

WEST MIDLANDS INTERCHANGE

RESPONSE TO SOUTH STAFFORDSHIRE DISTRICT COUNCIL REVIEW – REV3

1 Introduction

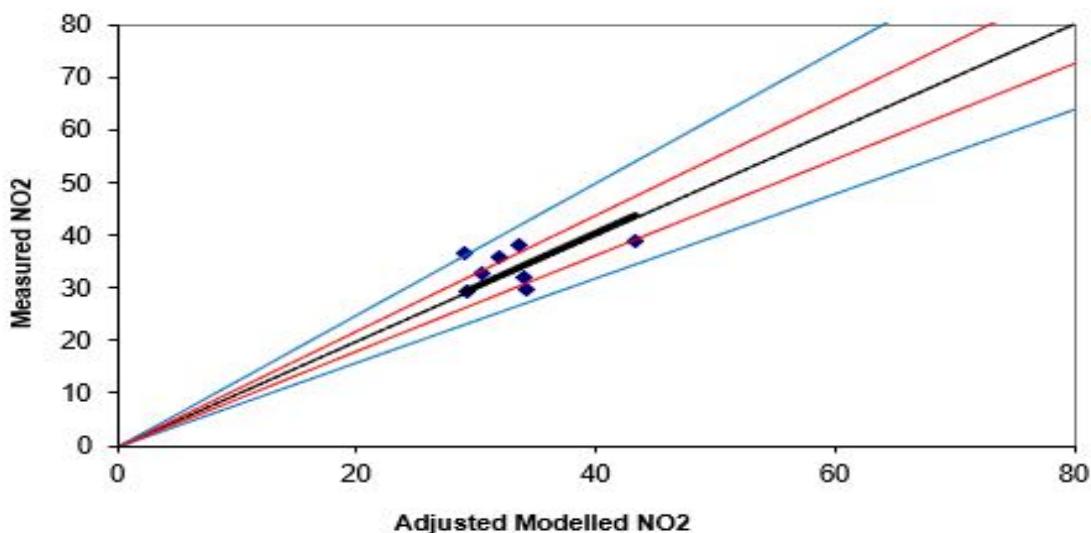

- 1.1 South Staffordshire District Council (SSDC) commissioned Air Quality Consultants (AQC) to undertake a review of Chapter 7 of the West Midlands Interchange (WMI) Environmental Statement (AQC reference J3582A/1/F1, dated 4 December 2018).
- 1.2 A response to the initial AQC Report was provided by Ramboll on behalf of the Applicant on 17th December 2018, the results of which have been incorporated into an updated AQC review dated 8 January 2019 (AQC reference J3582A/1/F2). A revised response note based on the original air quality modelling was prepared and issued on 24th January 2019, and a meeting held with SSDC and AQC on 21st February 2019 to discuss the results.
- 1.3 Following the meeting, it was agreed that a further review of the ES modelling would be undertaken. This was provided in a note dated 11th March 2019. A further response was received from AQC, dated 1st April 2019, and this note presents a final update of the 11th March 2019 data with respect to the SSDC area. Comments within the 1st April 2019 AQC response are addressed as follows:
- The x and y axis of the graph have now been re-labelled. For the avoidance of doubt the model verification factor was calculated and applied correctly.
 - For the motorway verification sites ES4 and PE alone, the model verification factor would have been 1.22 and therefore slightly lower results would have been reported for the motorway receptors than are reported here-in had this factor being used. However, taking into account the need to present a reasonable worst case assessment, and given that it does not adversely impact on the conclusions of the assessment, a single verification factor incorporating these monitoring points is considered acceptable.
 - Updated results at receptors 3a, 3b, PS_42a and 41a are included in this note as per our email correspondence of 29th March 2019.
 - The results for the baseline concentration of PM₁₀ and PM_{2.5} in 2028 have been updated. The increases in PM₁₀ and PM_{2.5} concentrations in 2028 are now consistent with the NO₂ results for the same receptor location.
- 1.4 Overall there is no change to the conclusions of the 11th March 2019 note by the revisions made herein, and we acknowledge AQC's confirmation that the air quality objectives are unlikely to be exceeded in the opening year or beyond and that the overall impacts of WMI will be 'not significant'.

