffic and close to the emergency generators.
1.2.2 The selected receptors are considered representative of other nearby sensitive receptors that have not been explicitly modelled, but can be expected to experience a similar level of impact to those reported.

## Human Health Sensitive Receptors

1.2.3 The human health sensitive receptors are listed in Table 14.3.1 and the locations shown on Figure 14.4. The pollutant impacts predicted at the human health sensitive receptors located in close proximity to the Braint and Tŷ Fodol Construction Compounds, are from the combined emissions of additional construction phase vehicle movements and emergency generator emissions. Elsewhere within the study area, annual mean impacts predicted are as a result of additional construction phase vehicle movements only, where they have the potential to have a significant effect. Impacts to hourly mean $\mathrm{NO}_{2}$ and daily mean $\mathrm{PM}_{10}$ concentrations are predicted for emergency generators alone, in line with IAQM guidance, at receptors located closest to the Braint and Tŷ Fodol Construction Compounds.

Table 14.3.1: Human Health Sensitive Receptors

## Ecologically Sensitive Receptors

1.2.4 The ecologically sensitive receptors considered are listed in Table 14.3.2 and the locations shown on Figure 14.4. Long-term concentrations of oxides of nitrogen $\left(\mathrm{NO}_{x}\right)$, sulphur dioxide $\left(\mathrm{SO}_{2}\right)$, and deposition rates for nutrient nitrogen, acid as nitrogen and acid as sulphur, are reported for ecological receptors located within 10 km of the Braint and Ty Fodol Construction Compounds, and include the combined contribution of emissions from construction phase vehicle movements and emergency generators. Long-term pollutant concentrations at ecological receptors located beyond 10 km from the Braint and Tŷ Fodol Construction Compounds include the Proposed Development emissions associated with construction-related vehicle movements only. Impacts to daily mean $\mathrm{NO}_{x}$ concentrations are predicted for emergency generator emissions alone at receptors located within 10 km of the Braint and Ty Fodol Construction Compounds.

## 3 Meteorological Conditions

1.3.1 The dispersion modelling of both road traffic emissions and emergency generator emissions requires the input of hourly sequential meteorological data measured at a site that is representative of the study area. This is usually achieved by selecting a meteorological station as close to the site as possible, although other stations may be used if the local terrain and conditions vary considerably or if the closest station does not provide sufficient data.
1.3.2 One year of hourly sequential observation data (2016) from Mona Meteorological Station, on Anglesey, has been used to quantify road traffic emissions impacts. 2016 data has been used to match the year of traffic data used to inform the assessment, as well as the year of projected baseline $\mathrm{NO}_{2}$ measurement data. The meteorological station is located in Bodffordd in central Anglesey, and conditions there are considered to be representative of those experienced in the wider air quality study area.
1.3.3 The dispersion of emissions from a point source (i.e. generator stack/exhaust) is largely dependent on atmospheric stability and turbulent mixing in the atmosphere, which in turn are dependent on wind speed and direction, ambient temperature, cloud cover and the friction created by buildings and local terrain. Therefore, a further four years of hourly sequential observation data (2012-2015, as well as 2016) from Mona Meteorological Station have been used to quantify potential emergency generator impacts at the Braint and Ty Fodol Construction Compounds. The worst year of impact predicted at each receptor is then reported. A meteorological data sensitivity test is tabulated in Sub-Appendix 14.3.A.
1.3.4 Wind rose plots for the meteorological data used in the assessment are presented in Figure 14.3.1 below.
1.3.5 The plots show that each year of meteorological data considered is fairly consistent, with a large predominance of winds blowing from the southwest, which is typical of conditions across much of the UK. However, winds could blow from all directions over the course of a year.

Figure 14.3.1: Mona Wind Direction and Wind Speed Plot (2012-2016)

## 4 Road Traffic Emissions Modelling

1.4.1 The model conditions that are specific to the quantification of road traffic emissions impacts that have been used for this assessment are summarised in Table 14.3.3. Further model inputs are then described in more detail in the following paragraphs.

| Table 14.3.3: ADMS Roads - General Model Conditions |  |
| :--- | :--- |
| Variables | ADMS Roads Model Input |
| Surface roughness at source | 0.5 m |
| Minimum Monin-Obukhov <br> length for stable conditions | 10 m |
| Terrain types | Flat |
| Receptor locations | X, Y coordinates determined by GIS, Z = 1.5 m |
| Traffic data | Annual Average Daily Traffic (AADT) flow data <br> including total flow, \%HGV and average speed for <br> modelled scenarios |
| Emissions | NOx, PM 10, PM 2.5 |
| Emission factors | EFT Version 8.0.1 emission factor dataset (projected <br> rates for 2016 (base EFT year) and 2016 (base <br> project year) considered) |
| Background pollutant <br> concentrations | Defra background maps (projected concentrations <br> for 2016) |
| Meteorological data | 1 year (2016) hourly sequential data from Mona <br> Meteorological Station |
| Emission profiles | No - robustly assumes an even distribution of <br> emissions over 24 hours |
| Receptors | Selected human sensitive and ecologically receptors <br> (See Table 14.3.1 and Table 14.3.2) |
| Model output | Long-term annual mean NOx concentrations <br> Long-term annual mean PM <br> Long-term annual mean PM 2.5 <br> Loncentrations |

### 1.5 TRAFFIC DATA

1.5.1 The dispersion model ADMS Roads calculates the contribution of pollutants emitted from vehicles using the following parameters:

- $\quad$ Traffic volume: The number of vehicles travelling a length of road in a given time will affect the subsequent emissions and dispersion of pollutants;
- Fleet composition: The proportion of Heavy Goods Vehicles (HGVs) (including buses) to Light Goods Vehicles (LGVs) will affect the mass emissions of pollutants; and
- Fleet velocity: The speed of the fleet affects the mass emissions of pollutants.
1.5.2 Traffic data was provided for the air quality assessment and is summarised in Sub-Appendix 14.3.A. The data was screened to identify road links that are predicted to experience an increase in traffic flow that has the potential to have a significant effect on local air quality, in line with current guidance (Ref 14.15).
1.5.3 The baseline AADT flow data is based on 24 -hour traffic count data gathered over several weeks at locations across Anglesey and Gwynedd (see Chapter 13 Traffic and Transport (Document 5.13)). The future baseline traffic data incudes the year on year growth anticipated for Anglesey and Gwynedd, through the application of TEMPRO factors. The construction phase traffic data also includes Proposed Developmentrelated vehicle movements. The cumulative scenario traffic data includes flows associated with major proposed and committed developments in the area, including the Proposed Wylfa Newydd Project.

### 1.6 VEHICLE EMISSIONS

1.6.1 Emission factors have been sourced from the Emissions Factors Toolkit (EFT) Version 8.0.1 (Ref 14.21). The baseline scenario was modelled using emission rates projected for 2016, to match the baseline traffic data, the year of projected annual mean measurement data and the year of hourly sequential meteorological data.
1.6.2 The EFT includes emission rates projected for future years, which show a decrease in vehicle emissions based on assumptions on improvements in emissions technology and the evolution of the UK vehicle fleet. However, there is some uncertainty in the rate at which emissions rates are improving. It has therefore been assumed in this assessment that the 2016 emission factors used to represent the baseline (2016) conditions would be representative of the future year (2023) scenarios. This is considered a robust assumption for 2023, as some improvement in emissions technology and evolution of the vehicle fleet is likely to occur between now and 2023.

### 1.7 BACKGROUND POLLUTANT CONCENTRATIONS

1.7.1 The background pollutant concentration data used in the assessment to represent background conditions at human sensitive receptors has been sourced from Defra's background pollutant concentration maps (Ref 14.20). Background data was obtained for the 1 km by 1 km grid squares within which the selected air quality sensitive receptors are located, for the year 2016, the baseline year of this assessment.
1.7.2 The background pollutant concentration maps include background concentrations for future years, which show a gradual decrease in concentrations. However, there is some uncertainty in the rate at which background pollutant concentrations are improving. Therefore, it has been assumed in this assessment that the 2016 background pollutant concentrations used to represent the baseline (2016) conditions would be representative of the future year (2023) scenarios. This is considered a robust assumption for 2023, as some improvement in background pollutant concentrations could potentially occur between now and 2023. The background data used in the assessment of road traffic emissions at human sensitive receptors are presented in Table 14.3.4.

Table 14.3.4: Background Pollutant Concentration Data - Human Health Sensitive Receptors

1.7.3 The background pollutant concentration and deposition data used in the assessment to represent background conditions at ecologically sensitive receptors has been sourced from the Air Pollution Information System (APIS) background pollutant concentration maps (Ref 14.32). Background data was obtained for the 5 km by 5 km grid squares within which the selected air quality sensitive receptors are located, for the year 2016, the base year of the current APIS background maps. The 2016 data was used to represent conditions in 2016 and 2023, in light of uncertainty in the projected improvements in background pollutant concentrations of coming years. Again, this is considered to be a robust approach. The background data used in the assessment of emissions impacts at ecologically sensitive receptors are presented in Table 14.3.5.

## $1.8 \quad \mathrm{NO}_{\mathrm{x}}$ TO NO 2 CONVERSION

1.8.1 For road traffic emissions calculations, a ' $\mathrm{NO} \mathrm{x}_{\mathrm{x}}$ to $\mathrm{NO}_{2}$ ' conversion spreadsheet has been made available by the Defra as a tool to calculate the road $\mathrm{NO}_{2}$ contribution from modelled road $\mathrm{NO}_{x}$ contributions (Ref 14.34). The tool comes in the form of a Microsoft Excel spreadsheet and uses local authority specific data to calculate annual mean concentrations of $\mathrm{NO}_{2}$ from dispersion model output values of annual mean concentrations of $\mathrm{NO}_{x}$ and background $\mathrm{NO}_{2}$ concentrations.

### 1.9 MODEL VERIFICATION

## Introduction

1.9.1 To account for model bias, Defra guidance (Ref 14.18) suggests model verification should be undertaken, whereby modelled predictions are made at set locations where there is measurement data available. The variation between modelled predictions and monitored concentrations at these locations is then analysed and the resultant factor(s) applied to modelled output at other representative locations, to account for model bias.

## Measurement Data

1.9.2 The measurement data used for model verification has been obtained from a Project-specific baseline diffusion tube survey. The survey was set up in March 2017, before the Proposed Development Construction Traffic Routes were confirmed. However, diffusion tubes were located adjacent to roads that were assumed likely to experience construction phase traffic movements. The analysis certificates provided by the laboratory are shown in Sub-Appendix 14.3.C.