2 Adjustment to the Model Set Up

- 2.1 In light of the discussions held at the 21st February 2019 meeting, a review of the receptor and monitoring locations has been undertaken and we have taken the opportunity to check all aspects of the model set up. As outlined in the email of 29th March 2019, where receptors are close to an elevated section of the motorway then the motorway has been raised to reflect the relative elevations between the source and receptor.

- 2.2 Initial comments within the AQC review concerned the model verification and comparison with the monitored data. Only monitoring points where we can verify the location have been used in the assessment and we have corrected monitoring point locations where the grid references provided in the SSDC Annual Status Report have proved to be incorrect. We have further reviewed the Defra guidance TG.16 concerning the use of monitoring points for model verification and in line with paragraph 7.524, all of the monitoring points have been grouped together as they are associated with trunk roads or motorways in open settings, and not urban areas. In particular, monitoring locations ES4 and PE, whilst influenced by emissions from a motorway, are not particularly close to the motorway.
- 2.3 The resultant model verification factor is 1.3833 compared to 2.2 in the ES which indicates an improved model performance, with the graph of monitored against predicted NO₂ concentrations shown below.

- 2.4 The following table provides a comparison of the measured and predicted concentrations in 2016, along with the model verification statistics.

Table 1 – Model Verification for SSDC		
Monitoring Point	2016 Measured	2016 Modelled
PE - Auto	39.0	43.4
HA2 - DT	37.9	33.6
HA5 - DT	31.9	34.1
HA6 - DT	29.7	34.3
SA2 - DT	32.6	30.4
SA5 - DT	36.5	29.0
SA6 - DT	29.3	29.2
ES4 - DT	35.6	31.9

Table 1 – Model Verification for SSDC

Monitoring Point	2016 Measured	2016 Modelled
Verification Statistics		
Correlation co-efficient		0.47
RMSE		4.2
Fractional bias		0.0