## Annualisation

1.9.3 The baseline data currently available from the Project-specific survey accounts for a period of 8-12 months depending on the measurement location. Periods of less than 12 months were due to diffusion tubes being lost on some months. This period mean data has been 'annualised' to a projected calendar annual mean for 2016, following the method described in Defra guidance (Ref 14.18).
1.9.4 This process requires obtaining data from continuous monitoring stations for the same 12-month period in which the diffusion tube measurements were gathered, as well as for the full calendar year that the measured values are to be projected to, and comparing the difference between the two datasets. The guidance states that the monitoring data should be
gathered from continuous monitoring stations located within 50 miles of the survey area. In this instance, there are no continuous monitoring stations within 50 miles of the survey area. Instead, an analysis of the $\mathrm{NO}_{2}$ data available on the Welsh Air Quality website (Ref 14.28) for all continuous monitoring stations in Wales, where sufficient data ( $>85 \%$ ) are available for the survey period and the 2016 calendar year, was undertaken. This process is summarised in Table 14.3.6. Due to the data gaps as a result of missing tubes in some months, multiple factors are calculated based on the periods of survey data gathered at each diffusion tube measurement location.

1.9.5 The analysis showed that the period mean concentration data gathered at the continuous monitoring stations in Wales were lower than the 2016 annual mean concentrations at the vast majority of locations for all periods considered. The average factors for each period were used to project the measured survey diffusion tube data into an annual mean concentration value to represent 2016.
1.9.6 Once projected to calendar year 2016 values, the survey diffusion tube measurement data was adjusted for diffusion tube bias. In the absence of a continuous $\mathrm{NO}_{x}$ monitoring station in the study area to allow a Projectspecific co-location study, this was done using a diffusion tube bias adjustment factor made available by Defra (Ref 14.35). The adjustment factor was calculated based on co-location studies (comparing triplicate diffusion tube measurements gathered at the exact location of continuous $\mathrm{NO}_{\mathrm{X}}$ monitoring stations) undertaken by a number of local authorities across the UK in 2017 (the year in which the bulk of the survey diffusion tubes were analysed), using the same provider and analyser of diffusion tubes and the same preparation and analysis methods as used for the Project-specific survey. The calculation of the diffusion tube bias adjustment factor is summarised in Table 14.3.7.

1.9.7 A summary of the annualisation (and diffusion tube bias adjustment) of the Project-specific survey data is provided in Table 14.3.8. The table demonstrates that at the majority of roadside locations, projected annual mean concentrations of $\mathrm{NO}_{2}$ are well below the air quality objective values. However, the survey has also identified roadside locations where concentrations are in excess of the objective value. This is predicted to occur at locations adjacent to the A55 on Anglesey (A15) and in Gwynedd (G1), adjacent to parking laybys, at a location adjacent to the A5025 near Menai Bridge (A19), and at a location adjacent to the A487 on the approach to Bangor (G7).

| G8 | 07/03/17 to 02/08/17, 30/08/17 to 27/09/17 \& 02/11/17 to 05/03/18 | 26.5 | 29.9 | 26.6 |
| G9 | 07/03/17 to 05/03/18 | 12.6 | 14.6 | 13.0 |
| G10 | 07/03/17 to 05/03/18 | 27.5 | 32.0 | 28.5 |

* It should be noted that measurements were taken at roadside locations and these concentrations are not necessarily representative of relevant human exposure. A15 and G1 are however considered by IACC and GC respectively to be at sensitive locations with regard to the hourly $\mathrm{NO}_{2}$ objective.

## Verification

1.9.8 Annual mean $\mathrm{NO}_{2}$ concentrations were predicted using the dispersion model at the same locations where the survey measurements were gathered, assuming 2016 vehicle emission rates and background pollutant concentrations, with 2016 meteorological data. The locations used were limited to the diffusion tubes that were sited adjacent to roads that would experience an increase in traffic flow as a result of the Proposed Development construction phase (i.e. roads for which Project traffic data was available). The measurements gathered at locations adjacent to some sections of the A55 were not included in the verification exercise (A15 and G1), because the measurements were influenced by HGVs idling and
accelerating at low speeds at layby locations, the emissions of which were not accounted for in the model. Furthermore, the measurement locations at the laybys are not representative of the relevant long-term exposure considered by the dispersion modelling. Diffusion tube A19 was also omitted from the verification exercise. Measurements at this location were consistently elevated for no identifiable reason and the model struggled to perform at this specific location. The A5025 adjacent to which diffusion tube A19 is located is not intended to be a main construction route.
1.9.9 Figure 14.3 .2 shows that, the model under-predicted annual mean $\mathrm{NO}_{2}$ concentrations by an average of $68 \%$ across the study area. Therefore, further analysis was undertaken to account for this model bias.

Figure 14.3.2 Comparison of Modelled and Measured $\mathrm{NO}_{2}$ Concentrations

1.9.10 The next step requires the comparison of modelled and measured road $\mathrm{NO}_{x}$ contributions. Modelled road $\mathrm{NO}_{x}$ was taken directly from the dispersion model output and measured road $\mathrm{NO}_{x}$ was obtained by inputting the projected annual mean survey data into Defra's $\mathrm{NO}_{x}$ to $\mathrm{NO}_{2}$ conversion tool (Ref 14.34).
1.9.11 $\mathrm{NO}_{\mathrm{x}}$ factors were calculated for the model as a whole, and for the model split into geographic areas. The model-wide road $\mathrm{NO}_{\mathrm{x}}$ factor was 2.4714 . The calculated factors are provided in Table 14.3.9.

| Table 14.3.9: Calculating Road NOx Contribution Factors |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- |
|  | Road NOx Contribution $\left(\mu \mathrm{g} / \mathrm{m}^{3}\right)$ | Modelled Area |  |  |

| Road NO $^{2}$ Contribution Factors |  |  |  |  |
|  |  |  | Model-wide | 2.613 |
|  |  |  | Anglesey (A55/A5) | 2.325 |

Table 14.3.9: Calculating Road NOx Contribution Factors

| Tube ID | Road NOx Contribution $\left(\mu \mathrm{g} / \mathrm{m}^{3}\right)$ |  | Modelled Area |  |
| :--- | :--- | :--- | :--- | :--- |
|  | Modelled | Measured |  |  |
|  | Anglesey (elsewhere) |  |  | 2.410 |
|  | Gwynedd (A55/A487) | 2.898 |  |  |
|  | Gwynedd (elsewhere) | 2.276 |  |  |

1.9.12 The factors calculated and summarised in Table 14.3.9 were applied to the modelled road $\mathrm{NO}_{x}$ contributions for the relevant collection of modelled diffusion tube locations. The adjusted modelled road $\mathrm{NO}_{x}$ was then converted to adjusted modelled total $\mathrm{NO}_{2}$ concentrations using Defra's $\mathrm{NO}_{\mathrm{x}}$ to $\mathrm{NO}_{2}$ conversion tool (Ref 14.34). A comparison was then made of adjusted modelled total $\mathrm{NO}_{2}$ and measured total $\mathrm{NO}_{2}$ concentrations, which is shown in Figure 14.3.2. This comparison identified that the model performed marginally better after the use of the geographical road $\mathrm{NO}_{\mathrm{x}}$ factors, rather than the model-wide factor. The figure shows that the adjusted model performs well, with predicted annual mean $\mathrm{NO}_{2}$ concentrations now around $1 \%$ of measured values.
1.9.13 Further analysis of the adjusted model was undertaken by calculating the Root Mean Square Error (RMSE), Correlation Coefficient (CC) and Fractional Bias (FB) between the adjusted modelled and measured datasets. The results of this analysis are summarised in Table 14.3.10 and demonstrate that the adjusted model performs well with CC, RMSE and FB values within the ideal margins desired.

Table 14.3.10: Statistical Analysis of Adjusted Model

| Statistical <br> Parameter | Formula | Purpose | Ideal Value | Adjusted <br> Model <br> Value |
| :--- | :--- | :--- | :--- | :--- |
| CC | $r=\left[\frac{\sum_{\frac{N}{N}(\text { Obs,-Avg.Obs })(\text { Pred }- \text {-Avg.Pred })}^{\text {Stdev.Obs } \times \text { Stdev.Pred }}}{}\right]$ | Quality of <br> relationship <br> between <br> model and <br> measurements | $1.00=$ <br> Perfect <br> relation- <br> ship | 0.97 |

Table 14.3.10: Statistical Analysis of Adjusted Model

| Statistical <br> Parameter | Formula | Purpose | Ideal Value | Adjusted <br> Model <br> Value |
| :--- | :--- | :--- | :--- | :--- |
|  |  | measurements | $10 \%$ of the <br> AQO <br> $(4.00)$ is <br> considered <br> the ideal |  |
| FB | $F B=\frac{(\text { Avg.Obs }- \text { Avg.Pred })}{0.5(\text { Avg.Obs }+ \text { Avg.Pred })}$ | Level of <br> systematic <br> model under or <br> over prediction <br> against <br> measurements | $0=$ no <br> systematic <br> under or <br> over <br> prediction | 0.03 |

1.9.14 The model bias adjustment factors calculated were applied to modelled road $\mathrm{NO}_{x}$ contributions of each receptor considered in the assessment. The bias adjustment factor applied was dependent on the location of each receptor and which set of tubes were most representative of them.
1.9.15 In the absence of measured $\mathrm{PM}_{10}$ and $\mathrm{PM}_{2.5}$ at roadside locations in the study area, the same factors calculated for the modelled road $\mathrm{NO}_{\mathrm{x}}$ contribution were applied to the road $\mathrm{PM}_{10}$ and road $\mathrm{PM}_{2.5}$ contributions.