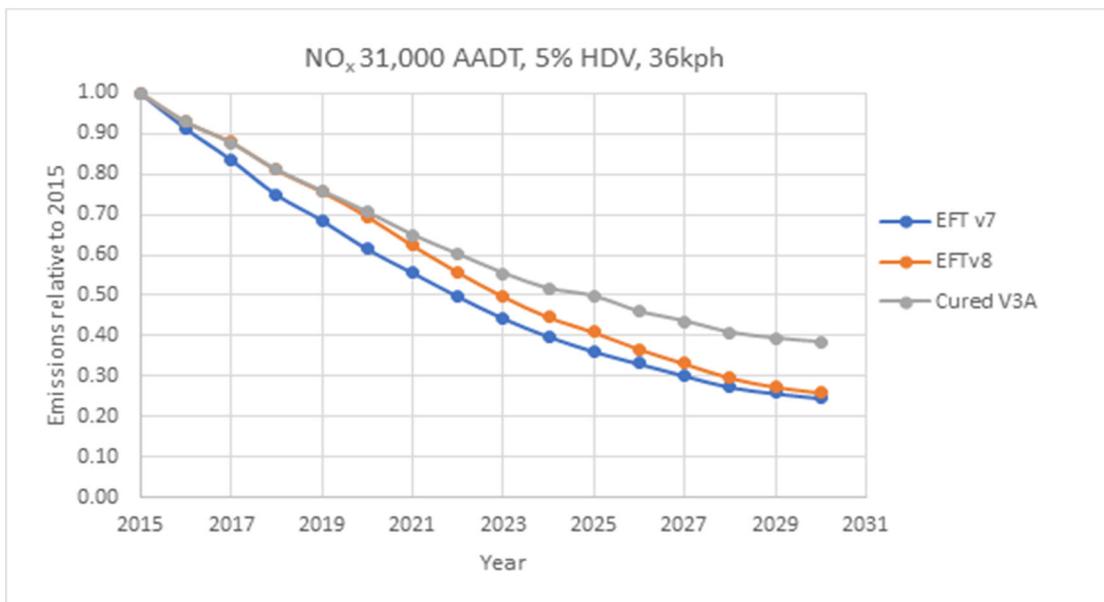

- 2.5 In evaluating the model verification there are two pairs of three monitoring points close together in each of the AQMAs; HA2, HA5, HA6 and SA2, SA5 and SA6. Each monitoring point is a similar distance from the road, but the monitoring results are different. In this case, the model predicts similar results at the monitoring locations consistent with the distance from the road.
- 2.6 In terms of the overall model performance, as noted in 7.541 of TG16, in the first instance the RMSE error is statistic to evaluate. Paragraph 7.542 confirms that where the RMSE is greater than 25% of the objective (i.e. $10\mu\text{g}/\text{m}^3$ for annual mean NO_2), then the model set up should be re-evaluated. Ideally the RMSE should be less than $4\mu\text{g}/\text{m}^3$, and the calculated value is just above this which confirms an adequate overall model performance.
- 2.7 The fractional bias indicates that the model is not tending to overpredict or underpredict.
- 2.8 Finally, whilst the correlation co-efficient does not indicate a close correlation between the measured and predicted concentrations, paragraph 7.544 of TG16 indicates that that this statistic could be applied in cases where large datasets such as hourly observations are being compared. This is not the case here.
- 2.9 Overall, it is considered that the model verification is within accepted parameters.

3 Results

- 3.1 Model results based on the revised model parameters are presented in Appendix 1 for the human health receptors within SSDC area. Where receptors are located at the same location as monitoring points, these have been combined.
- 3.2 Whilst there are differences in the predicted concentrations at the modelled receptor locations, the pattern of the results and the development impact are consistent between the two sets of predictions.
- 3.3 For NO_2 in 2021, the revised predictions show two slight impacts compared to one previously, with all other impacts negligible. There is one receptor location with a predicted exceedance in the baseline and ‘with development’ scenarios compared with three in the original modelling, but at this location the development has a negligible impact. The proposed development does not cause any additional exceedances and the impacts within the existing AQMAs are negligible. By 2028, there are no predicted exceedances and all of the impacts are negligible.
- 3.4 For PM_{10} and $\text{PM}_{2.5}$ concentrations, all of the development impacts are negligible for all of the assessed years.
- 3.5 As discussed at our meeting, the predicted concentrations are a function of the changes in traffic over the lifetime of the development combined with how vehicle emissions are predicted to change.

- 3.6 In terms of the traffic data, it includes all potential committed developments (as per paragraph 15.125 of the ES) which in many cases are potential schemes. Furthermore, the 2021 traffic data includes all movements associated with the committed developments when many of the schemes may not be operational or complete by this time. In addition, the modelling assumes that 25% of the WMI development (if consented) will be operational in 2021. Given that consent (if granted) won't be issued until 2020 and then there is a period which requires addressing pre-commencement DCO Requirements (like planning conditions) and then the construction period, it is considered highly unlikely that 25% of the development will be operational by 2021. In terms of the traffic data therefore, the predictions for 2021 are likely to overestimate both the total pollutant concentrations and the development contribution.
- 3.7 In addition, the Defra Emissions Factor Toolkit (EFT) predicts very significant reductions in NO_x emissions from the vehicle fleet. A graph of the relative NO_x emissions from the vehicle fleet over time is shown below; for both the Defra EFT predictions and AQC's CURED.

- 3.8 The graph illustrates that the reduction in vehicle NO_x emissions is likely to outweigh all but the most significant increases in vehicle flows, so effects (in terms of NO₂) from the WMI development will reduce over time and NO₂ concentrations will decline even as traffic from WMI increases. This effect is illustrated in the modelling results.

4 Conclusions

- 4.1 As requested, the model set up has been reviewed and revised predictions made. Overall however, there are no changes to the conclusions of the original assessment and the development will not have a significant effect on pollutant concentrations in SSDC.