### 1.10 PREDICTING THE NUMBER OF DAYS IN WHICH THE DAILY MEAN $\mathrm{PM}_{10}$ OBJECTIVE IS EXCEEDED

1.10.1 In order to assess model results against the Air Quality Strategy daily mean objective for $\mathrm{PM}_{10}$, the guidance document LAQM.TG(03) (Ref 14.36) sets out the method by which the number of days in which the $\mathrm{PM}_{10}$ 24-hr objective is exceeded can be obtained based on a relationship with the predicted $\mathrm{PM}_{10}$ annual mean concentration.
1.10.2 The most recent Defra guidance suggests no change to this method. As such, the formula used within this assessment is below, where C denotes the annual mean concentration of $\mathrm{PM}_{10}$ :

No. of Exceedance $s=0.0014 * C^{3}+\frac{206}{C}-18.5$

### 1.11 PREDICTING THE NUMBER OF HOURS IN WHICH THE HOURLY MEAN NO ${ }_{2}$ OBJECTIVE IS EXCEEDED

1.11.1 The assessment evaluates the likelihood of exceeding the hourly mean $\mathrm{NO}_{2}$ objective by comparing predicted annual mean $\mathrm{NO}_{2}$ concentrations at all receptors to an annual mean equivalent threshold of $60 \mu \mathrm{~g} / \mathrm{m}^{3} \mathrm{NO}_{2}$. The threshold of $60 \mu \mathrm{~g} / \mathrm{m}^{3}$ is derived from research projects which identified that the hourly mean $\mathrm{NO}_{2}$ objective is unlikely to be exceeded if annual mean concentrations are predicted to be less the $60 \mu \mathrm{~g} / \mathrm{m}^{3}$ (Ref 14.40 \& Ref 14.41).
1.11.2 Where predicted concentrations are below this value, it can be concluded that the hourly mean $\mathrm{NO}_{2}$ objective $\left(200 \mu \mathrm{~g} / \mathrm{m}^{3} \mathrm{NO}_{2}\right.$ not more than 18 times per year) would most likely be achieved, particularly at locations that experience low background $\mathrm{NO}_{2}$ levels.

## 5 Emergency Generator Emissions Modelling

1.12.1 The general model conditions used for this assessment are summarised in Table 14.3.11. Further model inputs are then described in more detail in the following paragraphs.

| Variables | ADMS Roads Model Input |
| :---: | :---: |
| Surface roughness at source | 0.5 m |
| Minimum Monin-Obukhov length for stable conditions | 10 m |
| Terrain types | Flat |
| Receptor locations | $\mathrm{X}, \mathrm{Y}$ coordinates determined by GIS, $\mathrm{Z}=1.5 \mathrm{~m}$ |
| Sources | $n$ diesel-fired generators |
| Source location | X, Y, Z |
| Emissions | $\mathrm{NO}_{\mathrm{x}}, \mathrm{PM}_{10}, \mathrm{PM}_{2.5}, \mathrm{SO}_{2}, \mathrm{CO}$ |
| Emission Data | Based on supplier data |
| Meteorological data | 5 years (2012-2016) hourly sequential data from Mona Meteorological Station |
| Emission profiles | 100\% load 24 hours per day |
| Receptors | Selected human sensitive and ecologically receptors |
| Model output | Long-term annual mean $\mathrm{NO}_{\times}$concentrations |
|  | Short-term 24-hour mean $\mathrm{NO}_{x}$ concentrations |
|  | Short-term 1-hour mean $\mathrm{NO}_{x}$ concentrations |
|  | Long-term annual mean $\mathrm{PM}_{10}$ concentrations |
|  | Short-term 24-hour mean $\mathrm{PM}_{10}$ concentrations |
|  | Long-term annual mean $\mathrm{PM}_{2.5}$ concentrations |
|  | Long-term annual mean $\mathrm{SO}_{2}$ concentrations |

### 1.13 EMISSION PARAMETERS

1.13.1 The dispersion model ADMS 5 calculates the contribution of pollutants emitted from the emergency generator sources using the parameters summarised in Table 14.3.12. The values modelled for each parameter have been obtained from the data sheet for a Caterpillar 3516C diesel
generator (see Sub-Appendix 14.3.D). Whilst the actual generator to be used to generate power for the shaft and tunnel construction in the event of a failure to the primary power source is not confirmed at this stage, the amount of energy demand required is known. The Caterpillar 3516C generator is considered to be representative of the size of generator required to facilitate the shaft and tunnel construction.
1.13.2 For the assessment of emergency generator emissions, the assessment considers two TBM scenarios, one that assumes that the drive shaft would be sunk at Braint and the reception shaft would be sunk at Tŷ Fodol, and another that assumes the drive shaft would be sunk at Tŷ Fodol and the reception shaft sunk at Braint, and a drill and blast scenario.
1.13.3 For both TBM scenarios and the drill and blast scenario, the tunnelling works would require an energy demand of 12 MVA. For TBM, the sinking of the drive shaft and construction of the tunnel would require an energy demand of 9 MVA , and the sinking of the reception shaft would require a demand of 3 MVA . This equates to 7.2 MW and 2.4 MW respectively. In the event of an emergency, this power demand can be met by six Caterpillar 3516C generators at the drive shaft tunnel head house site, operating continuously at $70 \%$ load, and two Caterpillar 3516C generators operating continuously at $80 \%$ load at the reception shaft tunnel head house site.

Table 14.3.12: Emergency Generator Emissions Parameters

| Parameter | Drive Shaft |  | Reception Shaft |  |

| $\mathrm{SO}_{2}$ Emission Rate ( $\mathrm{g} / \mathrm{s}$ ) | 0.00000012 |  |  |  |

### 1.14 MODELLED SCENARIOS

1.14.1 The quantification of emergency generator emissions to annual mean pollutant concentrations has assumed that all eight generators could be operational for up to 500 hours per year ( $5.7 \%$ of the year). This is made up of 52 hours of testing and 448 hours of emergency operation per generator, per year. The assumed 448 hours of emergency operation is considered to be a robust estimate of the number of hours in which the primary power source could be out of operation.
1.14.2 The modelled contribution of emergency generator emissions to annual mean concentrations has been added to the contribution of construction vehicle emissions to estimate combined impacts at receptors located near to Construction Traffic Routes and the Braint and Tŷ Fodol Construction Compounds.
1.14.3 The quantification of emergency generator emissions to short-term pollutant concentrations (including daily mean $\mathrm{PM}_{10}$ and $\mathrm{NO}_{\mathrm{X}}$, and hourly
mean $\mathrm{NO}_{2}$ ) has assumed that generator testing and/or emergency operation could occur over any hourly or daily period in a year. This is considered to represent a robust estimate of short-term impacts, in that it assumes the operation of the emergency generators would coincide with the worst meteorological conditions at each sensitive receptor considered (i.e. the worst 24 -hour period of meteorological conditions at each ecological site considered for daily mean $\mathrm{NO}_{\mathrm{x}}$, the 35 worst 24 -hour periods of meteorological conditions for daily mean $\mathrm{PM}_{10}$ and the 18 worst meteorological hours for hourly mean $\mathrm{NO}_{2}$ ). In reality, each emergency generator would be operational for just 52 hours per year for testing, and a limited number of hours when the primary power source is down. Assuming 500 hours of operation in total, this would account for $5.7 \%$ of the year, so it is unlikely that it would coincide with the worst-case meteorological conditions set out above. It is also considered unlikely that the emergency generators would be in operation for a consecutive period of more than 24 hours.

### 1.15 BACKGROUND POLLUTANT CONCENTRATIONS

1.15.1 The background pollutant concentration data for annual mean concentrations of $\mathrm{NO}_{2}$ and $\mathrm{PM}_{10}$ at receptors considered for emergency generator emissions are listed in Table 14.3.13. Background pollutant concentrations for annual mean $\mathrm{NO}_{x}$ and annual mean nutrient nitrogen deposition and acid as nitrogen deposition rates are listed in Table 14.3.14.
1.15.2 The background pollutant concentration data for hourly mean $\mathrm{NO}_{2}$ concentrations and daily mean $\mathrm{PM}_{10}$ concentrations for the 1 km by 1 km grid square within which the human health sensitive receptors are located is provided in Table 14.3.4. The background pollutant concentration data for daily mean $\mathrm{NO}_{x}$ concentrations is provided in Table 14.3.5. In line with guidance and advice from the Environment Agency (EA) (which is applicable in Wales), the hourly mean $\mathrm{NO}_{2}$ background concentration is derived by doubling the annual mean background concentration. The daily mean $\mathrm{PM}_{10}$ and $\mathrm{NO}_{x}$ background concentrations are derived by multiplying the annual mean background concentration by 1.5.

### 1.16 $\mathrm{NO}_{\mathrm{x}}$ TO NO 2 CONVERSION

1.16.1 The contribution to annual mean concentrations of $\mathrm{NO}_{2}$ from the emergency generator emissions is derived from the modelled $\mathrm{NO}_{x}$ output, assuming that $70 \%$ of $\mathrm{NO}_{\mathrm{x}}$ emissions are emitted as or converted to $\mathrm{NO}_{2}$ as the plume disperses.
1.16.2 The contribution of hourly mean concentrations of $\mathrm{NO}_{2}$ from the emergency generator assumes that $35 \%$ of total hourly $\mathrm{NO}_{x}$ emissions are emitted as or converted to $\mathrm{NO}_{2}$ as the plume disperses.
1.16.3 This approach is recommended by the Environment Agency (Ref 14.19).

### 1.17 SPECIAL MODEL TREATMENT

## Building Downwash

1.17.1 Whilst the Braint and Tŷ Fodol Construction Compounds would contain some single storey buildings and structures, the nearest air quality sensitive receptors are located far enough away from the emergency generator exhausts such that the presence and height of those building and structures would be unlikely to influence the concentrations predicted.

## Terrain

1.17.2 The terrain in the vicinity of the Braint and Ty Fodol Construction Compounds is variable, due to the size of the area covered. However, there are no major gradients or pronounced changes in height between the stacks/exhausts and the nearest air quality sensitive receptors. For this reason, flat terrain has been assumed within the modelling assessment.
1.17.3 Sub-Appendix 14.3.E provides a sensitivity analysis of modelling dispersion from emergency generator emissions with the influence of terrain.

### 1.18 PREDICTING THE LIKELIHOOD OF EXCEEDING THE HOURLY MEAN $\mathrm{NO}_{2}$ AIR QUALITY OBJECTIVE

1.18.1 To consider the impact on short term $\mathrm{NO}_{2}$ concentrations from emergency generator operation, the assessment has considered the approach set out in the Environment Agency's Briefing Note: Diesel Generator Short Term $\mathrm{NO}_{2}$ Impact Assessment (Ref 14.26).
1.18.2 The Air Quality Modelling \& Assessment Unit (AQMAU) of the Environmental Agency completed an assessment of short-term $\mathrm{NO}_{2}$ impacts associated with diesel generator operation. The report described a
statistical methodology for assessing air quality impacts (with a focus on $\mathrm{NO}_{2}$ ) for sites with multiple generator sets where the frequency and timing of operation is uncertain. It describes how a hypergeometric distribution can be used to randomly select multiple hours within a year (each with specific meteorological data) and predict the probability of an exceedance of the relevant air quality standard based on the number of random hours selected. A probability of less than $5 \%$ (i.e. a one in 20 -year event) can be used as an indicator for "unlikely exceedances". This distribution analysis has been completed for the operation of the emergency generator plant at the Braint and Tŷ Fodol Construction Compounds.
1.18.3 This analysis identified that at the receptor most likely to be affected by short-term emergency generator emissions (R5/02987), the continuous operation of all emergency generators for a full year would not cause an exceedance of the hourly mean $\mathrm{NO}_{2}$ air quality objective value.

## Sub-Appendix A - Meteorological Data Sensitivity Analysis

### 1.19 INTRODUCTION

1.19.1 The dispersion model of emergency generator emissions was modelled using five years of hourly sequential meteorological data from the station at Mona on Anglesey.

### 1.20 RESULTS

1.20.1 The results of the meteorological data sensitivity analysis are provided in Table 14.3.15 and Table 14.3.16. The analysis focuses on predicted annual mean and hourly mean concentrations of $\mathrm{NO}_{X}$ (without any adjustment), at the two receptors nearest to the Braint and Ty Fodol Construction Compounds, assuming continuous of operation.
1.20.2 The tables demonstrate that there is limited variation in modelled predictions at those receptors as a result of differing meteorological data, with the majority of predictions being within $10 \%$ of the maximum value.

${ }^{1}$ Speed data given as provided from the traffic surveys undertaken for the assessment. Where speed data is not available, professional judgement has been used to estimate average speed, based on the speed limit of the link. Speeds have been reduced on the approach to junctions. The speed limit assumed for the Access Tracks was 10 mph .

## Comment：Results are not blank subtracted

Results have been corrected to a temperature of $293 \mathrm{~K}\left(20^{\circ} \mathrm{C}\right)$
Travel blank received with sample set L02500 and reported on both reports．

## Comment: Results are not blank subtracted

Tube 1031551 contained water droplets. Result may be compromised.
Tubes marked ** were diluted to read within our UKAS accredited calibration range.
Results reported as $<0.010$ are below the reporting limit.
Results have been corrected to a temperature of $293 \mathrm{~K}\left(20^{\circ}\right)$

## Comment: Results are not blank subtracted

Results have been corrected to a temperature of $293 \mathrm{~K}\left(20^{\circ}\right)$

Overall M.U. $\pm 7.8 \%$
Tube Preparation : 20\% TEA / Water

## Limit of Detection $\quad 0.010 \mu \mathrm{gNO}_{2}$

Analysed on UV 08 Camspec M550

#### Abstract

The Diffusion Tubes have been tested within the scope of Gradko International Ltd. Laboratory Quality Procedures calculations and assessments involving the exposure procedures and periods provided by the client are not within the scope of our UKAS accreditation. Those results obtained using exposure data shall be indicated by an asterisk (*). Any queries concerning the data in this report should be directed to the Laboratory Manager Gradko International Ltd. This report is not to be reproduced, except in full, without the written permission of Gradko International Ltd.

PERFORMANCE DEFINITIONS

## PERFORMANCE DEFINITIONS DM9600

APPLICATION:
Engine performance tolerance values below are representative of a typical production engine tested in a calibrated dynamometer test cell at SAE J1995 standard reference conditions. Caterpillar maintain ISO9001:2000 certified quality management systems for engine test Facilities to assure accurate calibration of test equipment. Engine test data is corrected in accordance with SAE J1995. Additional reference material SAE J1228, J1349, ISO 8665, 3046-1:2002E, 3046-3:1989, 1585, 2534, 2288, and 9249 may apply in part or are similar to SAE J1995. Special engine rating request(SERR)test data shall be noted.
PERFORMANCE PARAMETER TOLERANCE FACTORS:

| Power $\quad+/-3 \%$ |
| :--- |
| Torque $\quad+/-3 \%$ |
| Exhaust stack temperature $+/-8 \%$ |
| Inlet airflow $\quad+/-5 \%$ |
| Intake manifold pressure-gage + +/-10 |
| Exhaust flow $\quad+/-6 \%$ |
| Specific fuel consumption $+/-3 \%$ |
| Fuel rate $\quad+/-5 \%$ |
| Heat rejection $\quad+/-5 \%$ |
| Heat rejection exhaust only $+/-10 \%$ |

Torque is included for truck and industrial applications, do not use for Gen Set or steady state applications.

On C7-C18 engines, at speeds of 1100 RPM and under these values are provided for reference only, and may not meet the tolerance listed.

These values do not apply to C280/3600. For these models, see the tolerances listed below.

C280/3600 HEAT REJECTION TOLERANCE FACTORS
Heat rejection +/-10\%
Heat rejection to Atmosphere $+/-50 \%$
Heat rejection to Lube Oil +/- 20\%
Heat rejection to Aftercooler +/- 5\%

TEST CELL TRANSDUCER TOLERANCE FACTORS:

| Torque | $+/-0.5 \%$ |
| :--- | ---: |
| Speed | $+/-0.2 \%$ |
| Fuel flow | $+/-1.0 \%$ |
| Temperature | $+/-2.0 \mathrm{C}$ degrees |
| Intake manifold pressure $\quad+/-0.1 \mathrm{kPa}$ |  |

OBSERVED ENGINE PERFORMANCE IS CORRECTED TO SAE J1995 REFERENCE AIR AND FUEL CONDITIONS

REFERENCE ATMOSPHERIC INLET AIR
FOR 3500 ENGINES AND SMALLER
SAE J1228 reference atmospheric pressure is 100 KPA (29.61 in hg)
and standard temperature is 25 (77) at $60 \%$ relative
humidity
FOR 3600 ENGINES
Engine rating obtained and presented in accordance with ISO 3046/1 and SAE J1995 JAN90 standard reference conditions of 25, 100 KPA $30 \%$ relative humidity and 150 M altitude at the stated aftercooler water temperature.

REFERENCE EXHAUST STACK DIAMETER
The Reference Exhaust Stack Diameter published with this dataset is
only used for the calculation of Smoke Opacity values displayed in this dataset. This value does not necessarily represent the actual stack diameter of the engine due to the variety of exhaust stack adapter options available. Consult the price list, engine order or general dimension drawings for the actual stack diameter size ordered or options available

## REFERENCE FUEL

DIESEL
Reference fuel is \#2 distillate diesel with a 35API gravity;
A lower heating value is $42,780 \mathrm{KJ} / \mathrm{KG}(18,390 \mathrm{BTU} / \mathrm{LB})$ when used at
29 (84.2), where the density is $838.9 \mathrm{G} /$ Liter
(7.001 Lbs/Gal)

GAS
Reference natural gas fuel has a lower heating value of $33.74 \mathrm{KJ} / \mathrm{L}$ ( $905 \mathrm{BTU} / \mathrm{CU} \mathrm{Ft}$ ). Low BTU ratings are based on $18.64 \mathrm{KJ} / \mathrm{L}$ ( $500 \mathrm{BTU} /$ CU FT) lower heating value gas. Propane ratings are based on 87.56 $\mathrm{KJ} / \mathrm{L}(2350 \mathrm{BTU} / \mathrm{CU} \mathrm{Ft}$ ) lower heating value gas.

ENGINE POWER (NET) IS THE CORRECTED FLYWHEEL POWER (GROSS) LESS EXTERNAL AUXILIARY LOAD
Engine corrected gross output includes the power required to drive standard equipment; lube oil, scavenge lube oil, fuel transfer, common rail fuel, separate circuit aftercooler and jacket water pumps. Engine net power available for the external (flywheel) load is calculated by subtracting the sum of auxiliary load from the corrected gross flywheel out put power. Typical auxiliary loads are radiator cooling fans, hydraulic pumps, air compressors and battery charging alternators.

ALTITUDE CAPABILITY
Altitude capability is the maximum altitude above sea level at standar d temperature and standard pressure at which the engine could develop full rated output power on the current performance data set. Standard temperature values versus altitude could be seen on TM2001.

Engines with ADEM MEUI and HEUI fuel systems operating at conditions above the defined altitude capability derate for atmospheric pressure and temperature conditions outside the values defined, see TM2001. Mechanical governor controlled unit injector engines require a setting change for operation at conditions above the altitude defined on the engine performance sheet. See your Caterpillar technical representative for non standard ratings.

## REGULATIONS AND PRODUCT COMPLIANCE

TMI Emissions information is presented at 'nominal' and 'Potentia Site Variation' values for standard ratings. No tolerances are applied to the emissions data. These values are subject to change at any time. The controlling federal and local emission requirements need to be verified by your Caterpillar technical representative. Log on to the Technology and Solutions Divisions (T\&SD) web page (http://tsd.cat.com/etsd/index.cfm?tech_id=2635ICAL) for information including federal regulation applicability and time lines for implementation. Information for labeling and tagging requirements is also provided

## NOTES

Regulation watch covers regulations in effect and future regulation changes for world, federal, state and local. This page includes items on the watch list where a regulation change or product change might be pending and may need attention of the engine product group. For additional emissions information log on to the TMI web page.

Additional product information for specific market application is available.
Customer's may have special emission site requirements that need to be verified by the Caterpillar Product Group engineer

## Sub-Appendix E - Terrain Data Sensitivity Analysis

### 1.21 INTRODUCTION

1.21.1 The dispersion model of emergency generator emissions was modelled with the assumption that the terrain between the source and the nearest receptors was relatively flat. This analysis provides the model output at a selection of air quality sensitive receptors with the influence of terrain. The terrain data used had a resolution of 50 m .

### 1.22 RESULTS

1.22.1 The results of the terrain data sensitivity analysis are provided in Table 14.3.17. The analysis focuses on predicted annual mean and hourly mean contributions of $\mathrm{NO}_{\mathrm{x}}$ from the emergency generators (without any adjustment), assuming TBM from Braint.
1.22.2 The table demonstrates that there is generally limited variation in modelled predictions at the receptors likely to be most affected as a result of the use of terrain data, with the majority of predictions being within $10 \%$ of the maximum annual mean value, and within $20 \%$ of the maximum hourly mean value. The table also shows that the addition of terrain decrease the $\mathrm{NO}_{x}$ contribution at the majority of receptor locations considered.

Table 14.3.17: Analysis of Terrain Data Sensitivity - TBM from Braint

| Receptor <br> ID | Modelled Grid <br> Reference |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
